The requirements for exit passageways are very similar to those required for enclosures for interior exit stairways (see Section 1022.4). The only openings that are permitted in fire-resistance-rated exit passageways are doors that lead either from normally occupied spaces, from the enclosure for the exit stairway and doors leading to the outside. This restriction on openings essentially prohibits the use of windows in an exit passageway except for those exterior windows that are not exposed to any hazards. This requirement is not intended to prohibit windows or other openings in the exterior walls of the exit enclosure. The verbiage "unprotected exterior openings" includes windows or doors not required to be protected by either Section 705.8 or 1022.7. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E 119 and UL 263. The objective of this provision is to minimize the possibility of fire spreading into an exit passageway and endangering the occupants or even preventing the use of the exit at a time when it is most needed. The limitation on openings applies regardless of the fire protection rating of the opening protective. The limitation on openings from normally occupied areas is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, that has an opening into the exit passageway, thereby resulting in smoke spreading into the exit passageway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. Note that exit passageways prohibit elevators from opening directly into the passageway. There are some exceptions for these unoccupied spaces in exit passageways in covered malls (see Section 402.4.6).

The third paragraph addresses when the vertical enclosure for an exit stairway or ramp transitions to the exit passageway. While the exit passageway is an extension of the protection offered by the vertical exit, there must still be a door (i.e., opening protective) between the bottom of the stairway or ramp enclosure and the exit passageway. This is to prevent any smoke that may migrate into the exit passageway from also moving up the exit stairway or ramp. This door is not required if the exit stairway and exit passageway are protected by pressurization (see Section 1022.10.1).

Elevators may not open into exit passageways. The difficulty is to have elevator doors that can meet the opening protectives for a fire barrier, but still operate effectively. For additional information on elevator lobbies and doors, see the commentary for Sections 713.14 and 1018.6.

These opening limitations are very similar to those required for an exit enclosure (see Section 1022.3).

1023.6 Penetrations. Penetrations into and openings through an *exit passageway* are prohibited except for required *exit* doors, equipment and ductwork necessary for independent pressurization, sprinkler piping, standpipes, electrical raceway for fire department communication and electrical race-

way serving the *exit passageway* and terminating at a steel box not exceeding 16 square inches ($0.010 m^2$). Such penetrations shall be protected in accordance with Section 714. There shall be no penetrations or communicating openings, whether protected or not, between adjacent *exit passageways*.

Exception: Membrane penetrations shall be permitted on the outside of the *exit passageway*. Such penetrations shall be protected in accordance with Section 714.3.2.

❖ This section specifically lists the items that are allowed to penetrate an exit passageway. This is consistent for all types of exit enclosures, including enclosures for exit stairways or ramps (see Section 1022.5) and exit passageways. In general, only portions of the building service systems that serve the exit passageways are allowed to penetrate the exit passageway. Section 714 addresses through penetrations and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. If the ductwork serving the exit passageway does penetrate a rated wall or floor/ceiling assembly, a fire and smoke damper is required by Section 717.5.3. This requirement is not intended to prohibit windows in the exterior walls of exit passageways that are not required to be rated.

The exception allows for electrical boxes or fire alarm pull stations to be installed on the outside of the enclosure, provided that the boxes are installed so that the required fire-resistance rating is not reduced (see Section 714.3.2).

SECTION 1024
LUMINOUS EGRESS PATH MARKINGS

1024.1 General. *Approved* luminous egress path markings delineating the exit path shall be provided in high-rise buildings of Group A, B, E, I, M, and R-1 occupancies in accordance with Sections 1024.1 through 1024.5.

Exception: Luminous egress path markings shall not be required on the *level of exit discharge* in lobbies that serve as part of the exit path in accordance with Section 1027.1, Exception 1.

❖ Improved safety for individuals negotiating stairs during egress of a high-rise building is provided by improving the visibility of stair treads and handrails under emergency conditions. A second source of emergency power for exit illumination, exit signs and stair shaft pressurization systems in smokeproof enclosures is currently mandated for high-rise buildings. In the event of an emergency that disconnects utility power, the emergency power source should engage, causing the stair shaft to be illuminated and smoke free by the pressurization system. Unfortunately, such systems can fail under demand conditions. The provisions of Section 1024 add an additional level of safety to the egress path by requiring the installation of photoluminescent or self-illuminating marking systems which do not require electrical power and its associated wiring and circuits. An additional means for ensuring that occupants can safely egress a building via exit stairways is now available even if the emergency power supply and system fails to operate. The groups indicated have a high anticipated occupant load or occupants may not be as familiar with the space. Note that the provisions only require these markings within the enclosure for the exit stairway, exit ramp and the exit passageway used for enclosure continuation. The markings are not required before reaching the exit (i.e., exit access) or after leaving the exit (i.e., exit discharge).

The exception indicates that if the exit stairway enclosure discharges through the lobby (see Section 1027.1, Exception 1), the egress markings would not be required outside the stairway enclosure for the portion from the stairway enclosure to the door leading to the outside. If the exit stairway discharges through an exit passageway, the exit path markings must continue to the door leading to the outside. The current text is silent for the options of vestibules and horizontal exits, but since Sections 1024.1 through 1024.5 only address within the enclosure for the exit, and not the exit discharge, exit path markings in the vestibule or after the horizontal exit are not required.

1024.2 Markings within exit components. Egress path markings shall be provided in *interior exit stairways*, *interior exit ramps* and *exit passageways*, in accordance with Sections 1024.2.1 through 1024.2.6.

❖ Luminous egress path markings are required inside the enclosure for exit stairways or ramps for all floors. If the stairway connects to an exit passageway as part of the travel down to the level of exit discharge or on the level of exit discharge, the path markings must also be continued in the exit passageway.

The subsections include marking the tread nosings, the surrounding edges of landings and any exit passageways, handrails and any protruding objects within the protected enclosure.

All exit path markings are required to be solid and continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent along the entire exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

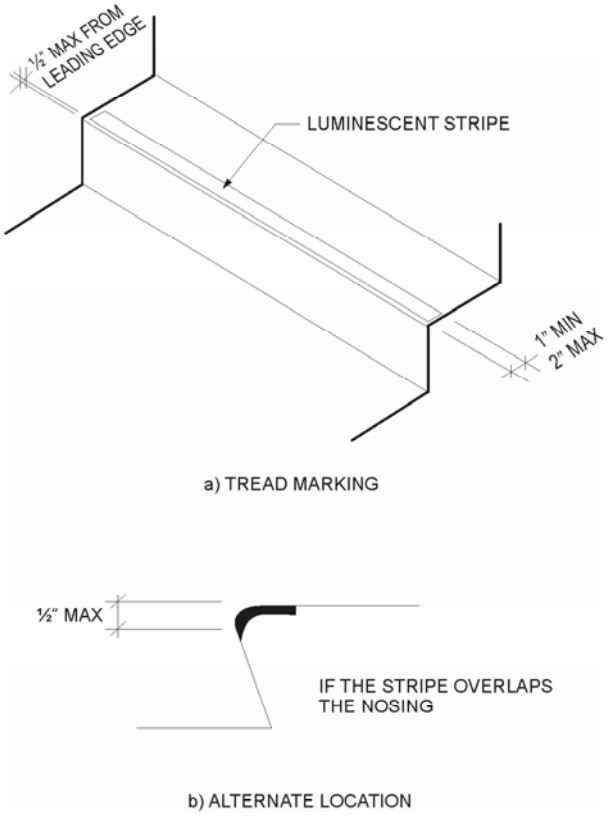
1024.2.1 Steps. A solid and continuous stripe shall be applied to the horizontal leading edge of each step and shall extend for the full length of the step. Outlining stripes shall have a minimum horizontal width of 1 inch (25 mm) and a maximum width of 2 inches (51 mm). The leading edge of the stripe shall be placed at a maximum of $^1/_2$ inch (13 mm) from the leading edge of the step and the stripe shall not overlap the leading edge of the step by not more than $^1/_2$ inch (13 mm) down the vertical face of the step.

Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

❖ Luminous stripes are required the full width of the stairway on all tread nosings and along the leading edge of stair landings. These demarcation lines serve to identify the transition from the stair steps to the landing, which is important to minimize the risk of a fall inside of a stairway enclosure that is not illuminated. In order to clearly identify the leading edge of the step, the front edge of the stripe must be within $^1/_2$ inch (13 mm) plus or minus of the leading edge or the tread (see Figure 1024.2.1).

The code does not specify any minimum slip-resistance requirements for luminous products installed on walking surfaces. However, Section 1003.4 does require all walking surfaces for means of egress to be slip resistant. Persons with vision impairments often rely on high contrast elements to delineate changes in elevation such as that required in Sections 1009.7.4 and 1028.11.2. In medium light conditions, the luminous materials may be hard to discern. Luminous materials installed adjacent to dark contrasting materials may help with both situations.

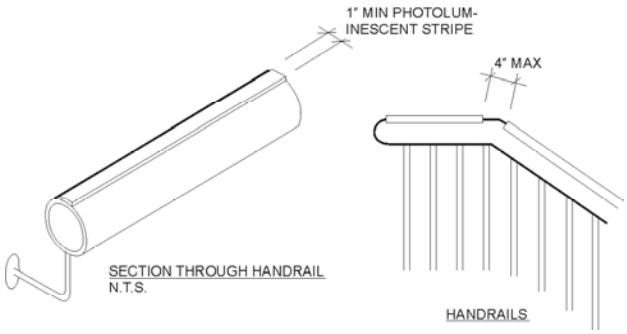
The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.



1024.2.2 Landings. The leading edge of landings shall be marked with a stripe consistent with the dimensional requirements for steps.

❖ The edge of the landing at the top of the steps must be marked in the same manner as the tread nosing so that a person can tell where the steps start. See the commentary to Section 1024.2.1 and Figure 1024.2.1.

1024.2.3 Handrails. All *handrails* and handrail extensions shall be marked with a solid and continuous stripe having a minimum width of 1 inch (25 mm). The stripe shall be placed on the top surface of the *handrail* for the entire length of the *handrail*, including extensions and newel post caps. Where *handrails* or handrail extensions bend or turn corners, the stripe shall not have a gap of more than 4 inches (102 mm).



Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

❖ The handrail must have a glow-in-the-dark stripe down the entire length. The 1-inch (25 mm) minimum width stripe needs to be on the top of the handrail both so it can charge and so that someone would be best able to see it in the dark. Bends or turns may result in a break in the marking which must not be more than 4 inches (102 mm) maximum (see Figure 1024.2.3).

For SI: 1 inch = 25.4 mm.

Figure 1024.2.1
LEADING EDGE OF STEP AND LANDING

For SI: 1 inch = 25.4 mm.

Figure 1024.2.3
HANDRAIL MARKINGS

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.2.4 Perimeter demarcation lines. Stair landings and other floor areas within *interior exit stairways*, *interior exit ramps* and *exit passageways*, with the exception of the sides of steps, shall be provided with solid and continuous demarcation lines on the floor or on the walls or a combination of both. The stripes shall be 1 to 2 inches (25 mm to 51 mm) wide with interruptions not exceeding 4 inches (102 mm).

Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

❖ In addition to the leading edge of the landing, the landing must have a luminous stripe all the way around the edge. If the enclosure includes any type of exit passageway, that corridor must also have a perimeter stripe. The stripe can be on the floor or on the wall at baseboard height (see Sections 1024.2.4.1 and 1024.2.4.2).

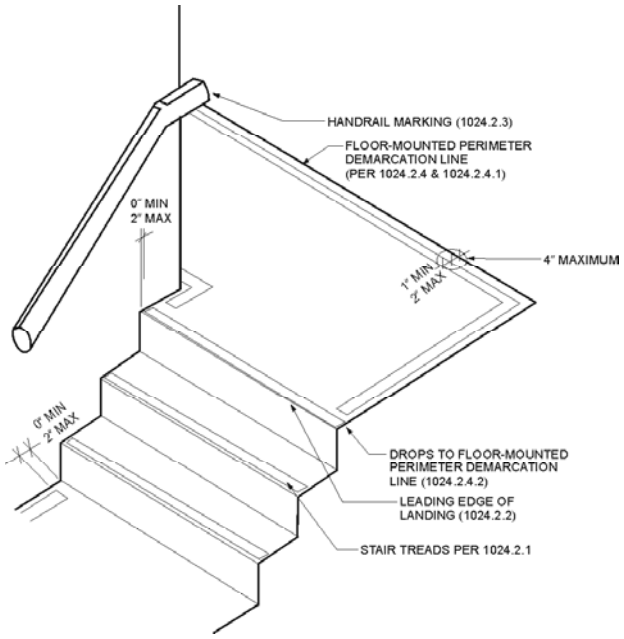
The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.2.4.1 Floor mounted demarcation lines. Perimeter demarcation lines shall be placed within 4 inches (102 mm) of the wall and shall extend to within 2 inches (51 mm) of the markings on the leading edge of landings. The demarcation lines shall continue across the floor in front of all doors.

Exception: Demarcation lines shall not extend in front of *exit discharge* doors that lead out of an *exit* and through which occupants must travel to complete the exit path.

❖ Luminous stripes shall extend all the way around any stair landings. This section specifies the option of stripes on the floor (see Figure 1024.2.4.1). On a typical landing, the stripe will extend across the front of the door, indicating to someone moving down the stairway that they should continue (see Figure 1024.2.4.3). At the level of exit discharge the occupant has a different visual queue. The line should not extend in front of the door leading to the exterior (see Figure 1024.2.6). This should allow people to understand which door they need to move through to get to safety.

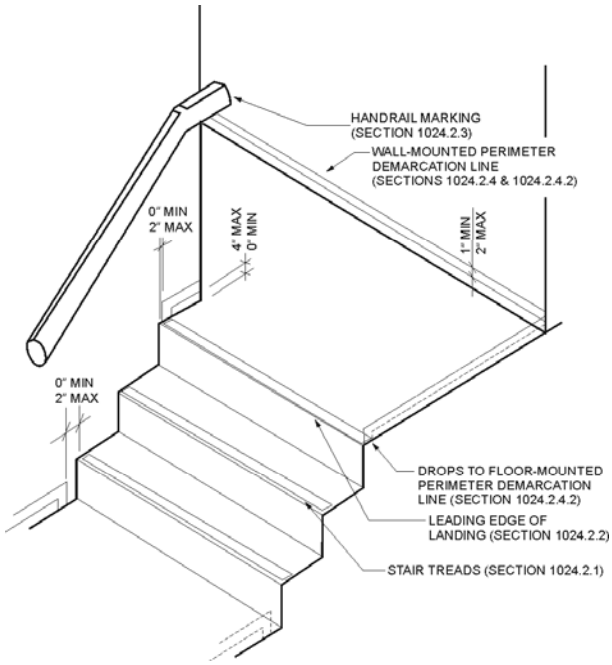
1024.2.4.2 Wall mounted demarcation lines. Perimeter demarcation lines shall be placed on the wall with the bottom edge of the stripe no more than 4 inches (102 mm) above the finished floor. At the top or bottom of the *stairs*, demarcation lines shall drop vertically to the floor within 2 inches (51 mm) of the step or landing edge. Demarcation lines on walls shall transition vertically to the floor and then extend across the floor where a line on the floor is the only practical method of outlining the path. Where the wall line is broken by a door, demarcation lines on walls shall continue across the face of the door or transition to the floor and extend across the floor in front of such door.



Exception: Demarcation lines shall not extend in front of *exit discharge* doors that lead out of an *exit* and through which occupants must travel to complete the exit path.

❖ Luminous stripes that surround the stairway landings can be on the floor or on the wall. This section specifies the option of stripes on the wall (see Figure 1024.2.4.2). See the commentary to Sections 1024.2.4 and 1024.2.4.1.

1024.2.4.3 Transition. Where a wall mounted demarcation line transitions to a floor mounted demarcation line, or vice-versa, the wall mounted demarcation line shall drop vertically to the floor to meet a complimentary extension of the floor mounted demarcation line, thus forming a continuous marking.



❖ While the luminous perimeter stripes on landing can be on either the wall or the floor, when they transition from one to another, the lines should appear continuous. See Section 1024.2.4.2 for special requirements for when the wall perimeter marking transitions to the floor stripe indicating leading edge of the landing.

When perimeter lines cross a door frame, the lines can transition or stay on the same plain (see Figure 1024.2.4.3).

For SI: 1 inch = 25.4 mm.

PERIMETER DEMARCATION LINES—
WALL-MOUNTED OPTION

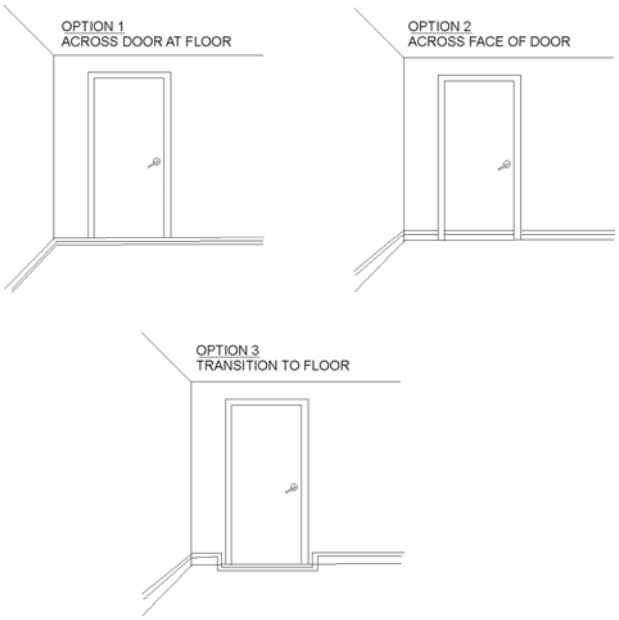

Figure 1024.2.4.3
PERIMETER DEMARCATION LINES—
OPTIONS AT DOORS INTO EXIT ENCLOSURES

1024.2.5 Obstacles. Obstacles at or below 6 feet 6 inches (1981 mm) in height and projecting more than 4 inches (102 mm) into the egress path shall be outlined with markings no less than 1 inch (25 mm) in width comprised of a pattern of alternating equal bands, of luminescent luminous material and black, with the alternating bands no more than 2 inches (51 mm) thick and angled at 45 degrees. Obstacles shall include, but are not limited to, standpipes, hose cabinets, wall projections, and restricted height areas. However, such markings shall not conceal any required information or indicators including but not limited to instructions to occupants for the use of standpipes.

❖ Any obstacles within the stairway must be marked with a dashed line of diagonal slashes (see Figure 1024.2.5). The markings of obstacles are consistent with the intent of protruding object provisions in Section 1003.3. However, there is a difference in the height of 6 feet, 6 inches (1981 mm) instead of 6 feet, 8 inches (2032 mm). Items permitted within the enclosures for exit stairways are limited by Sections 1022.2 and 1022.5.

1024.2.6 Doors within the exit path. Doors through which occupants must pass in order to complete the exit path shall be provided with markings complying with Sections 1024.2.6.1 through 1024.2.6.3.

❖ Doors within an enclosure for an exit stairway can lead directly to the exterior, pass through a horizontal exit (Section 1027.1, Exception 3) or lead to an exit passageway on the level of exit discharge, to a lobby or vestibule at the level of exit discharge (Section 1027.1, Exceptions 2 and 3) or to an exit passageway on a transition level. Doors at these locations should be marked as indicated in the following three subsections. Combined with the landing markings not extending across the bottom of this door, this will provide several visual cues to indicate that this is the door to continue through to get out of the building (see Figure 1024.2.6).

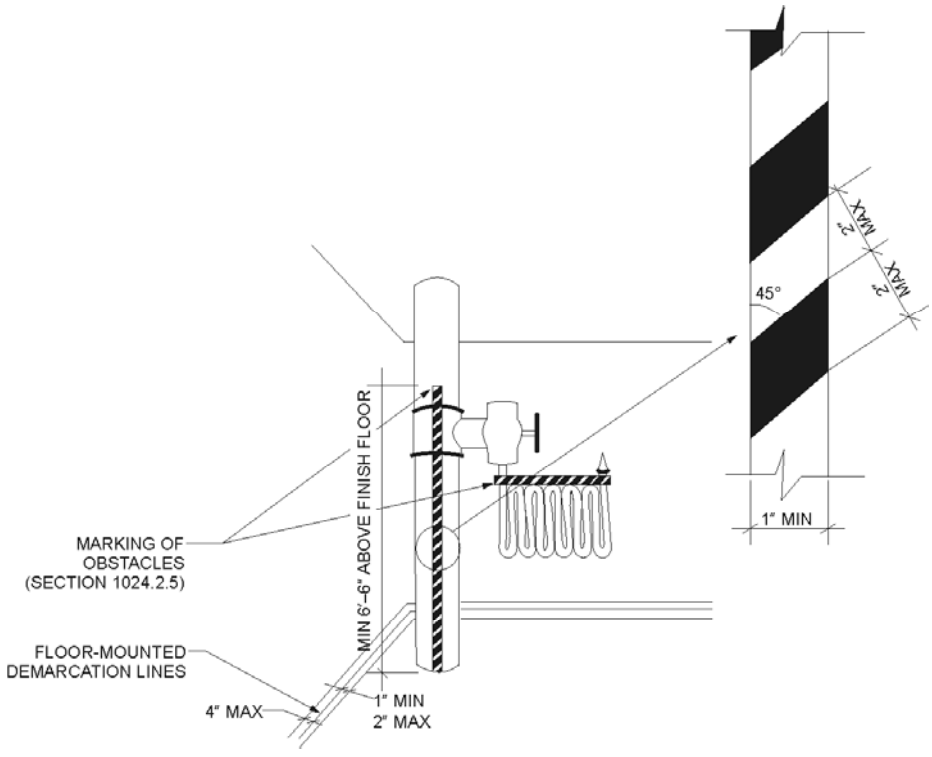
The NIST egress study of the World Trade Center indicated that transition floors can cause delays in egress because people hesitate when it is unclear about which way they should continue. Effectively marking these doors in four different ways will decrease that hazard. Which doors to mark is consistent with the exit sign requirements within exit enclosures in Section 1011.1.

1024.2.6.1 Emergency exit symbol. The doors shall be identified by a low-location luminous emergency exit symbol complying with NFPA 170. The exit symbol shall be a minimum of 4 inches (102 mm) in height and shall be mounted on the door, centered horizontally, with the top of the symbol no higher than 18 inches (457 mm) above the finished floor.

❖ The door shall include a low luminous level exit symbol within 18 inches (457 mm) of the floor. For an example of the emergency exit symbol, see Figure 1024.2.6.1. The sign on the door can be just this symbol or it can also contain additional information such as a directional arrow or "EXIT."

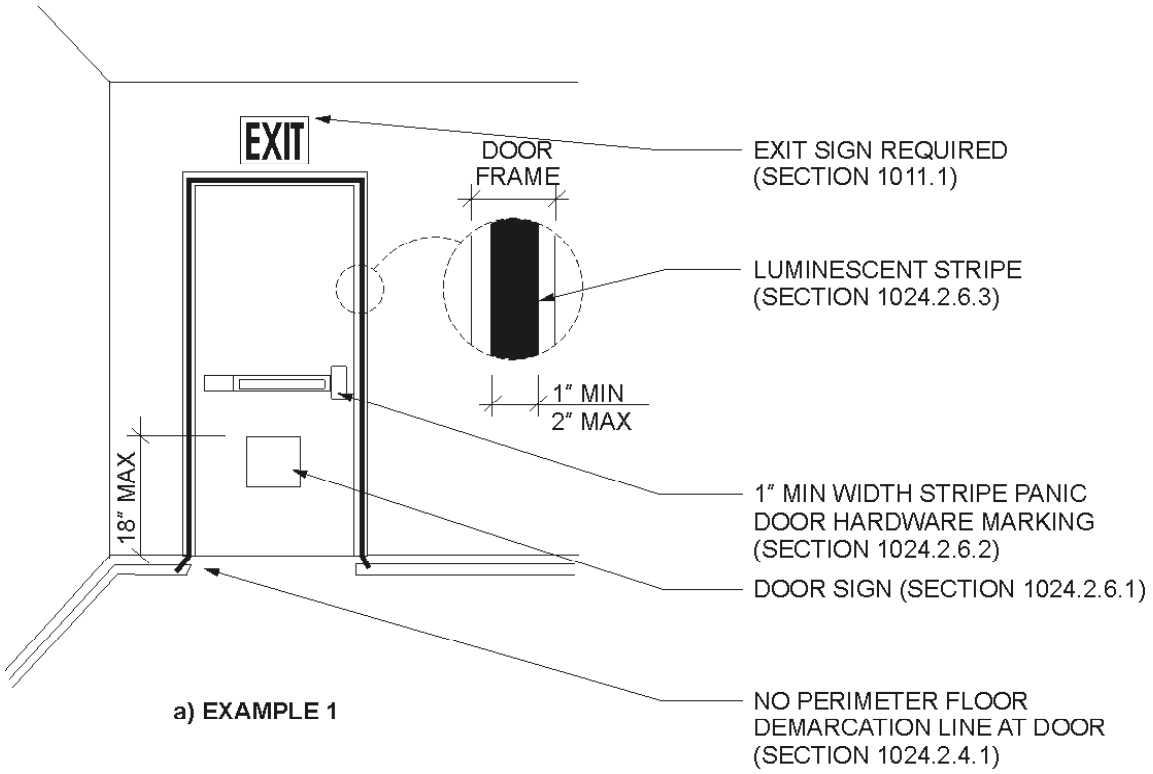
1024.2.6.2 Door hardware markings. Door hardware shall be marked with no less than 16 square inches (406 mm^2) of luminous material. This marking shall be located behind, immediately adjacent to, or on the door handle or escutcheon. Where a panic bar is installed, such material shall be no less than 1 inch (25 mm) wide for the entire length of the actuating bar or touchpad.

❖ Door hardware locations must be clearly visible. If a panic bar is used, a luminous stripe with a minimum width of 1 inch (25 mm) should be provided down the entire length of the activation bar/paddle [see Figure 1024.2.6, Example 1]. If lever hardware is used, a donut, square or rectangle with a minimum area of 16 square inches (10 322 mm^2) should be provided behind the hardware [see Figure 1024.2.6, Example 2]. There is also the option of marking the door handle itself, but it would be difficult to get 16 square inches (10 322 mm^2) of visible surface area. Plus, over time, a finish on the hardware has a greater chance of wearing off with normal use. The language does allow freedom for the designer to decide with wear and hardware options which configuration would give the best results.



1024.2.6.3 Door frame markings. The top and sides of the door frame shall be marked with a solid and continuous 1-inch- to 2-inch-wide (25 mm to 51 mm) stripe. Where the door molding does not provide sufficient flat surface on which to locate the stripe, the stripe shall be permitted to be located on the wall surrounding the frame.

❖ Doors must be marked along the sides and top with stripes similar to those provided on the stair nosing. Door frames come in a variety of shapes. If there is not space on the door for the marking stripe, the stripe can be around the perimeter of the door [see Figure 1024.2.6, Examples 1 and 2].



For SI: 1 inch = 25.4 mm.

OBSTACLE MARKINGS

For SI: 1 inch = 25.4 mm,
1 square inch = 645.16 mm.

Figure 1024.2.6
EXAMPLES OF EXIT DOOR TO EXTERIOR OPTIONS

1024.3 Uniformity. Placement and dimensions of markings shall be consistent and uniform throughout the same enclosure.

❖ All exit path markings are required to be solid and continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent for the path of travel along the exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.4 Self-luminous and photoluminescent. Luminous egress path markings shall be permitted to be made of any material, including paint, provided that an electrical charge is not required to maintain the required luminance. Such materials shall include, but not be limited to, *self-luminous* materials and *photoluminescent* materials. Materials shall comply with either:

1. UL 1994; or
2. ASTM E 2072, except that the charging source shall be 1 footcandle (11 lux) of fluorescent illumination for 60 minutes, and the minimum luminance shall be 30 millicandelas per square meter at 10 minutes and 5 millicandelas per square meter after 90 minutes.

❖ Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Sections 411.7 and 1024) or exit signs (see Section 1011.5) may be photoluminescent or self-luminous (see definitions in Chapter 2). An example of photoluminescent material is paint or tape that is charged by exposure to light. When the lights are turned off, the product will "glow" in the dark. Self-luminous products do not need an outside light source to charge them like photoluminescent materials do.

A variety of materials can comply with the referenced standards for egress path markings—UL 1994, and ASTM E 2072 and for signs—UL 924.

ASTM E 2072 allows the use of paints and coatings, which can be useful because it avoids a potential tripping hazard, especially in locations where the surface substrate may not be even. The luminescence of the selected marking system must provide an illumination of 1 foot-candle (11 lux) for 60 minutes, which is consistent with the requirement in Section 1006.2 for the illumination of walking surfaces. Section 1006.3 does require the emergency lighting system to have power for 90 minutes, however, due to normal battery considerations, the IFC only requires a 60-minute duration in existing buildings.

1024.5 Illumination. Where *photoluminescent* exit path markings are installed, they shall be provided with the minimum *means of egress* illumination required by Section 1006 for at least 60 minutes prior to periods when the building is occupied.

❖ Analogous to rechargeable batteries, many photoluminescent egress path markings require exposure to light to perform properly. Thus, photoluminescent egress path markings must be exposed to a minimum 1 foot-candle (11 lux) of light energy at the walking surface for at least 60 minutes prior to the building being occupied. The charging rate for photoluminescent egress path markings is based on the wattage of lamps used to provide egress path illumination. Therefore it is important to verify that the specified lamps have sufficient wattage to meet the specified time period. This requirement may be a concern for buildings developed with the *International Energy Conservation Code*® (IECC®) or trying for LEED certification.

Note that this requirement does not apply to self-luminous materials since these materials operate independently of the external power source. See the definitions for "Photoluminescent" and "Self-luminous" in Chapter 2.

SECTION 1025
HORIZONTAL EXITS

1025.1 Horizontal exits. *Horizontal exits* serving as an *exit* in a *means of egress* system shall comply with the requirements of this section. A *horizontal exit* shall not serve as the only *exit* from a portion of a building, and where two or more *exits* are required, not more than one-half of the total number of *exits* or total exit width shall be *horizontal exits*.

Exceptions:

1. *Horizontal exits* are permitted to comprise two-thirds of the required *exits* from any building or floor area for occupancies in Group I-2.
2. *Horizontal exits* are permitted to comprise 100 percent of the *exits* required for occupancies in Group I-3. At least 6 square feet (0.6 m^2) of accessible space per occupant shall be provided on each side of the *horizontal exit* for the total number of people in adjoining compartments.

❖ Horizontal exits can provide up to 50 percent of the exits from a given area of a building. The percentage is higher for Group I-2 and I-3 occupancies where the evacuation strategy is defend in place rather than direct egress (see Figure 1025.1 for a typical horizontal exit arrangement). However, a horizontal exit cannot serve as the only exit from a single exit space. Section 1025.4 allows for some areas to have all the exits from a space to be horizontal exits under specific conditions. A horizontal exit can be designed for either one-way or two-way operation, depending on the exiting needs of each side of the wall providing the horizontal exit.

A horizontal exit may be an element of a means of egress when in compliance with the requirements of this section. The actual horizontal exit is the protected door opening in a wall, or the open-air balcony or bridge that separates two areas of a building. A horizontal exit is often used in hospitals and in prisons where it is not feasible or desirable that all occupants exit the facility (see Chapter 2 for the definition of a "Horizontal exit").

Horizontal exits and their associated "refuge areas" are considered to provide the same or higher level of protection as an "area of refuge" for people who cannot use the egress system. Sections 1007.3 and 1007.4 allow for a horizontal exit or an area of refuge as alternatives. See these sections for exceptions for buildings with sprinkler systems and/or where the path of travel has protection from the accumulation of smoke (i.e., open parking garages, open air assembly seating, smoke-protected assembly seating).

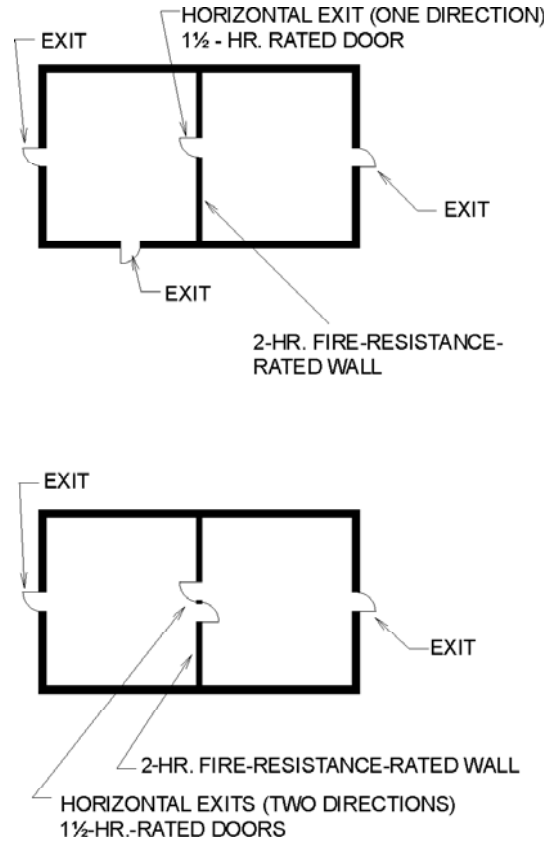

Figure 1025.1
TYPICAL HORIZONTAL EXITS

1025.2 Separation. The separation between buildings or refuge areas connected by a *horizontal exit* shall be provided by a *fire wall* complying with Section 706; or it shall be provided by a *fire barrier* complying with Section 707 or a *horizontal assembly* complying with Section 711, or both. The minimum *fire-resistance rating* of the separation shall be 2 hours. Opening protectives in *horizontal exits* shall also comply with Section 716. Duct and air transfer openings in a *fire wall* or *fire barrier* that serves as a *horizontal exit* shall also comply with Section 717. The *horizontal exit* separation shall extend vertically through all levels of the building unless floor assemblies have a *fire-resistance rating* of not less than 2 hours with no unprotected openings.

Exception: A *fire-resistance rating* is not required at *horizontal exits* between a building area and an above-grade *pedestrian walkway* constructed in accordance with Section 3104, provided that the distance between connected buildings is more than 20 feet (6096 mm).

Horizontal exits constructed as *fire barriers* shall be continuous from *exterior wall* to *exterior wall* so as to divide completely the floor served by the *horizontal exit*.

❖ The basic concept of a horizontal exit is that during a fire emergency, the occupants of a floor will transfer from one fire area to another. Separation between areas of a building can be accomplished by either a fire wall (see Section 706) a fire barrier (see Section 707) horizontal assemblies (see Section 711), or a combination thereof, with a fire-resistance rating not less than 2 hours. Any fire shutters or fire doors must have an opening protective of not less than $1^1/_2$ hours (see Table 716.5). Ducts and air transfer openings must comply with Section 717.

In buildings of Groups I-2 and I-3, it may also be desirable (while not mandatory) for the horizontal exit to serve as a smoke barrier. In such cases, the wall containing the horizontal exit must also comply with the requirements for a smoke barrier (see Section 709).

In order to decrease the amount of smoke able to migrate around the edges of a horizontal exit, the horizontal exit must extend from at least the floor to the deck above (i.e., fire barrier), as well as across the floor level from one side of the building to another. Moving up from floor to floor, there are two choices. One option is that the horizontal exit can extend vertically through all levels of the building (i.e., fire wall or fire barriers). The second option is to utilize fire barriers that are not aligned vertically (i.e., a combination of fire barriers and horizontal assemblies), but then the floor must have a 2-hour fire-resistance rating and no unprotected openings are permitted between any two refuge areas. The supporting construction would also have to be a minimum of 2 hours.

The exception is permitting a pedestrian walkway or sky bridge to act as a horizontal exit when buildings are at least 20 feet (6096 mm) apart.

1025.3 Opening protectives. *Fire doors* in *horizontal exits* shall be self-closing or automatic-closing when activated by a *smoke detector* in accordance with Section 716.5.9.3. Doors, where located in a cross-corridor condition, shall be automatic-closing by activation of a *smoke detector* installed in accordance with Section 716.5.9.3.

❖ For the safety of occupants using a horizontal exit, it is important that the doors be fire doors that are self-

closing or automatic closing by activation of a smoke detector. Smoke detectors that initiate automatic closing should be located at both sides of the doors (see the commentary to Section 907.3 for an additional explanation of the installation requirements). Any openings in the fire barriers or fire walls used as horizontal exits must be protected in coordination with the rating of the wall. There is a reference to Section 716 for opening protectives.

1025.4 Capacity of refuge area. The refuge area of a *horizontal exit* shall be a space occupied by the same tenant or a public area and each such refuge area shall be adequate to accommodate the original *occupant load* of the refuge area plus the *occupant load* anticipated from the adjoining compartment. The anticipated *occupant load* from the adjoining compartment shall be based on the capacity of the *horizontal exit* doors entering the refuge area. The capacity of the refuge area shall be computed based on a *net floor area* allowance of 3 square feet (0.2787 m^2) for each occupant to be accommodated therein.

Exception: The *net floor area* allowable per occupant shall be as follows for the indicated occupancies:

1. Six square feet (0.6 m^2) per occupant for occupancies in Group I-3.
2. Fifteen square feet (1.4 m^2) per occupant for ambulatory occupancies in Group I-2.
3. Thirty square feet (2.8 m^2) per occupant for nonambulatory occupancies in Group I-2.

The refuge area into which a *horizontal exit* leads shall be provided with *exits* adequate to meet the occupant requirements of this chapter, but not including the added *occupant load* imposed by persons entering it through *horizontal exits* from other areas. At least one refuge area exit shall lead directly to the exterior or to an *interior exit stairway* or *ramp*.

Exception: The adjoining compartment shall not be required to have a *stairway* or door leading directly outside, provided the refuge area into which a *horizontal exit* leads has *stairways* or doors leading directly outside and are so arranged that egress shall not require the occupants to return through the compartment from which egress originates.

❖ The building area on the discharge side of a horizontal exit must serve as a refuge area for the occupants of both sides of the floor areas connected by the horizontal exit. Therefore, adequate space must be available on each side of the wall to hold the full occupant load of that side, plus the number of occupants from the other side that may be required to use the horizontal exit. Explaining the anticipated occupant load is easiest with an example. If one side of the horizontal exit contained an assembly space with 750 occupants, three exits would be required. If one of the exits through the horizontal exit was a double door, that double exit door would have a capacity of 320 (64 inches/0.2 = 320 occupants). Therefore, the refuge area must be sized for the occupant load in the space, plus the 320 people that might come through the horizontal exit. This is a higher number than would be anticipated if the occupant load of the assembly space was divided equally between the three exits, but it is also not the entire occupant load of the assembly space.

These refuge areas are meant to hold the occupants temporarily in a safe place until they can evacuate the premises in an orderly manner or, in the case of hospitals and like facilities, to hold bedridden patients and other nonambulatory occupants in a protected area until the fire emergency has ended. The size of the refuge area is based on the nature of the expected occupants. In the case of Group I-3, the area will be used to hold the occupants until deliberate egress can be accomplished with staff assistance or supervision. In other cases, it is assumed that the occupants simply wait in line to egress through the required exit facilities provided on the discharge side. Although similar language is used in describing the "area of refuge" for an accessible means of egress, Section 1007.6 specifies area requirements that are insufficient for use as a "refuge area" for a horizontal exit. Care must be taken when applying both principles to the same horizontal exit.

The 3-square-feet (0.28 m^2) per occupant requirement is based on the maximum permitted occupant density at which orderly movement to the exits is reasonable. The 30-square-feet (2.8 m^2) per hospital or nursing home patient requirement is based on the space necessary for a bed or litter. It should be noted that 30 square feet (2.8 m^2) is not based on the total occupant load, as would be determined in accordance with Section 1004.1, but rather on the number of nonambulatory patients. The 15-square-feet (1.4 m^2) requirement for occupancies in Group I-2 facilities is based on each ambulatory patient having a staff attendant.

In a single-tenant facility, any of the spaces that are constantly available (e.g., not lockable) can be used as places of refuge. However, in spaces housing more than one tenant, public refuge areas, such as corridors or passageways, must be provided and be accessible at all times. This requirement is necessary because if a horizontal exit connected two areas occupied by different tenants, the tenants could (for privacy and security purposes) render the necessary free access through the horizontal exit ineffective. When the horizontal exit discharges into a public or common space, such as a corridor leading to an exit, each tenant can obtain the desired security.

Note that the capacity of the exit (such as an exit stairway) from the refuge area to which the horizontal exit leads is required to be sufficient for the design occupant load in the area, and does not include those who come into the space from other areas via the horizontal exit. This is because the adjacent refuge area is of sufficient safety to house occupants during a fire or until the egress system is available.

The door through the horizontal exit and the second exit must meet the separation requirements in

Section 1015.2.1. Measurement of the travel distance stops at the doorway that serves as the horizontal exit. There are not travel distance requirements for the distance from the horizontal exit to the exit (i.e., exterior exit doorway, exit stairway or exit ramp) on the other side; however, the areas on each side need to be evaluated for all means of egress requirements individually.

When there is one horizontal exit and two fire compartments, at least one exit from each side of the horizontal exit must go directly to the outside of an exit stairway or ramp enclosure (see Figure 1025.1). The exception allows for a central building/fire area with access to two horizontal exits and no direct exterior exit door or exit stairway/ramp enclosure as long as the piece on each side has access to exterior exits or exit stairways/ramps (see Figure 1025.4).

SECTION 1026
EXTERIOR EXIT STAIRWAYS AND RAMPS

1026.1 Exterior exit stairways and ramps. *Exterior exit stairways* and *ramps* serving as an element of a required *means of egress* shall comply with this section.

❖ Stairways and ramps can be exit access, exit or exit discharge elements. Exterior exit access and exit discharge stairs and ramps typically involve a change of elevation of less than a story. Exterior exit access stairways or ramps between stories must comply with Section 1009.3, and where permitted as part of the required means of egress are limited by Section 1021. Exit stairways and ramps traverse a full story or more. Interior exit stairways and ramps must be enclosed in accordance with Section 1022. This section addresses exterior stairways and ramps that function as exit elements.

Exterior exit stairways and ramps are an important element of the means of egress system and must be designed and constructed so that they will serve as a safe path of travel. The general requirements in Section 1009 also apply to exterior stairways (for ramp provisions, see Section 1010).

Outdoor stadiums and open parking garages are examples of buildings that may appear to have exterior exit stairways, but are only actually required to have exit access stairways (Section 1021.1, Exceptions 1 and 2).

1026.2 Use in a means of egress. *Exterior exit stairways* shall not be used as an element of a required *means of egress* for Group I-2 occupancies. For occupancies in other than Group I-2, *exterior exit stairways* and *ramps* shall be permitted as an element of a required *means of egress* for buildings not exceeding six stories above *grade plane* or which are not high-rise buildings.

❖ This section specifies the conditions where exterior exit ramps or stairways can be used as required exits. Exterior exit stairways are not permitted for Group I-2 since quick evacuation of nonambulatory patients from buildings using exterior stairways is impractical. Some patients may not be capable of self-preservation and, therefore, may require assistance from staff. The period of evacuation of nonambulatory patients could become lengthy, especially in bad weather conditions.

Exterior stairways or ramps are not allowed to be required exits in buildings that exceed six stories in height due to the hazard of using such a stairway or ramp in poor weather. Some persons may not be willing to use such a stair due to vertigo. When confronted with a view from a great height, vertigo sufferers can become confused, disoriented and dizzy. They could injure themselves, become disoriented or refuse to move (freeze). In a fire situation, they could become an obstruction in the path of

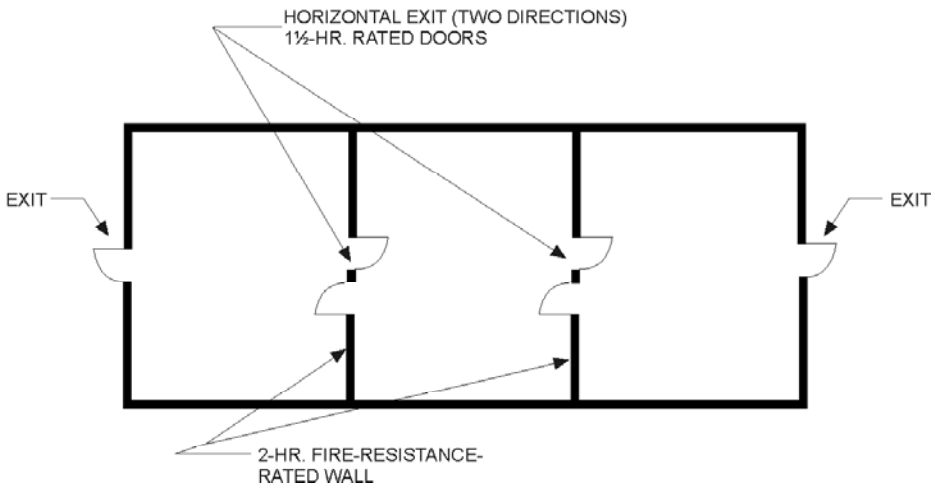

Figure 1025.4
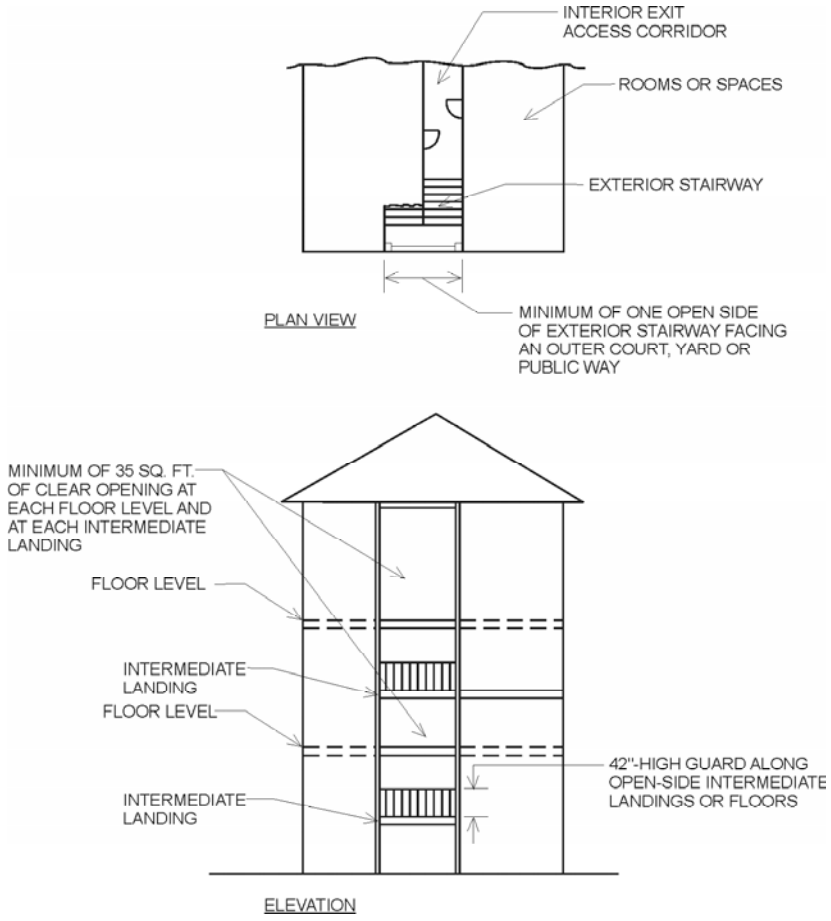
REFUGE AREA EXCEPTION

travel, possibly causing panic and injuries to other users of the exit.



1026.3 Open side. *Exterior exit stairways* and *ramps* serving as an element of a required *means of egress* shall be open on at least one side. An open side shall have a minimum of 35 square feet (3.3 m^2) of aggregate open area adjacent to each floor level and the level of each intermediate landing. The required open area shall be located not less than 42 inches (1067 mm) above the adjacent floor or landing level.

❖ An important factor in exterior exit stairways or ramps is natural ventilation. Sufficient natural ventilation is necessary so that smoke will not be trapped above the stairway or ramp walking surfaces, thereby compromising safe egress.

The exterior exit stairway or ramp must have at least one of its sides directly facing an outer court, yard or public way. This will allow the products of combustion escaping from the interior of the building to quickly vent to the outdoor atmosphere and let the building occupants egress down the exterior exit stairway or ramp. Since exterior exit stairways or ramps are partially bounded by exterior walls, a minimum amount of exterior openness is specified by the code.

The openings on each and every floor level and landing must total 35 square feet (3.3 m^2) or greater. The openings for which credit is given must occur higher than 42 inches (1067 mm) above each floor and intermediate landing levels. [The bottom edge of the opening is consistent with the height requirements for guards (see Section 1013.3)]. With a standard 8-foot (2438 mm) ceiling height minus the 42 inch (1067 mm) high guard and a typical 8-foot-wide (2438 mm) opening, the result would be 4.5 feet x 8 feet = 36 square feet (3.34 m^2). Openings of this height and area readily dissipate the smoke buildup from the exterior exit stairway or ramp (see Figure 1026.3).

1026.4 Side yards. The open areas adjoining *exterior exit stairways* or *ramps* shall be either *yards*, *courts* or *public*

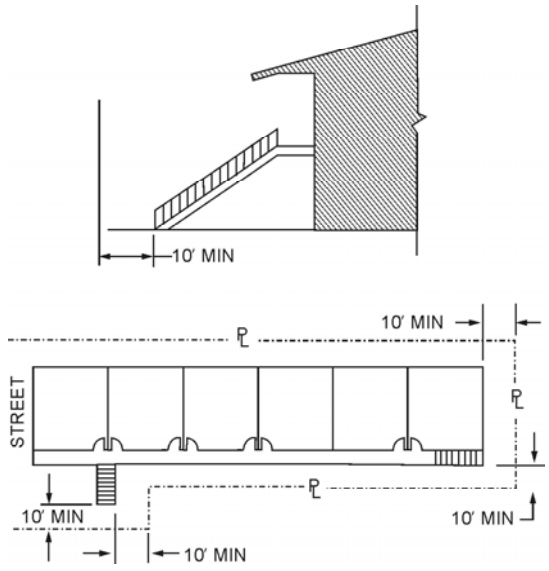
For SI: 1 inch= 25.4 mm;
1 square foot = 0.0929 mm.

Figure 1026.3
EXTERIOR STAIRWAY

ways; the remaining sides are permitted to be enclosed by the *exterior walls* of the building.

❖ This section simply specifies the type of areas that the exterior opening of the exterior exit stairway or ramp is to adjoin. These open spaces will enable the smoke to dissipate from the exterior exit stairway or ramp so it will be usable as a required exit. See Section 1026.3 for a discussion of the opening requirements. See Sections 1027.4 and 1206 for the minimum sizes of yards and courts.

1026.5 Location. *Exterior exit stairways* and *ramps* shall have a minimum fire separation distance of 10 feet (3048 mm) measured from the exterior edge of the *stairway* or *ramp*, including landings, to adjacent lot lines and from other buildings on the same lot unless the adjacent building *exterior walls* and openings are protected in accordance with Section 705 based on *fire separation distance*.



❖ The location requirements of this section protect the users of the exterior exit stairway or ramp from the effects of a fire in another building on the same lot or an adjacent lot. The separation distance reduces the exposure to heat and smoke. If the exterior exit stairway or ramp is closer than specified, then adjacent buildings' exterior walls and openings are to be protected in accordance with Section 705 so that the users of the exterior exit stairway or ramp are protected. The reason for a minimum required distance to a lot line is to provide for a future building that could be built on an adjacent lot. While buildings on the same lot can be considered one building for height and area limitations (see Section 503.1.2), they must be separated by a minimum of 10 feet (3048 mm) if there is a path for exit discharge between them. It is not intended that the distance be measured to an imaginary lot line between buildings on the same lot.

Requirements are the same for exterior egress balconies (Section 1019.4). For an illustration of exterior egress balconies and exterior exit stairways working together, see Figure 1026.5.

1026.6 Exterior stairway and ramp protection. *Exterior exit stairways* and *ramps* shall be separated from the interior of the building as required in Section 1022.2. Openings shall be limited to those necessary for egress from normally occupied spaces.

Exceptions:

1. Separation from the interior of the building is not required for occupancies, other than those in Group R-1 or R-2, in buildings that are no more than two stories above *grade plane* where a *level of exit discharge* serving such occupancies is the first story above *grade plane*.
2. Separation from the interior of the building is not required where the *exterior stairway* or *ramp* is served by an exterior *ramp* or balcony that connects two remote *exterior stairways* or other *approved exits* with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be a minimum of 50 percent of the height of the enclosing wall, with the top of the openings no less than 7 feet (2134 mm) above the top of the balcony.
3. Separation from the interior of the building is not required for an *exterior stairway* or *ramp* located in a building or structure that is permitted to have unenclosed *exit access stairways* in accordance with Section 1009.3.

For SI: 1 foot = 304.8 mm.

Figure 1026.5
EXTERIOR BALCONY AND STAIRWAY ADJACENT TO LOT LINE

4. Separation from the interior of the building is not required for *exterior stairways* or *ramps* connected to open-ended *corridors*, provided that Items 4.1 through 4.5 are met:

   4.1. The building, including *corridors*, *stairways* or *ramps*, shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2.

   4.2. The open-ended *corridors* comply with Section 1018.

   4.3. The open-ended *corridors* are connected on each end to an *exterior exit stairway* or *ramp* complying with Section 1026.

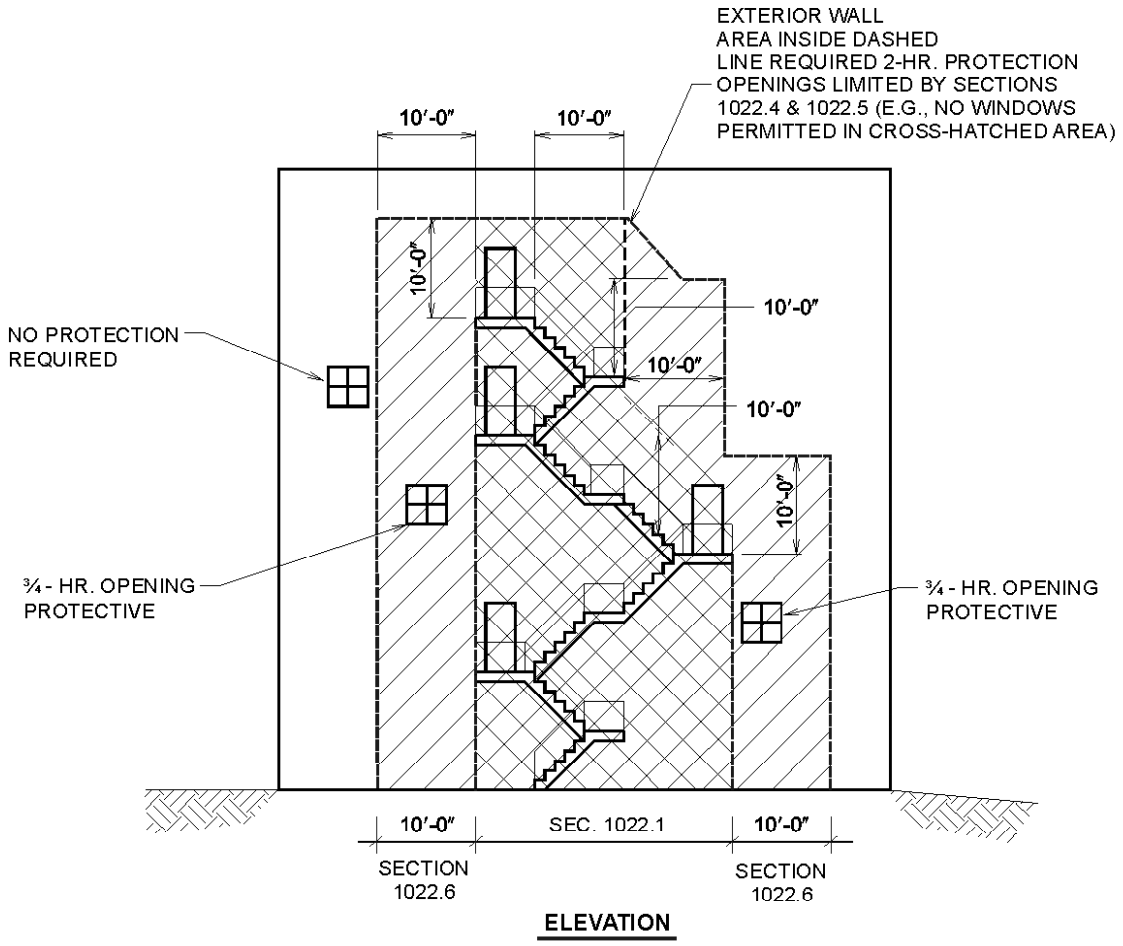
   4.4. The *exterior walls* and openings adjacent to the *exterior exit stairway* or *ramp* comply with Section 1022.7.

   4.5. At any location in an open-ended *corridor* where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3.3 m^2) or an *exterior stairway* or *ramp* shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

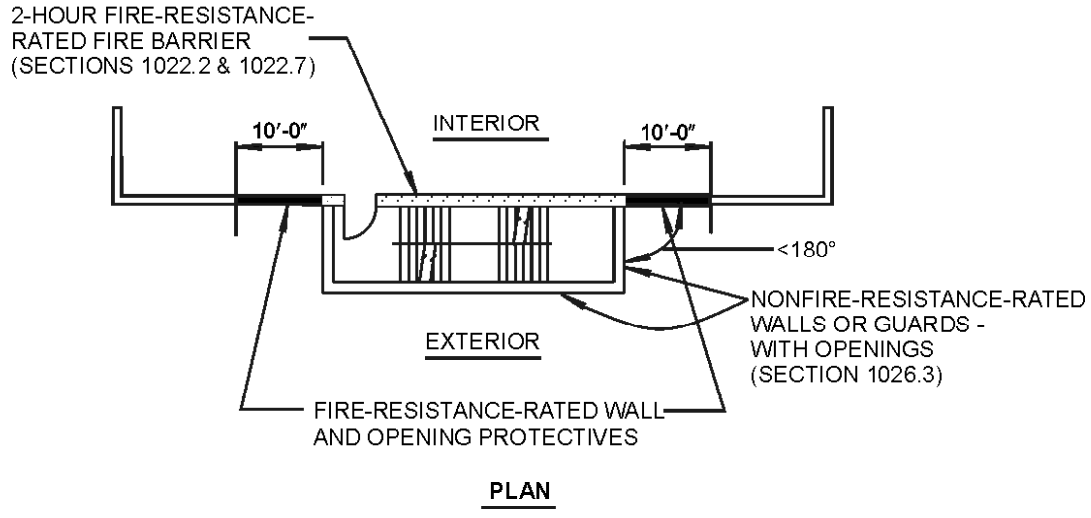
❖ Exterior exit stairways or ramps must be protected from interior fires that may project through windows or other openings adjacent to the exit stairway or ramp, possibly endangering the occupants using this means of egress to reach grade. The protection of an exterior exit stairway or ramp is to be obtained by separating the exterior exit from the interior of the building using exterior walls having a fire-resistance rating of at least 1 hour with opening protectives. Consistent with the protection required in Sections 1022.2 and 1022.7 for interior exit stairways, the fire-resistance rating must be provided for a distance of 10 feet (3048 mm) horizontally and vertically from the ramp or stairway edges, and from the ground to a level of 10 feet (3048 mm) above the highest landing.

All window and door openings falling inside the 10-foot (3048 mm) horizontal separation distance as well as all window and door openings 10 feet (3048 mm) above the topmost landing and below the stairway must be protected with minimum $^3/_4$-hour fire protection-rated opening protectives [see Figure 1026.6(1)].

Openings within the width of the stairway must only be from normally occupied spaces. This is consistent with the requirements for vertical exit enclosures (see Sections 1022.4 and 1022.5).



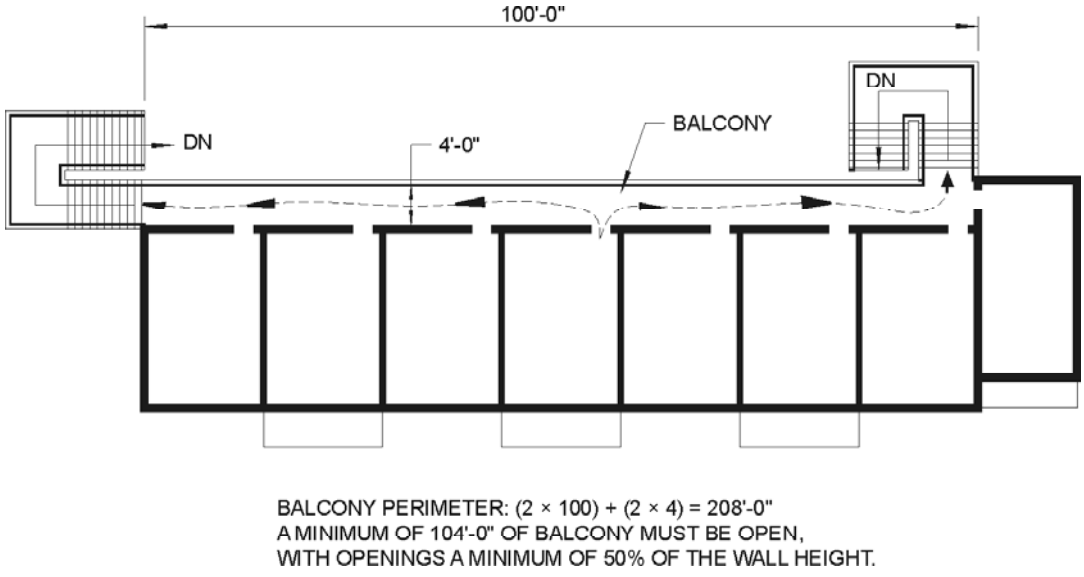
Exception 1 indicates that opening protectives are not required for occupancies (other than Groups R-1 and R-2) that are two stories or less above grade when the level of exit discharge is at the lower story. The reason for this exception is that in cases of fire in low buildings, the occupants are usually able to evacuate the premises before the fire can emerge through exterior wall openings and endanger the exit ramp or stairways. In hotels and apartments, however, the occupants' response to a fire emergency could be significantly reduced because they may be either unfamiliar with the surroundings or sleeping.



Exception 2 allows the opening protectives to be omitted when an exterior exit access balcony is served by two exits and when the exits are remote from each other. Remoteness is regulated by Section 1015.2. This exception is applicable to all groups. In such instances, it is unlikely that the users of the exterior stairway or ramp will become trapped by fire, since they have the option of using the balcony to gain access to either of the two available exits, and the products of combustion will be vented directly to the outside (see Section 1019.1 regarding exterior balconies). At least one-half of the total perimeters of the exterior balcony must be permanently open to the outside. The requirement for at least one-half the height of that level to be open allows for columns, solid guards and architectural or decorative elements, such as arches. With the top of the opening at least 7 feet (2134 mm) above the walking surface, products of combustion can vent and allow occupant passage below the smoke layer [see Figure 1026.6(2)].

Exception 3 exempts exterior stairways or ramps from protection when Section 1009.3 permits unenclosed interior exit access stairways. This would be areas such as open parking garages, individual dwelling units in Groups R-2 and R-3, etc.

Exception 4 deletes the requirement for a separation between the interior of the building and the exterior wall area immediately adjacent to the exit stairway where an open-ended corridor (breezeway) interfaces with an exterior stairway or ramp. The separation is not needed due to the NFPA 13 or 13R sprinkler system required in all areas of the building, including the open-ended corridor. The other characteristics of the open-ended corridor described in this exception are needed so that it is safe to be used in the event of a fire. The requirements for an exterior stairway or ramp at each end, and the additional openings or exterior stairways or ramps where the open-ended corridor has a change of direction of greater than 45 degrees (0.79 rad) are for adequate ventilation of the open-ended corridor. The corridor may be required to be rated per Table 1018.1. The reference back to Section 1022.7 results in any exterior walls that form an angle less than 180 degrees (3.14 rad) from the side of the exterior exit stairway to be protected for a distance of 10 feet (3048 mm) [see Figure 1026.6(3)]. Exit access travel distance on an open-ended corridor is measured to the first riser of an exterior stair or the beginning slope of an exterior ramp.



Similar separation language is used in describing the exterior wall requirements for an exterior area for assisted rescue that is provided at an exit located above grade level. Where there are steps, they are merely part of the exit discharge, not exterior exit stairways as addressed in this section.

EXAMPLE OF EXCEPTION 4

SECTION 1027
EXIT DISCHARGE

1027.1 General. *Exits* shall discharge directly to the exterior of the building. The *exit discharge* shall be at grade or shall provide direct access to grade. The *exit discharge* shall not reenter a building. The combined use of Exceptions 1 and 2 shall not exceed 50 percent of the number and capacity of the required exits.

Exceptions:

1. A maximum of 50 percent of the number and capacity of *interior exit stairways* and *ramps* is permitted to egress through areas on the *level of exit discharge* provided all of the following are met:
    1.1. Such enclosures egress to a free and unobstructed path of travel to an exterior *exit* door and such *exit* is readily visible and identifiable from the point of termination of the enclosure.
    1.2. The entire area of the *level of exit discharge* is separated from areas below by construction conforming to the *fire-resistance rating* for the enclosure.
    1.3. The egress path from the *interior exit stairway* and *ramp* on the *level of exit discharge* is protected throughout by an *approved automatic sprinkler system*. All portions of the *level of exit discharge* with access to the egress path shall either be protected throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, or separated from the egress path in accordance with the requirements for the enclosure of *interior exit stairways* or *ramps*.
2. A maximum of 50 percent of the number and capacity of the *interior exit stairways* and *ramps* is permitted to egress through a vestibule provided all of the following are met:
    2.1. The entire area of the vestibule is separated from areas below by construction conforming to the *fire-resistance rating* for the enclosure.
    2.2. The depth from the exterior of the building is not greater than 10 feet (3048 mm) and the length is not greater than 30 feet (9144 mm).
    2.3. The area is separated from the remainder of the *level of exit discharge* by construction providing protection at least the equivalent of *approved* wired glass in steel frames.
    2.4. The area is used only for *means of egress* and *exits* directly to the outside.
3. *Horizontal exits* complying with Section 1025 shall not be required to discharge directly to the exterior of the building.

❖ The exit discharge is the third piece of the means of egress system, which includes exit access, exit and exit discharge. The general provisions for means of egress in Sections 1003 through 1013 are applicable to the exit discharge. The basic provision is that exits must discharge directly to the outside of the building. The exit discharge is the path from the termination of the exit to the public way. When it is not practical to discharge directly to the outside, there are four alternatives: an exit passageway (see Section 1023), an exit discharge lobby (see Sections 1027.1, Exception 1), an exit discharge vestibule (see Section 1027.1, Exception 2) or a horizontal exit (see Sections 1025 and 1027.1, Exception 3).

While Exceptions 1 and 2 could be applicable for exit passageways and exit ramps, most of the real-life application of the exceptions is for exit stairways. This commentary for Section 1027 will be limited to interior exit stairways that are enclosed in accordance with Section 1022 (see Sections 1009.3 and 1021 for exit access stairway requirements). Up to 50 percent of the interior exit stairways in a building may use either Exception 1 or 2; therefore, neither exception is viable for a single-exit building. In a two- or three-exit building, either a lobby or a vestibule can be used for exit discharge for one of the exit stairways. In a four-exit building, two of the exit stairways can use either a lobby or a vestibule for exit discharge.

An interior exit discharge lobby is permitted to receive the discharge from an exit stairway in lieu of the stairway discharging directly to the exterior. A fire door must be provided at the point where the exit stairway discharges into the lobby. Without an opening protective between the stairway and a lobby, it would be possible for the stairway to be directly exposed to smoke movement from a fire in the lobby. The opening protective provides for full continuity of the vertical component of the exit arrangement. Additionally, in buildings where stair towers must be pressurized, pressurization would not be possible without a door at the lobby level.

An exit discharge lobby is the sole location recognized in the code where an exit element can be used for purposes other than pedestrian travel for means of egress. The lobby may contain furniture or decoration and nonoccupiable spaces may open directly into the lobby. The lobby, and all other areas on the same level that are not separated from the lobby by fire barriers consistent with the rating of the stair enclosure, must be sprinklered in accordance with an NFPA 13 or NFPA 13R system [see Figure 1027.1(1)]. If the entire level is sprinklered, no separation is required. In this case, the automatic sprinkler system is antici-

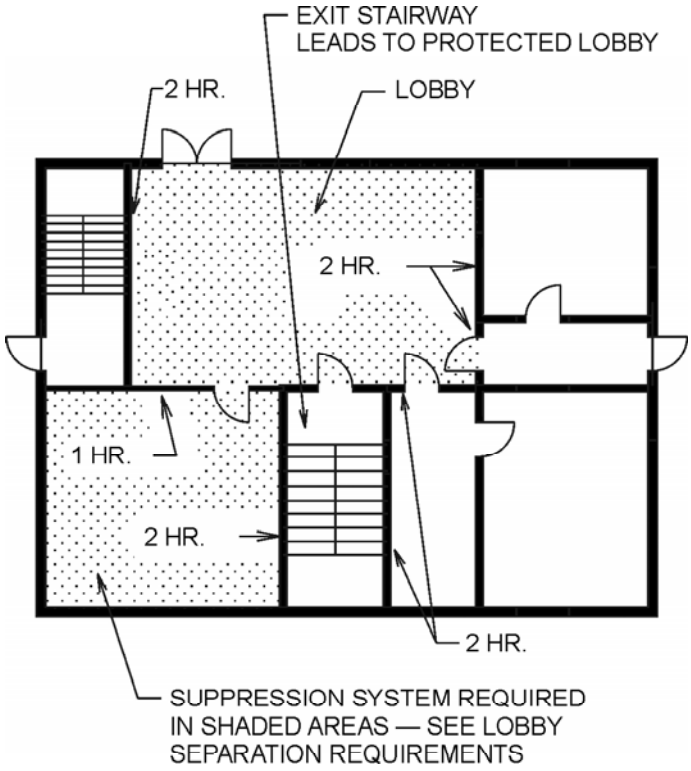
pated to control and (perhaps) eliminate the fire threat so as not to jeopardize the path of egress of the occupants. The lobby floor and any supporting construction must be rated the same as the stairway enclosure. If the lobby is slab on grade, this requirement is not applicable. This is consistent with the fundamental concept that an exit enclosure provides the necessary level of protection from adjacent areas. A path of travel through the lobby must be continually clear and available. The exit door leading out of the building must be visible and identifiable immediately when a person leaves the exit. This does not mean the exterior exit door must be directly in front of the door at the bottom of the stairway, but the intent is that it should be within the general range of vision. It should not be required that a person must turn completely around or go around a corner to be able to see the way out.

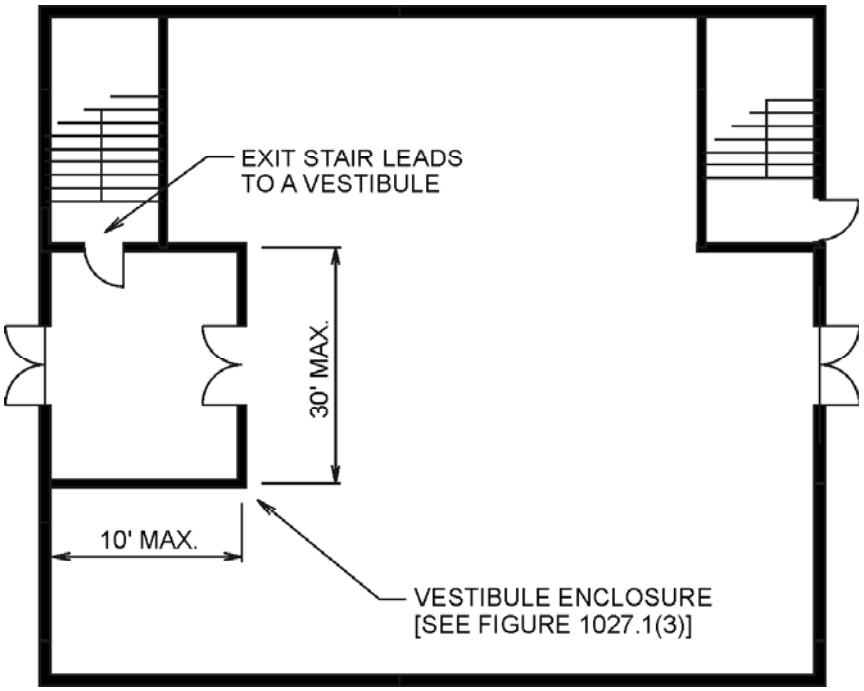
An exit is also allowed to discharge through a vestibule, provided it complies with the specified requirements of Exception 2. Vestibules utilizing this provision are not to be used for other purposes, such as access to closets, furniture/seating, drinking fountains, vending machines, etc. The vestibule floor and any supporting construction must be rated the same as the stairway enclosure. If the vestibule is slab on grade, this requirement is not applicable. The interior walls of the vestibule must be constructed with materials no less substantial than wired glass in steel frames. Doors are typically opening protectives with a fire protection rating of at least 20 minutes. The size of the vestibule is limited so that it cannot be used for other activities, and the travel distance from the exit stairway to the exterior exit doorway is limited [see Figures 1027.1(2) and 1027.1(3)].

Exception 3 acknowledges that horizontal exits utilize refuge areas and are not required to exit to the exterior. Many hospitals and correctional facilities use horizontal exits to "defend in place" rather than require an immediate building evacuation. There are exit stairways or exits available from the refuge areas, so occupants can move to the outside if they need to (see Section 1025 for additional information).

1027.2 Exit discharge capacity. The capacity of the *exit discharge* shall be not less than the required discharge capacity of the *exits* being served.

❖ This section specifies the exit discharge capacity. The exit discharge is required to be designed for the required capacity of all the exits it serves. If the exit discharge serves two exits, it is to be designed for the sum of the occupants served by both exits. Note that the capacity of the exit discharge is not required to match the capacity of both exits, which is typically higher than the sum of the occupants served by both exits.





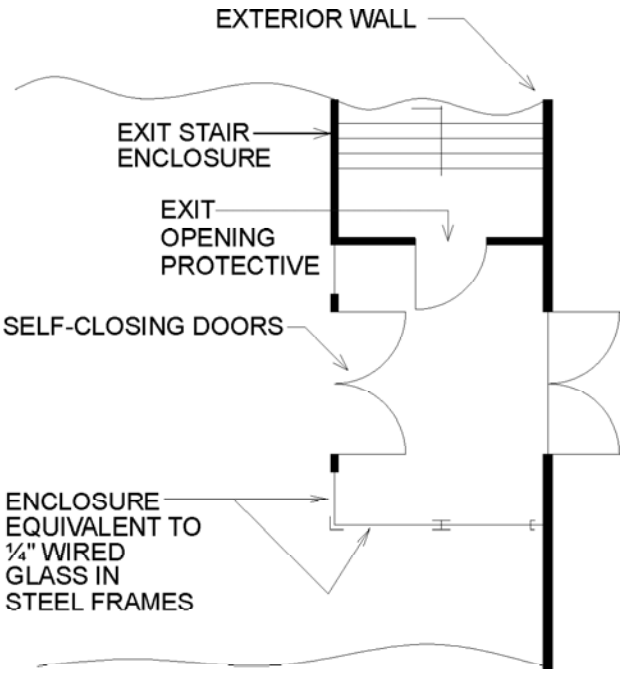


Figure 1027.1(1)
PROTECTION OF LOBBY WITH AN EXIT DISCHARGE

For SI: 1 foot = 304.8 mm.

Figure 1027.1(2)
VESTIBULE WITH EXIT DISCHARGE

For SI: 1 inch = 25.4 mm.

Figure 1027.1(3)
SEPARATION DETAILS FOR VESTIBULE WITH EXIT DISCHARGE

1027.3 Exit discharge components. *Exit discharge* components shall be sufficiently open to the exterior so as to minimize the accumulation of smoke and toxic gases.

❖ An exit discharge component could be a large open space where people could discharge in a number of different directions or it could be limited to a narrower path by landscaping or walls (i.e., egress court). In all cases, the space must be open enough to the outside that smoke and fumes will vent upward and away from people evacuating the building.

1027.4 Egress courts. *Egress courts* serving as a portion of the *exit discharge* in the *means of egress* system shall comply with the requirements of Section 1027.

❖ A portion of the exit discharge that is partially confined by exterior walls or other elements that confine the discharge path to a single narrow route is regulated as an egress court.

This section and the following subsections address the detailed requirements for egress courts. It is essential that exterior egress courts that serve occupants from an exit to a public way be sufficiently open to prevent the accumulation of smoke and toxic gases in the event of a fire as well as wide enough to accommodate the number of occupants leaving in that direction.

See Section 1206 for additional minimum width and openness requirements when yards and courts are needed for natural light or ventilation.

1027.4.1 Width. The minimum width of *egress courts* shall be determined as specified in Section 1005.1, but such width shall not be less than 44 inches (1118 mm), except as specified herein. *Egress courts* serving Group R-3 and U occupancies shall not be less than 36 inches (914 mm) in width. The required width of *egress courts* shall be unobstructed to a height of 7 feet (2134 mm).

Exception: Encroachments complying with Section 1005.7.

Where an *egress court* exceeds the minimum required width and the width of such *egress court* is then reduced along the path of exit travel, the reduction in width shall be gradual. The transition in width shall be affected by a *guard* not less than 36 inches (914 mm) in height and shall not create an angle of more than 30 degrees (0.52 rad) with respect to the axis of the *egress court* along the path of egress travel. In no case shall the width of the *egress court* be less than the required minimum.

❖ The width of an exterior court is to be determined in the same fashion as for an interior corridor. The width is not to be less than required to serve the number of occupants from the exit or exits and not less than the minimum specified in this section (see also Section 1206). A cross reference back to Section 1005.7 from the exceptions for width in corridors (see Section 1018.3), aisles (see Section 1017.1), exit passageways (see Section 1023.2) and exit courts (see Section 1027.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

Many egress courts are significantly larger than required. Thus, the code allows such an egress court to decrease in width along the path of travel to the public way. The gradual transition requirement is so the flow of the occupants will be uniform without pockets of congestion. The transition requirements should be applied to egress courts where a reduction results in a width that is near the minimum based on the number of occupants served. It is this condition where the uniform flow of occupants is essential.

1027.4.2 Construction and openings. Where an *egress court* serving a building or portion thereof is less than 10 feet (3048 mm) in width, the *egress court* walls shall have not less than 1-hour fire-resistance-rated construction for a distance of 10 feet (3048 mm) above the floor of the *court*. Openings within such walls shall be protected by opening protectives having a fire protection rating of not less than $^3/_4$ hour.

Exceptions:

1. *Egress courts* serving an *occupant load* of less than 10.
2. *Egress courts* serving Group R-3.

❖ The purpose of this section is to protect the occupants served by the egress court from the building that they are exiting from. If occupants must walk closely by the exterior walls of the court, the walls are required to have the specified fire-resistance rating and the openings are required to be protected as specified. This requirement is only for the first 10 feet (3048 mm) above the level of the egress court since the exposure hazard from walls and openings above 10 feet (3048 mm) is reduced. The two exceptions provide for egress courts that serve a very low number of occupants and the specified residential occupancy where the protection requirement would be located.

1027.5 Access to a public way. The *exit discharge* shall provide a direct and unobstructed access to a *public way*.

Exception: Where access to a *public way* cannot be provided, a safe dispersal area shall be provided where all of the following are met:

1. The area shall be of a size to accommodate at least 5 square feet (0.46 m^2) for each person.
2. The area shall be located on the same lot at least 50 feet (15 240 mm) away from the building requiring egress.
3. The area shall be permanently maintained and identified as a safe dispersal area.
4. The area shall be provided with a safe and unobstructed path of travel from the building.

❖ There are instances where the path of travel to the public way is not safe or not achievable due to site constraints or security concerns. The provisions in this section specify what would constitute a safe area to allow occupants of a building to assemble in an emergency. The 5 square feet (0.28 m^2) would allow adequate space for standing persons as well as

some space for persons in wheelchairs or on stretchers. Everyone who is expected to wait in this dispersal area for fire department assistance must be a minimum of 50 feet (15 240 mm) away from the building. This refuge must always remain open and not be used for parking, storage or temporary structures. A safe dispersal area is commonly found at schools or jails. Stadiums are more specifically addressed in Section 1008.2.1. Walls or fences may surround the building and part of the site due to other safety concerns. These walls and fences could stop occupants from reaching the public way.

SECTION 1028
ASSEMBLY

1028.1 General. A room or space used for assembly purposes which contains seats, tables, displays, equipment or other material shall comply with this section.

❖ Although most of the provisions in Section 1028 focus on fixed seating auditoriums or theaters, this section also addresses loose seats, tables, displays, equipment, etc. Assembly spaces that contain elements that would affect the path of travel for the means of egress must comply with this section. Assembly spaces require special consideration due to the large occupant loads and possible low lighting (e.g., nightclubs, theaters). Spaces used for assembly seating may appear in buildings of other occupancy types; for example a library in a school, or a meeting room in office building. For evaluation of the occupant load and the means of egress in these spaces, they should be regulated based on their function, rather than their occupancy group.

1028.1.1 Bleachers. *Bleachers*, *grandstands* and *folding and telescopic seating*, that are not building elements, shall comply with ICC 300.

❖ On February 24, 1999, the Bleacher Safety Act of 1999 was introduced in the House of Representatives. The bill, which cites the ICC and the code, authorizes the Consumer Product Safety Commission (CPSC) to issue a standard for bleacher safety. This was in response to concerns relative to accidents on bleacher-type structures. As a result, the CPSC developed and revised the *Guidelines for Retrofitting Bleachers*. The ICC Board of Directors decided that a comprehensive standard dealing with all aspects of both new and existing bleachers was warranted and authorized the formation of the ICC Consensus Committee on Bleacher Safety. The committee is comprised of 12 members, including the requisite balance of general, user interest and producer interest.

ICC 300 was completed in December 2001, and submitted to ANSI on January 1, 2002. ICC 300 was reissued with some revisions in 2007 and 2012. While the term "bleachers" is generic, the standard addresses all aspects of tiered seating associated with bleachers, grandstands and folding and telescopic seating. These types of seating are supported on dedicated structural systems, which in turn may sit on the ground or on a building floor system. Single seats or bench seats bolted down to a stepped floor are not considered a bleacher or grandstand and should comply with Section 1028. See the definitions in Chapter 2 for "Building element," "Bleachers," "Grandstands" and "Folding and telescopic seating." While ICC 300 is consistent and also relies on Chapter 10 of the code for some provisions, the standard addresses items specific to these types of seating arrangement. For example, the minimum number of exits from a bleacher is addressed in ICC 300, Section 404.1; however, to determine the minimum number of exits from the room the bleacher is located in Section 1021 is applicable. The bleacher standard references Chapter 11 of the code and ICC A117.1 for accessibility requirements.

1028.1.1.1 Spaces under grandstands and bleachers. When spaces under *grandstands* or *bleachers* are used for purposes other than ticket booths less than 100 square feet (9.29 m^2) and toilet rooms, such spaces shall be separated by *fire barriers* complying with Section 707 and *horizontal assemblies* complying with Section 711 with not less than 1-hour fire-resistance-rated construction.

❖ Sometimes spaces under grandstands are used for other purposes such as bathrooms, concession stands, storage, etc. If that space caught on fire, it could jeopardize the safe evacuation options for persons on the bleachers. For safety, the spaces below must be separated from the bleachers by fire-resistance-rated construction. This is typically the roof and back walls of the concession stand or storage room. If the space below is either a small ticket booth or bathrooms of any size, the potential fire load is low enough that these spaces are not required to be separated.

Note that Section 903.2.1.5 requires enclosed spaces with an area of over 1,000 square feet (93 m^2) and under an outdoor bleacher system to be sprinklered.

While the path for means of egress passing under the bleachers (i.e., vomitory) is not specifically addressed in this section, when a bleacher system is outside, the capacity factors for determining minimum egress width [Table 404.5(3) of ICC 300] are based on the assumption that the egress route is essentially open to the outside and, therefore, has a limited chance for the accumulation of smoke along that route. Two of the three legacy codes specifically exempted open means of egress routes under bleachers from separation requirements.

1028.2 Assembly main exit. In a building, room or space used for assembly purposes that has an *occupant load* of greater than 300 and is provided with a main *exit*, the main *exit* shall be of sufficient width to accommodate not less than one-half of the *occupant load*, but such width shall not be less than the total required width of all *means of egress* leading to the *exit*. Where the building is classified as a Group A occu-

pancy, the main *exit* shall front on at least one street or an unoccupied space of not less than 10 feet (3048 mm) in width that adjoins a street or *public way*. In a building, room or space used for assembly purposes where there is no well-defined main *exit* or where multiple main *exits* are provided, *exits* shall be permitted to be distributed around the perimeter of the building provided that the total width of egress is not less than 100 percent of the required width.

❖ Assembly buildings as well as other buildings that include spaces that function as assembly spaces (i.e., the band classroom in a school, the training room in an office, the cafeteria in a large factory) present an unusual life safety problem that includes frequent high occupant densities and therefore large occupant loads and the opportunity for irrational mass response to a perceived emergency, i.e., panic. For this reason, the code requires a specific arrangement of the exits. Studies have indicated that in any emergency, occupants will tend to egress via the same path of travel used to enter the room and building. Therefore, a main entrance to the building must also be designed as the main exit to accommodate this behavior, even if the required exit capacity might be more easily accommodated elsewhere. The main entrance (and exit) must be sized to accommodate at least 50 percent of the total occupant load of the structure and must front on a large, open space, such as a street, for rapid dispersal of the occupants outside the building. The remaining exits must also accommodate at least 50 percent of the total occupant load from each level (see Figure 1028.2). The total occupant load includes those within the theater seating area, the foyer and any other space (e.g., ticket booth, concession stand, offices, storage and the like). When the assembly space is within a mixed use building, the intent is that the main exits from the space comply with these provisions for one-half the capacity, but not necessarily that they lead directly to the outside. Egress requirements from the building would depend on how it was anticipated for the assembly space occupants to disperse. For example, an office building may have a large training/conference room where the path of exit access travel from the room goes out a main exit from the space and then disseminates into the general floor egress system. The room exit access doors may need to meet the 50-percent criteria, but once the occupants leave the room and enter the general floor egress system, exit capacity can be dispersed.

The required width of the means of egress in places of assembly is more often determined by the occupant load than in most other occupancies. In other occupancies, the minimum required widths and the travel distances will often determine the required widths of the exits.

This section only requires the main exit to accommodate 50 percent of the occupant load when there is a single main entrance. Therefore, a large stadium or civic center, in which there are numerous entrances (and exits), need not comply with the main entrance criteria.

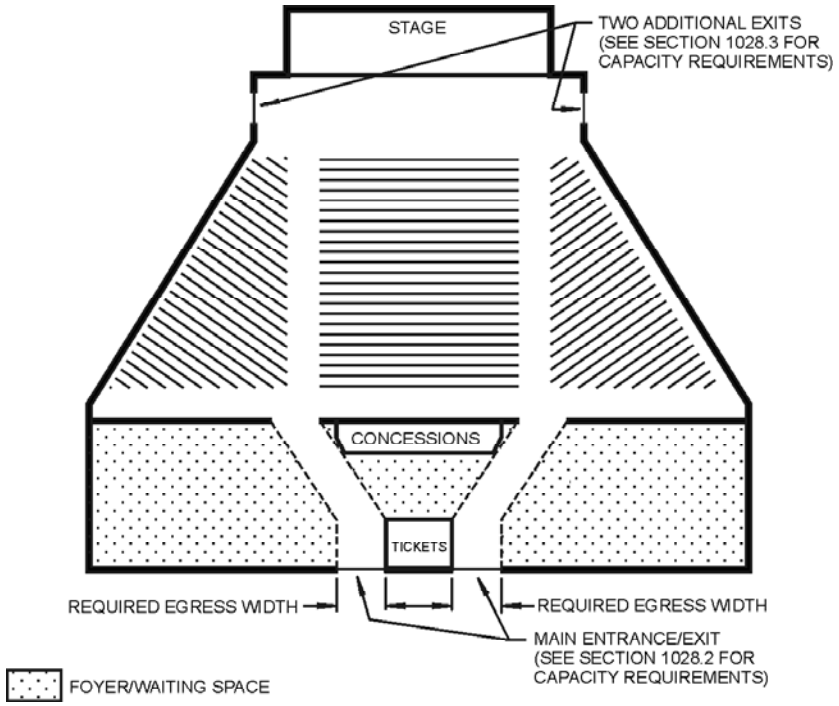

Figure 1028.2
GROUP A-1 WITH WAITING SPACE

1028.3 Assembly other exits. In addition to having access to a main *exit*, each level in a building used for assembly purposes having an *occupant load* greater than 300 and provided with a main *exit*, shall be provided with additional *means of egress* that shall provide an egress capacity for at least one-half of the total *occupant load* served by that level and shall comply with Section 1015.2. In a building used for assembly purposes where there is no well-defined main *exit* or where multiple main *exits* are provided, *exits* for each level shall be permitted to be distributed around the perimeter of the building, provided that the total width of egress is not less than 100 percent of the required width.

❖ This section provides for the egress of one-half of the total occupant load by way of exits other than the main exit that is described in Section 1028.2. Assembly buildings as well as other buildings that include spaces that function as assembly spaces that are provided with multiple entrances but no single main entrance do not provide a well-defined main exit; therefore, the total required exit width needs to be distributed around the perimeter of the space or building. Examples of these assemblies would be a school gymnasium or a large stadium or civic center in which there are numerous entrances (and exits).

1028.4 Foyers and lobbies. In Group A-1 occupancies, where persons are admitted to the building at times when seats are not available, such persons shall be allowed to wait in a lobby or similar space, provided such lobby or similar space shall not encroach upon the required clear width of the *means of egress*. Such foyer, if not directly connected to a public street by all the main entrances or *exits*, shall have a straight and unobstructed *corridor* or path of travel to every such main entrance or *exit*.

❖ In theaters, people may be arriving and waiting for the next show while another group has yet to exit. This is extremely common in multiplex theater complexes. In every case, the main entrance (exit) and all other exits are to be constantly available for the entire building occupant load.

For example, because of the queuing of large crowds, particularly in theaters where a performance may be in progress and people must wait to attend the next one, standing space is often provided. For reasons of safety, such spaces cannot be located in or interfere with established paths of egress from the assembly areas. While a facility may choose to separate the route for means of egress using partitions or railings from the general lobby space to allow for easy traffic flow through the lobby to the street, it is not required to designate these areas (see Figure 1028.2).

1028.5 Interior balcony and gallery means of egress. For balconies, galleries or press boxes having a seating capacity of 50 or more located in a building, room or space used for assembly purposes, at least two *means of egress* shall be provided, with one from each side of every balcony, gallery or press box and at least one leading directly to an *exit*.

❖ This section states the threshold where two means of egress are required based on the occupant load of the interior balcony, gallery or press box. Note that one of the means of egress must lead directly to an exit. While Section 1009.3, Exception 9 does not require the exit access stairways serving the balcony to be enclosed in an exit enclosure, requiring direct access to an exit would be either an exit stairway surrounded by a protected enclosure (see Section 1022) or a door leading directly to the exterior. These requirements will ensure that at least one path of travel is always available and occupants face a minimum number of hazards.

For balconies, galleries or press boxes with 50 or fewer occupants, see Section 1028.8. When balconies, galleries or press boxes contain wheelchair spaces, the area must also meet the accessible means of egress requirements (Sections 1007.1, Exception 3, and 1028.8).

1028.6 Width of means of egress for assembly. The clear width of *aisles* and other *means of egress* shall comply with Section 1028.6.1 where smoke-protected seating is not provided and with Section 1028.6.2 or 1028.6.3 where smoke-protected seating is provided. The clear width shall be measured to walls, edges of seating and tread edges except for permitted projections.

❖ The means of egress width for spaces used for assembly is to be in accordance with this section and the referenced sections instead of the criteria specified in Section 1005 when dealing with the means of egress within the seating area. The width factors in Section 1028.6 and its subsections apply to those doorways, passageways, aisle steps, ramped aisles and level aisles that serve the assembly seating areas.

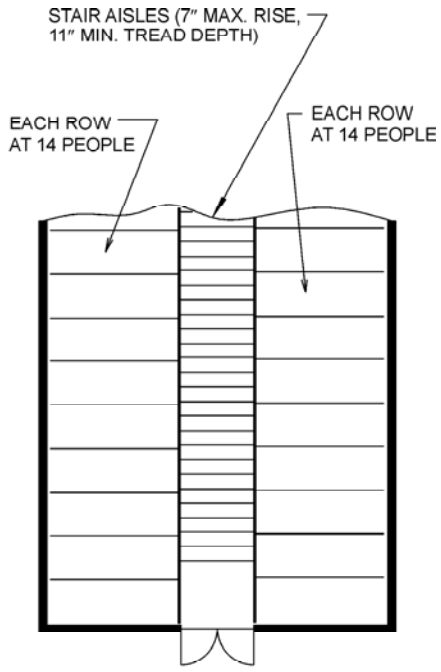
The Board for the Coordination of Model Codes (BCMC) issued a report on means of egress dated June 10, 1985. The provisions in Section 1028 are based on this report. This report limits the application of these provisions to aisles and aisle accessways that provide exit access within the room or space with the assembly seating. This would include aisle accessways, level aisles, aisle steps and ramped aisles. The primary concern for occupant safety would be that where the different provisions for the capacity requirements in Sections 1028 and 1005 were utilized, there would not be a bottleneck in the path of travel for means of egress. For example, a common configuration at football fields is to have the seating area raised several feet above grade. Where a step or series of steps leading to grade from a raised seating area are a continuation of the aisle steps, the width of the aisle steps between seats and

the steps without adjacent seats should be the same. In theaters, commonly the occupants leave the seating area for a concourse or lobby area that leads to exit stairways between floor levels. In this situation the capacity requirement in Section 1005.3 would be applicable for the exit stairway. For the many situations between these two scenarios, the decision would be based on the configuration of the seating and exit stairways between levels.

For example, in a facility without smoke protection and an occupant load of 800, doorways would need to be calculated based on 0.20 inches (5.1 mm) per occupant (see Item 4 of Section 1028.6.1). An occupant load of 800 x 0.2 inches (4064 mm) = 160 inches (4064 mm) of egress width capacity, which translates into not less than five doors [assuming each with a minimum 32-inch (813 mm) clear opening]. This facility needs to have not less than three distinct means of egress (Section 1021.2.4). A main exit must accommodate not less than one-half of the occupant load (Section 1028.2). Therefore, the result would be not less than six doors: three located at the main exit and three others distributed to at least two other locations (Section 1028.3).

Different means of egress width criteria are also specified for assembly seating where smoke protection is provided versus areas it is not provided. The egress width for smoke-protected seating is allowed to be less than for areas where smoke protection is not provided, since the smoke level is required to be maintained at least 6 feet (1829 mm) above the floor of the means of egress, according to Section 1028.6.2.1.

1028.6.1 Without smoke protection. The clear width of the *means of egress* shall provide sufficient capacity in accordance with all of the following, as applicable:



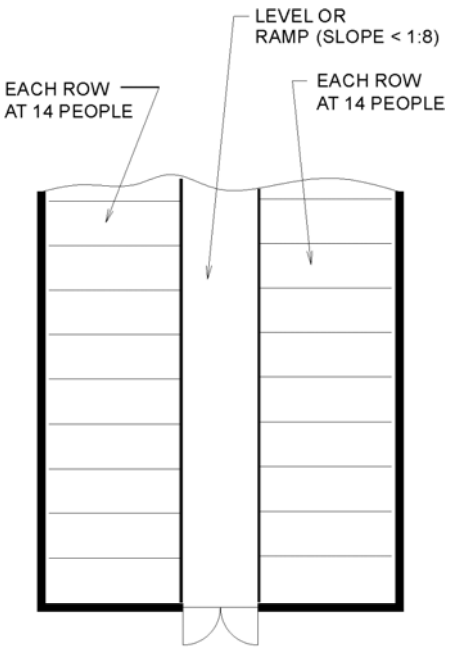
1. At least 0.3 inch (7.6 mm) of width for each occupant served shall be provided on *stairs* having riser heights 7 inches (178 mm) or less and tread depths 11 inches (279 mm) or greater, measured horizontally between tread *nosings*.
2. At least 0.005 inch (0.127 mm) of additional *stair* width for each occupant shall be provided for each 0.10 inch (2.5 mm) of riser height above 7 inches (178 mm).
3. Where egress requires *stair* descent, at least 0.075 inch (1.9 mm) of additional width for each occupant shall be provided on those portions of *stair* width having no *handrail* within a horizontal distance of 30 inches (762 mm).
4. Ramped *means of egress*, where slopes are steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have at least 0.22 inch (5.6 mm) of clear width for each occupant served. Level or ramped *means of egress*, where slopes are not steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have at least 0.20 inch (5.1 mm) of clear width for each occupant served.

❖ This section prescribes the criteria needed to calculate the clear widths of aisles and aisle accessways in order to provide sufficient capacity to handle the occupant loads established by the "catchment areas" described in Section 1028.9.2. Clear width is to be measured to walls, edges of seating and tread edges.

The criteria for determining the required widths are based on analytical studies and field tests that used people to model egress situations [see Figures 1028.6.1(1) and 1028.6.1(2)].

Criterion 1 addresses the method for determining the required egress width for aisles and aisle accessways that are stepped. This method corresponds with the requirements of Section 1005.3.1 for egress width per occupant of stairways in an unsprinklered building.

Criterion 2 addresses the method for determining the additional stair width required for aisle and aisle accessway stairs with risers greater than 7 inches (178 mm).



For SI: 1 inch = 25.4 mm.

Figure 1028.6.1(1)
COMPUTATION OF WIDTH FOR STEPPED AISLES

Criterion 3 addresses the method for determining the additional stair width where a handrail is not located within 30 inches (762 mm). Due to the increased chance of falling and not being within reach of a handrail, the capacity per occupant is increased by 25 percent for the entire stairway. For example, to calculate the capacity of a 72-inch-wide (1829 mm) stepped aisle, the answer would be 72 inches/0.375 inch = 192 occupants.

Criterion 4 addresses the method for determining the required widths for level or ramped and level means of egress. Where slopes are less than 1:12 (see definition for "Ramp"), the capacity requirements are also less. Level floors are quicker to negotiate than ramped surfaces for persons with limited mobility.

For SI: 1 inch = 25.4 mm.

Figure 1028.6.1(2)
COMPUTATION OF WIDTH FOR LEVEL, SLOPED OR RAMPED AISLES

1028.6.2 Smoke-protected seating. The clear width of the *means of egress* for *smoke-protected assembly seating* shall not be less than the *occupant load* served by the egress element multiplied by the appropriate factor in Table 1028.6.2. The total number of seats specified shall be those within the space exposed to the same smoke-protected environment. Interpolation is permitted between the specific values shown. A life safety evaluation, complying with NFPA 101, shall be done for a facility utilizing the reduced width requirements of Table 1028.6.2 for *smoke-protected assembly seating*.

Exception: For an outdoor *smoke-protected assembly seating* with an *occupant load* not greater than 18,000, the clear width shall be determined using the factors in Section 1028.6.3.

❖ Special consideration is given to facilities with features that will prevent the means of egress from being blocked by smoke. Facilities to be considered smoke protected by Sections 1028.6.2.1 through 1028.6.2.3 are permitted increases in travel distance, egress capacity, longer dead-end aisles and increased row lengths. Smoke control increases allowable egress time. Typically, model codes based on research by Dr. John Fruin and others recognize the need for occupants exposed to the fire environment to evacuate to a safe area within 90 seconds of notification and to reach a refuge area within 5 minutes. With the increases permitted for smoke-protected facilities, these times are effectively doubled since the time available for safe egress also increases.

The exception is a pointer to the specific criteria for outdoor seating areas. For outdoor stadiums with 18,000 seats or greater, use Table 1028.6.2.

TABLE 1028.6.2. See page 10-176.

❖ This section requires the egress component to be of adequate size to accommodate the occupant load. For smoke-protected seating, the egress width per occupant is based on Table 1028.6.2. Typically, the larger the facility, the higher the ceiling; therefore, more space for smoke containment is associated with more time for egress. The egress width per occupant for nonsmoke-protected seating is to be based on Section 1028.6.1 and is similar to the provisions in Table 1005.1.

1028.6.2.1 Smoke control. *Means of egress* serving a *smoke-protected assembly seating* area shall be provided with a smoke control system complying with Section 909 or natural ventilation designed to maintain the smoke level at least 6 feet (1829 mm) above the floor of the *means of egress*.

❖ The means of egress and the assembly seating area are required to have some type of smoke control system that will prevent smoke buildup from encroaching on the egress path. This may be a mechanical smoke control system, designed in accordance with Section 909, or natural ventilation as in open-air stadiums.

In either type of system, the major consideration is that a smoke-free environment be maintained at least 6 feet (1829 mm) above the floor of the means of egress for a period of at least 20 minutes.

1028.6.2.2 Roof height. A *smoke-protected assembly seating area* with a roof shall have the lowest portion of the roof deck not less than 15 feet (4572 mm) above the highest *aisle* or *aisle accessway*.

Exception: A roof canopy in an outdoor stadium shall be permitted to be less than 15 feet (4572 mm) above the highest *aisle* or *aisle accessway* provided that there are no

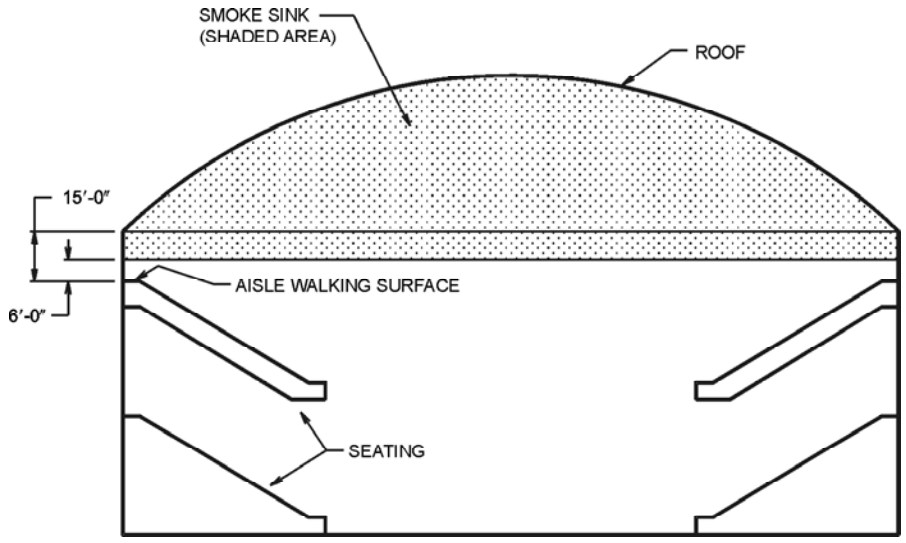
objects less than 80 inches (2032 mm) above the highest *aisle* or *aisle accessway*.

❖ One element of a smoke-protected assembly seating facility is that the lowest portion of the roof is required to be at least 15 feet (4572 mm) above the highest aisle or aisle accessway. The objective of this provision is to have a minimum 6-foot (1829 mm) smoke-free height to accommodate safe egress through the area. The additional 9 feet (2743 mm) of height is to provide a volume of space that will act to dissipate smoke. The measurement of the height is shown in Figures 1028.6.2.2(1) and 1028.6.2.2(2).

1028.6.2.3 Automatic sprinklers. Enclosed areas with walls and ceilings in buildings or structures containing *smoke-protected assembly seating* shall be protected with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1.

Exceptions:

1. The floor area used for contests, performances or entertainment provided the roof construction is more than 50 feet (15 240 mm) above the floor level and the use is restricted to low fire hazard uses.
2. Press boxes and storage facilities less than 1,000 square feet (93 m^2) in area.
3. Outdoor seating facilities where seating and the *means of egress* in the seating area are essentially open to the outside.



❖ If there are areas in the smoke-protected assembly seating structure enclosed by walls and ceilings, the entire structure is to be provided with an automatic sprinkler designed to meet the requirements of NFPA 13.

Exception 1 indicates that the area over the playing field or performance area is not required to be sprinklered if the use of the floor area is restricted. If the facility is used for conventions, trade shows, displays or similar purposes, sprinklers are required throughout, since the occupancy would no longer be a low fire-hazard use. A characteristic of a low fire-hazard occupancy is that the fuel load due to combustibles is

TABLE 1028.6.2
WIDTH OF AISLES FOR SMOKE-PROTECTED ASSEMBLY

TOTAL NUMBER OF SEATS IN THE SMOKEPROTECTED ASSEMBLY SEATING	INCHES OF CLEAR WIDTH PER SEAT SERVED			
	Stairs and aisle steps with handrails within 30 inches	Stairs and aisle steps without handrails within 30 inches	Passageways, doorways and ramps not steeper than 1 in 10 in slope	Ramps steeper than 1 in 10 in slope
Equal to or less than 5,000	0.200	0.250	0.150	0.165
10,000	0.130	0.163	0.100	0.110
15,000	0.096	0.120	0.070	0.077
20,000	0.076	0.095	0.056	0.062
Equal to or greater than 25,000	0.060	0.075	0.044	0.048

For SI: 1 inch = 25.4 mm.

For SI: 1 foot = 304.8 mm.

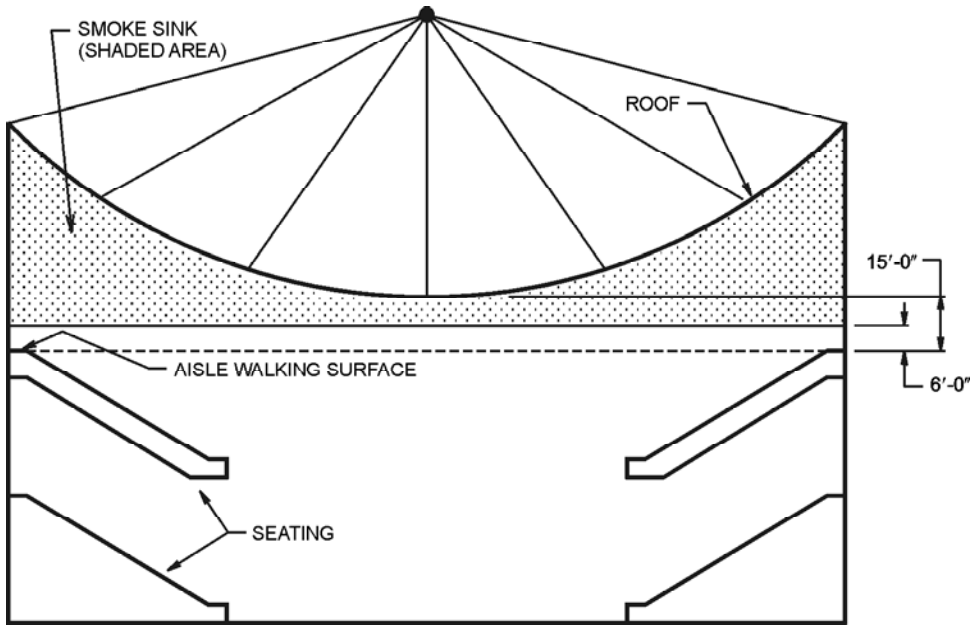
Figure 1028.6.2.2(1)
ROOF HEIGHT (CONVEX DOME ROOF)

approximately 2 pounds per square foot (9.8 kg/m^2) or less.

In order for the contest, performance or entertainment area to be nonsprinklered, the roof over that area must be at least 50 feet (15 240 mm) above the floor in addition to the floor area meeting the low fire-hazard criteria. The 50-foot (15 240 mm) criterion was selected because the response time for sprinklers at this height is extremely slow. It is estimated that the response time for standard sprinklers [50 feet (15 240 mm) above a floor with a fire having a heat release rate of 5 British thermal units (Btu) per square foot per second] exceeds 15 minutes. Therefore, it is not reasonable to install sprinklers at that height with little expectation of timely activation [see Figure 1028.6.2.3(1)]. Note that if this exception is utilized, the tradeoffs for a fully sprinklered building, such as increased height and area limitations or decreased corridor ratings, are no longer permitted.

Exception 2 indicates that automatic sprinklers are not required in small spaces in buildings. Sprinklers are required in press box and storage areas of outdoor facilities when the area exceeds 1,000 square feet (93 m^2). The primary reason for sprinklers in these areas is that both are anticipated to have a relatively large combustible load when compared to the main seating and participant areas. Additionally, in the case of storage areas, there is an increased potential for an undetected fire condition to occur [see Figure 1028.6.2.3(2)].

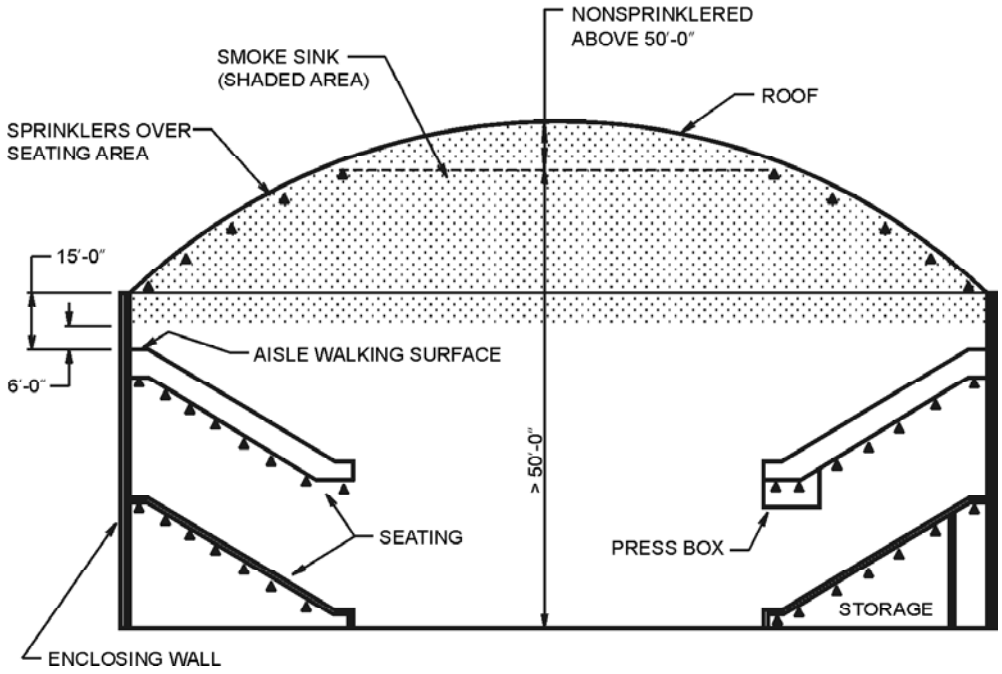
Exception 3 provides for outdoor seating facilities where smoke entrapment is not a safety concern.



1028.6.3 Width of means of egress for outdoor smoke-protected assembly seating. The clear width in inches (mm) of *aisles* and other *means of egress* shall be not less than the total *occupant load* served by the egress element multiplied by 0.08 (2.0 mm) where egress is by *aisles* and *stairs* and multiplied by 0.06 (1.52 mm) where egress is by *ramps*, *corridors*, tunnels or vomitories.

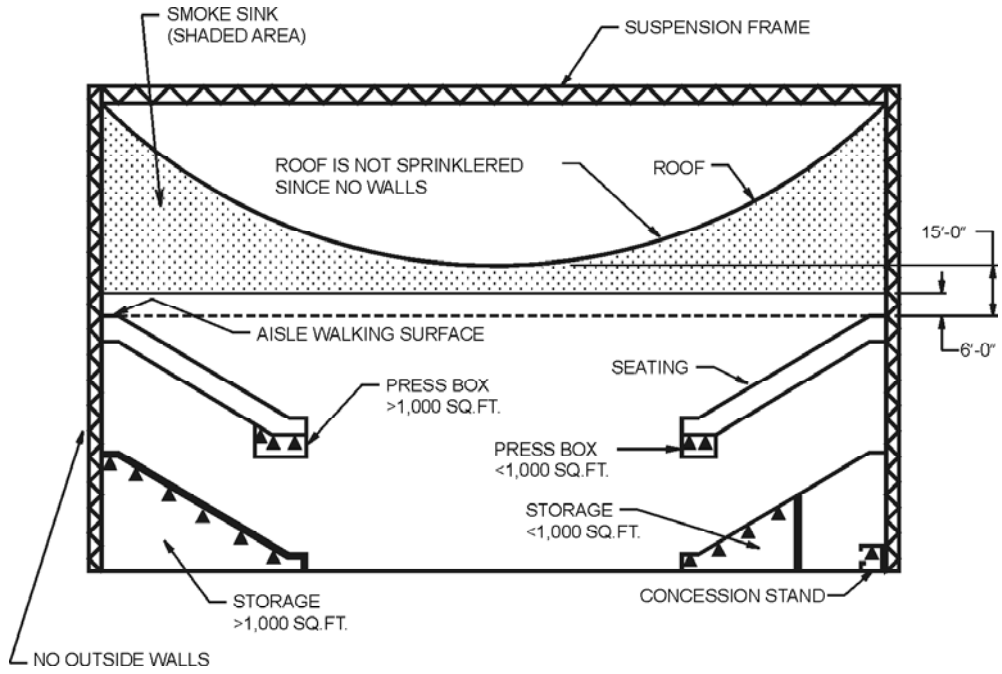
Exception: The clear width in inches (mm) of *aisles* and other *means of egress* shall be permitted to comply with Section 1028.6.2 for the number of seats in the outdoor *smoke-protected assembly seating* where Section 1028.6.2 permits less width.

❖ This section has the coefficients for the determination of the width of egress required for outdoor smoke-protected assembly areas. Note that the coefficients are significantly less when compared to the values in Section 1028.6.1 for assembly areas without smoke protection. The coefficients are also less than those for smoke-protected assembly seating in Table 1028.6.2 except for very large assembly areas. The exception in this section would apply where the coefficients in Table 1028.6.2 are less than those in this section.



Low coefficients are a result of the very low hazards for outdoor smoke-protected assembly areas and increased egress time.

Generally, an outdoor assembly area meets the smoke control requirements of Section 1028.6.2 by natural ventilation and does not require an automatic sprinkler system according to Section 1028.6.2.3, Exception 3.



For SI: 1 foot = 304.8 mm.

Figure 1028.6.2.2(2)
ROOF HEIGHT (CONCAVE SUSPENDED ROOF)

For SI: 1 foot = 304.8 mm.

Figure 1028.6.2.3(1)
INDOOR SEATING SPRINKLERED AREAS (CONVEX DOME ROOF)

For SI: 1 foot = 304.8 mm,
1 square foot = 0.0929 m^2.

Figure 1028.6.2.3(2)
INDOOR SEATING SPRINKLERED AREAS (CONCAVE SUSPENDED ROOF)

1028.7 Travel distance. *Exits* and *aisles* shall be so located that the travel distance to an *exit* door shall not be greater than 200 feet (60 960 mm) measured along the line of travel in nonsprinklered buildings. Travel distance shall not be more than 250 feet (76 200 mm) in sprinklered buildings. Where *aisles* are provided for seating, the distance shall be measured along the *aisles* and *aisle accessway* without travel over or on the seats.

Exceptions:

1. *Smoke-protected assembly seating*: The travel distance from each seat to the nearest entrance to a vomitory or concourse shall not exceed 200 feet (60 960 mm). The travel distance from the entrance to the vomitory or concourse to a *stair*, *ramp* or walk on the exterior of the building shall not exceed 200 feet (60 960 mm).
2. Open-air seating: The travel distance from each seat to the building exterior shall not exceed 400 feet (122 m). The travel distance shall not be limited in facilities of Type I or II construction.

❖ This section includes the travel distance limits for an assembly occupancy, which are the same as those in Table 1016.2 for Group A. The travel distance is to be measured along the same path as the occupants would normally take to exit the facility.

Exception 1 provides an extended travel distance for smoke-protected assembly seating that meets the requirements of Sections 1028.6.2 through 1028.6.2.3. Exception 2 applies to outdoor open-air seating areas where the smoke and fire hazard is very low. The Type I and II construction referred to in this exception is described in Section 602.

1028.8 Common path of egress travel. The *common path of egress travel* shall not exceed 30 feet (9144 mm) from any seat to a point where an occupant has a choice of two paths of egress travel to two *exits*.

Exceptions:

1. For areas serving less than 50 occupants, the *common path of egress travel* shall not exceed 75 feet (22 860 mm).
2. For *smoke-protected assembly seating*, the *common path of egress travel* shall not exceed 50 feet (15 240 mm).

❖ The maximum travel distance down a single access row of seating to a location where a patron would have two choices for a way out of the space is 30 feet (9144 mm). In smoke-protected seating, the common path of travel can be up to 50 feet (15 240 mm).

If the room or space (e.g., box, gallery or balcony) has 50 or fewer occupants, the travel distance can be increased to 75 feet (22 860 mm). For example, this allows for a path of travel from a box seat, out of the box and to a main aisle or even a corridor located outside the assembly room itself.

When this section is referenced for accessible means of egress (see Section 1007.1, Exception 3), the utilization of Exception 1 would include the entire occupant load of the box, gallery or balcony, not just the number of wheelchair spaces and/or companion seats. Wheelchair spaces that are integrated into the general seating would have the same common path of travel distance of 30 feet (9144 mm) before the person needing the accessible route could choose two different paths for accessible means of egress. This provides the same level of protection for the persons in the accessible seating as provided for others within the space.

Both Sections 1014.3 and 1028.8 must be considered when determining the common path of travel requirements for a building. Section 1014.3 regulates the means of egress from a room or space. Section 1028.8, however, regulates the distance to a decision point within a room or space used for assembly seating where a single access row of seating is provided to a location where a patron would have two choices for a way out of the space.

1028.8.1 Path through adjacent row. Where one of the two paths of travel is across the *aisle* through a row of seats to another *aisle*, there shall be not more than 24 seats between the two *aisles*, and the minimum clear width between rows for the row between the two *aisles* shall be 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row between *aisles*.

Exception: For *smoke-protected assembly seating* there shall not be more than 40 seats between the two *aisles* and the minimum clear width shall be 12 inches (305 mm) plus 0.3 inch (7.6 mm) for each additional seat.

❖ In establishing the point where the occupants of a row served by a single access aisle have two distinct paths of travel, the code allows one of those paths to be through the rows of an adjacent seating area or section. This requirement increases the row widths for the single-access seating section and the adjacent dual-access seating section. This allows the occupants to either travel down the single access aisle or readily traverse the oversized row widths to gain access to a second means of egress (see Figure 1028.8.1). This exception allows a greater number of seats spaced with a minimum clearance of 12 inches (305 mm) for smoke-protected assembly seating that complies with Sections 1028.6.2 through 1028.6.2.3 or Section 1028.6.3. For the base width requirements for single- and dual-access rows, see the commentary to Sections 1028.10.2 through 1028.10.2.2.

1028.9 Assembly aisles are required. Every occupied portion of any building, room or space used for assembly purposes that contains seats, tables, displays, similar fixtures or equipment shall be provided with *aisles* leading to *exits* or *exit access doorways* in accordance with this section. *Aisle accessways* for tables and seating shall comply with Section 1028.10.1.

❖ This section requires that each assembly space have designated aisles. For aisle accessway requirements, see Section 1028.10. For aisles in other occupancies, see Section 1017.

1028.9.1 Minimum aisle width. The minimum clear width for *aisles* shall be as shown:

1. Forty-eight inches (1219 mm) for *aisle stairs* having seating on each side.

   Exception: Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

2. Thirty-six inches (914 mm) for *aisle stairs* having seating on only one side.

   Exception: Twenty-three inches (584 mm) between an *aisle stair handrail* and seating where an *aisle* does not serve more than five rows on one side.

3. Twenty-three inches (584 mm) between an *aisle stair handrail* or *guard* and seating where the aisle is subdivided by a *handrail*.

4. Forty-two inches (1067 mm) for level or ramped *aisles* having seating on both sides.

   Exceptions:

   1. Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.
   2. Thirty inches (762 mm) where the *aisle* does not serve more than 14 seats.

5. Thirty-six inches (914 mm) for level or ramped *aisles* having seating on only one side.

   Exception: Thirty inches (762 mm) where the *aisle* does not serve more than 14 seats.

❖ The clear widths of aisles and other means of egress established by the formulas given in Section 1028.6 must not be less than the minimum width requirements of this section. The development of minimum width requirements is based on the association of aisle capacity with the path of exit travel as influenced by the different features of aisle construction. The purpose is to create an aisle system that would provide an even flow of occupant egress. The minimum width of the aisles is also based on an anticipated movement of people in two directions. Note that each exception is only applicable to the item directly above.

1028.9.2 Aisle width. The *aisle* width shall provide sufficient egress capacity for the number of persons accommodated by the catchment area served by the *aisle*. The catchment area served by an *aisle* is that portion of the total space that is served by that section of the *aisle*. In establishing catchment areas, the assumption shall be made that there is a balanced

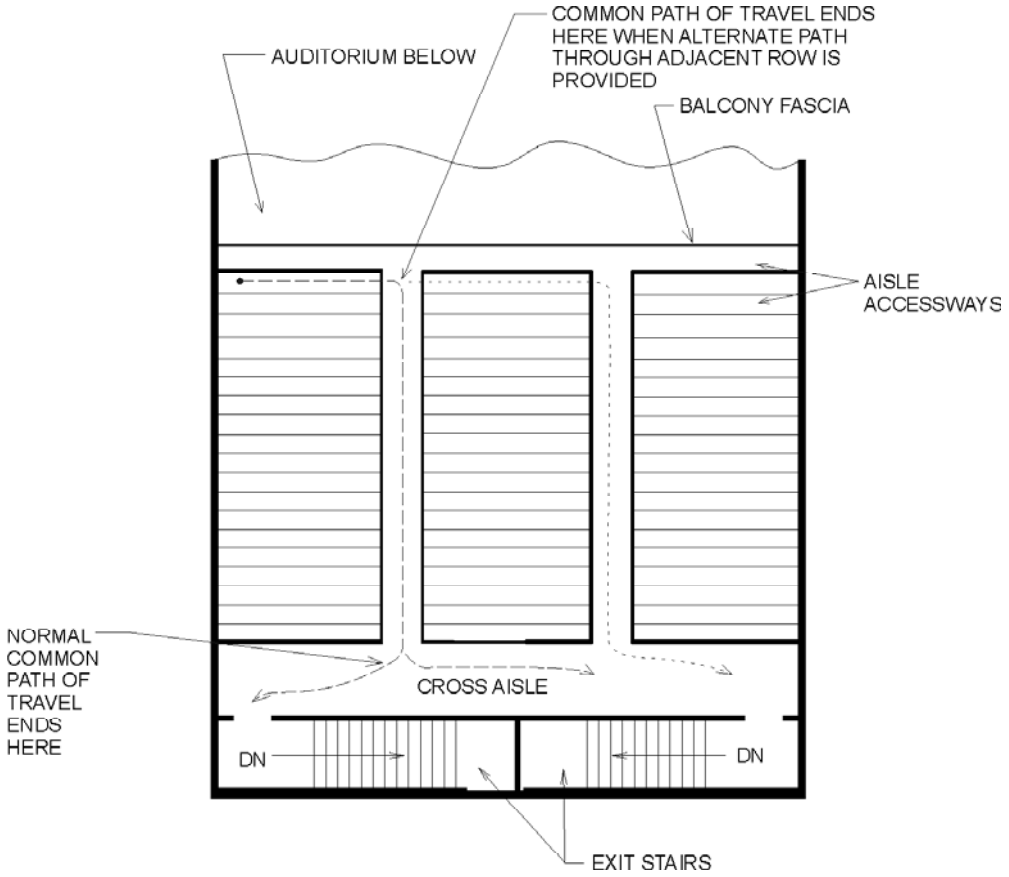


Figure 1028.8.1
PATH THROUGH ADJACENT ROWS

use of all *means of egress*, with the number of persons in proportion to egress capacity.

❖ The determination of required aisle and aisle accessway width is a function of the occupant load. In calculating the required widths, the assumption is that in a system or network of aisles and aisle accessways serving an occupied area, people will normally exit the area in a way that will distribute the occupant load throughout the system in proportion to the egress capacity of the aisles and aisle accessways. Each aisle and aisle accessway would take its tributary share (catchment area) of the total occupant load (see Figure 1028.9.2).

In addition to the provisions in this section, the requirement for the capacity of the main exit and other exits must also be considered (see Sections 1028.2 and 1028.3). While this section assumes an equal distribution, Section 1028.2 requires that where the facility has a main exit, the main exit and the access thereto must be capable of handling 50 percent of the occupant load.

1028.9.3 Converging aisles. Where *aisles* converge to form a single path of egress travel, the required egress capacity of that path shall not be less than the combined required capacity of the converging *aisles*.

❖ Where one or more aisles or aisle accessways meet to form a single path of egress travel, that path must be sized to handle the combined occupant capacity of the converging aisles and aisle accessways (see Figure 1028.9.3). The reason for this requirement is to maintain the natural pace of travel all the way through the aisle accessways or aisles to the exits and to minimize the queuing of occupants.

This section requires combining the required occupant capacity of converging aisles and aisle accessways, but not necessarily the required widths. For example, if two 48-inch (1219 mm) aisles converge, the result need not be a 96-inch (2438 mm) aisle unless the 48-inch (1219 mm) width of the aisles is required based on the requirements of Section 1028.6 for the actual occupant load served. However, if the 48-inch (1219 mm) width is not based on the

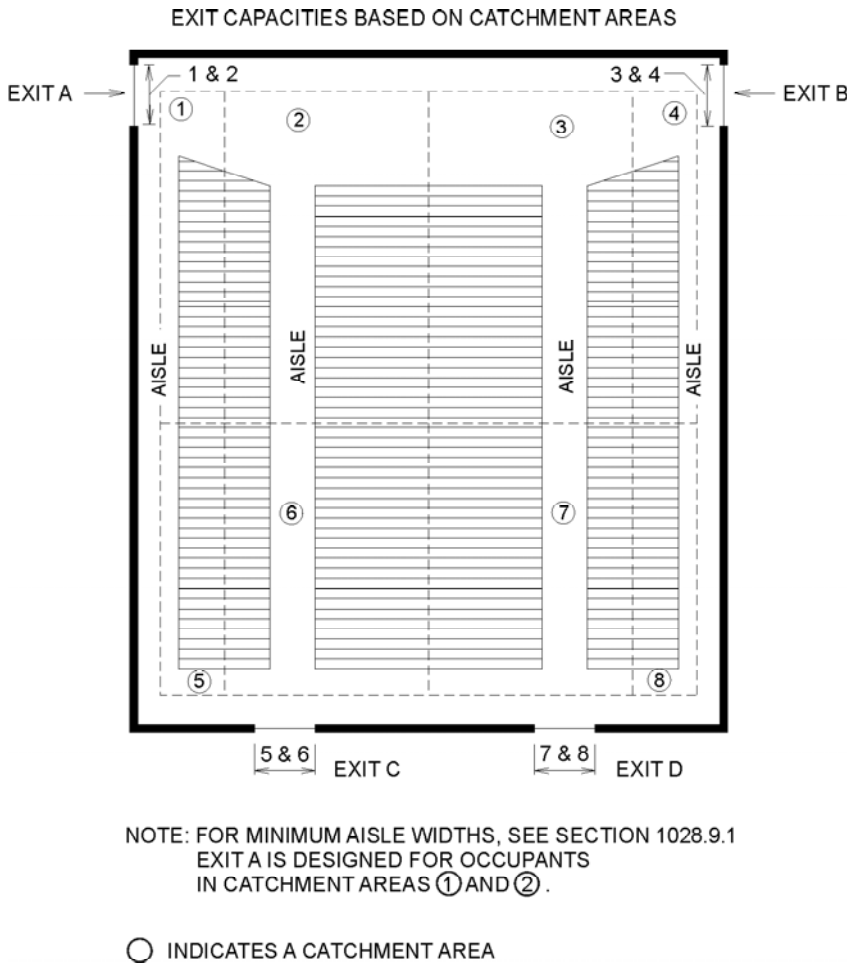

Figure 1028.9.2
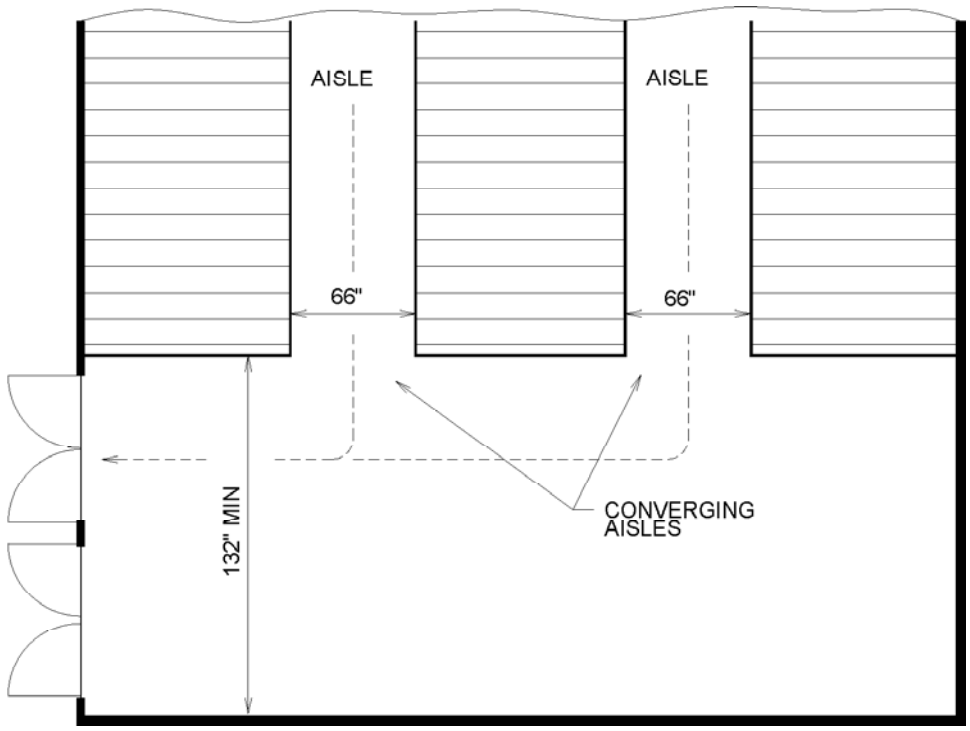
TYPICAL AISLE CATCHMENTS

occupant load but is required to comply with the minimum aisle width requirements of Section 1028.9.1, the resulting aisle width must be sized for the total occupant load served by the converging aisles, as determined by Section 1028.6, but not less than the minimum widths of Section 1028.9.1.

1028.9.4 Uniform width. Those portions of *aisles*, where egress is possible in either of two directions, shall be uniform in required width.



❖ Aisles that connect or lead to opposite exits must be of uniform width throughout their entire length to allow for exit travel in two directions without creating a traffic bottleneck (see Figure 1028.9.4).

1028.9.5 Assembly aisle termination. Each end of an *aisle* shall terminate at cross *aisle*, foyer, doorway, vomitory or concourse having access to an *exit*.

Exceptions:

1. Dead-end *aisles* shall not be greater than 20 feet (6096 mm) in length.
2. Dead-end *aisles* longer than 20 feet (6096 mm) are permitted where seats beyond the 20-foot (6096 mm) dead-end *aisle* are no more than 24 seats from another *aisle*, measured along a row of seats having a minimum clear width of 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row.
3. For *smoke-protected assembly seating*, the dead-end *aisle* length of vertical *aisles* shall not exceed a distance of 21 rows.
4. For *smoke-protected assembly seating*, a longer dead-end *aisle* is permitted where seats beyond the 21-row dead-end *aisle* are not more than 40 seats from another *aisle*, measured along a row of seats having an *aisle* accessway with a minimum clear width of 12 inches (305 mm) plus 0.3 inch (7.6 mm) for each additional seat above seven in the row.

❖ Both ends of a cross aisle must terminate at either an intersecting aisle, a foyer, a doorway or a vomitory (lane) that gives access to an exit(s). Each exception allows an aisle to have a dead-end of limited length. Exceptions 1 and 2 address dead-end aisles in assembly spaces with or without smoke protection. Exceptions 3 and 4 address dead-end aisles only in smoke-protected assembly seating. In accordance with Exception 1, dead-end aisles (similar to corridors and passageways) that terminate at one end of a cross aisle or at a foyer, doorway or vomitory must not be more than 20 feet (6096 mm) in length. The intent of the row width requirements in the exceptions is to provide sufficient clear width between rows of seating to allow the occupants in times of emergency to pass quickly from a dead-end aisle to the aisle at the opposite end. In Exception 2, the 0.6-inch (15

For SI: 1 inch = 25.4 mm.

Figure 1028.9.3
COMPUTATION OF EXIT PASSAGE FOR CONVERGING AISLES

mm) increase beyond seven seats is consistent with the minimum width determined in accordance with Section 1028.10.2 for single access rows. The code recognizes that one dead-end aisle may not be usable, thus creating a single access row condition. Exceptions 3 and 4 allow longer dead-end aisles for smoke-protected assembly seating that complies with Sections 1028.6.2 through 1028.6.2.3 or Section 1028.6.3 (see Figure 1025.9.5).

The overall purpose of this section is to provide aisle/seating arrangements that would allow the occupants to seek safe and rapid passage to exits in case of fire or other emergency.

1028.9.6 Assembly aisle obstructions. There shall be no obstructions in the required width of *aisles* except for *handrails* as provided in Section 1028.13.

❖ Except for handrails, aisles are required to be clear of any obstructions so that the full width is available for egress purposes. Handrails are allowed to project into the required aisle width in the same manner as handrail projections in stairways.

1028.10 Aisle accessways. *Aisle accessways* for seating at tables shall comply with Section 1028.10.1. *Aisle accessways* for seating in rows shall comply with Section 1028.10.2.

❖ Aisle accessways are paths for means of egress between rows of seats or between tables. The aisle accessway leads to aisles, which in turn lead towards exits from the space. This is the same idea as moving through a room full of furniture to a corridor to reach an exit. In both situations, the path for means of egress is confined. For aisle accessway requirements in other occupancies, see Section 1017.

1028.10.1 Seating at tables. Where seating is located at a table or counter and is adjacent to an *aisle* or *aisle accessway*, the measurement of required clear width of the *aisle* or *aisle accessway* shall be made to a line 19 inches (483 mm) away from and parallel to the edge of the table or counter. The 19-inch (483 mm) distance shall be measured perpendicular to the side of the table or counter. In the case of other side boundaries for *aisle* or *aisle accessways*, the clear width shall be measured to walls, edges of seating and tread edges, except that handrail projections are permitted.

Exception: Where tables or counters are served by *fixed seats*, the width of the *aisle accessway* shall be measured from the back of the seat.

❖ Most seating at tables should be adjacent to aisles or aisle accessways. In measuring the width of an aisle or aisle accessway for movable seating, the measurement is taken at a distance of 19 inches (483 mm) perpendicular to the side of the table or counter. This 19-inch (483 mm) space from the edge of the table or counter to the line where the aisle or aisle accessway measurement begins is intended to represent the space occupied by a typical seated occupant. This dimension is also considered to be

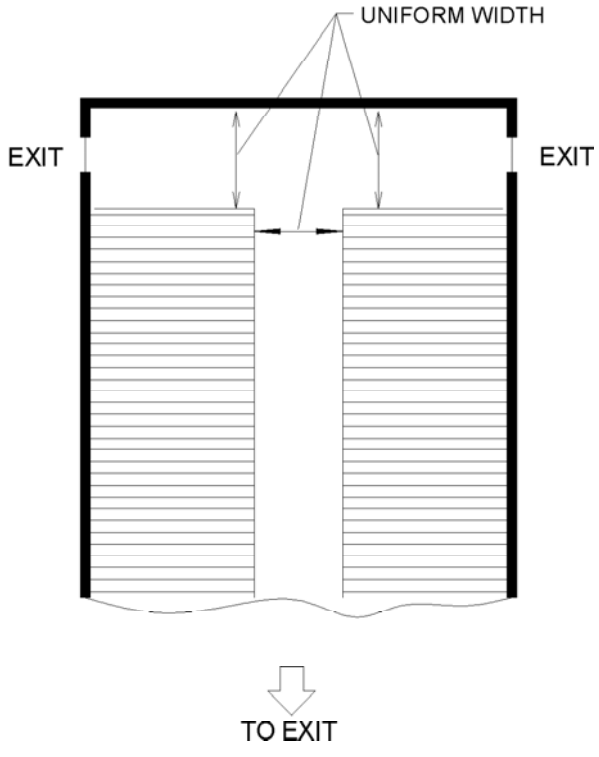


Figure 1028.9.4
AISLE WITH OPPOSITE EXITS

adequate to accommodate seats with armrests that are too high to fit under the table where fixed seats are used. The aisle width is permitted to be measured from the back of the seat based upon the exception. As indicated in Figure 1028.10.1, where seating abuts an aisle or aisle accessway, 19 inches (483 mm) must be added to the required aisle or aisle accessway width for seating on only one side and 38 inches (965 mm) for seating on both sides. When seating will not be adjacent to the aisles or aisle passageways, as is the case when tables are at an angle to the aisle or aisle accessway, the measurement may be taken to the edge of the seating, table, counter or tread. Sections 1028.10.1.1 and 1028.10.1.2 address width and travel along aisle accessways. For aisles between tables, see Section 1028.9.

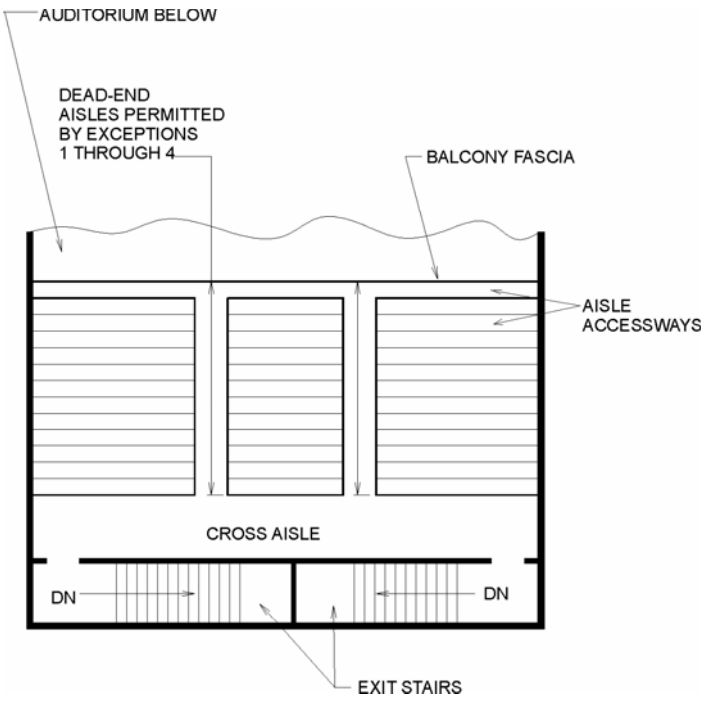
1028.10.1.1 Aisle accessway width for seating at tables. *Aisle accessways* serving arrangements of seating at tables or counters shall have sufficient clear width to conform to the capacity requirements of Section 1005.1 but shall not have less than a minimum of 12 inches (305 mm) of width plus $^1/_2$ inch (12.7 mm) of width for each additional 1 foot (305 mm), or fraction thereof, beyond 12 feet (3658 mm) of *aisle accessway* length measured from the center of the seat farthest from an *aisle*.

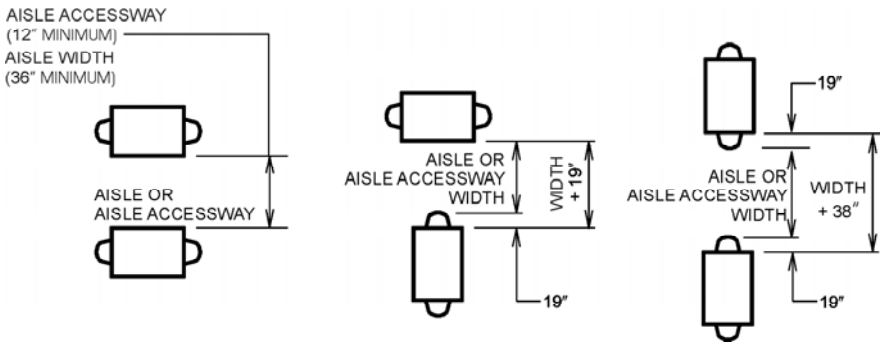
Exception: Portions of an *aisle accessway* having a length not exceeding 6 feet (1829 mm) and used by a total of not more than four persons.

❖ This section specifies two criteria for the determination of the required width of aisle accessways at tables: the requirements of Section 1005.1 for capacity based on the number of occupants and the option described in this section. The aisle accessway width is to be the wider of the two requirements. The aisle accessway width between tables is determined similarly to the aisle accessway between rows of seats that view an event.

The relationship of tables and seating sometimes results in a situation in which it is difficult to determine which chairs are served by which aisle accessway; therefore, the width of the aisle accessway is a function of the distance from the aisle. The same minimum 12 inches (305 mm) is used and is increased $^1/_2$ inch (12.7 mm) for each additional foot of travel beyond 12 feet (3658 mm).

Recognizing that the normal use of table and chair seating will require some clearance for access and service, the exception eliminates the minimum width criteria if the distance to the aisle [or an aisle accessway of at least 12 inches (305 mm)] is less than 6 feet (1829 mm) and the number of people served is not more than four. Therefore, the first 6 feet (1829 mm) are not required to meet any minimum width criteria. After the first 6 feet (1829 mm), the requirements for an aisle accessway will apply. The length of the aisle accessway is then restricted by Section 1028.10.1.2. When the maximum length of the aisle accessway is reached, either an aisle, corridor or exit access door must be provided (see Figure 1028.10.1.1).





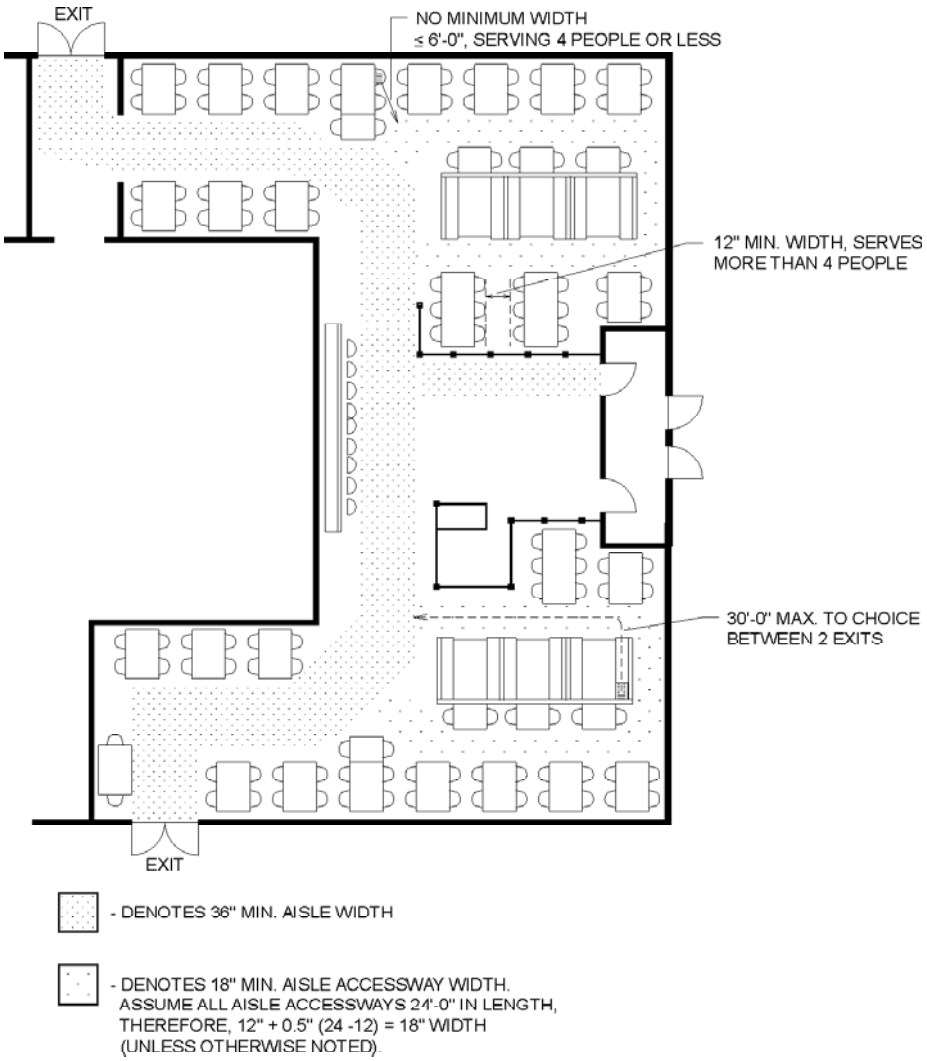


Figure 1028.9.5
TYPICAL BALCONY ARRANGEMENT

For SI: 1 inch = 25.4 mm.

Figure 1028.10.1
AISLE AND AISLE ACCESSWAY MEASUREMENT WITH SEATING AND TABLES

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1028.10.1.1
ACCESS FOR TABLES AND SEATING

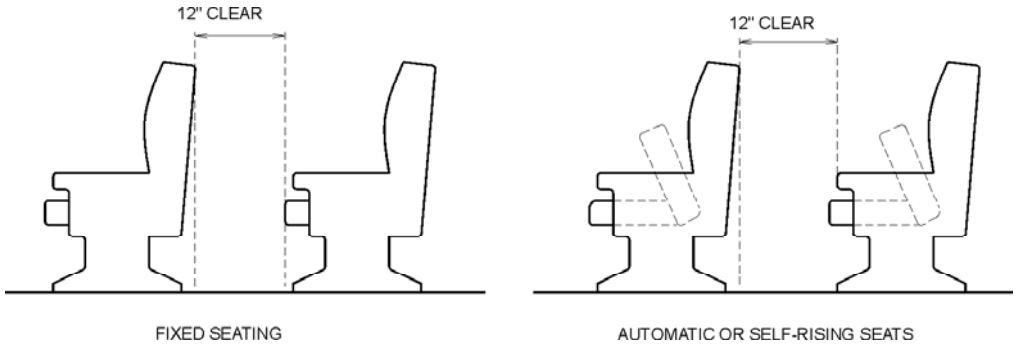
1028.10.1.2 Seating at table aisle accessway length. The length of travel along the *aisle accessway* shall not exceed 30 feet (9144 mm) from any seat to the point where a person has a choice of two or more paths of egress travel to separate *exits*.

❖ At some point in the exit access travel, it is necessary to reach an aisle complying with the minimum widths of Section 1028.9.1. Aisle accessway travel distance for seating at tables is not to exceed 30 feet (9144 mm), which may represent a dead-end condition (see Figure 1028.10.1.1).

1028.10.2 Clear width of aisle accessways serving seating in rows. Where seating rows have 14 or fewer seats, the minimum clear *aisle accessway* width shall not be less than 12 inches (305 mm) measured as the clear horizontal distance from the back of the row ahead and the nearest projection of the row behind. Where chairs have automatic or self-rising seats, the measurement shall be made with seats in the raised position. Where any chair in the row does not have an automatic or self-rising seat, the measurements shall be made with the seat in the down position. For seats with folding tablet arms, row spacing shall be determined with the tablet arm in the used position.

Exception: For seats with folding tablet arms, row spacing is permitted to be determined with the tablet arm in the stored position where the tablet arm when raised manually to vertical position in one motion automatically returns to the stored position by force of gravity.

❖ The requirements of this section are applicable to theater-type seating arrangements. This includes both "continental" and "traditional" seating arrangements. Theater-type seating is characterized by a number of seats arranged side by side and in rows. In this type of seating arrangement, the potential exists for a large number of occupants to be present in a confined environment where the ability of the occupants to move quickly is limited. In order to egress, people are required to move single file within a narrow row (i.e., aisle accessway) before reaching an aisle; both the aisle or aisle accessway limit movement toward an exit. To provide adequate passage between rows of seats, this section requires that the clear width between the back of a row to the nearest projection of the seating immediately behind must be at least 12 inches (305 mm) (see Figure 1028.10.2). Where chairs are manufactured with automatic or self-lifting seats, the minimum width requirement may be measured with the seats in a raised position. Commonly used in college lecture halls, seats with built in tablet arms are provided so that students can take notes.



When tablet arm chairs are used, the required width is to be determined with the tablet arm in its usable position. The exception allows for folding tablet arms that fall back into the stored position when a person rises out of the seat. With seats occupied and tablets raised, students egressing en-mass down the row would at most encounter one tablet to move out of the way. With these types of arms, the aisle accessway can be measured for the seat or arm as indicated in Figure 1028.10.2.

With respect to self-rising seats, ASTM F 851 provides one method of determining acceptability.

1028.10.2.1 Dual access. For rows of seating served by *aisles* or doorways at both ends, there shall not be more than 100 seats per row. The minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.3 inch (7.6 mm) for every additional seat beyond 14 seats, but the minimum clear width is not required to exceed 22 inches (559 mm).

Exception: For s*moke-protected assembly seating*, the row length limits for a 12-inch-wide (305 mm) *aisle accessway*, beyond which the *aisle accessway* minimum clear width shall be increased, are in Table 1028.10.2.1.

❖ Where rows of seating are served by aisles or doorways located at both ends of the path of row travel, the number of seats that may be used in a row may be up to, but not more than, 100 (continental seating) and the minimum required clear width aisle accessway of 12 inches (305 mm) between rows of seats must be increased by 0.3 inch (8 mm) for every addi-

For SI: 1 inch = 25.4 mm.

Figure 1028.10.2
MINIMUM REQUIRED ROW WIDTH CLEARANCE FOR AISLE ACCESSWAYS

tional seat beyond 14, but not more than a total of 22 inches (559 mm) (see Figure 1028.10.2.1). For example, in a row of 24 seats, the minimum clear width would compute to 15 inches (381 mm) [12 + (0.3 x 10)]. For a row of 34 seats, a clear width of 18 inches (457 mm) would be required. Increases in the clear width between rows of seats would occur up to a row of 46 seats. From 47 to 100 seats, a maximum clear width between rows of 22 inches (559 mm) would apply.

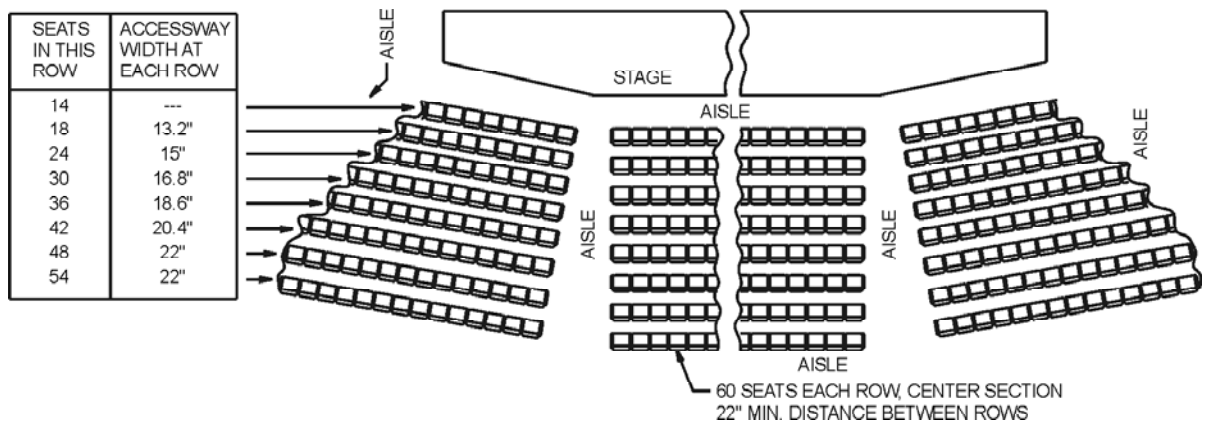
Since the row is to provide access to an aisle in both directions, the minimum width applies to the entire length of the row aisle accessway.

The exception allows more seats in a row with the minimum 12-inch (305 mm) seat spacing since safe egress time is extended for this condition.

When a second means of egress for occupants of a single access row is possible through an adjacent dual access row, see Section 1028.8.1.

TABLE 1028.10.2.1
SMOKE-PROTECTED ASSEMBLY AISLE ACCESSWAYS

TOTAL NUMBER OF SEATS IN THE SMOKEPROTECTED ASSEMBLY SEATING	MAXIMUM NUMBER OF SEATS PER ROW PERMITTED TO HAVE A MINIMUM 12-INCH CLEAR WIDTH AISLE ACCESSWAY	
	Aisle or doorway at both ends of row	Aisle or doorway at one end of row only
Less than 4,000	14	7
4,000	15	7
7,000	16	8
10,000	17	8
13,000	18	9
16,000	19	9
19,000	20	10
22,000 and greater	21	11



For SI: 1 inch = 25.4 mm.

❖ Table 1028.10.1 recognizes the increased egress time available in smoke-protected assembly seating areas. Therefore, the table permits greater lengths of rows that have the minimum 12 inches (305 mm) of clear width. When a row exceeds the lengths identified in the table, the row width is to be increased in accordance with Section 1028.10.2.1 [0.3 inch (8 mm) per additional seat] for dual access rows and Section 1028.10.2.2 [0.6 inch (15 mm) per additional seat] for single access rows. Column one in this table is based on the total number of seats contained within the assembly space, not the seats per level.

1028.10.2.2 Single access. For rows of seating served by an *aisle* or doorway at only one end of the row, the minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.6 inch (15.2 mm) for every additional seat beyond seven seats, but the minimum clear width is not required to exceed 22 inches (559 mm).

Exception: For *smoke-protected assembly seating*, the row length limits for a 12-inch-wide (305 mm) *aisle accessway*, beyond which the *aisle accessway* minimum clear width shall be increased, are in Table 1028.10.2.1.

❖ Where rows of seating are served by an aisle or doorway at only one end of a row, the minimum clear width of 12 inches (305 mm) between rows of seats must be increased by 0.6 inch (15 mm) for every additional seat beyond seven, but not more than a total of 22 inches (559 mm) (see Figure 1028.10.2.2). While this section does not specify the maximum number of seats permitted in a row, the 30-foot (9144 mm) common path of travel limitation (see Section 1028.8) essentially restricts the single access row to approximately 20 seats, based on an 18-inch (457 mm) width per seat. A row of 12 seats would compute to a required minimum width of 15 inches [12 + (0.5 x 5)]. Similarly, a row of 17 seats would require a clear width of 18 inches (457 mm) and so on. Since dual access is not provided, incremental increases would be permitted in the aisle accessway width as shown in Figure 1028.10.2.2. Incremental increases in the

For SI: 1 inch = 25.4 mm.

Figure 1028.10.2.1
TYPICAL DUAL ACCESS ROW—MINIMUM AISLE ACCESSWAY WIDTH

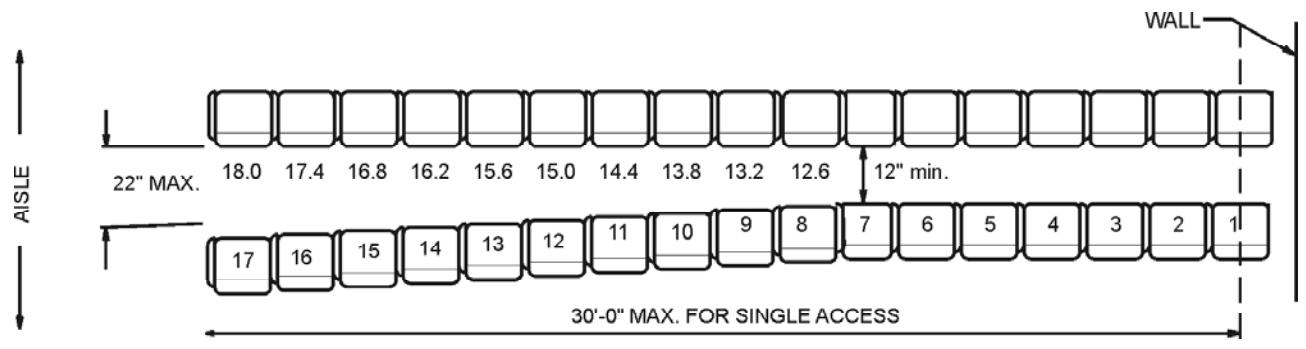
required width would occur up to the maximum number of seats, which is determined by the 30-foot (9144 mm) dead-end limitation.

The reason for increasing the row accessway widths incrementally with increases in the number of seats per row is to provide more efficient passage for the occupants who are using the aisle accessway. As a practical matter, where dual-access (see Section 1028.10.2.1) and single-access seating arrangements are used together, the largest computed clear width dimension would normally be applied by the designer to both arrangements so that the rows of seats will be in alignment. When a second means of egress for occupants of a single access row is possible through an adjacent dual access row, see Section 1028.8.1.

1028.11 Assembly aisle walking surfaces. *Aisles* with a slope not exceeding one unit vertical in eight units horizontal (12.5-percent slope) shall consist of a *ramp* having a slip-resistant walking surface. *Aisles* with a slope exceeding one unit vertical in eight units horizontal (12.5-percent slope) shall consist of a series of risers and treads that extends across the full width of *aisles* and complies with Sections 1028.11.1 through 1028.11.3.

❖ Assembly facilities such as theaters and auditoriums often require sloping or stepped floors to provide seated occupants with preferred sightlines for viewing presentations (for sightlines for wheelchair spaces, see Section 1108.2). Aisles must, therefore, be designed to accommodate the changing elevations of the floor in such a manner that the path of travel will allow occupants to leave the area at a rapid pace with minimal possibilities for stumbling or falling during times of emergency.

This section requires that aisles with a gradient of one unit vertical and eight units horizontal (12.5 percent slope) or less must consist of a ramp with a slip-resistant surface. Aisles with a gradient exceeding one unit vertical and eight units horizontal (12.5-percent slope) must consist of a series of treads and risers that comply with the requirements of Sections 1028.11.1 through 1028.11.3. Note that ramps that serve as part of an accessible route to and from accessible wheelchair spaces must comply with the more restrictive requirements for ramps in Section 1010 (see Section 1010.1, Exception 1).



While not specifically indicated for stepped aisles, such floor surfaces must also be slip resistant in accordance with Section 1003.4. Field testing and uniform enforcement of the concept of slip resistance is not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification KK-L-165C] and the floor surface is greater than 0.5. Laboratory test procedures can determine the static coefficient of resistance.

What must be recognized here is that stepped aisles are part of the floor construction and are intended to provide horizontal egress. Tread and riser construction for this purpose should not be compared to the requirements for treads and risers in conventional stairways that serve as means of vertical egress. Sometimes, because of design considerations, the gradient of an aisle is required to change from a level floor to a ramp and then to steps. In cases where there is no uniformity in the path of travel, occupants tend to be considerably more cautious, particularly in the use of stepped aisles, than they would normally be in the use of conventional stairways.

1028.11.1 Treads. Tread depths shall be a minimum of 11 inches (279 mm) and shall have dimensional uniformity.

Exception: The tolerance between adjacent treads shall not exceed $^{3}/_{16}$ inch (4.8 mm).

❖ Depths of treads are not to be less than 11 inches (279 mm) and uniform throughout each flight, except that a variance of not more than $^{3}/_{16}$ inch (4.8 mm) is permitted between adjacent treads to accommodate variations in construction. While the minimum tread depth provision is the same as the limiting dimension for treads in interior stairways (see Section 1009.7.2),

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1028.10.2.2
TYPICAL SINGLE ACCESS ROW—MINIMUM AISLE ACCESSWAY WIDTH

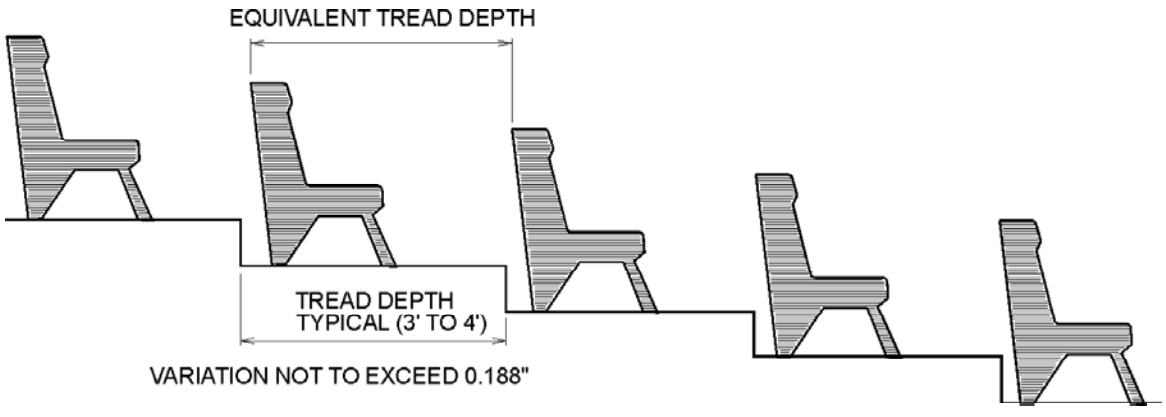
it rarely applies in the construction of stepped aisles. A more common form of stepped aisle construction is to provide a tread depth equal to the back-to-back distance between rows of seats. This way the treads can be extended across the full length of the row and serve as a supporting platform for the seats. Other arrangements might require two treads between rows of seats.

In theaters, for example, the back-to-back distance between rows of fixed seats usually ranges somewhere between 3 and 4 feet (914 and 1219 mm), depending on seat style and seat dimensions as well as the ease of passage between the rows (see Figure 1028.11.1). The selection of single-tread or two-tread construction between rows of seats depends on the gradient and suitable riser height (see Section 1028.11.2), as needed for sightlines.

In comparing this section with Section 1028.11.2, it is significant to note the emphasis placed on the tread dimension. While not desirable, the code permits riser heights to deviate; however, tread dimensions must not vary beyond the $^{3}/_{16}$-inch (4.8 mm) tolerance.

1028.11.2 Risers. Where the gradient of *aisle stairs* is to be the same as the gradient of adjoining seating areas, the riser height shall not be less than 4 inches (102 mm) nor more than 8 inches (203 mm) and shall be uniform within each *flight*.

Exceptions:



1. Riser height nonuniformity shall be limited to the extent necessitated by changes in the gradient of the adjoining seating area to maintain adequate sightlines. Where nonuniformities exceed $^{3}/_{16}$ inch (4.8 mm) between adjacent risers, the exact location of such nonuniformities shall be indicated with a distinctive marking stripe on each tread at the *nosing* or leading edge adjacent to the nonuniform risers. Such stripe shall be a minimum of 1 inch (25 mm), and a maximum of 2 inches (51 mm), wide. The edge marking stripe shall be distinctively different from the contrasting marking stripe.
2. Riser heights not exceeding 9 inches (229 mm) shall be permitted where they are necessitated by the slope of the adjacent seating areas to maintain sightlines.

❖ In stepped aisles where the gradient of the aisle is the same as the gradient of the adjoining seating area, riser heights are not to be less than 4 inches (102 mm) nor more than 8 inches (203 mm) (see Figure 1028.11.2). For the safety of the occupants, risers should have uniform heights, where possible, throughout each flight of steps. However, nonuniformity of riser heights is permitted in cases where changes to the gradient in the adjoining seating area are required because of sightlines and other seating layout considerations.

Where variations in height exceed $^{3}/_{16}$ inch (4.8 mm) between adjacent risers, a distinctive marking stripe between 1 and 2 inches (25 and 51 mm) wide is to be located on the nosings of each tread as a visual warning to the occupants to be cautious. Frequently, this is done with "runway" lights. Note that this stripe must be different from the tread contrast marking stripes required in Section 1028.11.3. These stripes must be visible in lighted conditions; therefore, they are not required to comply with the provisions for luminous tread markings in Section 1024.

In comparing this section with Section 1028.11.1, it is significant to note the emphasis placed on the tread dimension. While not desirable, the code permits riser heights to deviate; however, Section 1028.11.1 does not permit tread dimensions to vary beyond the $^{3}/_{16}$-inch (4.8 mm) tolerance.

1028.11.3 Tread contrasting marking stripe. A contrasting marking stripe shall be provided on each tread at the *nosing* or leading edge such that the location of each tread is readily apparent when viewed in descent. Such stripe shall be a mini-

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1028.11.1
TYPICAL SEATING PLATFORMS ALSO USED AS STEPPING AISLES

mum of 1 inch (25 mm), and a maximum of 2 inches (51 mm), wide.

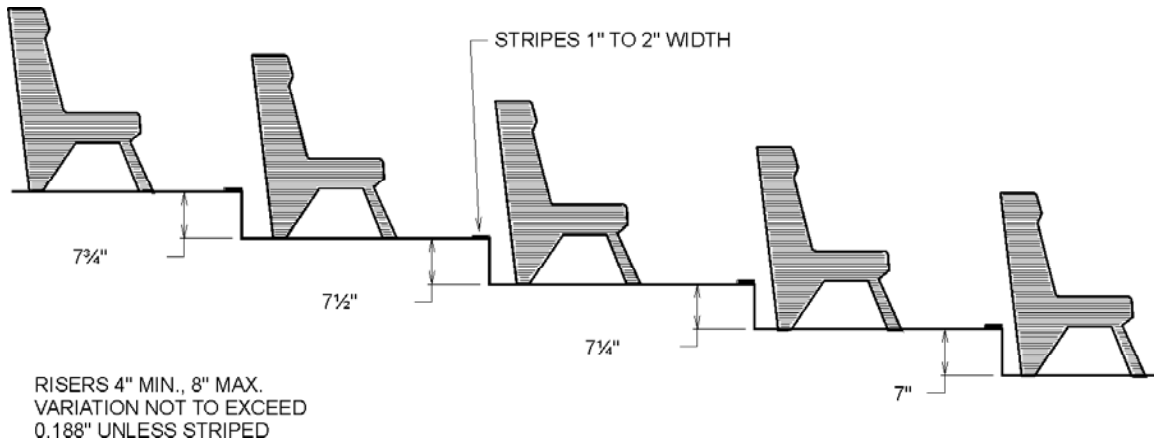
Exception: The contrasting marking stripe is permitted to be omitted where tread surfaces are such that the location of each tread is readily apparent when viewed in descent.

❖ The exception provides for the omission of the contrasting marking stripe where the tread is readily apparent such as when aisle stair treads are provided with a roughened metal nosing strip or where lighted nosings occur. In this situation, the user is aware of the treads without the marking stripe. This stripe must be different from the marking stripe required for nonuniform risers in Section 1028.11.2, Exception 1.

These stripes must be visible in lighted conditions; therefore, these stripes are not required to comply with the provisions for luminous tread markings in Section 1024.

1028.12 Seat stability. In a building, room or space used for assembly purposes, the seats shall be securely fastened to the floor.

Exceptions:



1. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating and with 200 or fewer seats, the seats shall not be required to be fastened to the floor.
2. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating, the seats shall not be required to be fastened to the floor.
3. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating and with greater than 200 seats, the seats shall be fastened together in groups of not less than three or the seats shall be securely fastened to the floor.
4. In a building, room or space used for assembly purposes where flexibility of the seating arrangement is an integral part of the design and function of the space and seating is on tiered levels, a maximum of 200 seats shall not be required to be fastened to the floor. Plans showing seating, tiers and *aisles* shall be submitted for approval.
5. Groups of seats within a building, room or space used for assembly purposes separated from other seating by railings, *guards*, partial height walls or similar barriers with level floors and having no more than 14 seats per group shall not be required to be fastened to the floor.
6. Seats intended for musicians or other performers and separated by railings, *guards*, partial height walls or similar barriers shall not be required to be fastened to the floor.

❖ The purpose of this section is to require that assembly seating be fastened to the floor where it would be a significant hazard if loose and subject to tipping over. The exceptions allow loose assembly seating for situations where the hazard is lower, such as floors where ramped or tiered seating is not used, where no more than 200 seats are used and for box seating arrangements where a limited number of seats are within railings, guards or partial height walls.

1028.13 Handrails. Ramped *aisles* having a slope exceeding one unit vertical in 15 units horizontal (6.7-percent slope) and *aisle stairs* shall be provided with *handrails* in compliance with Section 1012 located either at one or both sides of the *aisle* or within the *aisle* width.

Exceptions:

1. *Handrails* are not required for ramped *aisles* having a gradient no greater than one unit vertical in eight

For SI: 1 inch = 25.4 mm.

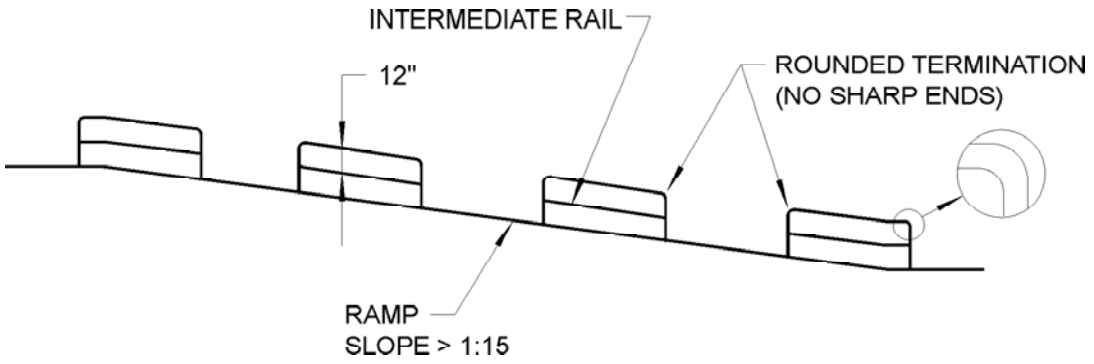
Figure 1028.11.2
TYPICAL RISER CONSTRUCTION IN STEPPED AISLES

units horizontal (12.5-percent slope) and seating on both sides.

2. *Handrails* are not required if, at the side of the *aisle*, there is a *guard* that complies with the graspability requirements of *handrails*.
3. Handrail extensions are not required at the top and bottom of *aisle stair* and *aisle ramp* runs to permit crossovers within the *aisles*.

❖ For the safety of occupants, handrails must be provided in aisles where ramps exceed a gradient of one unit vertical in 15 units horizontal (6.67-percent slope) (see Figure 1028.13). Handrails can be on one side, both sides or in the center of the aisle. Typically, handrails are in the center of the aisle when there is seating on both sides or on one side when the aisle is adjacent to the side walls of the room or a guard. Sections 1009.12 and 1010.8 specify that handrails are required on both sides of stairways or ramps. The exceptions to these sections allow for Section 1028.13 to be utilized for handrail location when dealing with steps and ramps within assembly seating areas. This would include handrails being within 30 inches (762 mm) (Section 1012.9) of the stairway width. Safety for aisles with center handrails wider than 60 inches (1524 mm) and side aisles wider than 30 inches (762 mm) is specifically addressed with the capacity increases in Sections 1028.6.1 and 1028.6.2. What the reference to Section 1012 will require are the provisions for handrail height, graspability and fittings. Continuity, extensions, clearance and projections are more specifically addressed in Section 1028.9.1, this section and subsequent subsections. Section 102.1 states that when a specific requirement conflicts with a general requirement,, the specific requirement is applicable.

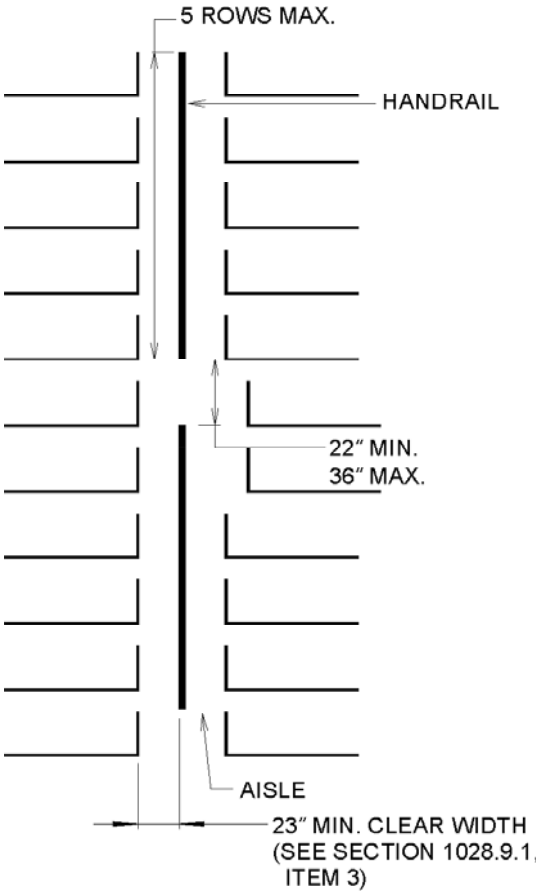
Exception 1 omits the handrail requirements where ramped aisles are steeper, but the seats on both sides of the aisle effectively reduce the fall hazard.



Exception 2 allows handrails to be omitted where there is a guard at the side of the aisle with a top rail that complies with the requirements for handrail graspability (see Section 1012.3). Note that the guard must meet the height and opening requirements specified in Section 1013 or 1028.14, as applicable.

While Section 1028.13.1 does allow for discontinuous handrails, and Exception 3 (as well as Section 1012.6, Exception 2) exempts handrail extensions, the handrail must extend the full run of the aisle stair. Stopping the handrail short of the bottom riser flight would be considered a code violation.

1028.13.1 Discontinuous handrails. Where there is seating on both sides of the *aisle*, the *handrails* shall be discontinuous with gaps or breaks at intervals not exceeding five rows to facilitate access to seating and to permit crossing from one side of the *aisle* to the other. These gaps or breaks shall have a clear width of at least 22 inches (559 mm) and not greater than 36 inches (914 mm), measured horizontally, and the *handrail* shall have rounded terminations or bends.



❖ Where aisles have seating on both sides, handrails may be located at the sides of the aisles, but are typically located in the center of the aisle. The width of each section of the subdivided aisle between the handrail and the edge of seating is not to be less than 23 inches (584 mm) measured to the handrail centerline (see Section 1028.9.1, Item 3).

For reasons of life safety in fire situations and also as a practical matter in the efficient use of the facility, a handrail down the middle of an aisle should not be continuous along its entire length. Crossovers must be provided by means of gaps or breaks in the handrail installation. Such openings must not be less than 22 inches (559 mm) nor more than 36 inches (914 mm) wide, and must be provided at intervals not exceeding the distance of five rows of seats (see Figure 1028.13.1). All handrail terminations should be designed to have rounded ends or bends to avoid possible injury to the occupants (see Figure 1028.13).

For SI: 1 inch = 25.4 mm.

Figure 1028.13
TYPICAL RAILING FOR RAMPED AISLES WITH RAILING IN THE AISLE

For SI: 1 inch = 25.4 mm.

Figure 1028.13.1
DISCONTINUOUS AISLE HANDRAILS

1028.13.2 Intermediate handrails. Where *handrails* are provided in the middle of *aisle stairs*, there shall be an additional intermediate *handrail* located approximately 12 inches (305 mm) below the main *handrail*.

❖ Handrail installations down the middle of an aisle must be constructed with intermediate rails located 12 inches (305 mm) below and parallel to main handrails. This provides handholds for children and prevents them from ducking under the rail or using the rail like a gym apparatus (see Figure 1028.13).

1028.14 Assembly guards. *Guards* adjacent to seating in a building, room or space used for assembly purposes shall comply with Sections 1028.14.1 through 1028.14.3.

❖ This section establishes the scope of the guard provisions within assembly seating. Depending on the event, the sightline constraints can be for a wide viewing angle. For example, to see the entire football field, a person may have to look right and left. Good design will establish a balance between safety and sight issues that will need to be evaluated on a case-by-case basis.

The purpose of Section 1028.4.1 is to provide for occupant safety with guards along elevated cross aisles, typically in aisles that occupants use to move side to side across the seating bowl. If there is only an aisle accessway between the seats and the guard, then Section 1028.14.2 is applicable. If the aisle is moving down through the seating towards a dropoff, then Section 1028.14.3 is applicable.

1028.14.1 Cross aisles. Cross *aisles* located more than 30 inches (762 mm) above the floor or grade below shall have *guards* in accordance with Section 1013.

Where an elevation change of 30 inches (762 mm) or less occurs between a cross *aisle* and the adjacent floor or grade below, *guards* not less than 26 inches (660 mm) above the *aisle* floor shall be provided.

Exception: Where the backs of seats on the front of the cross *aisle* project 24 inches (610 mm) or more above the adjacent floor of the *aisle*, a *guard* need not be provided.

❖ The purpose of this section is to provide for occupant safety with guards along elevated cross aisles. The minimum height of the guard is a function of the cross-aisle elevation above the adjacent floor or grade below [i.e., 42 inches (1067 mm) high with more than a 30-inch (762 mm) drop-off and 26 inches (660 mm) high with a 30-inch (762 mm) or less drop-off]. When the seatbacks adjacent to cross aisles are a minimum of 24 inches (610 mm) above the floor level of the cross aisle, they will serve as the guard (see Figure 1028.14.2 for an illustration of the requirements in this section).

1028.14.2 Sightline-constrained guard heights. Unless subject to the requirements of Section 1028.14.3, a fascia or railing system in accordance with the *guard* requirements of Section 1013 and having a minimum height of 26 inches (660 mm) shall be provided where the floor or footboard elevation is more than 30 inches (762 mm) above the floor or grade below and the fascia or railing would otherwise interfere with the sightlines of immediately adjacent seating. At *bleachers*, a *guard* must be provided where required by ICC 300.

Exception: The height of the *guard* in front of seating shall be measured from the adjacent walking surface.

❖ The purpose of this section is to provide for occupant safety with guards along elevated seating for areas other than cross aisles, like at the front of a raised area or balcony level. The seats would only have an access aisle between the seat and the dropoff.

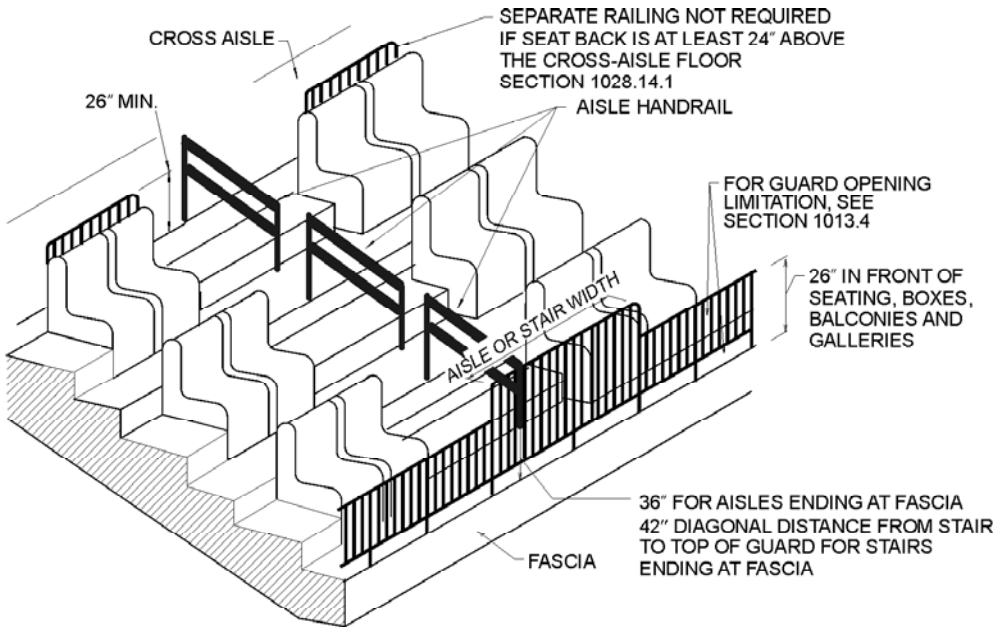
This section specifies a height of 26 inches (660 mm) for guards along facias. This is to provide a reasonable degree of safety while improving sightlines for persons seated immediately behind a facia or balcony edge. The guard opening configuration must comply with Section 1013.3 (see Figure 1028.14.2 for an illustration of the requirements in this section).

The exception was added to clarify that the height for the guard is measured from the floor, not from the top of the seat board as required in ICC 300 (Section

408.1, Item 1, of ICC 300). Since bleachers do not typically have backs or arms, people often walk down the seating rows when exiting rather than moving to the aisle steps, thus requiring an additional level of safety at dropoffs.

1028.14.3 Guards at the end of aisles. A fascia or railing system complying with the *guard* requirements of Section 1013 shall be provided for the full width of the *aisle* where the foot of the *aisle* is more than 30 inches (762 mm) above the floor or grade below. The fascia or railing shall be a minimum of 36 inches (914 mm) high and shall provide a minimum 42 inches (1067 mm) measured diagonally between the top of the rail and the *nosing* of the nearest tread.

❖ This section applies only where the foot end of aisles (the lower end) is greater than 30 inches (762 mm) above the adjacent floor or grade below. This typically occurs where aisles move down through rows of seating to the front edge of a balcony or raised seating area. The guard must satisfy both of the specified height requirements to provide safety for persons at the end of the aisle in case someone trips moving down the ramp or aisle steps. The 36-inch (914 mm) minimum height is measured from the floor vertically to the top of the guard. The minimum 42-inch (1067 mm) diagonal dimension from the nosing of the nearest stair tread to the top of the fascia or guard provides sufficient height to arrest a fall from the nearest aisle riser (see Figure 1028.14.2 for an illustration of the requirements in this section). The end result could be a guard with a vertical height of more than 36 inches (914 mm).



SECTION 1029
EMERGENCY ESCAPE AND RESCUE

1029.1 General. In addition to the *means of egress* required by this chapter, provisions shall be made for *emergency escape and rescue openings* in Group R-2 occupancies in accordance with Tables 1021.2(1) and 1021.2(2) and Group R-3 occupancies. Basements and sleeping rooms below the fourth story above *grade plane* shall have at least one exterior *emergency escape and rescue opening* in accordance with this section. Where basements contain one or more sleeping rooms, *emergency escape and rescue openings* shall be required in each sleeping room, but shall not be required in adjoining areas of the basement. Such openings shall open directly into a *public way* or to a *yard or court* that opens to a *public way*.

Exceptions:

1. Basements with a ceiling height of less than 80 inches (2032 mm) shall not be required to have *emergency escape and rescue openings*.
2. *Emergency escape and rescue openings* are not required from basements or sleeping rooms that have an *exit* door or *exit access* door that opens directly into a *public way* or to a *yard*, *court* or exterior exit balcony that opens to a *public way*.
3. Basements without *habitable spaces* and having no more than 200 square feet (18.6 m^2) in floor area shall not be required to have *emergency escape and rescue openings*.

❖ This section requires emergency escape and rescue provisions in residential buildings where occupants

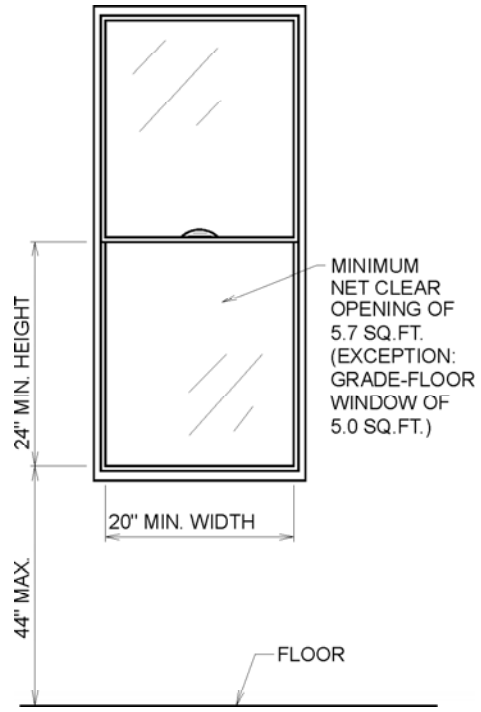
For SI: 1 inch = 25.4 mm.

Figure 1028.14.2
TYPICAL BALCONY GUARDS AT FASCIA

may be sleeping during a potential fire buildup, but are capable of self-preservation (Groups R-2, R-3 and R-4). Group R-2 apartment buildings permitted to have a single exit are also required to have emergency escape openings by Table 1021.2(1), Note a. Group R-2 congregate residences permitted to have a single exit are also required to have an emergency escape and rescue opening by Table 1021.2(2), Note a. All Group R-4 congregate residences would also be required to have emergency and escape rescue openings because Group R-4 follows Group R-3 provisions unless specifically mentioned otherwise (Section 310.6).

All basements and each bedroom/sleeping room are to be provided with an exterior window or door that meets the minimum size requirements and is operable for emergency escape by methods that are obvious and clearly understood by all users. Sleeping rooms four stories or more above grade are not required to be so equipped, since fire service access at that height, as well as escape through such an opening, may not be practical or reliable. Since single-exit apartment buildings are limited to three stories and most Group R-3 and R-4 buildings are two or three stories, this limit is not applicable very often. The provision for basements is in recognition that they typically have only a single means of egress without alternative routes.

It is important to note that this window is only an element of escape and does not comprise any part of the means of egress unless it is a door conforming with normal egress requirements.



Exceptions 1 and 3 are intended to exempt basements that would not be likely to be finished as living space, and thus have sleeping rooms in them.

The intent of Exception 2 is to permit sleeping rooms with a direct access to an exterior-type environment, such as a street or exit balcony, to not have an emergency escape window. The open atmosphere of the escape route would increase the likelihood that the means of egress be available even with the delayed response time for sleeping residents. This would also exempt walk-out basements.

1029.2 Minimum size. *Emergency escape and rescue openings* shall have a minimum net clear opening of 5.7 square feet (0.53 m^2).

Exception: The minimum net clear opening for grade-floor *emergency escape and rescue openings* shall be 5 square feet (0.46 m^2).

❖ The dimensional criteria of the openings are intended to permit fire service personnel (in full protective clothing with a breathing apparatus) to enter from a ladder, as well as permit occupants to escape. The net clear opening area and minimum dimensions are intended to provide a clear opening through which an occupant can pass to escape the building or a fire fighter can pass to enter the building for rescue or fire suppression activities. Since the emergency escape windows must be usable to all occupants, including children and guests, the required opening dimensions must be achieved by the normal operation of the window from the inside (e.g., sliding, swinging or lifting the sash). It is impractical to assume that all occupants can operate a window that requires a special sequence of operations to achieve the required opening size. While most occupants are familiar with the normal operation by which to open the window, children and guests are frequently unfamiliar with any special procedures that may be necessary to remove or tilt the sashes. The time spent in comprehending the special operation unnecessarily delays egress from the bedroom and could lead to panic and further confusion. Thus, windows that achieve the required opening dimensions only through operations such as the removal of sashes or mullions are not permitted. It should be noted that the minimum area cannot be achieved by using both the minimum height and minimum width specified in Section 1029.2.1 (see Figure 1029.2).

For SI: 1 inch = 25.4 mm, 1 square foot = 0.0929 m^2.

Figure 1029.2
EMERGENCY ESCAPE WINDOW

1029.2.1 Minimum dimensions. The minimum net clear opening height dimension shall be 24 inches (610 mm). The minimum net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

❖ Note that the minimum dimensions in this section and the minimum area requirements in Section 1029.2

both apply. Thus, a grade-floor window that is only 24 inches (610 mm) in height must be 30 inches (762 mm) wide to meet the 5-square-foot (0.46 m^2) area requirement of Section 1029.2 for grade-floor window (see Figure 1029.2).

1029.3 Maximum height from floor. *Emergency escape and rescue openings* shall have the bottom of the clear opening not greater than 44 inches (1118 mm) measured from the floor.

❖ This section limits the height of the bottom of the clear opening to 44 inches (1118 mm) or less such that it can be used effectively as an emergency escape (see Figure 1029.2). For a minimum sill height that may affect the emergency escape window, see Section 1013.8.

1029.4 Operational constraints. *Emergency escape and rescue openings* shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are permitted to be placed over *emergency escape and rescue openings* provided the minimum net clear opening size complies with Section 1029.2 and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening. Where such bars, grilles, grates or similar devices are installed in existing buildings, *smoke alarms* shall be installed in accordance with Section 907.2.11 regardless of the valuation of the *alteration*.

❖ If security grilles, decorations or similar devices are installed on escape windows, such items must be readily removable to permit occupant escape without the use of any tools, keys or a force greater than that required for the normal operation of the window. This would include any window fall prevention devices and window opening control devices required by Section 1013.8.

Where bars, grilles, grates or other devices that prevent full operation of the window are placed over the emergency escape and rescue opening, it is important that they are easily removable. Thus, the requirements for ease of operation are the same as required for windows.

Where smoke alarms are not already provided and when items that could possibly slow the opening of emergency escape and rescue windows are installed in existing buildings, smoke alarms must also be installed. Smoke alarms are necessary to provide advance warning of a fire for safety purposes.

1029.5 Window wells. An *emergency escape and rescue opening* with a finished sill height below the adjacent ground level shall be provided with a window well in accordance with Sections 1029.5.1 and 1029.5.2.

❖ Emergency escape and rescue openings that are partially or completely below grade need to have window wells so that they can be used effectively (see Figure 1029.5).

1029.5.1 Minimum size. The minimum horizontal area of the window well shall be 9 square feet (0.84 m^2), with a minimum dimension of 36 inches (914 mm). The area of the window well shall allow the *emergency escape and rescue opening* to be fully opened.

❖ This section specifies the size of the window well that is needed for a rescue person in full protective clothing and breathing apparatus to use the rescue opening. The required 9 square feet (0.84 m^2) is the size of the window well. Thus, the window well must project away from the plane of the window at least 3 feet (914 mm), and the required dimension in the plane of the window along the wall is also 3 feet (914 mm) (see Figure 1029.5).

1029.5.2 Ladders or steps. Window wells with a vertical depth of more than 44 inches (1118 mm) shall be equipped with an *approved* permanently affixed ladder or steps. Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center (o.c.) vertically for the full height of the window well. The ladder or steps shall not encroach into the required dimensions of the window well by more than 6 inches (152 mm). The ladder or steps shall not be obstructed by the *emergency escape and rescue opening*. Ladders or steps required by this section are exempt from the *stairway* requirements of Section 1009.

❖ This section specifies that a ladder or steps be provided for ease of getting into and out of window wells that are more than 44 inches (1118 mm) deep.

Usually ladder rungs are embedded in the wall of the window well. The 44-inch (1118 mm) dimension is the depth of the window well, not the distance from the bottom of the window well to grade. Thus, if the floor of a window well is 40 inches (1016 mm) below grade, but the wall of the window well projects above grade by 6 inches (152 mm), steps or a ladder are required since the vertical depth is 46 inches (1168 mm).

It is important that the ladder not obstruct the operation of the emergency escape window (see Figure 1029.5).

Chapter 11: Accessibility

General Comments

Chapter 11 contains provisions that set forth requirements for accessibility of buildings and their associated sites and facilities for people with physical disabilities. Existing building criteria is addressed in Section 3411. Appendix E is included in the code to address accessibility for items in the new *Americans with Disabilities Act Accessibility Guidelines* (ADAAG) that were not typically enforceable through the standard traditional building code enforcement approach system (e.g., beds, room signage).

In July 2004, the United States Architectural and Transportation Barriers Compliance Board (Access Board) published new design guidelines under the name *Americans with Disabilities Act and Architectural Barriers Act Accessibility Guidelines*, otherwise known as the "ADA/ABA Guidelines." On September 15, 2010 the U.S. Department of Justice (DOJ) published/ adopted the 2004 ADA/ABA Guidelines, officially renaming them the *2010 Standards for Accessible Design*. For purposes of the following discussion, the 2010 document will be referred to as the "2010 Standard," in this commentary while the original guidelines of 1991 are referred to as just "ADAAG." For additional technical assistance and information on the 2010 Standard, visit the Access Board website at www.access-board.gov.

The *International Residential Code*® (IRC®) references Chapter 11 for accessibility provisions; therefore, this chapter may be applicable to housing covered under the IRC (see commentary, Sections 1107.6 and 1107.6.3). Structures referenced to Chapter 11 from the IRC would be considered Group R-3.

Section 1101 contains the broad scope statement of the chapter and identifies the baseline criteria for accessibility as being in compliance with this chapter and 2009 ICC A117.1. ICC A117.1 *Accessible and Useable Buildings and Facilities* is the consensus national standard that sets forth the technical details, dimensions and construction specifications for accessibility.

Section 1102 contains a list of terms that are associated with accessibility. For the complete definitions and their commentary, see Chapter 2 of this code.

Section 1103 describes the applicability of the provisions of this chapter. Accessibility is broadly required in all buildings, structures, sites and facilities. Those specific circumstances in which accessibility is not required (or is limited) are set forth as exceptions.

Section 1104 contains the requirements for interior and exterior accessible routes. An accessible route is a key component of the built environment that provides a person with a disability access to spaces, elements, facilities and buildings. Note that ramps are addressed in Section 1010.

Section 1105 contains requirements for accessible entrances to buildings and structures. Note that requirements for accessible means of egress are addressed in Section 1007.

Section 1106 sets forth the requirements for accessible parking facilities and passenger loading zones.

Section 1107 contains various accessibility requirements that are unique to occupancies that contain dwelling units and sleeping units and are applicable in addition to other general requirements of this chapter. Specific provisions unique to Group I and R occupancies are included. The Type B dwelling- and sleeping-unit requirements in this section are coordinated with the requirements found in the *Fair Housing Accessibility Guidelines* (FHAG). Requirements for institutional and transient lodging are also consistent with the 2010 Standard. When federal funding is provided for the project, there may be a higher level of accessibility required.

Section 1108 contains various accessibility requirements that are unique to specific occupancies, other than Groups I and R, and are applicable in addition to all other general requirements of Chapter 11. Specific provisions unique to assembly seating, performance areas, self-storage and judicial facilities are included.

Section 1109 contains various requirements that are applicable to features and facilities that are not occupancy related, including requirements for toilet and bathing facilities; sinks; kitchens; drinking fountains; sauna/steam rooms; elevators; lifts; storage facilities; detectable warnings; seating at tables, counters and work surfaces; service facilities; controls and operating mechanisms; fuel dispensing systems; and recreational facilities.

Section 1110 sets forth requirements for signage identifying certain required accessible elements.

History—Building Codes and Federal Laws

Access to buildings and structures for people with physical disabilities has been a subject that building codes have regulated since the early 1970s. They have consistently relied on a consensus national standard, CABO/ANSI A117.1, as the technical basis for accessibility. The title of CABO/ANSI A117.1 is now ICC/ANSI A117.1 to reflect that the International Code Council® (ICC®) is the secretariat for this standard. Accessibility is not a new subject to the construction regulatory community. There has been a great deal of emphasis and awareness placed on the subject of accessibility through the passage of two federal laws. The Americans with Disabilities Act (ADA) and the Fair Housing Amendment Act (FHA) are federal regulations that

affect building construction as it relates to accessibility.

ADA, signed into law in July 1990, is a very broad civil rights law designed to protect persons with disabilities. There are five sections of the ADA that address different aspects of civil rights for people with disabilities. Title I deals with employment and generally prohibits discrimination against disabled people in employment. Title II deals with public services, including access to all services and facilities receiving federal funding, and access to public transportation, including buses, rail lines and passenger transit facilities. Title III requires access to a large category of buildings and structures in a manner that is equal or comparable to that available to the general public. Note that FHA is a companion document to ADA. FHA deals with residential and institutional living arrangements that, for the most part, are not covered under ADA. Title IV deals with accessible telecommunication facilities and Title V further defines miscellaneous issues dealing with ADA compliance.

Titles II and III of the ADA overlap numerous requirements customarily regulated by building codes. When ADA was originally written, Title II facilities had the option to follow either the FED-STD-795-88, *Uniform Federal Accessibility Standards* (UFAS) or ADAAG for compliance with accessibility requirements. Title II facilities include those receiving federal funding for the building or for programs offered in the building, i.e., colleges, schools, park districts, local and state governments, hospitals, etc. Implementation of Title III of the ADA was based on the requirements of ADAAG. Both UFAS and ADAAG set forth scoping and technical requirements for building design and construction. The federal government is interested in bringing more uniformity to federal accessibility standards and is continuously looking at ways in which harmonization of all federal and private-sector standards can be accomplished. In many ways, UFAS and ADAAG are similar to a building code and in fact cover many of the same matters that are dealt with in such codes. With this in mind, the Access Board developed new and additional requirements within the past decade. The new requirements are organized in a building code format. The ICC and Access Board both worked toward coordination between the federal and building code requirements. The 2010 Standard will replace UFAS (1984) and ADAAG (1991) as the standard referenced for compliance with ADA and another federal law, the Architectural Barriers Act (ABA, 1968). From September 15, 2010 to March 15, 2012, compliance with either the 1991 ADAAG or the 2010 Standard will be an option. Beginning March 15, 2012, compliance with the 2010 Standard will be required for all new construction and as well as for alterations to existing facilities.

It is important to emphasize, however, that the ADA (a law) is written as civil rights legislation and not as a building code. The enforcement mechanism for civil rights laws is significantly different than that for traditional building regulation. The ADA does not preempt the adoption or enforcement of accessibility-related codes by state and local governments. All buildings constructed within a jurisdiction must comply with locally adopted building codes and any applicable state codes, as well as the 2010 Standard; however, as a federal law, state and local governments have neither the authority nor the responsibility to enforce ADA. Enforcement of ADA is the responsibility of the U.S. DOJ. As previously described, ADA covers a large range of issues dealing with disabilities. Under Titles II and III, the scoping and technical requirements of the 2010 Standard deal directly with accessibility of buildings. Typically, enforcement of these regulations takes place after the construction process. Any differences between the regulations and proposed design must be ultimately reconciled by the building owner or designer. Building code compliance is typically evaluated during the plan review and construction process. This is a less costly time to make required changes to a facility that are necessary for compliance. Again, the building official is expected to enforce the code adopted by the state or local jurisdiction, and any applicable state laws. The building official is not responsible for interpretation or enforcement of ADA unless the state or local jurisdiction has referenced ADAAG or the 2010 Standard in a state's accessibility laws. No attempt should be made to represent that the 2010 Standard is being interpreted or enforced by the building official or the jurisdiction when the 2010 Standard has not been specifically adopted by the jurisdiction.

The concept of two completely separate and independent, broad-based sets of regulations that affect building design and construction may sound onerous, but the situation may not be quite as bad as it appears. The reason is that the code has a high level of consistency with the 2010 Standard. Since the early 1990s, code change activity has incorporated the recommendations of the Council of American Building Officials' (CABO) Board for the Coordination of the Model Codes (BCMC) [succeeded in 1995 by the ICC Board for the Development of the Model Codes (BDMC)]. The BDMC undertook the effort to review comprehensively all facets of the accessibility issue. This effort included a comparison of ADAAG with the provisions of the model codes in use at that time. The BDMC's recommendations were ultimately reflected in codes. This work has continued to evolve as the industry learns and new technologies become readily available. There are still differences between the code and the 2010 Standard, but they are minimal and will become less in future code editions.

Efforts for coordination with the federal accessibility requirements are ongoing. Representatives from interested accessibility groups, Department of Housing and Urban Development (HUD) and the Access Board have been attending and participating in the code change process for the code and ICC A117.1. Additionally, the ICC has participated in the public comment process on the development of federal regulations. The ICC has worked toward, and will continue to strive for, accessibility regulations that reflect the highest possible degree of

consistency with federal regulations and, more importantly, reasonable and appropriate provisions to meet the needs of people with disabilities.

The FHA is federal legislation promulgated by HUD that extends fair housing protection against discrimination on the basis of family status or persons with disabilities. The standard for FHA is the FHAG, which sets forth accessibility scoping and technical requirements for a broad category of residential construction. The scope of ADAAG generally excludes occupancies that are covered by FHAG; however, FHA is being interpreted to overlap the scope of the coverage of ADA in some respects (e.g., dorms, nursing homes). Residential buildings that are covered by FHAG must also comply with the locally adopted building code. The same circumstances with respect to differences in the requirements and responsibility for enforcement described for ADA also exist with FHA.

Again, as a federal law, building officials have neither the responsibility nor the authority to enforce the requirements of FHAG. Inquiries regarding those laws should be referred to the DOJ or HUD. Until such time that their laws are coordinated with and consider traditional code enforcement mechanisms and methods, building officials are advised not to attempt to interpret or enforce these laws. Permit applicants should be advised that the work they propose has not been reviewed for compliance with FHAG.

Due to concerns about residential construction complying with all applicable codes and laws, the National Association of Home Builders (NAHB), along with others, approached the model code groups about incorporating the FHAG requirements into the model code requirements. Since the FHA is a civil rights law rather than a building code, careful study was needed to interpret them into enforceable language that could be utilized in model codes. Through the efforts of the BDMC, recommendations to the model codes were proposed in 1994. The "adaptable" dwelling unit requirements were carried forward as a Type A unit, with the FHA requirements reflected in the Type B units.

In 2000, HUD reviewed the 2000 edition of the IBC and the referenced accessibility standard ICC/ANSI A117.1-1998 for compliance with FHAG. Based on HUD's report, a series of modifications were proposed as part of the 2000 code change cycle. The proposed modifications were accepted by the voting members and were incorporated into the 2001 Supplement to the IBC and eventually into the 2003, 2006 and 2009 editions of the code. As a result of the earlier code changes, HUD eventually issued press releases stating that the 2000 code with the 2001 Supplement and 2003 code (with the ICC/ANSI A117.1-1998 accessibility standard) and the 2006 IBC (with the ICC/ANSI A117.1-2003 accessibility standard) could be considered "safe harbor" for anyone wanting to comply with FHAG scoping and technical requirements. The original safe harbor status that was bestowed on the 2000 IBC and its accessory documents was identified in the preamble of HUD's *Fair Housing Act Design Manual*.

With the 2003 and the 2006 editions of the code being safe harbor documents, architects and developers could design and be reviewed for compliance with the code through the typical building code review process. At the same time, they would also be in compliance with the building requirements for the FHAG. At the time this commentary was written, HUD had not completed its review of the 2009 and 2012 editions of the code for safe-harbor status. Since the code is developed through a code change/public comment process, there have been changes to items in Chapter 11. This is typically a good way for new concerns, concepts or procedures to be incorporated into the requirements. It is the ICC's opinion that none of these changes have jeopardized the safe-harbor status between FHA and the code requirements in this edition.

Philosophy

The fundamental philosophy of the code on the subject of accessibility is that everything is required to be accessible. This is reflected in the basic applicability requirement (see Section 1103.1). The code's scoping requirements then address the conditions under which accessibility is not required in terms of exceptions to this general mandate. In the early 1990s, building codes tended to describe where accessibility was required in each occupancy, and any circumstance not specifically identified was excluded. The more recent codes represent a fundamental change in approach. Now one must think of accessibility in terms of "if it is not specifically exempted, it must be accessible."

Another important concept is that of "mainstreaming." There are many accessibility issues that not only benefit people with disabilities, but also provide a tangible benefit to people without disabilities. This type of requirement can be set forth in the code as generally applicable without necessarily identifying it specifically as an accessibility-related issue. Such a requirement would then be considered as having been mainstreamed. For example, the limitation on objects protruding into corridors, aisles and passageways (see Section 1003.3) is intended to aid people with a vision impairment by reducing the potential for unintended contact that may cause injury. Clearly, this has an additional benefit to people without a vision impairment. A protruding object can be encountered by a sighted person who is simply not paying close attention. The concept of mainstreaming is responsive to the desire of people with disabilities to not be singled out and categorized separately from the remainder of society. It is therefore important to recognize that, while the provisions of Chapter 11 are specifically grouped and identified as accessibility related, they do not represent all of the issues that must be taken into consideration when evaluating accessibility in buildings.

There are many items that have some basis in accessibility requirements, but actually result in more "user-friendly" buildings for all of us. Physical disabilities can be permanent or temporary; can affect all age groups; can involve all levels of abilities and can range from per-

sons with minor visual, hearing or mobility impairments to persons who are blind, deaf or confined to a wheelchair. Everyone will benefit from accessible features in buildings, either directly or indirectly through those they care for. With some foresight in designing our built environment, access into and throughout buildings can be better for everyone throughout their lifetimes.

Purpose

The purpose of this chapter is to set forth requirements for accessibility applicable to those elements of the built environment that are included within the scope of the code. There are two categories or types of requirements that must be addressed in order to accomplish accessibility: scoping and technical. Scoping requirements describe what and where accessibility is required, or how many accessible features or elements must be provided. For example, a requirement that at least one of the first 25 sleeping units in a hotel must be accessible is referred to as a scoping requirement because it describes what and how many accessible features are required. Another example of scoping is the exception for detached one- and two-family dwellings from accessibility requirements because it defines what is not required to be accessible. A technical requirement is intended to refer to a statement indicating how accessibility is to be accomplished. For example, a requirement indicating that in order for a parking space to be accessible, it must have a width of 96 inches (2438 mm) with an adjacent 60-inch (1524 mm) access aisle is considered a technical requirement. The provisions of Chapter 11 are scoping requirements in that they all address what and where accessibility is required or how many accessible elements are required. ICC A117.1 indicates how to make something accessible and is the consensus national standard that is referenced for establishing technical requirements. In addition to the provisions of Chapter 11, there are accessibility-related technical requirements elsewhere in the code. These are subject-matter-specific provisions that have been main-streamed into the chapter or section of the code that deals with those subjects. As such, the code and its references regulate accessibility comprehensively by setting forth the scoping and technical requirements that establish the minimum level of accessibility required in the built environment.

SECTION 1101
GENERAL

1101.1 Scope. The provisions of this chapter shall control the design and construction of facilities for accessibility to physically disabled persons.

❖ This section establishes the scope of the chapter as providing for design and construction of facilities for accessibility to disabled persons. The scope is broadly inclusive of all aspects of construction that affect the ability of people with disablities to approach, enter and utilize a facility. The term "facility," as defined in Chapter 2, includes not only buildings and structures, but also the site on which they are located. Features of a site, such as parking areas and paths of travel from a public way to a structure, affect accessibility and are, therefore, within the scope of Chapter 11. Chapter 11, in conjunction with mainstreamed provisions throughout the code, sets forth scoping requirements.

1101.2 Design. Buildings and facilities shall be designed and constructed to be *accessible* in accordance with this code and ICC A117.1.

❖ This section establishes the primary and fundamental relationship of ICC A117.1 to the code. The code text is intended to "scope" or provide thresholds for application of required accessibility features. The referenced standard contains technical provisions indicating how compliance with the code is achieved. In short, Chapter 11 specifies what, when and how many accessible features are required; the referenced standard indicates how to make that feature accessible. Compliance with both the code and the standard is required.

In accordance with Section 102.4, standards are utilized only to the extent that they are referenced. Note that ICC A117.1 includes technical criteria for several items that are not actually scoped in the code. Such items are not required to comply with ICC A117.1 criteria unless specifically scoped by the authority have jurisdiction. Some examples of items in ICC A117.1 that are not referenced by the code are:

Section 403.6 – Corridor handrails

Section 504 – Stairways

Section 704 – Telephones
(scoped in IBC Appendix E)

Section 707 – Automatic Teller Machines
(scoped in IBC Appendix E)

SECTION 1102
DEFINITIONS

1102.1 Definitions. The following terms are defined in Chapter 2:

❖ This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code. For example, the defined term "Accessible" is applicable to where a space or element is required

to be designed to address the needs of persons with mobility, hearing or vision impairments; however, when other chapters provide criteria for equipment or construction elements to be accessible for maintenance or inspections (i.e., Section 110.1), the intent is for an inspector or maintenance person to have physical and visual access to that element—not wheelchair access.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms that may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

ACCESSIBLE.

ACCESSIBLE ROUTE.

ACCESSIBLE UNIT.

TYPE B UNIT.

WHEELCHAIR SPACE.

SECTION 1103
SCOPING REQUIREMENTS

1103.1 Where required. *Sites*, buildings, *structures*, *facilities*, elements and spaces, temporary or permanent, shall be *accessible* to persons with physical disabilities.

❖ This section establishes the broad principle that all buildings, structures and their associated sites and facilities are required to be accessible to persons with physical disabilities. This would include anyone who utilizes a space, including occupants, employees, students, spectators, participants and visitors. The approach taken by the code on the subject of accessibility is to require all construction to be accessible and then provide for the acceptable level of inaccessibility that is reasonable and logical. In codes created before the early 1990s, the approach was to list the conditions and occupancies to which the accessibility requirements applied; however, this is no longer practical, since the exceptions are far fewer than the circumstances to which accessibility applies. The 15 exceptions to this section, Sections 1103.2.1 to 1103.2.15, reflect the extent to which accessibility in construction is either exempt or reduced in scope.

1103.2 General exceptions. *Sites*, buildings, *structures*, *facilities*, elements and spaces shall be exempt from this chapter to the extent specified in this section.

❖ Accessibility is generally applicable to all building sites and all spaces and elements within the constructed facilities except as specifically exempted in the subsections to Section 1103.2.

1103.2.1 Specific requirements. *Accessibility* is not required in buildings and *facilities*, or portions thereof, to the extent permitted by Sections 1104 through 1110.

❖ This section provides a correlative reference to the various sections in Chapter 11 that identify when the intended number of accessible elements in various occupancies is less than 100 percent. The number of accessible fixtures and elements required by the referenced sections are deemed to provide adequate accessibility for those circumstances. For example, Section 1106 does not require all parking spaces in a parking facility to be accessible, Section 1107.6.1 does not require all sleeping units in Group R-1 to be fully accessible and Section 1109.9 does not require all storage to be accessible.

1103.2.2 Existing buildings. Existing buildings shall comply with Section 3411.

❖ The second section is a reference to the existing building criteria in Section 3411 for accessibility concerns in existing buildings. In accordance with Section 3401.5, the *International Existing Building Code*® (IEBC®) could also be used (see commentary, Section 3411).

1103.2.3 Employee work areas. Spaces and elements within employee work areas shall only be required to comply with Sections 907.9.1.2, 1007 and 1104.3.1 and shall be designed and constructed so that individuals with disabilities can approach, enter and exit the work area. Work areas, or portions of work areas, that are less than 300 square feet (30 m^2) in area and located 7 inches (178 mm) or more above or below the ground or finish floor where the change in elevation is essential to the function of the space shall be exempt from all requirements.

❖ This section states that elements within individual work areas are not required to be accessible, with the exception of visible alarms (see Section 907.5.2.3), accessible means of egress (see Section 1007) and circulation paths (see Section 1104.3.1). The

assumption is that the employment nondiscrimination requirements of the ADA will provide for "reasonable accommodations" to the disability of the employee and the area in which they work. In other words, employers will modify individual work areas for the specific requirements of the individual utilizing the space. An accessible route will be required to each work area. An example of this is an individual work station in a laboratory. Installing sinks and built-in counters at accessible levels (see commentary, Sections 1109.3 and 1109.11) could make the station impractical for use by a person who is standing. Ergonomic researchers used to recommend a standing counter at a minimum of 36 inches (914 mm), but are now advising even higher counters to reduce fatigue. When a station is required to be adapted for an individual, it would be revised based on the individual's needs and abilities. An accessible route to each work station in the laboratory would be required so that access to and from that station would be available. Note that the 36-inch (914 mm) clear width for the accessible route is the same as the minimum required width of an exit access aisle. For exceptions to the route to work areas, see Section 1104.3.1.

There is an additional exception for work areas that need to be raised or lowered 7 inches (178 mm) or more above the floor and have an area of less than 300 square feet (14 m^2). Examples of raised work areas would include an area around a metal stamping machine, a safety manager's observation station on a production line or the pulpit area in a church. Raised courtroom areas are specifically addressed in Section 1108.4.1. An example of a lowered work area might be a pit under a car in a car-repair station.

An employee's work area can be something as simple as an office or cubicle, or it can extend over a much wider area. For example, an office space might include copy rooms, file rooms, mail rooms, etc., or a nurse or doctor in a clinic would have part of their work area in each exam room as well as at a central station area. In addition, not all employee-only spaces are considered work areas. Areas used by employees not for work (i.e., break rooms, bathrooms, corridors) would not fall under this exception (see the definition for "Employee work area").

1103.2.4 Detached dwellings. Detached one- and two-family *dwellings* and accessory structures, and their associated *sites* and facilities, are not required to be *accessible*.

❖ This section exempts detached one- and two-family dwellings from accessibility requirements. The key word here is "detached." For example, a structure containing four or more dwelling units, even if the dwelling units are separated by fire walls, would still be required to be accessible as indicated in Section 1107.

Although one- and two-family detached dwellings are typically regulated by the IRC, this exception in the code is still necessary. Single-family dwellings or duplexes that are four stories or higher would be designed and constructed under Group R-3 requirements of the code. The IRC references Chapter 11 of the code for accessibility requirements in Section R320. Those multiple-family structures with four or more dwelling units that qualify as townhouses or congregate residences with four or more sleeping units under the IRC are required to comply with the requirements for Group R-3 in Section 1107.6.3.

1103.2.5 Utility buildings. Occupancies in Group U are exempt from the requirements of this chapter other than the following:

1. In agricultural buildings, access is required to paved work areas and areas open to the general public.
2. Private garages or carports that contain required *accessible* parking.

❖ This section exempts Group U from accessibility requirements except as indicated, on the basis that such structures are a low priority when considering the need for accessibility. Areas in utility buildings that are required to be accessible would be paved work areas or areas open to the general public, such as if a farmer included a farmstand within his or her barn or buildings in which accessible parking spaces are located.

1103.2.6 Construction sites. Structures, *sites* and equipment directly associated with the actual processes of construction including, but not limited to, scaffolding, bridging, materials hoists, materials storage or construction trailers are not required to be *accessible*.

❖ This section exempts structures directly associated with the construction process because the need for accessibility on a continuous or regular basis in those circumstances is unlikely to arise. Portable toilets that are for the construction workers would be exempted. Note that all structures that may be involved during a construction project are not exempt—only those specifically involved in the actual process of construction. For example, if mobile units are brought into house classrooms during a school addition, these classrooms must be accessible. A construction trailer that also serves as a sales office would also be required to be accessible.

1103.2.7 Raised areas. Raised areas used primarily for purposes of security, life safety or fire safety including, but not limited to, observation galleries, prison guard towers, fire towers or lifeguard stands, are not required to be *accessible* or to be served by an *accessible route*.

❖ If there is a reason to elevate an area for concerns about security or safety, these areas are not required to be accessible (see Figure 1103.2.7).

1103.2.8 Limited access spaces. Nonoccupiable spaces accessed only by ladders, catwalks, crawl spaces, freight ele-

Figure 1103.2.7
EXAMPLE OF RAISED AREA EXCEPTION

vators or very narrow passageways are not required to be *accessible*.

❖ Nonoccupiable, limited access spaces are considered areas where work could not reasonably be performed by a person using a wheelchair due to the physical requirements of the job activity. These areas are not required to be accessible.

1103.2.9 Equipment spaces. Spaces frequented only by personnel for maintenance, repair or monitoring of equipment are not required to be *accessible*. Such spaces include, but are not limited to, elevator pits, elevator *penthouses*, mechanical, electrical or communications equipment rooms, piping or equipment catwalks, water or sewage treatment pump rooms and stations, electric substations and transformer vaults, and highway and tunnel utility facilities.

❖ Spaces that only contain heating, ventilation and air conditioning (HVAC), electrical, elevator, communication and similar types of equipment are considered areas where work could not reasonably be performed by a person utilizing a wheelchair due to the physical requirements of the job activity. These areas are not required to be accessible.

1103.2.10 Single-occupant structures. Single-occupant structures accessed only by passageways below grade or elevated above grade including, but not limited to, toll booths that are accessed only by underground tunnels, are not required to be *accessible*.

❖ This section addresses facilities such as toll booths, which are raised to facilitate access to higher vehicles as well as to provide protection from being struck by vehicles. Access to these spaces are often lanes by tunnel or bridge. Some of these types of facilities could also be covered by Section 1103.2.3.

1103.2.11 Residential Group R-1. Buildings of Group R-1 containing not more than five *sleeping unit*s for rent or hire that are also occupied as the residence of the proprietor are not required to be *accessible*.

❖ This section exempts small bed-and-breakfast or transient boarding house facilities that are also the home of the owner.

1103.2.12 Day care facilities. Where a day care facility is part of a *dwelling unit*, only the portion of the structure utilized for the day care facility is required to be *accessible*.

❖ When an adult day care or child day care facility is part of a person's home, the accessibility requirements are only applicable to the portion of the home that constitutes the day care facility, not the home itself. For other home-based businesses, see the discussion on live/work units in Sections 419 and 1103.2.13.

1103.2.13 Live/work units. In live/work units constructed in accordance with Section 419, the portion of the unit utilized for nonresidential use is required to be *accessible*. The residential portion of the live/work unit is required to be evaluated separately in accordance with Sections 1107.6.2 and 1107.7.

❖ Live/work units are dwelling units in which a significant portion of the space includes a nonresidential use operated by the tenant/owner. Although the entire unit is classified as a Group R-2 occupancy for construction purposes, for accessibility purposes it is viewed more as a mixed-use condition. The residential portion of the unit is regulated differently for accessibility purposes than the nonresidential portion.

The floor area of the dwelling unit that is intended for residential use is regulated under the provisions of Section 1107.6.2 for Group R-2 occupancies. The requirements for an Accessible unit, Type A unit or Type B unit would be applied based upon the specific residential use of the unit and the number of units in the structure. The exceptions for Type A and Type B units set forth in Section 1107.7 would also exempt such units where applicable. For example, a two-story dwelling unit above the work unit in a nonelevator building would not be subject to Type B requirements due to the exemption in Section 1107.7.2. The code does not clarify if a two-story live/work unit with the business on the entire first floor and the residence on the entire second floor would be considered a multi-story dwelling unit for purposes of the exception in Section 1107.7.2. Just as a reminder, Type B units are applied per structure, not per building, so legal property lines may not be relevant when evaluating accessibility requirements (see Section 1107).

In the nonresidential portion of the unit, full accessibility would be required based upon the intended use. For example, if the nonresidential area of the unit is utilized for hair care services, all elements related to the service activity must be accessible. This would include site parking where provided, site and building accessible routes, the public entrance, and applicable patron services. In essence, the work portion of the

live/work unit would be regulated in the same manner as a stand-alone commercial occupancy.

1103.2.14 Detention and correctional facilities. In detention and correctional facilities, *common use* areas that are used only by inmates or detainees and security personnel, and that do not serve holding cells or housing cells required to be *accessible*, are not required to be *accessible* or to be served by an *accessible route*.

❖ Section 1107.5.5 addresses when sleeping units, special holding or housing cells and medical care units in detention and correctional facilities are required to be accessible. If the purpose of any common or shared space is to serve only the associated cells that are not required to be accessible (e.g., shared bathrooms or living space serving a specific group of cells), then those common or shared spaces are not required to be accessible.

1103.2.15 Walk-in coolers and freezers. Walk-in coolers and freezers intended for employee use only are not required to be *accessible*.

❖ Walk-in coolers and freezers usually have features that make accessibility difficult. For thermal efficiency they may have raised floors, special door seals, unconventional door-operating hardware, tight internal storage, wheeled racking systems, etc. For these and other reasons they are not required to have an accessible entry or to be accessible within. Walk-in coolers and freezers may also be considered exempted under Section 1103.2.3. Coolers that are accessed from the front by customers would need to comply with operable parts and display criteria on the public side (see Sections 1109.9.2 and 1109.13).

SECTION 1104
ACCESSIBLE ROUTE

1104.1 Site arrival points. *Accessible routes* within the *site* shall be provided from public transportation stops; *accessible* parking; *accessible* passenger loading zones; and public streets or sidewalks to the *accessible* building entrance served.

Exception: Other than in buildings or facilities containing or serving *Type B units*, an *accessible route* shall not be required between *site* arrival points and the building or facility entrance if the only means of access between them is a vehicular way not providing for pedestrian access.

❖ The intent of this section is to require an accessible route from the point at which one enters the site to any buildings or facilities that are required to be accessible on that site. It is presumed that people with disabilities are capable of gaining access to the site from such locations as accessible parking, public transportation stops, loading zones, public streets or sidewalks.

The exception addresses vehicular routes that provide the only route between an arrival point and an accessible entrance. An accessible route for pedestrian access is not required except in buildings or structures having or serving Type B units. For example, if there is a bus stop at the front of an industrial complex, but the only route to the building entrance is via a long driveway, an accessible pedestrian route to that entrance from the bus stop is not required. For special considerations in residential developments, see the commentary to Sections 1107.4, 1107.7.4, 1107.7.5, 1109.15.1 and 1109.15.2.

1104.2 Within a site. At least one *accessible route* shall connect *accessible* buildings, *accessible* facilities, *accessible* elements and *accessible* spaces that are on the same *site*.

Exception: An *accessible route* is not required between *accessible* buildings, *accessible* facilities, *accessible* elements and *accessible* spaces that have, as the only means of access between them, a vehicular way not providing for pedestrian access.

❖ Developments may include several buildings on the same site. The intent of this section is to require an accessible route to all facilities offered on a site. Often sites are designed such that the only way to reach a building or facility is by automobile. If there are multiple, separated parking areas serving one or more buildings on a site, an accessible route is required between all such parking facilities and the buildings they serve. If there is an exterior feature, such as a swimming pool, located on a site containing multiple buildings, an accessible route is required from each building to the swimming pool. The exception clarifies that an accessible route is not required where no pedestrian access is otherwise intended or provided to a particular building or feature on the site. For special considerations in residential developments with recreational facilities, see the commentary to Sections 1107.3 and 1109.15.

1104.3 Connected spaces. When a building or portion of a building is required to be *accessible*, an *accessible route* shall be provided to each portion of the building, to *accessible* building entrances connecting *accessible pedestrian walkways* and the *public way*.

Exceptions:

1. In a building, room or space used for assembly purposes with *fixed seating*, an *accessible route* shall not be required to serve levels where *wheelchair spaces* are not provided.
2. In Group I-2 facilities, doors to *sleeping unit*s shall be exempted from the requirements for maneuvering clearance at the room side provided the door is a minimum of 44 inches (1118 mm) in width.

❖ This section requires that there be at least one route from an accessible entrance to all required accessible features within a building. If an area is addressed with a specific exception, then an accessible route is not required. For example, mechanical penthouses are exempt under Section 1103.2.9; therefore, an accessible route would not be required to this area.

Once someone gets into a space, they must also be able to evacuate in an emergency situation. This

may or may not be via the same route. For accessible means of egress requirements, see Section 1007.

Exception 1 reemphasizes that levels in assembly seating that do not contain wheelchair seating locations are not required to be accessed by an accessible route; however, the types of services available in the facility must be considered when determining what services must be available to accessible seats. A route is required to services from accessible seats in accordance with Section 1108.2.1.

Exception 2 recognizes the practical implications of door maneuvering clearances on the room side at inswinging doors in smaller sized patient sleeping rooms in hospitals and nursing homes. The maneuvering clearance is still required on the outside of the Accessible patient sleeping room door. Since the maneuvering clearance in ICC A117.1 is based on the size of the door, there is no credit provided for the wider 44-inch (1118 mm) door width (required in Section 1008.1.1 in Group I-2 for movement of bed) versus the standard 36-inch (914 mm) wide door. Without this exception a patient room would likely require extra width when a toilet room is located on the same wall as the door. Due to operational procedures and observation needs, the door position is normally open, therefore, the need for door maneuvering clearance on the interior side is reduced. At hospitals, nursing homes and rehabilitation centers, the patient room door is usually closed only when privacy is needed during procedures.

The percentage of Accessible units and Type B units in hospitals, nursing homes and rehabilitation centers is addressed in Sections 1107.5.2, 1107.5.3 and 1107.5.4. Maneuvering clearances are part of an accessible route, and accessible routes connect accessible elements; therefore, maneuvering clearances at patient sleeping rooms that are not Accessible or Type B units are not required since an accessible route is not required. For additional information on when Type B units are required in institutional facilities, see the commentary to Section 1107.

1104.3.1 Employee work areas. *Common use circulation paths* within *employee work areas* shall be *accessible routes*.

Exceptions:

1. *Common use circulation paths*, located within *employee work areas* that are less than 1,000 square feet (93 m^2) in size and defined by permanently installed partitions, counters, casework or furnishings, shall not be required to be *accessible routes*.
2. *Common use circulation paths*, located within *employee work areas*, that are an integral component of equipment, shall not be required to be *accessible routes*.
3. *Common use circulation paths*, located within exterior *employee work areas* that are fully exposed to the weather, shall not be required to be *accessible routes*.

❖ This requirement for common use circulation paths within employee work areas is consistent with the exception in Section 1103.2.3. An accessible route is required to each employee work area. When employees share work areas, an accessible route must be available throughout that area. Note that the accessible route minimum width of 36 inches (914 mm) clear is consistent with the minimum means of egress pathways.

Exception 1 addresses the accessible route within small employee work areas. Shared work areas that are less than 1,000 square feet (93 m^2) and confined by walls, partitions, permanently installed equipment, cabinets and counters are not required to have an accessible route through that particular area. The square footage limitation does not always pertain to a room, but also to part of a room. The intent was to allow such areas as the last two work stations down an aisle, two or three work stations in a small office, the employee side of a beverage bar, portions of commercial kitchens, etc. An accessible route is required to these areas, but not necessarily throughout the area. There can be multiple exceptions within the same area, such as in a commercial kitchen. Again, modifications would be performed at a later date based on employee needs.

Exception 2 permits nonaccessible areas around and through pieces of equipment. An example would be the shared work areas around a piece of assembly equipment in a factory where one or more persons are required to monitor and operate the machine and incoming or outgoing product.

Exception 3 is an exception for outdoor work areas. This would be applicable to landscapers, sewer workers, gravel pit crews, etc.

1104.3.2 Press boxes. Press boxes in a building, room or space used for assembly purposes shall be on an *accessible route*.

Exceptions:

1. An *accessible route* shall not be required to press boxes in *bleachers* that have points of entry at only one level, provided that the aggregate area of all press boxes is 500 square feet (46 m^2) maximum.
2. An *accessible route* shall not be required to free-standing press boxes that are elevated above grade 12 feet (3660 mm) minimum provided that the aggregate area of all press boxes is 500 square feet (46 m^2) maximum.

❖ Press boxes are required to be served by an accessible route. If the occupant load is five or less, this could be provided by a platform lift (see Section 1109.8, Item 3).

Exception 1 is mainly applicable to press boxes located at the back of the bleacher seating in an out-

door sports facility. The "point of entry at only one level" refers to access to the press box directly from the bleacher seating (see Figure 1104.3.2).

Exception 2 is mainly applicable to the free-standing press box. If that press box is either less than 12 feet (3677 mm) above the ground or more than 500 square feet (46 m^2) in area, it must be served by an accessible route. Historically, the 12-foot (3677 mm) height limit was chosen because that was the maximum rise for a platform lift in previous editions of ASME A18.1.

For both exceptions, if one press box is provided, the total area of the press box must be less than 500 square feet (46 m^2). If more than one press box overlooks the same playing field, the aggregate area of both press boxes must be less than 500 square feet (46 m^2). The aggregate area is not intended to be applicable to press boxes that happen to be on the same multiple-facility site. For example, if a high school has a football field with two press boxes, the area of those two press boxes must be added together; however, if the same high school also has a press box for the baseball field, the area of the press box in the baseball field would not be included with the area of the press boxes in the football field.

Figure 1104.3.2
EXAMPLE OF PRESS BOX
ACCESSED FROM BLEACHER SEATING

1104.4 Multilevel buildings and facilities. At least one *accessible route* shall connect each *accessible* level, including *mezzanines*, in multilevel buildings and facilities.

Exceptions:

1. An *accessible route* is not required to stories and *mezzanines* that have an aggregate area of not more than 3,000 square feet (278.7 m^2) and are located above and below *accessible* levels. This exception shall not apply to:
   1.1. Multiple tenant facilities of Group M occupancies containing five or more tenant spaces;
   1.2. Levels containing offices of health care providers (Group B or I); or
   1.3. Passenger transportation facilities and airports (Group A-3 or B).
2. Levels that do not contain *accessible* elements or other spaces as determined by Section 1107 or 1108 are not required to be served by an *accessible route* from an *accessible* level.
3. In air traffic control towers, an *accessible route* is not required to serve the cab and the floor immediately below the cab.
4. Where a two-story building or facility has one *story* with an *occupant load* of five or fewer persons that does not contain *public use* space, that *story* shall not be required to be connected by an *accessible route* to the *story* above or below.
5. Vertical access to elevated employee work stations within a courtroom is not required at the time of initial construction, provided a *ramp*, lift or elevator can be installed without requiring reconfiguration or extension of the courtroom or extension of the electrical system.

❖ At least one accessible route is required between levels in a facility. This requirement does not mandate an elevator. The accessible route between levels can be via ramps, platform lifts (where permitted), limited use/limited access (LULA) elevators, passenger elevators, etc. The intent of the exceptions is to allow limited areas to be inaccessible without restricting access to services available to the general public.

Exception 1 addresses conditions under which it may not be practical or economical to provide an accessible route in multilevel buildings. The primary economic consideration is that, in the vast majority of circumstances, the means of providing an accessible route to floor levels above or below the entrance level of the building will be by an elevator. This exception applies to levels above and below the entry level that have an aggregate area of 3,000 square feet (279 m^2) or less and does not include the area of the accessible level. For example, if a building had a second floor that is 2,000 square feet (186 m^2) and a basement that is 2,000 square feet (186 m^2), since the aggregate area of the basement and second floor is 4,000 square feet (372 m^2), at least one of the two floor areas would be required to be connected to the entrance level by an accessible route. There are certain facilities that, despite being relatively small in size, are not exempt from the requirement for an accessible route. Due to the critical nature of the services provided, offices of health care providers, passenger transportation facilities and airports are not included in this exception. Multitenant mercantile occupancies (i.e., five or more tenants in the facility), which include facilities such as shopping malls, are not included in the exception because individual retail stores have limited types of commodities (i.e., shoes, eyeglasses, sporting goods, etc.), and the exception

would mean that people with disabilities would not have access to the same range of goods that are available to the general public. In these cases, access must be provided such that people with disabilities may patronize all the establishments within the facility. The 3,000-square-foot (279 m^2) exception can be applied to a mercantile facility with fewer than five tenants.

A mezzanine is required by Section 505.2 to have a clear height below of at least 7 feet (2134 mm), therefore, Exception 1 cannot be applied to platforms or raised floor areas.

Exception 2 is a direct reference to the specific items addressed in Sections 1107 and 1108. It is not a general exception for Groups A, I, R and S. The purpose of Exception 2 is to address areas within specific occupancies where a single element would be repeated multiple times on a level. Where Sections 1107 and 1108 would allow construction of a floor level with no accessible features, this section is not intended to trigger an accessible route to that otherwise inaccessible level. For example, an accessible route would not be required to upper levels in a hotel with all public spaces and all required accessible sleeping units located on the ground floor. If an elevator is to be provided in a building that qualifies for this exception, and the elevator is not part of an accessible route, signage must be provided in accordance with Section 1110.2.

Exception 3 is specific to the unique situations found in air traffic control towers.

Exception 4 permits small nonpublic second floors to not require access. An example would be the second floor in a doctor's office that is used only for storage. The occupant load table in Section 1004.1.1 would limit this storage area to 1,500 square feet (139 m^2) [i.e., 300 square feet (28 m^2) per occupant x 5 occupants maximum = 1,500 square feet (28 m^2)]. If the second floor also contained a mechanical room, that area would be exempt under Section 1103.2.9; however, if the doctor chose later to expand exam rooms into this second floor, he or she would have to provide an accessible route. Another example would be a second level in an airport that included only operational offices. In this case, the area would be limited by the occupant load table in Section 1004.1.1 to 500 square feet (46 m^2) [i.e., 100 square feet (9 m^2) per occupant x 5 occupants maximum = 500 square feet (46 m^2)]. While the exception is specifically stated as applicable only to second-story buildings, it could be interpreted to apply to a one-story building with a basement level or a one-story building with a mezzanine.

Exception 5 is specific to raised platform areas used for employee work stations (judge, clerk, court reporter) in courtrooms. These areas are permitted to be constructed as adaptable for a future accessible route if and when a route is necessary for a mobility impaired employee. This exception does not apply to raised public areas in courtrooms such as witness stands or jury boxes. See Section 1108.4.1 for specific criteria for seating areas in a courtroom that are not employee areas, such as the gallery, the witness stand and the jury box.

1104.5 Location. *Accessible routes* shall coincide with or be located in the same area as a general *circulation path*. Where the *circulation path* is interior, the *accessible route* shall also be interior. Where only one *accessible route* is provided, the *accessible route* shall not pass through kitchens, storage rooms, restrooms, closets or similar spaces.

Exceptions:

1. *Accessible routes* from parking garages contained within and serving *Type B units* are not required to be interior.
2. A single *accessible route* is permitted to pass through a kitchen or storage room in an *Accessible unit*, *Type A unit* or *Type B unit*.

❖ One of the objectives of accessibility requirements is to normalize, to the extent possible, the facilities provided for disabled persons and those comparable facilities that exist for people without disabilities. In addition, the intent of this section is to avoid the circumstance where an interior path between facilities is provided but the only accessible route between those same facilities is an exterior path.

When only one accessible route is provided, this section puts limits on the types of spaces through which that accessible route may pass so that it is readily available. Spaces, such as storage rooms, restrooms, closets and kitchens, can be subject to being locked or their availability may be restricted to authorized personnel; therefore, they would not serve as reliable accessible routes for all building occupants.

Exception 1 addresses individual dwelling units that include their own garages and residential facilities with shared garage levels. This exception is limited to accessible parking for Type B units. It is intended to allow a person to exit the garage and enter through the front door, instead of requiring access from the garage into the unit directly. Section 1106.2 requires that when parking is provided within a building, accessible parking must also be located within the building. If this exception is utilized in accordance with Sections 1104.1 and 1107.4, an accessible route must be provided from the accessible parking spaces to the front door.

Exception 2 allows a single accessible route to pass through a kitchen or storage room within a unit that is required to be an Accessible, Type A or Type B dwelling or sleeping unit. Given the space limitations and typical arrangements of dwelling units, it is not unreasonable to allow access, for example, through a kitchen, to reach an eating area or an exterior patio as the only means of access.

1104.6 Security barriers. Security barriers including, but not limited to, security bollards and security check points shall

not obstruct a required *accessible route* or *accessible means of egress*.

Exception: Where security barriers incorporate elements that cannot comply with these requirements, such as certain metal detectors, fluoroscopes or other similar devices, the *accessible route* shall be permitted to be provided adjacent to security screening devices. The *accessible route* shall permit persons with disabilities passing around security barriers to maintain visual contact with their personal items to the same extent provided others passing through the security barrier.

❖ This requirement provides guidance for when a security feature is required along an accessible route. An example would be the security checkpoints in airports. The intent is that the route for a person with mobility impairments should move through security checkpoints as close to the typical route as possible. It is recognized that some people using wheelchairs or with braces could not move through standard security barriers, such as metal detectors.

SECTION 1105
ACCESSIBLE ENTRANCES

1105.1 Public entrances. In addition to *accessible* entrances required by Sections 1105.1.1 through 1105.1.6, at least 60 percent of all *public entrances* shall be *accessible*.

Exceptions:

1. An *accessible* entrance is not required to areas not required to be *accessible*.
2. Loading and *service entrances* that are not the only entrance to a tenant space.

❖ A facility is not accessible if the entrances into it are inaccessible. This section establishes a reasonable criteria for providing accessible entrances. A facility is not required to have all of its entrances accessible in order to provide reasonable accommodation to disabled persons. If a facility has multiple public entrances, as a minimum, it is not considered unreasonable to require at least 60 percent of the entrances to be accessible. In addition to the 60-percent accessible public entrances, entrances that have a specific function or provide access to only certain portions of the facility must be addressed (see commentary, Sections 1105.1.1 through 1105.1.6). Sections 1110.1 and 1110.2 require signage at all entrances if all entrances are not accessible. "Public entrance," "Restricted entrance" and "Service entrance" are defined in Chapter 2.

Doors that are only for means of egress are not considered when determining the number of entrances required to be accessible. However, these doors may need to be on an accessible route for accessible means of egress requirements (see Section 1007). Depending on the arrangement, sometimes the entrance requirements are more restrictive, and sometimes the means of egress requirements are more restrictive. For example, take a small tenant space with two exterior doors—the front door is the public entrance and the back door is the service entrance. Section 1105.1 along with Exception 2 would require only the front door to be on an accessible route for ingress into the building. However, when a space has two means of egress required, Section 1007.1 would require both doors to be on an accessible route for means of egress purposes.

Exception 1 is self-evident in that if a facility or portion of a facility is not required to be accessible, then the entrances to such facilities or spaces are not required to be accessible. An example would be an exterior entrance to the sprinkler room (see Section 1103.2.9).

Exception 2 exempts loading and service entrances from the accessibility requirement on the basis that such entrances are unlikely to be used on a regular basis and may be raised to allow truck unloading. Loading and service entrances are required to be accessible if they are the only means of access into a facility or tenant space. This is consistent with Section 1105.1.5.

The intent of the reference to Sections 1105.1.1 through 1105.1.6 is to provide reasonable and convenient availability of an accessible entrance from the accessible facilities provided on the site. All entrances that serve distinct arrival points on the site are required to be accessible. For example, a public entrance from a public parking structure must be accessible (see Section 1105.1.1), as well as the employees-only entrance adjacent to separate employee parking (see Section 1105.1.3). This should deter the formerly common practice of designating an entrance as "the handicapped entrance" (which is inappropriate) without regard to its location relative to such arrival points as accessible parking facilities, transportation facilities, passenger loading zones, taxi stands, public streets or sidewalks and tunnels or elevated walkways. In conjunction with Section 1104.5, this section also is intended to provide reasonable and convenient availability of an accessible entrance to the building's accessible vertical movement elements, such as the elevators. This would allow a person with disabilities to move readily throughout all levels of the building.

1105.1.1 Parking garage entrances. Where provided, direct access for pedestrians from parking structures to buildings or facility entrances shall be *accessible*.

❖ Occasionally, a parking garage is attached to an office building or mall. An accessible route must be provided from the accessible parking spaces in that parking garage to an accessible entrance into the office or mall portion of the building.

1105.1.2 Entrances from tunnels or elevated walkways. Where direct access is provided for pedestrians from a pedestrian tunnel or elevated walkway to a building or facility, at

least one entrance to the building or facility from each tunnel or walkway shall be *accessible*.

❖ Elevated walkways are sometimes provided between adjacent buildings for easy access or protection from the weather for people who must commonly move between certain buildings. Tunnels may serve the same purpose. Washington, DC, has tunnels between many of its congressional buildings. Chicago has a "pedway" system connecting the commuter train stations with the basement level of many buildings in the downtown area. Minneapolis deals with the extreme winter weather conditions in that city by having a system of elevated walkways that connect many of the downtown buildings (see Figure 1105.1.2). When these types of walkways or tunnels are provided, at least one of the building entrances off of these walkways or tunnels must be an accessible entrance.

Figure 1105.1.2
EXAMPLE OF ELEVATED WALKWAY ENTRANCE

1105.1.3 Restricted entrances. Where *restricted entrances* are provided to a building or facility, at least one *restricted entrance* to the building or facility shall be *accessible*.

❖ Where access into a specific entrance is controlled (see the definition for "Restricted entrance" in Chapter 2), at least one of that type of entrance must be accessible. An entrance that is locked is not necessarily a restricted entrance. For example, an apartment building may have multiple entrances for tenants where they enter with their key; however, there may be only one entrance for visitors if they need to access a tenant intercom system to gain entrance. The one visitor entrance is considered to be the restricted entrance and is required to be accessible.

1105.1.4 Entrances for inmates or detainees. Where entrances used only by inmates or detainees and security personnel are provided at judicial facilities, detention facilities or correctional facilities, at least one such entrance shall be *accessible*.

❖ Where access to a specific entrance is limited for security reasons to inmates or detainees and the staff supervising them, that entrance must be accessible. This type of situation could occur at courthouses, jails and police stations (see also Sections 1103.2.14, 1107.5.5 and 1108.4.2).

1105.1.5 Service entrances. If a *service entrance* is the only entrance to a building or a tenant space in a facility, that entrance shall be *accessible*.

❖ Loading and service entrances are required to be accessible if they are the only means of access into a facility or tenant space. Typically, loading and service entrances are exempted from the accessibility requirement on the basis that such entrances are unlikely to be used on a regular basis and may be raised to allow for truck unloading (see the definition for "Service entrance" in Chapter 2). This is consistent with Section 1105.1, Exception 2.

1105.1.6 Tenant spaces, dwelling units and sleeping units. At least one *accessible* entrance shall be provided to each tenant, *dwelling unit* and *sleeping unit* in a facility.

Exceptions:

1. An *accessible* entrance is not required to tenants that are not required to be *accessible*.
2. An *accessible* entrance is not required to *dwelling units* and *sleeping unit*s that are not required to be *Accessible units*, *Type A units* or *Type B units*.

❖ Each tenant space must have at least one accessible entrance. Dwelling and sleeping units that are Accessible, Type A or Type B units must have at least one accessible entrance. For multitenant buildings with shared entrances, the 60-percent entrance requirement in Section 1105.1 is also applicable. If a space, whether a tenant, dwelling unit or sleeping unit, does not have accessibility requirements, then an accessible entrance is not required.

SECTION 1106
PARKING AND PASSENGER LOADING FACILITIES

1106.1 Required. Where parking is provided, *accessible* parking spaces shall be provided in compliance with Table 1106.1, except as required by Sections 1106.2 through 1106.4. Where more than one parking facility is provided on a *site*, the number of parking spaces required to be *accessible* shall be calculated separately for each parking facility.

Exception: This section does not apply to parking spaces used exclusively for buses, trucks, other delivery vehicles,

law enforcement vehicles or vehicular impound and motor pools where lots accessed by the public are provided with an *accessible* passenger loading zone.

❖ Accessible parking facilities are an important component of building and site accessibility. This section addresses the number of parking spaces required. The location of such parking spaces in relation to accessible building entrances is addressed in Section 1106.6. Parking facility requirements are primarily intended to facilitate accessibility for people with a mobility impairment, not just persons that use wheelchairs.

This section is not intended to require that parking facilities be provided; rather, when parking is provided, the minimum number of accessible parking spaces specified herein must be provided. ICC A117.1 contains detailed requirements on the size and configuration of accessible parking spaces, including the required access aisle adjacent to the space, as well as the dimensional requirements for van-accessible parking spaces required by Section 1106.5.

Multitenant facilities, such as a shopping mall, or large facilities, such as hospitals or assembly occupancies, may have multiple parking lots or parking garages. If multiple parking lots, or a combination of parking garages and parking lots are provided for a facility, the number of spaces in each separate parking facility is utilized to determine the number of accessible spaces required. Accessible car and van parking would then be provided in each parking facility accordingly, except as otherwise permitted by Section 1106.6. What constitutes a multiple facility is somewhat subjective. Putting a line of trees or landscaping along the side of the parking spaces does not always constitute a separate facility. From a practical viewpoint, the separate facilities would serve specific groups of people (i.e., employee-only parking), provide different types of parking (i.e., surface lots, garage parking, covered parking) or serve distinct areas of the building (i.e., upper and lower levels as you move around a large mall).

In certain types of lots it is not logical to require accessible parking spaces. The exception helps to clarify these situations. Parking lots that contain only parking for buses, trucks and delivery vehicles would not need accessible parking spaces. Lots where the parked cars are limited to vehicles used by law enforcement, impound lots or motor pools are also not required to provide accessible spaces. An accessible passenger drop-off is required to be provided on the site, so that when a person with a mobility impairment comes to that site, he or she has a place to exit the arrival vehicle safely and enter a vehicle coming from the lot.

TABLE 1106.1. See next column.

❖ The ratio of required number of accessible parking spaces is based on the accessible parking requirements of the 2010 Standard. It does not reflect the demographic statistics on wheelchair usage that were used to scope other requirements in Chapter 11, because the majority of disabled parking permit and license plate holders in most states are ambulatory, mobility-impaired persons. The required ratios are intended to be responsive to the anticipated demand for all facilities, such that accessible parking spaces will be reasonably available on demand. Section 1110.1 states that signage is not required on the one required accessible parking space when the total number of parking spaces provided is four or less. This could be burdensome for the building tenant in that the accessible parking space, which is restricted for use only by authorized vehicles, could constitute anywhere from 25 to 100 percent of the available parking. This may unduly restrict the availability of parking for all other vehicles and patrons of the facility. The space must still be sized in accordance with a van-accessible space.

TABLE 1106.1
ACCESSIBLE PARKING SPACES

TOTAL PARKING SPACES PROVIDED	REQUIRED MINIMUM NUMBER OF ACCESSIBLE SPACES
1 to 25	1
26 to 50	2
51 to 75	3
76 to 100	4
101 to 150	5
151 to 200	6
201 to 300	7
301 to 400	8
401 to 500	9
501 to 1,000	2% of total
1,001 and over	20, plus one for each 100, or fraction thereof, over 1,000

1106.2 Groups R-2 and R-3. At least 2 percent, but not less than one, of each type of parking space provided for occupancies in Groups R-2 and R-3, which are required to have *Accessible*, *Type A* or *Type B dwelling* or *sleeping unit*s, shall be *accessible*. Where parking is provided within or beneath a building, *accessible* parking spaces shall also be provided within or beneath the building.

❖ This section provides a separate criterion for the required number of accessible parking spaces for occupancies in Groups R-2 and R-3 that include Accessible, Type A or Type B units. The 2-percent requirement is based on HUD's FHAG. Section 1107.7 identifies buildings where accessible units may not be required.

Where parking is provided within or beneath a building, accessible parking spaces also are to be provided within or beneath the building. If a combination of surface and covered parking is provided, accessible parking may be provided in both locations. This is intended to establish consistency in the type and location of parking spaces available to all people.

If parking is provided in individual private parking garages, 2 percent of the parking garages would have to contain accessible parking spaces (see the exception to Section 1106.5). Note that parking provided for visitors should comply with the numbers indicated in Table 1106.1.

In a development, typically parking for dwelling units is considered on a site basis rather than a building by building basis. Accessible parking should be dispersed throughout the development so as to provide the best access possible. It is not the intent to require accessible parking spaces at the entrance to every building, or within every strip of parking garages. For example, it would not be logical to ask for a surface space and a garage space for each building in developments with multiple four-unit buildings. See Section 1106.5 for a discussion of the distribution of van-accessible spaces.

1106.3 Hospital outpatient facilities. At least 10 percent, but not less than one, of care recipient and visitor parking spaces provided to serve hospital outpatient facilities shall be *accessible*.

❖ Certain facilities can be expected to have a higher demand for accessible parking spaces than that reflected in Table 1106.1. Medical outpatient facilities are one such facility. This section requires that at least 10 percent of the parking provided for patients and visitors of these types of facilities be accessible. Parking provided for the employees of these facilities should comply with Table 1106.1. If a hospital contains multiple clinics or types of facilities, the amount of parking dedicated to the outpatient facility is interpretive. Options for determining the number of accessible spaces could be based on the area percentage of the outpatient facilities to other facilities or the anticipated number of patients and visitors to these facilities in relation to other facilities.

1106.4 Rehabilitation facilities and outpatient physical therapy facilities. At least 20 percent, but not less than one, of the portion of care recipient and visitor parking spaces serving rehabilitation facilities specializing in treating conditions that affect mobility and outpatient physical therapy facilities shall be *accessible*.

❖ Medical facilities that specialize in treatment or other services for people with mobility impairments can be expected to have a higher demand for accessible parking spaces. In these cases, at least 20 percent of the parking spaces provided for visitors and care recipients are required to be accessible. Parking provided for the employees of these facilities should comply with Table 1106.1. If a hospital contains multiple types of facilities, the amount of parking dedicated to the rehabilitation and physical therapy facility is interpretive. Options for determining the number of accessible spaces could be based on the area percentage of the rehabilitation and physical therapy facilities to other facilities or the anticipated number of care recipients and visitors to these facilities in relation to other facilities.

1106.5 Van spaces. For every six or fraction of six *accessible* parking spaces, at least one shall be a van-accessible parking space.

Exception: In Group R-2 and R-3 occupancies, van-accessible spaces located within private garages shall be permitted to have vehicular routes, entrances, parking spaces and access aisles with a minimum vertical clearance of 7 feet (2134 mm).

❖ Vans that are specially equipped to accommodate a person using a wheelchair require wider parking spaces than the typical accessible parking space. This is because vans are usually equipped with a mechanized loading/unloading platform that extends outward from the passenger side of the vehicle. ICC A117.1 contains the dimensional requirements for van-accessible spaces. In order to accommodate the growing usage of these specially equipped vans, this section requires that one in every six accessible parking spaces, or a fraction thereof, be of a size to accommodate these vans. The requirement for van-accessible spaces is not intended to require a greater number of accessible spaces than required by Table 1106.1. For example, if Table 1106.1 requires six accessible parking spaces, one of those six must be van accessible. If seven accessible spaces are required by Table 1106.1, two of those seven are required to be van accessible. On the other hand, if only one accessible parking space is required by Table 1106.1, that space would be a van-accessible space.

The exception modifies the height criteria for van-accessible spaces in ICC A117.1 for private garages serving dwelling units. This is a reduction from the 98-inch (2489 mm) height requirement in ICC A117.1. Since many vans are now converted by lowering the floor rather than raising the roof, the 82-inch (2083 mm) height should accommodate most private passenger vans with lifts.

Note that the determination of the number of van-accessible spaces is not tied to separate facilities as the number of spaces is in Sections 1106.1 and 1106.2. However, distribution of van-accessible spaces throughout the accessible parking space in large facilities is good design practice. Van-accessible spaces can be used by cars with accessible placards. It is just common courtesy to leave the van-accessible space for vans when there are other accessible spaces available.

1106.6 Location. *Accessible* parking spaces shall be located on the shortest *accessible route* of travel from adjacent parking to an *accessible* building entrance. In parking facilities that do not serve a particular building, *accessible* parking spaces shall be located on the shortest route to an *accessible* pedestrian entrance to the parking facility. Where buildings have multiple *accessible* entrances with adjacent parking,

accessible parking spaces shall be dispersed and located near the *accessible* entrances.

Exceptions:

1. In multilevel parking structures, van-accessible parking spaces are permitted on one level.
2. *Accessible* parking spaces shall be permitted to be located in different parking facilities if substantially equivalent or greater accessibility is provided in terms of distance from an *accessible* entrance or entrances, parking fee and user convenience.

❖ As previously stated, the majority of disabled parking permits and license plate holders in most states are ambulatory, mobility-impaired persons. Travel distance, as well as severe weather conditions encountered when traversing from the parking lot to the building entrance, are more difficult for persons with mobility impairments to deal with than the general population. The intent of this section is to locate the parking so that the people utilizing the accessible parking spaces have to travel a minimum distance to an accessible entrance (see Figure 1106.6). This requirement is stated in performance terms and requires a degree of subjective judgment on the part of both the designer and the building official in determining the appropriate location for accessible spaces that meets the intent of this section. If a facility has multiple accessible entrances, accessible parking spaces are to be dispersed consistent with the location of these entrances.

Exception 1 is intended to acknowledge a practical difficulty associated with multilevel parking structures. In many cases, a multilevel parking structure will serve accessible building entrances on more than one or all of its parking levels. Specially equipped vans for persons using wheelchairs may be modified by raising the roof of the vehicle in order to provide greater interior headroom. Consequently, such vans require greater vertical clearances. Typical parking structure design may not easily accommodate the necessary vertical clearance for accessible vans due to their low floor-to-ceiling heights. It would be impractical and economically unjustified to require parking structures to be designed solely for the purpose of enabling van-accessible spaces to be located on upper levels. Accordingly, the exception allows the required van-accessible parking spaces to be located on only one level of a multilevel parking structure. The route to and from the space, as well as at the van space and associated access aisle, must meet the minimum clear height of 98 inches (2489 mm) as specified in Section 502.6 of ICC A117.1. This will usually be the entry level of the parking facility.

Exception 2 addresses sites where multiple parking facilities are provided to serve a single destination or facility. Since one or more of the parking lots or parking garages may be more attractive to users for various reasons, it is acceptable to locate the required accessible parking based on perceived user convenience and preferences, including distance, parking fees and amenities.

Figure 1106.6
EXAMPLE OF ACCESSIBLE PARKING SPACES

1106.7 Passenger loading zones. Passenger loading zones shall be *accessible*.

❖ This section does not require passenger loading zones to be provided; however, where provided, they must be accessible in accordance with Section 503 of ICC A117.1. For locations where passenger loading zones are required, see Sections 1106.7.1 through 1106.7.4.

1106.7.1 Continuous loading zones. Where passenger loading zones are provided, one passenger loading zone in every continuous 100 linear feet (30.4 m) maximum of loading zone space shall be *accessible*.

❖ The intent of this section is to address the continuous loading zones found at most larger airports as well as some other types of transportation facilities, such as commuter train "kiss-n-ride" drop-off areas. At least one 20-foot (6096 mm) section for every 100 feet (30 480 mm) of passenger loading zone must meet the accessibility provisions in Section 503 of ICC A117.1.

1106.7.2 Medical facilities. A passenger loading zone shall be provided at an *accessible* entrance to licensed medical and long-term care facilities where people receive physical or medical treatment or care and where the period of stay exceeds 24 hours.

❖ The requirement for accessible passenger loading zones is applicable to both medical and long-term care facilities. The most common examples are hospitals and nursing homes; however, this could also be applicable to some rehabilitation and assisted living facilities (typically Group I-2). Medical and long-term care facilities typically have a higher percentage of people with mobility impairments living in the facility or visiting on a regular basis. Due to their mobility impairment, such people will be frequently driven by a friend or family member, and it is desirable and convenient to drop them off at the entrance rather than parking and requiring them to travel from the parking

lot to the facility's entrance. As such, this section requires that a passenger loading zone be provided at no less than one accessible entrance to the facility.

1106.7.3 Valet parking. A passenger loading zone shall be provided at valet parking services.

❖ Valet parking is typically the public access point to a facility. When valet parking is provided, the passenger loading zone must be accessible so that it may be utilized by persons requiring wheelchairs. This would include the access aisle and an accessible route from the access aisle to the front entrance. Note that providing valet parking services does not eliminate the need for accessible parking spaces where parking is provided. Some vehicles that are modified for persons with disabilities may not be drivable by a valet attendant. In addition, valet parking may only be provided during certain periods of time, such as during dinner hours at a restaurant.

1106.7.4 Mechanical access parking garages. Mechanical access parking garages shall provide at least one passenger loading zone at vehicle drop-off and vehicle pick-up areas.

❖ Mechanical parking garages allow a much higher density of vehicles in a given footprint due to the elimination of ramps and drive lanes. With respect to the customer interface, mechanical garages are similar to valet parking and, therefore, require similar scoping for accessibility.

SECTION 1107
DWELLING UNITS AND SLEEPING UNITS

❖ The development of this section was part of the coordination effort with the FHA and the FHAG. For further explanation, see the general comments for this chapter.

One of the phrases developed as part of this coordination was the defined phrase "Intended to be occupied as a residence." This defines a type of dwelling or sleeping unit that is a person's home or place of abode. The intent of this language is to clarify that, consistent with the FHA, all dwelling units or sleeping units that can or will be used as a place of abode—even for a short period of stay—must meet the requirements for Type B dwellings. There is a presumption in the IBC that if a building is nontransient (i.e., occupants stay more than 30 days), it is covered by the requirements in this section. In addition, in coordination with the FHA, occupancies that allow stays of fewer than 30 days may be required to meet Type B design and construction requirements.

Accordingly, this commentary will provide guidance for determining when short-term occupancies that might not typically be viewed as housing are covered by this section. Such short-term Group R occupancies may include residential hotels and motels; corporate housing; seasonal vacation units; timeshares; boarding houses; dormitories and migrant-farm worker housing. Also included are some occupancies in Group I, such as nursing homes, assisted living facilities, hospices and homeless shelters.

The key factor in determining whether any of these occupancies are subject to Type B requirements is whether the occupant will have the right to return to the property and whether he or she would have anywhere else in which to return to. If it is intended that an occupant will have a right to return to the property and will not have anywhere else to return, the unit is "intended to be occupied as a residence" and must meet the Type B requirements regardless of the length of stay. Thus, for example, homeless shelters where occupants have a right to return nightly must comply with Type B unit criteria even if the occupants stay only a few nights. Additionally, nursing homes in which a resident moves after vacating his or her primary residence are subject to Type B requirements.

If the occupants have a right to return to the property but also have another place in which to return to, the unit may still be subject to Type B criteria. Additional factors must be considered to determine whether the property is a short-term dwelling or sleeping unit that must meet Type B criteria, or a transient property that is not required to comply with Type B criteria. These factors must be considered by owners, builders, developers, architects and other designers to determine whether or not a building must be designed and constructed in accordance with Type B unit requirements.

For additional discussion on the elements related to hotels, motels, corporate housing and seasonal vacation units and timeshares, see the commentary to Section 1107.6.1 (Group R-1). With respect to most other occupancies, the following factors are also relevant to determine whether the units are subject to Type B requirements:

1. Whether the property is to be marketed as short-term housing;
2. Whether the terms and length of occupancy will be established through a written agreement;
3. How payment will be calculated (e.g., on a daily, weekly, monthly or yearly basis); and
4. What types of amenities and services are offered with the occupancy.

For example, an assisted living facility that provides sleeping units and medical services to its occupants, and bills them on a monthly basis is subject to Type B design and construction requirements. In addition, housing for migrant farm workers that is provided in conjunction with the worker's employment (whether or not rent is paid) and contains amenities for cooking and sleeping would be subject to Type B criteria.

1107.1 General. In addition to the other requirements of this chapter, occupancies having *dwelling units* or *sleeping unit*s shall be provided with *accessible* features in accordance with this section.

❖ There are two basic types of facilities that this section covers: dwelling units and sleeping units. A "Dwelling unit" is defined in Chapter 2 as a single unit that contains permanent provisions for "living, sleeping, eating, cooking and sanitation." A "Sleeping unit" is defined in Chapter 2 as a room in which people sleep, which can include some of the provisions found in a dwelling unit but not all. Occupancy of dwelling units or sleeping units can be transient or nontransient. Dwelling units are typically apartments, condominiums, detached homes or townhouses. Dwelling units can be located in hotels that offer cabins, suites or rooms with kitchen facilities. Bedrooms within dwelling units are not considered sleeping units.

A sleeping unit could be a typical hotel guestroom; a bedroom in a congregate residence, such as a dorm, sorority house, fraternity house, convent, monastery or boarding house; a nursing home room or a jail cell.

1107.2 Design. *Dwelling units* and *sleeping unit*s that are required to be *Accessible units*, *Type A units* and *Type B units* shall comply with the applicable portions of Chapter 10 of ICC A117.1. Units required to be *Type A units* are permitted to be designed and constructed as *Accessible units*. Units required to be *Type B units* are permitted to be designed and constructed as *Accessible units* or as *Type A units*.

❖ There are three levels of accessibility that can be required in a dwelling unit or sleeping unit: Accessible units, Type A units and Type B units. All three types are defined in Chapter 2.

An Accessible unit is constructed for full accessibility in accordance with Section 1002 of ICC A117.1. For example, grab bars are in place in the bathrooms, a clear floor space is provided for front approach at the kitchen sink and bathroom lavatories, 32-inch (813 mm) clear width doors with maneuvering clearances and lever hardware are provided, etc. None of the elements in the unit are constructed for adaptability. The requirements for an Accessible unit provide a higher level of accessibility than either a Type A unit or a Type B unit.

A Type A unit has some elements that are constructed accessible [e.g., 32-inch (813 mm) clear width doors with maneuvering clearances and lever hardware] and some elements designed to be added or altered when needed (e.g., grab bars can be easily added in bathrooms since blocking in the walls is in place). Type A units follow the technical criteria in Section 1003 of ICC A117.1. This type of unit is less accessible than an Accessible unit and more accessible than a Type B unit.

The scoping or technical requirements for Type B units are consistent with the requirements for units required by the FHAG (see the definition for "Type B units" in Chapter 2). A Type B unit is constructed to a lower level of accessibility than either an Accessible unit or a Type A unit. While a person who uses a wheelchair could maneuver in a Type B unit, the technical requirements are geared more towards persons with lesser mobility impairments. Type B units follow the technical requirements in Section 1004 of ICC A117.1. Areas of a Type B unit are allowed to be totally nonaccessible (e.g., sunken living room, extra bedrooms on a mezzanine level). Side approach is permitted to sinks in the kitchen and lavatories in the bathroom rather than planning for a front approach. Some elements are constructed with a minimal level of accessibility [e.g., doors within the unit have a $31^{3}/_{4}$-inch (806 mm) clear width but do not require maneuvering clearances], while some elements are designed to be altered when needed (e.g., blocking in the walls of the bathroom for future installation of grab bars).

This section also takes into consideration the fact that Accessible unit requirements provide a higher level of accessibility than Type A requirements, and Type A requirements provide a higher level of accessibility than Type B requirements. Units are permitted to be constructed to a higher level of accessibility than required. In other words, Accessible units are constructed wheelchair ready. Type A units are constructed wheelchair friendly and Type B units are constructed wheelchair usable.

The technical criteria for each type of unit in ICC A117.1 is organized in the same order and section number for each element, so make comparisons between types easier. For example, looking at the door provisions in Sections 1002.5, 1003.5 and 1004.5 of ICC A117.1 would clarify that the maneuvering clearances are required at all doors that are part of the accessible route through an Accessible unit or a Type A unit, but for the Type B unit, the maneuvering clearance is only required at the front door to the unit, not within the unit. Another example would be the requirements for operable parts: Sections 1002.9 and 1003.9 address requirements for plumbing fixture and appliance controls, while in accordance with Section 1004.9, Type B units do not require plumbing fixture and appliance controls to meet operable parts requirements.

1107.3 Accessible spaces. Rooms and spaces available to the general public or available for use by residents and serving *Accessible units*, *Type A units* or *Type B units* shall be *accessible*. *Accessible* spaces shall include toilet and bathing rooms, kitchen, living and dining areas and any exterior spaces, including patios, terraces and balconies.

Exceptions:

1. Recreational facilities in accordance with Section 1109.15.
2. In Group I-2 facilities, doors to *sleeping unit*s shall be exempted from the requirements for maneuvering

clearance at the room side provided the door is a minimum of 44 inches (1118 mm) in width.

❖ Spaces available for use by residents or the general public that are associated with Accessible units, Type A units or Type B units are required to be accessible. This would include spaces within the unit and outside the unit in the same building, as well as facilities that may be outside the building somewhere else on the site. The intent is that a person with a disability could take full advantage of the amenities associated with his or her dwelling or sleeping unit. While it is fairly clear which elements within a unit must be accessible, the associated facilities outside the unit vary depending on the type of building and facilities provided. Public use spaces within a building would include lobby areas while spaces for residents could include shared storage areas or refuse rooms. Shared spaces in nursing homes or assisted living facilities might be dining rooms, therapy rooms and recreational rooms. In dormitories, residents may share study rooms, laundry rooms or mail rooms and facilities located remotely, such as cafeterias. Examples of shared spaces in congregate residences could include community kitchens, living rooms and shared bathrooms. Examples in apartment complexes could include grouped mailboxes, rental offices, exercise rooms and exterior spaces, such as community buildings and swimming pools.

Exception 1 allows for limited access to exterior recreational facilities when multiples of the same type of facility are provided. An example would be multiple tennis courts on the same site for use by residents in a complex (see Section 1109.15 for additional information). The net result is that a person with a disability, either a resident or guest, can access all Accessible, Type A and Type B units, as well as any associated facilities and public areas on the site.

Exception 2 recognizes the practical implications of door maneuvering clearances on the room side at inswinging doors in smaller sized patient sleeping rooms in hospitals and nursing homes. The maneuvering clearance is still required on the outside of the Accessible patient sleeping room door. Since the maneuvering clearance in ICC A117.1 is based on the size of the door, there is no credit provided for the wider 44-inch (1118 mm) door width (required in Section 1008.1.1 in Group I-2 for movement of bed) versus the standard 36-inch (914 mm) door. Without this exception a patient room would likely require extra width when a toilet room is located on the same wall as the door. Due to operational procedures and observation needs, the door position is normally open, therefore, the need for door maneuvering clearance on the interior side is reduced. At hospitals, nursing homes and rehabilitation centers, the patient room door is usually closed only when visitors or caregivers are present.

The percentage of Accessible units and Type B units in hospitals, nursing homes and rehabilitation centers is addressed in Sections 1107.5.2, 1107.5.3 and 1107.5.4. Maneuvering clearances are part of an accessible route, and accessible routes connect accessible elements; therefore, maneuvering clearances at patient sleeping rooms that are not Accessible or Type B units are not required since an accessible route is not required. For additional information on when Type B units are required in institutional facilities, see the commentary to Section 1107. This is consistent with Section 1104.3, Exception 2.

1107.4 Accessible route. At least one *accessible route* shall connect *accessible* building or facility entrances with the primary entrance of each *Accessible unit*, *Type A unit* and *Type B unit* within the building or facility and with those exterior and interior spaces and facilities that serve the units.

Exceptions:

1. If due to circumstances outside the control of the owner, either the slope of the finished ground level between *accessible* facilities and buildings exceeds one unit vertical in 12 units horizontal (1:12), or where physical barriers or legal restrictions prevent the installation of an *accessible route*, a vehicular route with parking that complies with Section 1106 at each *public* or *common use* facility or building is permitted in place of the *accessible route*.
2. Exterior decks, patios or balconies that are part of *Type B units* and have impervious surfaces, and that are not more than 4 inches (102 mm) below the finished floor level of the adjacent interior space of the unit.

❖ Section 1107.3 indicates which spaces associated with accessible dwelling and sleeping units (i.e., Accessible, Type A and Type B units) are required to be accessible. Section 1105 indicates which building entrances are required to be accessible. The intent of this section is twofold: that there will be at least one accessible route that connects required accessible building entrances with the entrance of all accessible dwelling and sleeping units, and that there also must be accessible routes connecting accessible unit entrances with all interior and exterior common and public use spaces and facilities that serve the accessible dwelling or sleeping unit. Some additional facilities that serve units that are not really considered spaces would be accessible parking (see Section 1106.1), passenger loading zones (see Section 1106.7) and public transportation stops located either on site or adjacent to the perimeter. In determining the site arrival points that serve an accessible unit, the designer should make a reasonable determination of how pedestrians and vehicles would arrive at the site.

HUD's review of the 2003 and 2006 editions of the code found that they meet or exceed the seven design and construction requirements of the FHA and are "safe harbor" documents for complying with the FHAG. To read the final report of the HUD review, go to http://www.hud.gov/offices/fheo/disabilities/modelcodes/. HUD stated, "Having a more recent edition of

the IBC recognized by HUD as a safe harbor will ensure that covered dwelling units will be built with the accessible features required by the Act." For additional information, see the commentary at the beginning of this chapter.

The following commentary concerning the accessible route serving dwelling units and sleeping units has been provided by HUD:

The five examples serve to illustrate a variety of conditions that may be encountered on nonlevel building sites where Exception 1 is applicable. These examples pertain to the accessible route between facilities on a site. In addition to the on-site accessible routes, the accessible route(s) between the site arrival point(s) and facilities on the site must be considered. Note that the exception in Section 1104.1 does not apply to facilities containing or serving Type B units.

The intent of this section is to ensure that there will be at least one accessible route that connects all accessible building and facility entrances with the entrance of all Accessible, Type A and Type B units. To qualify as an accessible route, that route must serve pedestrians (i.e., sidewalk or other walkway). People with disabilities who need the features of an Accessible, Type A or Type B dwelling or sleeping unit cannot use them if accessible routes are not provided from the entrances to buildings or facilities to the primary entrance of their dwelling or sleeping unit. There also must be accessible routes connecting accessible building or facility entrances with all interior and exterior spaces and facilities that serve such dwelling or sleeping units. For example, if a development has a recreational facility, such as a community center, persons with disabilities who need the features of an Accessible, Type A or Type B unit need an accessible route from their dwelling unit to that community center.

Exception 1 is intended to provide consistency with the federal FHA, which recognizes that, in very rare circumstances, an accessible pedestrian route between an accessible entrance to an accessible unit or an accessible entrance to a building containing accessible units and an exterior public use or common use facility may be impractical because of factors outside the control of the owner. Section 1107.4 requires an accessible pedestrian route between covered dwelling units and public use or common use areas and facilities that are required to be accessible, except in rare circumstances that are outside the control of the owner where extreme terrain or impractical site characteristics result in a finished grade exceeding 8.33 percent or physical barriers or legal restrictions prevent the installation of an accessible pedestrian route. In these cases, Exception 1 allows access to be provided by means of a vehicular route leading from the accessible parking serving the accessible unit to the accessible parking serving the public use or common use facility. Accessible parking complying with Section 1106 must be provided in each parking area. If a building containing accessible units also contains accessible features that are required by other code provisions or federal, state or local laws, then Exception 1 may not apply at all.

It is important to understand that compliance with the accessible design and construction requirements of the FHA is a legal obligation applicable to all architects, engineers, builders, developers and others involved in the design and construction of housing. HUD's regulations implementing the FHA make it clear that the burden of showing the applicability of exceptions is the responsibility of those individuals and entities involved in the design and construction of such housing. In order to ensure compliance with FHA, architects, engineers, developers, builders and others who use the code must make accessibility a priority at the planning and design phase of Group I and R developments, including the siting of housing and public use or common use areas. To do this, at the initial stage of site planning and design for all sites, before considering whether Exception 1 applies, persons and entities involved in the design of covered residential occupancies must determine whether and how the exceptions of Sections 1107.7.4 and 1107.7.5 apply.

After careful site planning and design has been completed, the following factors may then be considered to determine whether it is outside the control of the owner to provide an accessible pedestrian route between a building/Type B dwelling unit entrance and a given public use or common use facility. Each such route must be analyzed individually. Exception 1 will only apply when at least one of the following factors is present:

1. Legal restrictions outside the control of the owner. These include setback requirements, tree-save ordinances, easements, environmental restrictions and other limitations that prevent installation of an accessible pedestrian route without violating the law.
2. Physical barriers outside the control of the owner. These include physical characteristics of the site, which are outside the control of the owner that prevent the installation of an accessible pedestrian route.
3. On sites that qualify for the exceptions of Sections 1107.7.4 and 1107.7.5, the presence of extreme terrain or other unusual site characteristics (e.g., flood plain, wetlands) outside the control of the owner that would require substantial additional grading to achieve a slope that will allow for an accessible pedestrian route.

In considering whether the additional grading is substantial enough to qualify for Exception 1, the extent to which the builder has elected to grade the site for other purposes unassociated with accessibility must be considered. If grading for those other purposes is extensive, then substantial additional grad-

ing would be necessary to provide the required accessible pedestrian route. If grading for other purposes is not extensive, and substantial additional grading is necessary to provide an accessible pedestrian route, then reliance on Exception 1 would be appropriate. Note that when determining whether the additional grading is substantial, one may not consider the grading that the builder must perform to provide accessible pedestrian routes from site arrival points to the accessible entrances of accessible dwelling or sleeping units. If none of the factors above are present, Exception 1 does not apply. If one or more of these factors is present, then the next step in determining whether Exception 1 applies (i.e., the vehicular route is the only feasible option) is to consider alternative locations and designs for buildings, facilities and accessible pedestrian routes connecting each accessible building and accessible dwelling unit entrance and each public use or common use area required to be accessible to ensure that there is no other way to provide the required accessible pedestrian routes. It is important to recognize that if a road sloping 8.33 percent or less can be provided, then an accessible pedestrian route would also be feasible and must be provided.

Following are some examples to illustrate the proper application of Exception 1:

Example 1: An undisturbed site has slopes of 8.33 percent or less between required accessible entrances to Type B dwelling units and public use or common use areas and there are no legal restrictions or other unique characteristics preventing the construction of accessible routes. For aesthetic reasons, the developer would like to create some hills or decorative berms on the site. Because there are no extreme site conditions (severe terrain or unusual site characteristics such as flood plains), and no legal barriers that prevent installation of an accessible pedestrian route between the buildings/Type B dwelling units and any planned public use or common use facilities, the developer will still be obligated to provide accessible pedestrian routes. Exception 1 to Section 1107.4 is inapplicable in this circumstance.

Example 2: A developer plans to construct several buildings with Type B units clustered in a level area of a site that has some slopes of 10 percent. A swimming pool and tennis court will be added on the two opposing sides of the site. The builder plans grading that will result in a finished grade exceeding a slope of 8.33 percent along the route between the Type B units and the swimming pool and tennis court. There are no physical barriers or legal restrictions outside the control of the owner or builder that prevent him or her from reducing the existing grade to provide an accessible pedestrian route between the Type B units and the pool and tennis court. Therefore, the builder's building plan would not be approved under the code because it is within the owner's control to have the final grading fall below 8.33 percent and meet the slope and other requirements for an accessible pedestrian route. Accessible pedestrian routes between the Type B units, pool and tennis court must be provided.

Example 3: A multiple-family housing complex is built on two sections of a large piece of property, which is divided by a wide stream running through protected wetlands. Both sections of the property are at the same relative elevation and have dwelling units with accessible routes from site arrival points; however, a combination clubhouse and swimming pool is located on one section of the property. Access to each section is provided by an existing public road outside the boundary of the site, which includes a bridge over the stream. Environmental restrictions prevent construction of any type of paved surface between the two sections within the boundary of the site. If environmental restrictions do not prevent the construction of an accessible pedestrian route, such as a boardwalk, through the wetlands connecting the two sections, then the accessible pedestrian route must be provided even if a road cannot be provided. If construction of any type of pedestrian route is prohibited, then a vehicular route that utilizes the public road and bridge is permitted with parking complying with Section 1106 located at the clubhouse/swimming pool, even though the vehicular route relies on a public road instead of a road through the development.

Example 4: A narrow and deep site has a level section in the front taking up most of the site and another level section at the back that is located up a steep incline. The developer chooses to place all of the buildings/Type B dwelling units on the front section to provide for accessible routes from site arrival points to building entrances. After considering all options for siting buildings and facilities in different locations, including the priority of accessibility, the most feasible location for a planned swimming pool is at the top of the higher section to the rear of the property. Because of the narrowness of the site and the relative elevation of the upper level at the rear of the property, it is impracticable to construct an accessible pedestrian route to the pool; however, a road that slopes more than 8.33 percent can be provided. Under these circumstances, Exception 1 is applicable and access to the swimming pool on the upper level of the site may be provided by means of a vehicular route with parking complying with Section 1106 provided at the Type B dwelling units and the pool.

Example 5: A developer plans to build a multiple-family housing complex with nonelevator buildings on a site with hilly terrain. All of these buildings will have some Type B dwelling units. The developer plans to locate a tennis court on the site. There are gentle slopes exceeding 8.33 percent with existing trees between the entrances to the Type B units and the tennis court. There is also a tree-save ordinance in place. If the builder can grade the site to allow for an accessible pedestrian route to the tennis court with-

out disturbing the trees in violation of the tree-save ordinance, then an accessible pedestrian route between the Type B units and the planned location of the tennis court must be provided. If, however, the grading necessary to reduce the slope of the site near the trees to provide an accessible route would cause tree loss or damage in violation of the ordinance, then the developer cannot grade without violating the tree-save ordinance. The developer must then consider whether the tennis court can be relocated so it is served by an accessible pedestrian route, and if so, the tennis court must be relocated. If the tennis court cannot be relocated so it can be served by an accessible pedestrian route, then the developer may provide a vehicular route from the Type B dwelling units to the tennis court with parking complying with Section 1106 at the Type B dwelling units and the tennis court. Note, however, that if the developer can provide an accessible pedestrian route from some of the buildings without violating the ordinance, the developer must do so, even if it is necessary to provide a vehicular route from other buildings. Additionally, if the grading and construction of the proposed vehicular route can be limited to 8.33 percent by design and would not violate the tree-save ordinance, it is likely that an additional accessible walkway adjacent to the vehicular route would also fall under the scope of work that would not violate the tree-save ordinance and, therefore, must be provided, eliminating the use of Exception 1.

This completes the guidance on this topic provided by HUD for inclusion in this commentary.

Exception 2 is intended for application to Type B units with either a private deck, patio or balcony within an individual unit or to a shared deck, patio or balcony in a "residents only" area of a congregate residence. Decks, patios or balconies located in areas such as the community building or swimming pool should be constructed accessible. When the outside walking surface is impervious to water, such as concrete, there may be a 4-inch (102 mm) step-down between the inside finished floor surface and the outside floor surface. The step-down is permitted to address the concern of water infiltration under the doors at such locations. With a maximum 4-inch (102 mm) difference in elevation, adaptation for accessibility is achievable with raised sleepers and decking. Normal door threshold criteria apply.

1107.5 Group I. *Accessible units* and *Type B units* shall be provided in Group I occupancies in accordance with Sections 1107.5.1 through 1107.5.5.

❖ This section introduces five subsections that set forth the threshold for accessibility in institutional occupancies.

Note that among the various categories of institutional facilities, only Accessible units and Type B units are scoped. There are no requirements for Type A units in institutional occupancies. The criteria for Accessible units and Type B units are specified in Chapter 10 of ICC A117.1.

1107.5.1 Group I-1. *Accessible units* and *Type B units* shall be provided in Group I-1 occupancies in accordance with Sections 1107.5.1.1 and 1107.5.1.2.

❖ Group I-1 is comparable in many respects to Group R-2 in that it is a residential setting. The difference is that Group I-1 is a supervised environment because of the reduced abilities of the occupants; physical, mental or both (see Section 308.3).

1107.5.1.1 Accessible units. At least 4 percent, but not less than one, of the *dwelling units* and *sleeping unit*s shall be *Accessible units*.

❖ The threshold for accessibility in apartments (Group R-2), in accordance with Section 1107.6.2.1.1, is that 2 percent of the units are required to be Type A units. It is anticipated that Group I-1 will experience a greater demand for accessible facilities because of the nature of the occupants and the frequency of occupant turnover. As such, this section requires that 4 percent of the sleeping units and their associated facilities (e.g., bathing and toilet facilities) must meet the criteria for Accessible units.

1107.5.1.2 Type B units. In structures with four or more *dwelling units* or *sleeping unit*s *intended to be occupied as a residence*, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ As discussed in the general comments to this section, most Group I-1 assisted living facilities are intended to serve as a person's place of residence. Since a Group I-1 starts at an occupant load of 16 residents, the Type B criteria for any units that are not Accessible units are almost always required. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.2 Group I-2 nursing homes. *Accessible units* and *Type B units* shall be provided in nursing homes of Group I-2 occupancies in accordance with Sections 1107.5.2.1 and 1107.5.2.2.

❖ The requirements for accessibility in Group I-2 are based on the anticipated frequency of usage by disabled persons. There are different thresholds established for different types of health care occupancies, based on the nature of their activity (see Section 308.4). A nursing home is anticipated to have a high percentage of residents who use wheelchairs or some type of mobility aid.

1107.5.2.1 Accessible units. At least 50 percent but not less than one of each type of the *dwelling units* and *sleeping unit*s shall be *Accessible units*.

❖ Nursing homes, which generally provide long-term care, are more likely to have patients with physical disabilities. As such, 50 percent of the patient sleeping rooms and their associated facilities (e.g., bathing and toilet facilities) must meet the criteria for Accessi-

ble units. Sections 1104.3, Exception 2, and 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where residents are moved while in their beds.

Housing the elderly should not automatically be classified as a "nursing home." Some residential care/assisted living facilities provide quarters for residents that more closely represent a residential setting (i.e., sleeping, eating, cooking and sanitation within the individual living accommodations) and the residents are more ambulatory than in a nursing home. Based on the anticipated frequency of residents needing wheelchairs, these facilities might be more appropriately classified within the 4- or 10-percent requirement for Accessible units (see Sections 1107.5.1.1 and 1107.5.3.1).

1107.5.2.2 Type B units. In structures with four or more *dwelling units* or *sleeping units intended to be occupied as a residence*, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ As discussed in the general comments to this section, most Group I-2 nursing homes are intended to serve as a person's place of residence. The Type B criteria for any units that are not Accessible units are almost always required. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.3 Group I-2 hospitals. *Accessible units* and *Type B units* shall be provided in general-purpose hospitals, psychiatric facilities and detoxification facilities of Group I-2 occupancies in accordance with Sections 1107.5.3.1 and 1107.5.3.2.

❖ The requirements for accessibility in Group I-2 are based on the anticipated disabled occupants. There are different thresholds established for different types of health care occupancies based on the nature of their services and level of care provided. The anticipated need in hospitals is partially based on patients needing varying levels of assistance due to temporary disabilities resulting from illness or operations.

1107.5.3.1 Accessible units. At least 10 percent, but not less than one, of the *dwelling units* and *sleeping units* shall be *Accessible units*.

❖ While the anticipated percentage of patients in general-purpose hospitals is typically higher than 10 percent, there is also an anticipation that many of the patients will be routinely assisted by staff. Section 1109.2, Exception 5, exempts the bathrooms associated with critical care or intensive care. Sections 1104.3, Exception 2 and 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the Accessible patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where there is movement of patients in their beds. In the case of psychiatric facilities, detoxification facilities or residential care/assisted facilities, it is less likely that the typical patient will be physically disabled.

1107.5.3.2 Type B units. In structures with four or more *dwelling units* or *sleeping units intended to be occupied as a residence*, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ As discussed in the general comments to this section, most Group I-2 hospitals are not intended to serve as a person's place of residence, therefore, Type B units are not required in most hospitals. However, whether or not a Group I-2 psychiatric or detoxification facility is a person's place of abode is subject for interpretation. Please see the general discussion to this section for additional information. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.4 Group I-2 rehabilitation facilities. In hospitals and rehabilitation facilities of Group I-2 occupancies which specialize in treating conditions that affect mobility, or units within either which specialize in treating conditions that affect mobility, 100 percent of the *dwelling units* and *sleeping units* shall be *Accessible units*.

❖ The requirements for accessibility in Group I-2 are based on the anticipated frequency of usage by disabled persons. There are different thresholds established for different types of health care occupancies based on the nature of their activity. In rehabilitation facilities that specialize in treating conditions that affect mobility, the anticipated need is very high compared to other Group I-2 facilities. In such cases, it is realistic to presume that the majority, if not all, of the patients will have some degree of mobility impairment and will, thus, require accessible features. Accordingly, all patient rooms and their associated bathing and toilet facilities are required to be Accessible units. Section 1104.3, Exception 2, and Section 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where there is movement of patients in their beds. While this facility may also be intended to be occupied as a residence, Accessible unit requirements are more restrictive than Type B requirements, so those needs are already addressed.

1107.5.5 Group I-3. *Accessible units* shall be provided in Group I-3 occupancies in accordance with Sections 1107.5.5.1 through 1107.5.5.3.

❖ The requirement for accessibility in Group I-3 facilities was taken from the 2010 Standard (see Section

308.5 for Group I-3). Section 1107.5.5.1 contains requirements for general housing cells. Sections 1107.5.5.2 and 1107.5.5.3 are additional requirements for special types of cells or holding areas. While jail cells may be considered a detainee's residence, since the FHA does not cover detention and correctional facilities, Type B units are not required in Group I-3 occupancies.

1107.5.5.1 Group I-3 sleeping units. In Group I-3 occupancies, at least 2 percent, but not less than one, of the *dwelling units* and *sleeping unit*s shall be *Accessible units*.

❖ The requirement for sleeping units or cells in Group I-3 is for 2 percent of the general housing cells and their associated facilities to be Accessible units. The current trend in jail design is to group housing cells into "pods." Since the administration of the correctional facility will determine where detainees will reside, there are no requirements for distribution of the Accessible units. A correctional facility may decide to locate all its Accessible cells in one pod due to suicide prevention and other safety concerns. Sections 1103.2.14 and 1109.11 have exceptions for spaces shared by detainees for areas within the jail where Accessible units are not provided.

1107.5.5.2 Special holding cells and special housing cells or rooms. In addition to the *Accessible units* required by Section 1107.5.5.1, where special holding cells or special housing cells or rooms are provided, at least one serving each purpose shall be an *Accessible unit*. Cells or rooms subject to this requirement include, but are not limited to, those used for purposes of orientation, protective custody, administrative or disciplinary detention or segregation, detoxification and medical isolation.

Exception: Cells or rooms specially designed without protrusions and that are used solely for purposes of suicide prevention shall not be required to include grab bars.

❖ If special types of holding or housing cells are provided within a facility (e.g., orientation, protective custody, disciplinary detention, segregation, detoxification, medical isolation), at least one of each type must be an Accessible unit. A cell that is designed specifically for a suicide watch is required to meet Accessible unit criteria, but if a toilet is provided, grab bars are not required.

1107.5.5.3 Medical care facilities. Patient *sleeping unit*s or cells required to be *Accessible units* in medical care facilities shall be provided in addition to any medical isolation cells required to comply with Section 1107.5.5.2.

❖ When medical care facilities are provided within a detention or correctional facility, 10 percent of the units are required to be Accessible units. The intent is to be consistent with the hospital requirements found in Section 1107.5.3.1.

1107.6 Group R. *Accessible units*, *Type A units* and *Type B units* shall be provided in Group R occupancies in accordance with Sections 1107.6.1 through 1107.6.4.

❖ This section introduces four subsections that address accessibility requirements for occupancies in Group R. Criteria for Accessible units, Type A units and Type B units are specified in Chapter 10 of ICC A117.1.

The IRC references this chapter for accessibility provisions; therefore, this chapter may be applicable to housing covered under the IRC (see commentary, Section 1107.6.3). Structures referenced to Chapter 11 from the IRC would be considered Group R-3 for purposes of accessibility only.

1107.6.1 Group R-1. *Accessible units* and *Type B units* shall be provided in Group R-1 occupancies in accordance with Sections 1107.6.1.1 and 1107.6.1.2.

❖ The terms "dwelling unit" and "sleeping unit" are utilized instead of "guestrooms" so that the amenities in the units themselves are reflected. An exception applicable to small bed-and-breakfast style hotels is provided in Section 1103.2.11.

Hotels, motels, boarding houses and other short-term housing types are required to provide Accessible units. Where such facilities are also intended to be occupied as a residence, Type B unit criteria is applicable. For additional discussion, please see the general comments at the beginning of this chapter.

The following factors should be considered where persons can stay more or less than 30 days, including hotels, motels, corporate housing and seasonal vacation units, in determining the applicability of Type B unit criteria:

1. Amenities included inside the units, including kitchen facilities;
2. Whether the property is to be marketed to the public as short-term housing;
3. Whether the terms and length of the occupancy will be established through a lease or other written agreement; and
4. How payment is calculated (e.g., on a daily, weekly, monthly or yearly basis).

If the amenities and operation of the units are closer to those of apartments than of hotels, they are subject to Type B requirements. For example, if a hotel is marketed as short-term housing, payment is made monthly, and if the units contain kitchens, the hotel would be subject to Type B unit criteria. For additional information see the commentary at the beginning of this chapter and Section 1107.

1107.6.1.1 Accessible units. *Accessible dwelling units* and *sleeping units* shall be provided in accordance with Table 1107.6.1.1. All *dwelling units* and *sleeping units* on a site shall be considered to determine the total number of *Accessi-*

ble units. *Accessible units* shall be dispersed among the various classes of units. Roll-in showers provided in *Accessible units* shall include a permanently mounted folding shower seat.

❖ The required number of Accessible dwelling or sleeping units in Group R-1 is indicated in Table 1107.6.1.1. The table requires Accessible units to include a variety of bathing options. Where roll-in-type showers are provided, this section requires that they must include folding shower seats mounted on the shower wall. These showers can then serve the dual purpose of roll-in and transfer showers, which is a requirement in ICC A117.1. ICC A117.1 also provides for a fixed-seat option in roll-in showers. That alternative would be considered to provide an equivalent level of accessibility.

For sites where the hotel rooms are provided in multiple buildings, all the units on the site should be considered to determine the number of Accessible units. For example, if a hotel consists of several small buildings on a site, the same number of Accessible units would be required as if the hotel was constructed as a single structure.

Accessible units must be dispersed among the different types of units. This is not an automatic requirement to disperse the Accessible units to different floor levels. When different classes of dwelling or sleeping units are available, special amenities must also be made available in the Accessible units, including suites or larger rooms, kitchenettes, executive levels, etc. For example, if sleeping units with three options of single room, suit or kitchenettes are provided, and two Accessible units are required, the Accessible units must be provided in two of the three options. If no other types of amenities are provided on other levels, the hotel could provide the Accessible units on the main level. Some hotels chose to provide all Accessible units on the main level due to concerns for disabled guests' ease of escape from the building during an emergency, such as a fire. Keep in mind that services available to guests (i.e., pools, exercise rooms, laundry rooms) must also be on an accessible route for guests in the Accessible units.

TABLE 1107.6.1.1. See below.

❖ The number of Accessible dwelling and sleeping units required is coordinated with the 2010 Standard requirements. The ADAAG Review Federal Advisory Committee reviewed all the information and data provided by the industry in support of a lower number of Accessible units being required. The committee determined that accessible features are useful to persons with disabilities beyond those who use wheelchairs, and that good design would lessen the "institutional" impression that may make Accessible units less attractive to nondisabled guests. To accommodate wheelchair users in relatively large facilities, this table requires a minimum number of units to be equipped with roll-in-type showers. In accordance with Section 1107.6.1.1, the roll-in showers must have seats, therefore, they can serve the dual purpose of transfer and roll-in shower. ICC A117.1 provides options for roll-in showers with fold-up or permanent seats. The intent of the second column in this table is that different options (i.e., roll-in shower, transfer shower or bathtubs) are available in the Accessible units. It is not the intent of this column to prohibit roll-in showers with seats when there are only one or two Accessible units in the hotel.

1107.6.1.1.1 Accessible unit facilities. All interior and exterior spaces provided as part of or serving an *Accessible dwelling unit* or *sleeping unit* shall be *accessible* and be located on an *accessible route*.

Exceptions:

1. Where multiple bathrooms are provided within an *Accessible unit*, at least one full bathroom shall be *accessible*.
2. Where multiple-family or assisted bathrooms serve an *Accessible unit*, at least 50 percent but not less

TABLE 1107.6.1.1
ACCESSIBLE DWELLING UNITS AND SLEEPING UNITS

TOTAL NUMBER OF UNITS PROVIDED	MINIMUM REQUIRED NUMBER OF ACCESSIBLE UNITS WITHOUT ROLL-IN SHOWERS	MINIMUM REQUIRED NUMBER OF ACCESSIBLE UNITS WITH ROLL-IN SHOWERS	TOTAL NUMBER OF REQUIRED ACCESSIBLE UNITS
1 to 25	1	0	1
26 to 50	2	0	2
51 to 75	3	1	4
76 to 100	4	1	5
101 to 150	5	2	7
151 to 200	6	2	8
201 to 300	7	3	10
301 to 400	8	4	12
401 to 500	9	4	13
501 to 1,000	2% of total	1% of total	3% of total
Over 1,000	20, plus 1 for each 100, or fraction thereof, over 1,000	10 plus 1 for each 100, or fraction thereof, over 1,000	30 plus 2 for each 100, or fraction thereof, over 1,000

than one room for each use at each cluster shall be *accessible*.

3. Five percent, but not less than one bed shall be *accessible*.

❖ This section reinforces the provision in Section 1107.3, which requires that spaces that serve an Accessible unit are required to be accessible. Exception 1 addresses when an Accessible unit is a suite where multiple bathrooms are provided. Revisions in the 2009 edition of ICC A117.1 for Accessible units also allow this exception. Exception 2 would be utilized in a hotel with a group of bathrooms in a central location. This is consistent with Section 1109.2, Exception 3, which requires the bedrooms to be large enough to allow for the bed to be accessible. In a multiple-bedroom or a dormitory-type setup, such as in a scout camp, at least one bed would be accessible. ICC A117.1 requires beds to have an adjacent clear floor space and to be on a bed frame (instead of a platform) to allow for the use of a Hoyer lift for transfer.

1107.6.1.2 Type B units. In structures with four or more *dwelling units* or *sleeping units intended to be occupied as a residence*, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ Most hotels and motels are not intended to be occupied as a residence; therefore, the criteria for Type B units would not be applicable. However, in certain situations, extended-stay hotels or similar corporate housing arrangements are required to meet Type B unit criteria. For additional information on how to determine if this section is applicable, see the comments at the beginning of this chapter and Sections 1107 and 1107.6.1. The Accessible sleeping units required by Section 1107.6.1.1 exceed Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.2 Group R-2. *Accessible units*, *Type A units* and *Type B units* shall be provided in Group R-2 occupancies in accordance with Sections 1107.6.2.1 and 1107.6.2.2.

❖ The terms "dwelling unit" and "sleeping unit" are utilized instead of "apartment," "dorm room," "sleeping accommodations," "suites," etc., so that the amenities in the units themselves are reflected and for consistent application within all Group R-2 facilities. Since these types of facilities are intended to be occupied as a residence, Type B unit criteria would be applicable. For a complete discussion, please see the comments to this chapter and this section.

Timeshare properties require a different analysis. Timeshare owners have an interest in the property, yet they typically stay less than 30 days. For a timeshare property to be subject to Type B requirements, the owners must have an ownership interest in the property itself, rather than in just coming to the area for a vacation without ties to a particular property. The following additional factors must be considered to determine whether timeshare units must meet Type B design and construction requirements:

1. Whether traditional rights of ownership are to be unrestricted (e.g., whether the timeshare owner has the right to occupy, alter or exercise control over a particular unit over a period of time);
2. The nature of the ownership interest conveyed (e.g., fee simple); and
3. The extent to which operations resemble those of a hotel, motel or inn (e.g., reservation, central registration, meals, laundry service).

If an owner's rights regarding the units are subject to few restrictions and the operation of the units is closer to that of condominiums/apartments than hotels, the units are subject to Type B requirements.

1107.6.2.1 Apartment houses, monasteries and convents. *Type A units* and *Type B units* shall be provided in apartment houses, monasteries and convents in accordance with Sections 1107.6.2.1.1 and 1107.6.2.1.2.

❖ Unless they receive some type of federal funding, apartments and condominiums are not covered by the the 2010 Standard. Note that the code deals with apartments and condominiums in the same manner when dealing with accessibility requirements. However, owners of Type A units do have some options under the provisions for alterations in Section 3411.6.

Convents and monasteries are associated with religious organizations, so they also are not covered by ADA requirements. Since all these facilities may serve as a person's residence, they are covered by FHAG. A convent or monastery cannot be sued under FHA for selectively limiting its residents; however, it must comply with the FHAG construction requirements for the residential units that it provides. The scope for Type B units is consistent with FHAG requirements.

1107.6.2.1.1 Type A units. In Group R-2 occupancies containing more than 20 *dwelling units* or *sleeping units*, at least 2 percent but not less than one of the units shall be a *Type A unit*. All Group R-2 units on a *site* shall be considered to determine the total number of units and the required number of *Type A units*. *Type A units* shall be dispersed among the various classes of units.

Exceptions:

1. The number of *Type A units* is permitted to be reduced in accordance with Section 1107.7.
2. *Existing structures* on a *site* shall not contribute to the total number of units on a *site*.

❖ To be able to better accommodate a person who uses a wheelchair, 2 percent of apartments and condominiums are required to provide Type A units

within the development. Congregate residences, such as convents and monasteries, must also provide Type A units. (Other types of congregate living arrangements are addressed in Section 1107.6.2.2.) The housing industry has been concerned that dwelling units equipped with the full range of features to accomplish accessibility will not be marketable to people without disabilities. The Type A requirements are intended to accomplish a middle ground that will satisfy both needs. Allowances made during the construction process for future conversion for accessibility, such as reinforcement in bathroom walls for future installation of grab bars, will allow a unit to be altered later at a considerably lesser cost.

Type A units are required when the site contains more than 20 dwelling units or sleeping units. So that there is a consistent number of Type A units in multibuilding sites based on the size of a development as a whole, all the buildings are added together to determine the number required. For example, a 300-unit building would require six Type A units, and a development with 75 buildings with four units per building would also require six Type A units. Exception 2 is in recognition that a development may be built in stages. Only the units that are being constructed as part of that development phase are considered in determining the number of Type A units.

The Type A units must be dispersed among the classes of units provided. For example, if one-, two- and three-bedroom units are available with the development and two Type A units are required, it is the designer's choice as to which two of the options to provide as Type A units. The designer, however, cannot choose to only provide the one-bedroom option with both Type A units. This is not intended to require Type A units to be provided in different buildings in a multiple-building site. Many times in multiple-building developments, there are shared facilities such as clubhouses or pools. The designer may choose to locate the Type A units in the building closest to those amenities for ease of access for the residents. This is acceptable as long as the dispersion by type requirement is met.

In limited circumstances, townhouse-style units can be Group R-2 facilities (see Section 310.4). If multistory units are provided for the Type A units, ICC A117.1 would require an accessible route between levels. Within the dwelling, this can be provided by a passenger elevator, a LULA, a private residence elevator (see Section 1109.7) or a platform lift (see Section 1109.8, Item 4). A possible alternative would be to provide some single-story units within the development to meet Type A-unit requirements. If the amenities and size are the same, they could be considered the same type as a multilevel unit. The multistory exception in Section 1107.7.2 is not applicable to Type A units.

Exception 1 allows the number of Type A units to be reduced in accordance with Section 1107.7.5 when the building's first-floor elevation is required to be raised due to flood-plain regulations. This is the only exception that allows for a reduction in the number of Type A units required.

1107.6.2.1.2 Type B units. Where there are four or more *dwelling units* or *sleeping units intended to be occupied as a residence* in a single structure, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ When four or more dwelling or sleeping units are provided in a single structure, those units must meet Type B criteria (note the use of the term "structure" instead of "building"). The criteria is applicable if four dwelling units are built together, regardless of fire walls [see Figures 1107.6.2.1.2(1) and 1107.6.2.1.2(2)]. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

Type A units provided in accordance with Section 1107.6.2.1.1 exceed Type B unit requirements.

1107.6.2.2 Group R-2 other than apartment houses, monasteries and convents. In Group R-2 occupancies, other than

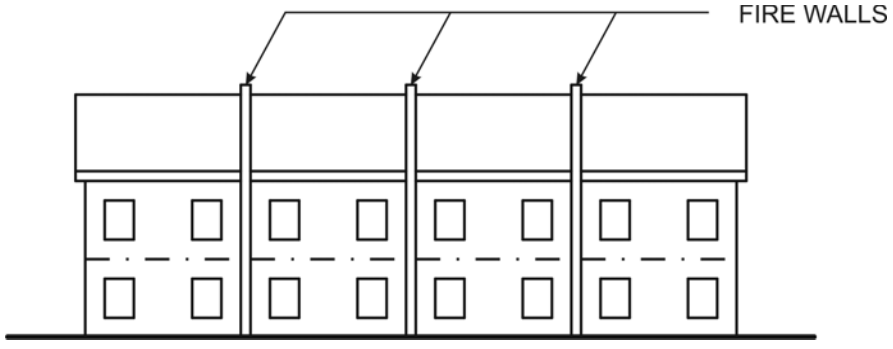

Figure 1107.6.2.1.2(1)
BUILDING WITH FIRE WALLS IS TREATED AS A SINGLE STRUCTURE

apartment houses, monasteries and convents, *Accessible units* and *Type B units* shall be provided in accordance with Sections 1107.6.2.2.1 and 1107.6.2.2.2.

❖ This would include congregate housing types, such as dormitories, boarding houses, fraternities and sororities. Nontransient hotels and motels would typically be grouped with these requirements since they may also be operating as transient and nontransient. A building used for two purposes must be designed for the most restrictive provisions (see Section 302.1). Time shares should comply with Section 1107.6.2.1 or 1107.6.2.2, based on whichever it most closely represents (see also commentary, Section 1107.6.2).

Dormitories are typically located in universities. Universities are required to make all programs accessible; therefore, dormitories are covered by ADA requirements. Boarding houses, fraternity houses and sorority houses have similar types of living arrangements; therefore, it seems logical that the same anticipated need should result in the same level of required Accessible units. Since all these facilities typically serve as a person's residence, they are covered by FHAG. The scope for Accessible units is consistent with ADA requirements for dormitories. The scope for Type B units is consistent with FHAG requirements.

1107.6.2.2.1 Accessible units. *Accessible dwelling units* and *sleeping units* shall be provided in accordance with Table 1107.6.1.1.

❖ The number of Accessible units required in these Group R-2 facilities is the same as that required in hotels and motels. All associated and shared areas (e.g., bathrooms, kitchens, study rooms) must also be accessible in accordance with Section 1002 of ICC A117.1. A certain number of the Accessible units must have associated bathrooms equipped with a roll-in shower.

1107.6.2.2.2 Type B units. Where there are four or more *dwelling units* or *sleeping units intended to be occupied as a residence* in a single structure, every *dwelling unit* and every *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ The FHA specifically considers dormitories as places where students live, even if it is just for the school year. Therefore, when four or more sleeping units are provided in a single structure, those units must meet Type B criteria. The Accessible sleeping units required by Section 1107.6.2.2.1 exceed Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.3 Group R-3. In Group R-3 occupancies where there are four or more *dwelling units* or *sleeping units intended to be occupied as a residence* in a single structure, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ When four or more dwelling or sleeping units are provided in a single structure, those units must meet Type B criteria (note the use of the term "structure" instead of "building"). Since Group R-3 structures can be a series of one or two dwellings per building separated by fire walls (see Section 310.5), the provisions for Type B units would apply to groups of R-3 units. Transient congregate residences with 10 or fewer occupants and nontransient congregate residences with 16 or fewer occupants are permitted to comply with Group R-3 construction requirements (see Section 310.5). Small bed-and-breakfast-type hotels are exempted from accessibility under Section 1103.2.11. These congregate residences may be

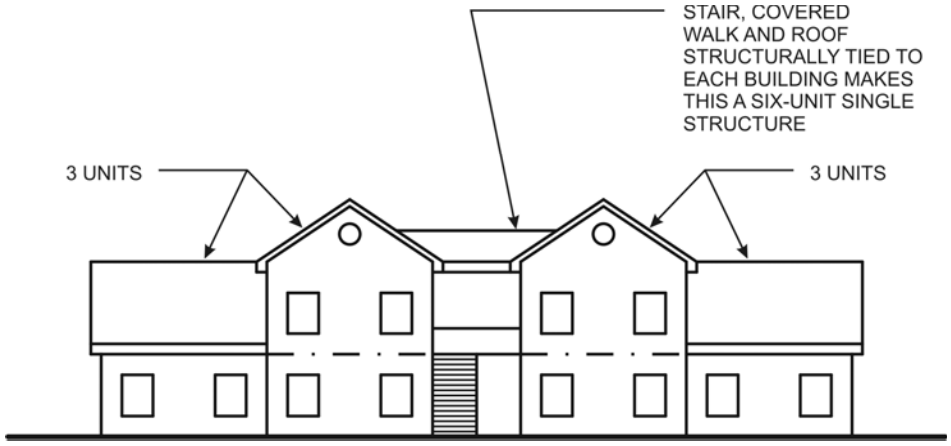

Figure 1107.6.2.1.2(2)
TWO STRUCTURALLY JOINED BUILDINGS ARE TREATED AS A SINGLE STRUCTURE

covered by ADAAG, so a designer/owner may want to consider providing Accessible units (see Sections 1107.6.1.1 and 1107.6.2.2.1) in facilities such as hotels, dormitories, sororities and fraternities. The criteria is applicable if four dwelling units are built together, regardless of fire walls. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

Section 101.2, Exception 1 states that detached one- and two-family dwellings and townhouses that are both three stories or less and have an independent means of egress must comply with the IRC. Section 1103.2.4 exempts detached single-family homes and duplexes from accessibility requirements, but not townhouses. In the IRC, townhouses are further defined as extending from foundation to roof and open on at least two sides; therefore, the typical side-by-side townhouse is constructed using the IRC. Any configuration of townhouses that does not meet all four criteria has to be constructed under the IBC as Group R-2 or possibly Group R-3. If the structure is divided into one- or two-dwelling units per building with fire walls, the structure is a Group R-3 (see commentary, Sections 310.4 and 310.5). Group I-1 and I-2 institutional-type facilities with five or fewer residents and Group R-4 facilities have the option of complying with the code or the IRC, since they often operate similar to a single-family home (see Sections 308.3.1, 308.3.2, 308.4.1 and 310.6). Day care facilities within single-family homes are specifically addressed under Section 1103.2.12. Live/work units are specifically addressed under Section 1003.2.13.

Section 320.1 of the IRC refers any structure with four or more sleeping units or dwelling units back to the code as Group R-3 buildings for accessibility requirements. Since these types of facilities typically serve as a person's permanent residence, the units must meet Type B criteria. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.4 Group R-4. *Accessible units* and *Type B units* shall be provided in Group R-4 occupancies in accordance with Sections 1107.6.4.1 and 1107.6.4.2.

❖ Group R-4 facilities are limited to between six and 16 residents. A Group R-4 is basically a small Group I-1 facility (see Sections 308.3.2 and 310.6). The Group R-4 occupancy was originally developed in response to some lawsuits filed under FHA concerning homes for mentally disabled adults. Under the past legacy codes, a structure where persons live in a supervised environment is a Group I occupancy. In neighborhoods zoned residential only, a variance is required if a group of mentally disabled adults wants to move into a single-family-style dwelling. Additionally, Group I facilities are typically required to be sprinklered throughout with an NFPA 13 system. This type of sprinkler system is not what is typically used in a single-family home. The 16-resident criteria is based on two things: (1) In the last census, 98 percent of the households in the United States that identified themselves as single family had 16 or fewer residents; and (2) In facilities where residents are capable of self-preservation, the number 16 also happens to be the limit of residents permitted in a building where an NFPA 13D sprinkler system can be utilized. Establishing these types of facilities as part of Group R eliminates potential conflict with the zoning issue. The limit on the number of residents and allowing the alternative sprinkler system addresses the discrimination in housing concerns and provides a reasonable level of sprinkler protection for the residents.

1107.6.4.1 Accessible units. At least one of the *dwelling* or *sleeping unit*s shall be an *Accessible unit*.

❖ The requirement for one sleeping unit and its associated facilities (e.g., bathing room) to meet Accessible unit criteria is consistent with Group I-1 requirements. All common rooms are required to be fully accessible. Section 1002 of ICC A117.1 provides the technical criteria for Accessible sleeping units.

1107.6.4.2 Type B units. In structures with four or more *dwelling units* or *sleeping unit*s *intended to be occupied as a residence*, every *dwelling unit* and *sleeping unit intended to be occupied as a residence* shall be a *Type B unit*.

Exception: The number of *Type B units* is permitted to be reduced in accordance with Section 1107.7.

❖ Since these types of facilities typically serve as a person's permanent residence, the sleeping unit must meet Type B criteria. The Accessible sleeping unit required by Section 1107.6.4.1 exceeds Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure. Since Group R-4 is a congregate residence, this section would be applicable when four or more sleeping units are provided.

1107.7 General exceptions. Where specifically permitted by Section 1107.5 or 1107.6, the required number of *Type A units* and *Type B units* is permitted to be reduced in accordance with Sections 1107.7.1 through 1107.7.5.

❖ Section 1107.5 or 1107.6 establish when Accessible, Type A or Type B units are expected to be provided. Section 1107.7 covers the general exceptions where it is reasonable and logical to not provide accessibility for some of the units. This would be consistent with the general provisions of Section 1103.2.1. Code users should start out with the assumption that everything, in this case Group I and R dwelling and sleeping units, is required to be accessible, and then back off from that level of accessibility when specific exceptions are indicated. Note that there are no exceptions for Accessible units. While Type A units are mentioned in Section 1107.7.1, the only exception for Type A units is found in Section 1107.7.5.

Sections 1107.7.1 through 1107.7.4 primarily deal with nonelevator buildings. If elevators are provided, except as addressed in Section 1107.7.3, all units in

the building are required to meet Type B criteria or better. Providing access to the upper floors in these cases would require either an elevator or a ramp system (or multiple elevators or ramps), both of which would be unreasonable. These exceptions are intended to be consistent with the scope of FHAG. It should be noted that these are only exceptions to the requirements for Type B dwelling units.

In accordance with Section 1107.2, Accessible and Type A units provide a higher level of accessibility than Type B units. Therefore, if Accessible or Type A units are provided on the accessible levels, this would exceed Type B-unit requirements. For clarity in the commentary for the exceptions, only Type B units will be mentioned.

1107.7.1 Structures without elevator service. Where no elevator service is provided in a structure, only the *dwelling units* and *sleeping unit*s that are located on stories indicated in Sections 1107.7.1.1 and 1107.7.1.2 are required to be *Type A units* and *Type B units*, respectively. The number of *Type A units* shall be determined in accordance with Section 1107.6.2.1.1.

❖ Only the units located on the floor levels defined in Sections 1107.7.1.1 and 1107.7.1.2 are required to contain Type A or Type B units when no elevator service is provided in the building. Floor levels that do not meet the criteria are not required to have an accessible route to that level, nor do the dwelling units or sleeping units on those levels have to meet Type A or Type B unit criteria. The building must still have the minimum number of Type A units required on the first floor.

1107.7.1.1 One story with Type B units required. At least one *story* containing *dwelling units* or *sleeping unit*s *intended to be occupied as a residence* shall be provided with an *accessible* entrance from the exterior of the structure and all units *intended to be occupied as a residence* on that *story* shall be *Type B units*.

❖ This section basically states that Type B units must be provided on at least one level of a building that is not equipped with elevator service. For example, on a flat site, a two-story structure with Type B dwelling units or sleeping units on the first floor would not require an accessible route to, or Type B units on, the second floor (see Figure 1107.7.1.1).

1107.7.1.2 Additional stories with Type B units. On all other stories that have a building entrance in proximity to arrival points intended to serve units on that *story*, as indicated in Items 1 and 2, all *dwelling units* and *sleeping unit*s *intended to be occupied as a residence* served by that entrance on that *story* shall be *Type B units*.

1. Where the slopes of the undisturbed *site* measured between the planned entrance and all vehicular or pedestrian arrival points within 50 feet (15 240 mm) of the planned entrance are 10 percent or less, and
2. Where the slopes of the planned finished grade measured between the entrance and all vehicular or pedestrian arrival points within 50 feet (15 240 mm) of the planned entrance are 10 percent or less.

Where no such arrival points are within 50 feet (15 240 mm) of the entrance, the closest arrival point shall be used unless that arrival point serves the *story* required by Section 1107.7.1.1.

❖ This section addresses the idea that a building could have two levels that would be provided with accessible routes. This could be a structure built into a hill or a building with the first level a few feet down and the second level a few feet up from grade level [see Figure 1107.7.1.2(1)].

The basic test for multiple accessible levels is to check for the slope between the building entrance and any arrival points within a 50-foot (15 240 mm) arc. If no arrival points (e.g., sidewalk, parking) are within that 50-foot (15 240 mm) arc, the closest arrival point should be used as a reference. If the slope between these two points is 10 percent or less both before and after grading of the site, than an accessible route is required to that level [see Figures 1107.7.1.2(2) and 1107.7.1.2(3)].

In the case of sidewalks, the closest point to the

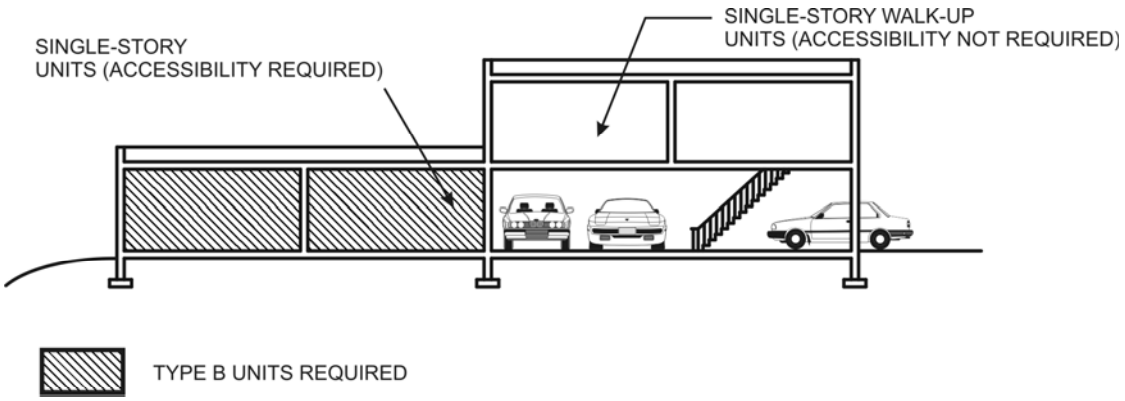

Figure 1107.7.1.1
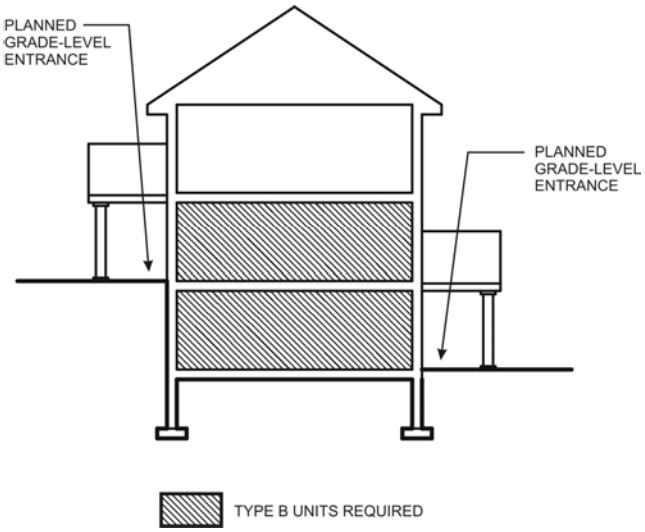
DWELLING UNITS ON ONE STORY

entrance will be where a public sidewalk entering the site intersects with the sidewalk to the entrance. In the case of resident parking areas, the closest point to the planned entrance will be measured from the entry point to the parking area that is located closest to the planned entrance. The measurement for elevation should be taken from the center of the entrance door to the top of the pavement at the arrival point.



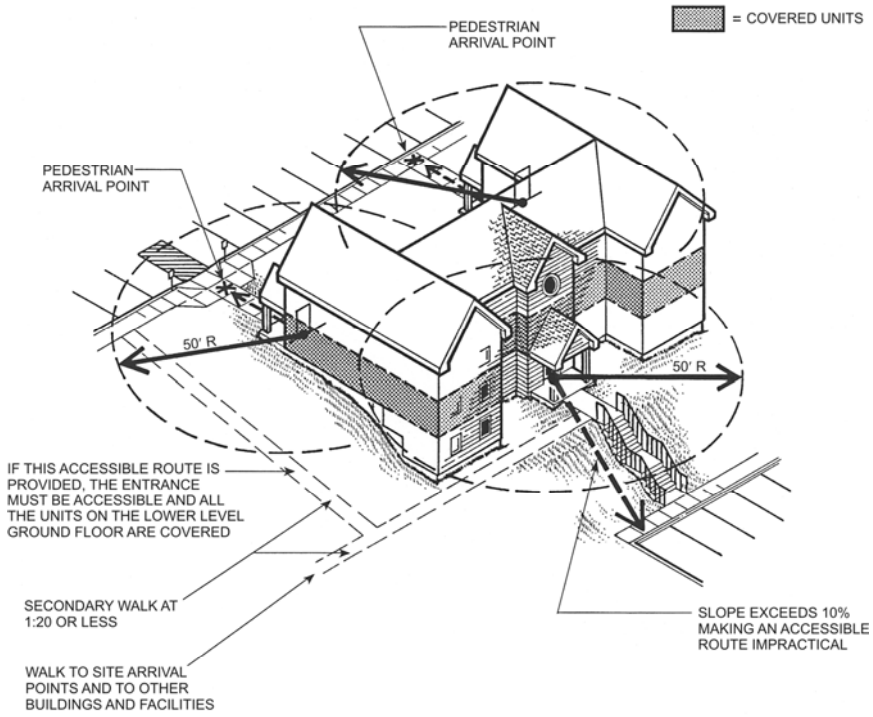


Figure 1107.7.1.2(1)
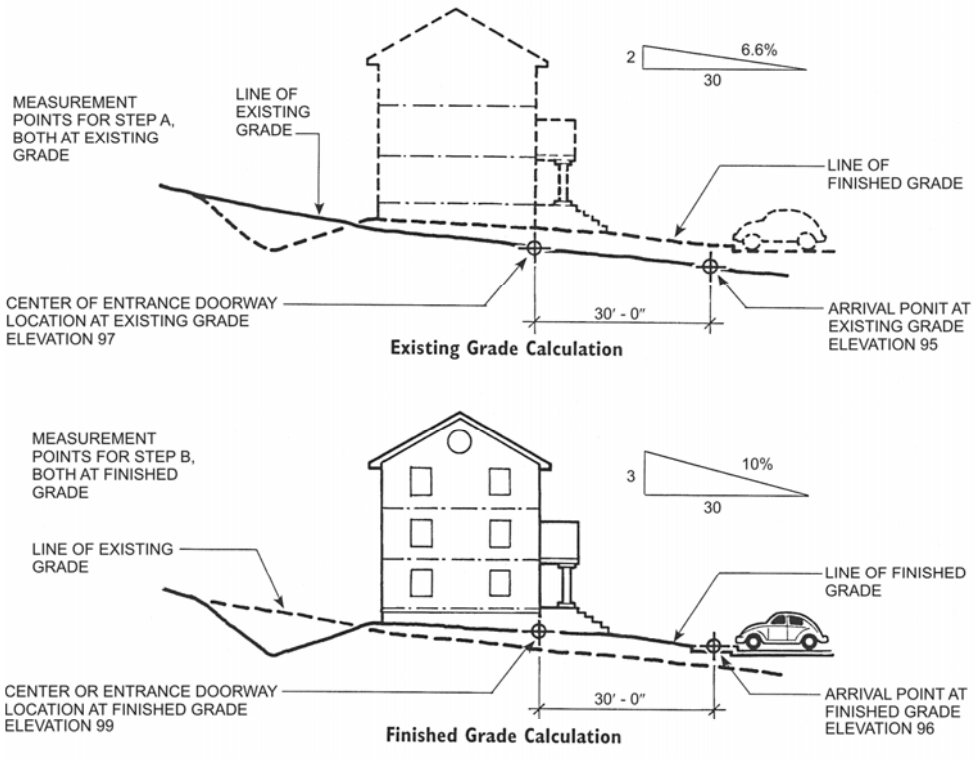
BUILDING HAS TWO ACCESSIBLE LEVELS, EACH WITH AN ACCESSIBLE ENTRANCE ON AN ACCESSIBLE ROUTE

For SI: 1 foot = 304.8 mm.

Figure 1107.7.1.2(2)
SINGLE BUILDING WITH MULTIPLE COMMON ENTRANCES—LOWER GROUND FLOOR UNITS MAY BE COVERED

1107.7.2 Multistory units. A *multistory dwelling* or *sleeping unit* which is not provided with elevator service is not required to be a *Type B unit*. Where a *multistory unit* is provided with external elevator service to only one floor, the floor provided with elevator service shall be the primary entry to the unit, shall comply with the requirements for a *Type B unit* and a toilet facility shall be provided on that floor.



❖ Section 1107.7.2 addresses multistory dwelling units (see the definition in Chapter 2). For example, the typical townhouse scenario, where there is a series of two-story units adjacent to each other in a single structure, would not require Type B units. If multistory units are provided in a building containing elevators and access is provided at only one floor level, that level must be accessible and contain a toilet facility [see Figures 1107.7.2(1) and 1107.7.2(2)].

1107.7.3 Elevator service to the lowest story with units. Where elevator service in the building provides an *accessible route* only to the lowest *story* containing *dwelling* or *sleeping units intended to be occupied as a residence*, only the units on that *story* which are *intended to be occupied as a residence* are required to be *Type B units*.

❖ Section 1107.7.3 exempts dwelling units located on upper floors as long as the dwelling units on the first floor containing dwelling units are at least Type B units. For example, a three-story structure has a business on the first floor with apartments on the second and third levels. An accessible route is required to the second level, and all dwelling units on that level are required to be Type B units; however, an accessible route and Type B units are not required to the third level. (Note: If an elevator is utilized to provide access to only the lowest level containing dwelling or sleeping units, this building would not be considered an "elevator" building) [see Figures 1107.7.3(1) and 1107.7.3(2)].

1107.7.4 Site impracticality. On a *site* with multiple nonelevator buildings, the number of units required by Section 1107.7.1 to be *Type B units* is permitted to be reduced to a percentage which is equal to the percentage of the entire *site* having grades, prior to development, which are less than 10 percent, provided that all of the following conditions are met:

1. Not less than 20 percent of the units required by Section 1107.7.1 on the *site* are *Type B units*;
2. Units required by Section 1107.7.1, where the slope between the building entrance serving the units on that *story* and a pedestrian or vehicular arrival point is no greater than 8.33 percent, are *Type B units*;
3. Units required by Section 1107.7.1, where an elevated walkway is planned between a building entrance serv-

For SI: 1 foot = 304.8 mm.

Figure 1107.7.1.2(3)
EXAMPLE FOR GRADE CALCULATIONS

ing the units on that *story* and a pedestrian or vehicular arrival point and the slope between them is 10 percent or less are *Type B units*; and

4. Units served by an elevator in accordance with Section 1107.7.3 are *Type B units*.

❖ Section 1107.7.4 addresses multiple buildings on a sloping site. For example, if an apartment complex was built on a steep or hilly site, the number of Type B dwelling units required on the ground floor could be reduced due to the difficulty of providing accessible routes. A minimum of 20 percent of the total ground floor units on the site must be Type B units, regardless of site complications (see Figure 1107.7.4).

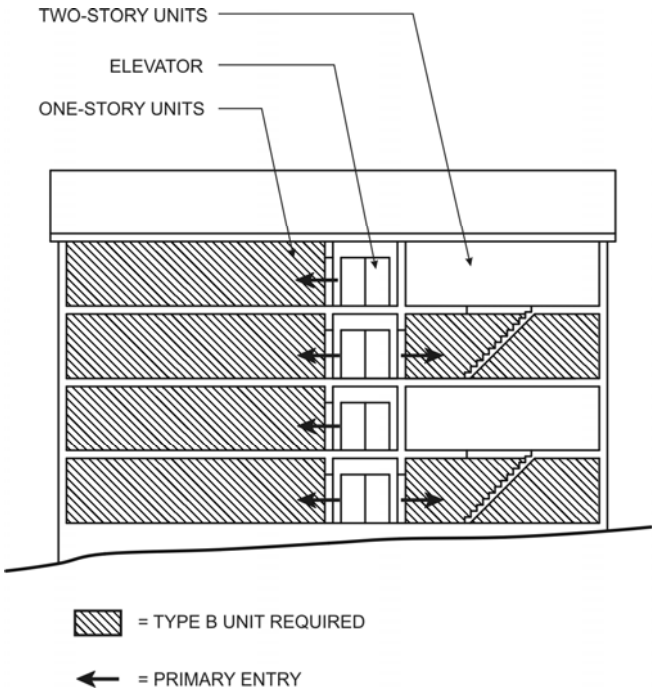


Figure 1107.7.2(1)

Figure 1107.7.5(1)
BUILDING MEETS BOTH ACCESSIBILITY CRITERIA FOR EXEMPTION

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1107.7.5(2)
BUILDING MUST COMPLY WITH ACCESSIBILITY REQUIREMENTS

1107.7.5 Design flood elevation. The required number of *Type A units* and *Type B units* shall not apply to a *site* where the required elevation of the lowest floor or the lowest horizontal structural building members of nonelevator buildings are at or above the *design flood elevation* resulting in:

1. A difference in elevation between the minimum required floor elevation at the primary entrances and vehicular and pedestrian arrival points within 50 feet (15 240 mm) exceeding 30 inches (762 mm), and
2. A slope exceeding 10 percent between the minimum required floor elevation at the primary entrances and vehicular and pedestrian arrival points within 50 feet (15 240 mm).

Where no such arrival points are within 50 feet (15 240 mm) of the primary entrances, the closest arrival points shall be used.

❖ Residential structures in flood hazard areas must be elevated (see Section 1612). If, based on the required floor elevation, the criteria in either Item 1 or 2 are met, it is considered that an accessible route to the units is not feasible. This section applies to both Type A and Type B dwelling units [see Figures 1107.7.5(1) and 1107.7.5(2)].

Flood-resistant requirements, in part, address concerns about public safety. The code provides for reductions in the level of accessibility in residential facilities without elevators that are elevated to comply with Section 1612. Note that the exception is based on the required design-flood elevation. If the first-floor elevation is higher than the design-flood elevation by choice, the measurement would still be from the design-flood elevation rather than the actual floor elevation.

SECTION 1108
SPECIAL OCCUPANCIES

1108.1 General. In addition to the other requirements of this chapter, the requirements of Sections 1108.2 through 1108.4 shall apply to specific occupancies.

❖ The criteria provided herein are occupancy specific, and are intended to result in a reasonable level of accessibility in areas with assembly seating, self-service storage facilities and judicial facilities.

1108.2 Assembly area seating. A building, room or space used for assembly purposes with *fixed seating* shall comply with Sections 1108.2.1 through 1108.2.5. Lawn seating shall comply with Section 1108.2.6. Assistive listening systems shall comply with Section 1108.2.7. Performance areas viewed from assembly seating areas shall comply with Section 1108.2.8. Dining areas shall comply with Section 1108.2.9.

❖ Sections 1108.2.1 through 1108.2.8 specifically address facilities with fixed seating utilized for purposes of viewing an event, typically facilities and spaces of occupancies of Groups A-1, A-3, A-4 and A-5. These criteria would also be applicable in assembly-type spaces with fixed seats that are located in buildings of other occupancies. The requirement for access to services; number and dispersion of wheelchair spaces and their associated companion seats; designated aisle seats; lawn seating; assistive listening systems and performance areas are addressed. The requirements for seating in areas for eating or drinking, typically Group A-2 spaces or facilities, and the dispersion of this seating are addressed in Section 1108.2.9.

1108.2.1 Services. If a service or facility is provided in an area that is not *accessible*, the same service or facility shall be provided on an *accessible* level and shall be *accessible*.

❖ This section establishes an important concept. The intent is that all types of services provided by a facility must be accessible. For example, a stadium may have a particular section of seating that is not accessible (assuming that the required number and dispersion of spaces is in compliance with the code). This section establishes that if a souvenir stand is located in or near that section, one of three circumstances would apply: an additional souvenir stand must be provided in the facility on an accessible level; the souvenir stand would have to be relocated to an accessible level or the section where the souvenir stand is located must be made accessible. This section also emphasizes that not only must that service or facility be located on an accessible level, but the service itself must also be accessible. Obviously, it would be inappropriate to locate a souvenir stand on an accessible level if the approach or entrance to that area is inaccessible.

1108.2.2 Wheelchair spaces. In theaters, *bleachers*, *grandstands*, stadiums, arenas and other *fixed seating* assembly areas, *accessible wheelchair spaces* shall be provided in accordance with Sections 1108.2.2.1 through 1108.2.2.4.

❖ The intent of this section is to provide a reasonable number of spaces in an assembly occupancy with fixed seating to accommodate persons who use wheelchairs. Demographic statistics from the National Center for Health Statistics on the number of noninstitutionalized Americans who use wheelchairs indicate that these requirements are realistic. These required wheelchair spaces consist of an open, available floor space in which the wheelchair takes the place of the fixed seat that would otherwise occupy that space. Section 1108.2.3 is consistent with ICC A117.1 in requiring companion seating adjacent to each wheelchair space.

1108.2.2.1 General seating. *Wheelchair spaces* shall be provided in accordance with Table 1108.2.2.1.

❖ The number of required wheelchair spaces is indicated in Table 1108.2.2.1 and is based on the total number of fixed seats set up to view the same event, with the exception of box seats covered in Sections 1108.2.2.2 and 1108.2.2.3. For example, the fixed seating on all levels and all types provided in a sports stadium, excluding box seats, is used to calculate the

number of required wheelchair spaces for the general seating. The requirements for box- or suite-type seating are calculated separately. Seating provided in different rooms, such as in a series of lecture halls in a university, must be calculated separately. Note that the percentage of wheelchair spaces is less for facilities with a capacity of more than 5,000. The industry has been able to provide statistics to show that the higher percentage of wheelchair spaces is not typically utilized in large facilities.

TABLE 1108.2.2.1
ACCESSIBLE WHEELCHAIR SPACES

CAPACITY OF SEATING IN ASSEMBLY AREAS	MINIMUM REQUIRED NUMBER OF WHEELCHAIR SPACES
4 to 25	1
26 to 50	2
51 to 100	4
101 to 300	5
301 to 500	6
501 to 5,000	6, plus 1 for each 150, or fraction thereof, between 501 through 5,000
5,001 and over	36 plus 1 for each 200, or fraction thereof, over 5,000

❖ This table sets forth the required number of wheelchair spaces based on the capacity of seating in the space containing the fixed seating. Any fixed seating with less than four seats is not required to provide wheelchair spaces. There is special criteria for wheelchair spaces in facilities with a seating capacity of over 500 and over 5,000. For example, six wheelchair spaces would be required for an assembly space with a seating capacity of 500. Seven wheelchair spaces would be required for a seating capacity of 501 through 650. Both of the last two rows use the term "or fraction thereof" to designate the next step up.

1108.2.2.2 Luxury boxes, club boxes and suites. In each luxury box, club box, and suite within arenas, stadiums and *grandstands*, *wheelchair spaces* shall be provided in accordance with Table 1108.2.2.1.

❖ When luxury boxes, club boxes or suites are provided, each luxury box, club box or suite must have an accessible route to that box and at least one wheelchair space and associated companion space. If the luxury box, club box or suite has more than 25 seats, the number of required wheelchair spaces is increased in accordance with Table 1108.2.2.1. For example, if a stadium has three luxury boxes with 51 seats in each, at least four wheelchair spaces and their associated companion seats must be provided in each box. While the total of all three luxury boxes (i.e., 153 occupants) would only require five total wheelchair spaces, these specific types of boxes must be calculated individually.

Luxury boxes are most commonly found in larger facilities, thus the reference to arenas, stadiums and grandstands. Boxes that are portions of balconies, such as in an opera house, or boxes separated by rails in general seating areas, such as behind home plate in baseball stadiums, are addressed in Section 1108.2.2.3.

1108.2.2.3 Other boxes. In boxes other than those required to comply with Section 1108.2.2.2, the total number of *wheelchair spaces* provided shall be determined in accordance with Table 1108.2.2.1. *Wheelchair spaces* shall be located in not less than 20 percent of all boxes provided.

❖ Examples of the boxes covered in this section are the seats separated by railings or low walls behind home plate in a baseball stadium [see Figure 1108.2.2.3(1)], or side balconies in opera houses [see Figure 1108.2.2.3(2)]. Luxury boxes are typically located in a separate level, and are often attached to

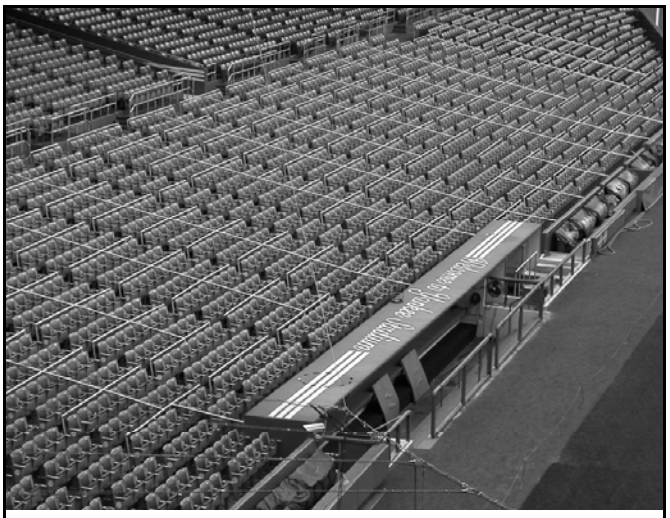

Figure 1108.2.2.3(1)
EXAMPLE OF BOX SEATING IN A SPORTS VENUE

Figure 1108.2.2.3(2)
EXAMPLE OF BOX SEATING IN A THEATER

some type of party room behind a group of seats.

When boxes other than luxury boxes, club boxes or suites are provided, at least 20 percent of the boxes must have an accessible route to that box and at least one wheelchair space and associated companion space in that box. The total number of box seats is utilized to calculate the total number of required wheelchair spaces in accordance with Table 1108.2.2.1. For example, if a stadium has five boxes with 51 seats in each, the total of all five boxes (i.e., 255 occupants) would require five total wheelchair spaces. The wheelchair spaces could be located in one box (i.e., 20 percent minimum) or dispersed to all five boxes. Note that there is additional dispersion criteria for assembly seating based on lines of sight in Section 802.8 of ICC A117.1, as well as dispersion by level in Section 1108.2.4.

1108.2.2.4 Team or player seating. At least one *wheelchair space* shall be provided in team or player seating areas serving areas of sport activity.

Exception: *Wheelchair spaces* shall not be required in team or player seating areas serving bowling lanes that are not required to be located on an *accessible route* in accordance with Section 1109.15.4.1.

❖ Accessible seating for sports teams and players is a logical code requirement that allows players to maintain team participation when injured. This requirement coordinates with the new 2010 Standard.

The exception acknowledges that only 5 percent of lanes in bowling facilities are required to be provided with an accessible route. Since teams sit at their lanes while playing, this provides a balance between player seating and access to the playing field (see Section 1109.15.4.1).

1108.2.3 Companion seats. At least one companion seat shall be provided for each *wheelchair space* required by Sections 1108.2.2.1 through 1108.2.2.3.

❖ A companion seat allows a friend, relative, associate, etc., to accompany a person using a wheelchair at an event and to share in the experience with the same level of companionship as others attending the event. The ICC A117.1 standard permits two wheelchair spaces to be located next to each other; however, each wheelchair space must also be adjacent to at least one companion seat. Accessible seating areas are sometimes provided with nonfixed companion chairs allowing the users to adjust the adjacency of seats and wheelchair spaces to their liking. If fixed seats are provided, the companion seat must have shoulder alignment with the person using the wheelchair space.

1108.2.4 Dispersion of wheelchair spaces in multilevel assembly seating areas. In *multilevel assembly seating* areas, *wheelchair spaces* shall be provided on the main floor level and on one of each two additional floor or *mezzanine* levels. *Wheelchair spaces* shall be provided in each luxury box, club box and suite within assembly facilities.

Exceptions:

1. In *multilevel assembly seating* areas utilized for worship services where the second floor or *mezzanine* level contains 25 percent or less of the total seating capacity, *wheelchair spaces* shall be permitted to all be located on the main level.
2. In *multilevel assembly seating* areas where the second floor or *mezzanine* level provides 25 percent or less of the total seating capacity and 300 or fewer seats, all *wheelchair spaces* shall be permitted to be located on the main level.
3. *Wheelchair spaces* in team or player seating serving areas of sport activity are not required to be dispersed.

❖ When facilities provide seating on multiple levels, wheelchair spaces must also be provided on multiple levels. For example, if a theater has a main level and a balcony level, wheelchair spaces must be provided on both. If a theater has a main level and two balcony levels, wheelchair spaces must be provided on the main level and at least one of the two balcony levels. While the term "level" is difficult to define in some assembly arrangements, the intent is to provide the wheelchair user with a choice of seating similar to what is available to all persons in the space. A "level" is not each time that there is a step-down to another row of seating. Subjective judgment on the part of both the designer and the building official is required for each individual facility.

There are three specific exceptions to this multilevel dispersion requirement.

Exception 1 is applicable to assembly spaces utilized for worship services. There is typically not a cost or line-of-sight issue in this type of facility, as there is in other assembly seating areas. The balcony is not required to contain accessible seating or have an accessible route, as long as accessible seating is provided on the main level and the balcony does not contain more than 25 percent of the seating.

Exception 2 is applicable to balconies in assembly facilities with a limited number of seats in the upper level. If accessible seating is provided on the main level and the balcony contains less than 25 percent of the seating and less than 300 seats, then the balcony is not required to contain accessible seating or have an accessible route.

Exception 3 relieves the requirement for wheelchair space dispersion among the various team or player seating options that may be provided in a facility. However, there must be at least one wheelchair space for each team.

The dispersement requirements in the code must be combined with the additional wheelchair dispersement requirements in ICC A117.1, including side to side (horizontally) across a venue, front to back (vari-

ety of distances) within the seating, and by type (distinct service or amenities) of seating. The standard also looks at requirements for line of sight or seated or standing spectators. Wheelchair spaces and their associated companion seats may be grouped, but must, at a minimum, be distributed into the number of locations indicated in Table 802.10 of ICC A117.1.

For requirements for accessible means of egress from these wheelchair spaces, please see Sections 1007.1, Exception 3, 1028.5.1 and 1028.8.

1108.2.5 Designated aisle seats. At least 5 percent, but not less than one, of the total number of aisle seats provided shall be designated aisle seats and shall be the aisle seats located closest to *accessible routes*.

Exception: Designated aisle seats are not required in team or player seating serving areas of sport activity.

❖ Designated aisle seats allow some persons with mobility impairments to be able to easily access certain seats along aisles. Due to an impairment, it may be difficult or impossible for some to move further into the narrow space between rows. It is not the intent of the designated aisle seats to be transfer locations. The person using this space can be someone using a walker, crutches or cane or anyone who may have difficulty with steps; hence, the requirement that the designated aisle seats be close to accessible routes. When seats have armrests, ICC A117.1 requires each designated aisle seat to have a folding or retractable armrest allowing easier access or better fit.

1108.2.6 Lawn seating. Lawn seating areas and exterior overflow seating areas, where fixed seats are not provided, shall connect to an *accessible route*.

❖ Lawn seating on both flat and sloped sites is fairly common at less formal venues. It may be the only type of seating provided or one of several options. Sometimes lawns are overflow areas, with or without movable chairs, located beyond the fixed seating areas. In any case, these lawn areas must be located on an accessible route. Access onto the lawn seating depends on the ability of the person and/or assistance from companions (see Figure 1108.2.6).

1108.2.7 Assistive listening systems. Each building, room or space used for assembly purposes where audible communications are integral to the use of the space shall have an assistive listening system.

Exception: Other than in courtrooms, an assistive listening system is not required where there is no audio amplification system.

❖ This section is intended to accommodate people with a hearing impairment. Assembly seating areas, such as stadiums, theaters, auditoriums, lecture halls and similar spaces, are required to make provisions for the use of assistive listening devices in accordance with Section 1108.2.7.1 and Table 1108.2.7.1. In these assembly areas, audible communication is often integral to the use and full enjoyment of the space. This requirement offers the possibility for individuals with hearing impairments to attend functions in these facilities without having to give advance notice and without disrupting the event in order to have a portable assistive listening system set up and made ready for use.

There are three primary types of listening systems available: induction loop, AM/FM and infrared. Each type of system has certain advantages and disadvantages that the designer should take into consideration when choosing the type of system that is most appropriate for the intended application. Signage notifying the general public of the availability of these systems must be provided in accordance with Section 1110.3.

If an audio amplification system is not provided within a facility, an assistive listening system is not required. Given the essential nature of the proceedings, this exception is not applicable to courtrooms. All courtrooms must have an assistive listening system.

1108.2.7.1 Receivers. Receivers shall be provided for assistive listening systems in accordance with Table 1108.2.7.1.

Exceptions:

1. Where a building contains more than one room or space used for assembly purposes, the total number of required receivers shall be permitted to be calculated according to the total number of seats in the building, provided that all receivers are usable with all systems and if the rooms or spaces used for assembly purposes required to provide assistive listening are under one management.
2. Where all seats in a building, room or space used for assembly purposes are served by an induction loop assistive listening system, the minimum number of

Figure 1108.2.6
EXAMPLE OF LAWN SEATING

receivers required by Table 1108.2.7.1 to be hearing-aid compatible shall not be required.

❖ Table 1108.2.7.1 specifies the number of required receivers in an assembly area. Exception 1 states that if a facility has more than one assembly space with an audio amplification system, such as a multiplex theater, then the total seating for all the spaces may be used to determine the number of receivers required.

Exception 2 states that since induction loop technology renders an entire space accessible to the assistive listening system, the hearing-aid compatible receivers are not necessary.

TABLE 1108.2.7.1. See below.

❖ Table 1108.2.7.1 specifies the number of required receivers in an assembly occupancy. At least 25 percent of the receivers provided (but not less than two receivers) must be hearing-aid compatible, as persons with hearing aids typically cannot use earpieces or headphone-equipped receivers. When determining the general number of receivers required, the table is to be applied as though it read "2 plus 1 for each additional 25 over 50, or a fraction thereof." For example, where 51 to 75 total seats are provided, three assistive listening devices are required. Where 76 to 100 total seats are provided, four assistive listening devices are required.

The number of required receivers is based on the capacity of the assembly areas. Note that as the size of the assembly area increases, the number of required receivers also increases; however, the percentage of receivers to seats decreases. This is based on the actual usage in large assembly areas.

1108.2.7.2 Ticket windows. Where ticket windows are provided in stadiums and arenas, at least one window at each location shall have an assistive listening system.

❖ An assistive-listening system is required at one window in each location where tickets are sold. Note that this is limited to stadiums and arenas where it is assumed that the technology is already provided for inside the space (see Section 1108.2.7). This will allow a person with a hearing impairment to be able to communicate with the ticket salesperson regarding date, cost and location of tickets being purchased. The New York Yankees and Minnesota Twin stadiums are currently using an induction-loop system at their ticket windows.

1108.2.7.3 Public address systems. Where stadiums, arenas and *grandstands* have 15,000 fixed seats or more and provide audible public announcements, they shall also provide prerecorded or real-time captions of those audible public announcements.

❖ If stadiums, arenas or grandstands provide public announcements, the same information should be displayed on some type of electronic signage. With seating of 15,000 or more, most stadiums, arenas and grandstands have electronic scoreboards that are capable of displaying text messages. This is especially important when dealing with emergency evacuation situations. Prerecorded messages related to emergencies should be worked out with the fire department as part of the fire and safety evacuation plans [see Section 404 of the *International Fire Code*® (IFC®)]. Fire alarm systems for assembly occupancies (Section 907.2.1.1) with an occupant load of 1,000 or more must include an emergency voice/alarm communication system. Where captioned audible public announcements are required for stadiums by this section, the emergency voice/alarm communication system must also be captioned (see Section 907.2.1.2). Specific criteria is provided in Section 907.5.2.2.4.

ICC A117.1 has new provisions for variable message signs (VMS), which provides guidance for appropriate case, style, size, spacing, contrast and rate of change. There are special allowances that address large assembly occupancies and the distance from the viewer to the sign.

1108.2.8 Performance areas. An *accessible route* shall directly connect the performance area to the assembly seating area where a *circulation path* directly connects a performance area to an assembly seating area. An *accessible route* shall be provided from performance areas to ancillary areas or facilities used by performers.

❖ Performance areas, such as stages, orchestra pits, band platforms, choir lofts and similar spaces, must be accessible. If there is a direct route from the seating to the performance area, there must also be an accessible route. For example, if steps are provided from the assembly seating area to the stage within

TABLE 1108.2.7.1
RECEIVERS FOR ASSISTIVE LISTENING SYSTEMS

CAPACITY OF SEATING IN ASSEMBLY AREAS	MINIMUM REQUIRED NUMBER OF RECEIVERS	MINIMUM NUMBER OF RECEIVERS TO BE HEARING-AID COMPATIBLE
50 or less	2	2
51 to 200	2, plus 1 per 25 seats over 50 seats*	2
201 to 500	2, plus 1 per 25 seats over 50 seats*	1 per 4 receivers*
501 to 1,000	20, plus 1 per 33 seats over 500 seats*	1 per 4 receivers*
1,001 to 2,000	35, plus 1 per 50 seats over 1,000 seats*	1 per 4 receivers*
Over 2,000	55, plus 1 per 100 seats over 2,000 seats*	1 per 4 receivers*

Note: * = or fraction thereof

the theater, then an accessible route (e.g., ramp or platform lift) to the stage must also be provided within the theater. An accessible route must also be provided to any ancillary areas, such as greenrooms or practice/warm-up rooms. The intent is that a person with mobility impairments could participate in the event. This could include high school graduation with students coming from the audience up onto the stage to receive their diplomas; participating with the community band; playing in the orchestra for a performance; acting in a production or giving a speech. Technical production areas for the stage are exempted under Section 1103.2.8.

1108.2.9 Dining and drinking areas. In dining and drinking areas, all interior and exterior floor areas shall be *accessible*.

Exceptions:

1. An *accessible route* between *accessible* levels and stories above or below is not required where permitted by Section 1104.4, Exception 1.
2. In buildings or facilities not required to provide an *accessible route* between stories, an *accessible route* to a *mezzanine* is not required, provided that the *mezzanine* contains less than 25 percent of the total area and the same services, decor and amenities are provided in the *accessible* area.
3. In sports facilities, tiered dining areas providing seating required to be *accessible* shall be required to have *accessible routes* serving at least 25 percent of the dining area, provided that *accessible routes* serve *accessible* seating and where each tier is provided with the same services.
4. Employee-only work areas shall comply with Sections 1103.2.3 and 1104.3.1.

❖ Dining and drinking areas most frequently occur in Group A-2 buildings (restaurants, cafeterias, nightclubs, dinner theaters, etc.). The provisions of this section are intended to govern such areas, rather than the criteria specified in Sections 1108.2.2 through 1108.2.5. This section requires the total floor area allotted for dining and drinking to be accessible, including areas with tables and chairs, bar seating, standing spaces, gaming areas, outdoor decks, etc. An accessible route would be required to dining areas that are raised or lowered by one or more risers. The intent is that a person with a disability may not be able to get to every seat, but they will still have a choice of tables. The four exceptions specifically address tiered dining areas in sports facilities and dining on mezzanine levels.

Exception 1, with a reference back to Exception 1 in Section 1104.4 exempts a basement, mezzanine or second floor from being served by an accessible route, provided the aggregate area of the nonaccessible levels is 3,000 square feet (278.7 m^2) or less. Keep in mind that a mezzanine is required by Section 505.2 to have a clear height below of at least 7 feet (2134 mm). Therefore, Exception 1 cannot be applied to platforms or raised floor areas.

Exception 2 is intended to acknowledge a practical and reasonable limitation in buildings with a mezzanine level that provides less than 25 percent of the total area for dining and drinking. In addition, all services and amenities provided in the mezzanine must also be available in an accessible area. Any mezzanine condition that does not meet the criteria of this exception does not qualify for the exception and must be served by an accessible route. Nonqualifying examples are as follows: a dining mezzanine that contains 25 percent or more of the total dining area; a raised or depressed dining area that is not actually a mezzanine; and a mezzanine level that contains the only area where a specific service or amenity is provided, like a bar or private party room. The area of the mezzanine is not limited by this exception to 3,000 square feet (278.7 m^2); it could be a larger area or a smaller area.

Exception 3 is for sports facilities. Some sports facilities also have accommodations for dining or picnicking while watching the event. For line-of-sight issues, the dining terraces are tiered. If the same services are available on the accessible level as any other level, only 25 percent of the dining area is required to be on an accessible route. Section 1109.8 allows platform lifts to provide access to these levels when the sporting event and dining facilities are outdoors, such as at a baseball park.

At this time the code does not contain specific information on tiered dining facilities that also have issue of line of sight for viewing an event, such as a dinner theater or dinner seating during a sport event such as at a racetrack. These types of spaces may want to look at the provisions for both dining (see Section 1108.2.9) and seating for viewing an event (see Section 1108.2.2) and develop a reasonable compromise.

Exception 4 is simply a reference to employee work area exceptions. Employee work areas may be within the mezzanine levels, such as the area behind a bar.

1108.2.9.1 Dining surfaces. Where dining surfaces for the consumption of food or drink are provided, at least 5 percent, but not less than one, of the dining surfaces for the seating and standing spaces shall be *accessible* and be distributed throughout the facility and located on a level accessed by an *accessible route*.

❖ Section 1108.2.9.1 establishes the criteria for the percentage of spaces at tables, booths, bars and counters that will be used for eating or drinking that must be accessible. This criteria is consistent with Section 1109.11 for the required percentage of accessible built-in surfaces in all other occupancies. The accessible surfaces are also required to be distributed throughout the facility such that a comparable choice of locations and types (i.e., tables, booths, counters, etc.) is available (see Figure 1108.2.9.1). This requirement, in conjunction with Section 1108.2.9, provides a reasonable and appropriate degree of accessibility throughout dining areas. The result is that a person with a mobility impairment will be able

to approach, enter and move about in the dining area. In addition, 5 percent of the total spaces at dining surfaces provided must be accessible. Each seating location at a table or seat section of a bar is considered a dining surface. The issue of whether a portion of a bar or dining counter in a restaurant is required to be accessible is subjective. The assumption is that if other types of seating are provided adjacent to the counter, then services provided at the counter will also be available at the adjacent seating; therefore, if adequate accessible seating is available adjacent to the bar area, the bar is not required to be lowered. If the bar is the only eating or dining surface in a restaurant or in a separate room in the restaurant, then a portion of the bar must be made accessible.

Figure 1108.2.9.1
EXAMPLE OF DINING SEATING

1108.3 Self-service storage facilities. *Self-service storage facilities* shall provide *accessible* individual self-storage spaces in accordance with Table 1108.3.

❖ This section addresses facilities that provide self-storage units or spaces. These types of facilities are often storage garages located in long rows. Some facilities also provide climate-controlled storage within large multistory warehouses. The key is that the storage is moved in and out and accessed by the renter of the space. The intent is to provide access for persons with disabilities to this service without requiring the entire facility to be accessible.

TABLE 1108.3
ACCESSIBLE SELF-SERVICE STORAGE FACILITIES

TOTAL SPACES IN FACILITY	MINIMUM NUMBER OF REQUIRED ACCESSIBLE SPACES
1 to 200	5%, but not less than 1
Over 200	10, plus 2% of total number of units over 200

❖ The minimum number of accessible spaces is based on the total number of self-storage spaces available in a facility.

1108.3.1 Dispersion. *Accessible* individual self-service storage spaces shall be dispersed throughout the various classes of spaces provided. Where more classes of spaces are provided than the number of required *accessible* spaces, the number of *accessible* spaces shall not be required to exceed that required by Table 1108.3. *Accessible* spaces are permitted to be dispersed in a single building of a multibuilding facility.

❖ Self-storage facilities may offer a variety of spaces, such as heated/nonheated, different sizes, etc. If the variety offered is greater than the number of accessible spaces required, the accessible spaces should be dispersed as much as possible. For example, if a facility offers the choice of a 10-foot by 10-foot (3048 mm by 3048 mm) unit and a 10-foot by 20-foot (3048 mm by 6096 mm) unit, but only one accessible space is required, then only one unit is required to be accessible. The choice of which unit is made accessible is up to the building owner or designer. When a facility has multiple buildings, accessible spaces are permitted to be located in a single building.

At this time, ICC A117.1 does not provide specific information on how to make a self-service storage unit accessible. Since overhead doors are not typically considered accessible, alternatives to be discussed between the owner/designer and code official are the possibility of man doors on the side of the unit or electric garage door openers.

1108.4 Judicial facilities. Judicial facilities shall comply with Sections 1108.4.1 through 1108.4.3.

❖ Accessibility in judicial facilities (e.g., courthouses) includes access to all public areas as well as special requirements for the courtrooms, holding cells and visitation areas. This section was added for coordination with new requirements for judicial facilities from the DOJ.

1108.4.1 Courtrooms. Each courtroom shall be *accessible* and comply with Sections 1108.4.1.1 through 1108.4.1.5.

❖ All courtrooms are required to be accessible for participants at every level. This would include participation as a employee of the court, counselor, litigant, juror, witness or observer. All courtrooms must be on an accessible route from both the public side and courtroom staff side. The waiting areas, lawyer meeting rooms and vestibule that are sometimes located immediately adjacent to the courtroom entrance must be accessible. Access must be readily available to the gallery, as well as the witness stand and jury box. Members of the jury must have an accessible route to the jury deliberation room. The witness box in a courtroom is often raised to have a line of sight between the judge and witness. It is not acceptable to ask someone to testify from an area outside the box; therefore, the witness box must always be accessible. Elements would include an accessible route to all portions of the courtroom unless limited by the following subsections which identify areas and features of courtrooms that have specific accessibility requirements.

An accessible route must also be available to the holding cells addressed in Section 1108.4.2.

The ICC was very proud to participate in a special Courthouse Access Advisory Committee that assisted the Access Board in developing recommendations for accessibility to courtrooms and courthouses. This report includes information on both requirements and recommended design practices. The committee was able to construct actual mock-ups to verify design configurations. The committee report can be located at http://www.access-board.gov/caac/.

1108.4.1.1 Jury box. A *wheelchair space* shall be provided within the jury box.

Exception: Adjacent companion seating is not required.

❖ Jury boxes may be configured in numerous ways, including with multiple tiers. At least one wheelchair space within the "box" is required. A wheelchair space adjacent to (or outside of) the jury box could not be used to satisfy the requirement. Since only jury members are seated in the jury box, companion seating is not required.

1108.4.1.2 Gallery seating. *Wheelchair spaces* shall be provided in accordance with Table 1108.2.2.1. Designated aisle seats shall be provided in accordance with Section 1108.2.5.

❖ Gallery seating in a courtroom is regulated similarly to other assembly seating areas with respect to wheelchair spaces, associated companion seating and designated aisle seats (see Figure 1108.4.1.2).

Figure 1108.4.1.2
GALLERY SEATING

1108.4.1.3 Assistive listening systems. An assistive listening system must be provided. Receivers shall be provided for the assistive listening system in accordance with Section 1108.2.7.1.

❖ Every courtroom must have an assistive listening system. Unlike other assembly occupancies, the requirement is not dependent upon an audio amplification system being provided. The assumption is that any person in a courtroom with a hearing impairment should be provided with an enhanced ability to hear the proceedings when desired. Issues of privacy may dictate the type of system provided within the courtrooms.

1108.4.1.4 Employee work stations. The judge's bench, clerk's station, bailiff's station, deputy clerk's station and court reporter's station shall be located on an accessible route. The vertical access to elevated employee work stations within a courtroom is not required at the time of initial construction, provided a *ramp*, lift or elevator can be installed without requiring reconfiguration or extension of the courtroom or extension of the electrical system.

❖ Employee work stations in courtrooms are permitted to be constructed as adaptable for a future accessible route if and when a route is necessary for a mobility impaired employee. Depending on the type of courtroom (i.e., panel, trial, jury, traffic), employee work stations will vary. The judge is typically raised to establish a level of authority over the courtroom and to have his or her eyes approximately level with those of the standing lawyers. Associated clerk stations are raised to ease interaction with the judge. The vertical portion of the accessible route (ramp, platform lift, elevator) can be an adapting element and is expected to be predesigned and readily incorporated into the courtroom when needed. This option is consistent with the modification for employees based on the need of the employee expressed in Section 1103.2.3. This option does not apply to the raised public areas in courtrooms, namely, witness stands, jury boxes and galleries, which are required to be constructed accessible.

1108.4.1.5 Other work stations. The litigant's and counsel stations, including the lectern, shall be *accessible*.

❖ The well of the court typically contains the area for the litigant's and counselor's tables and a lectern for lawyers to address the judge and/or jury. Depending on the courtroom, this configuration may vary. The tables should be constructed appropriately for a front approach for work stations (see Figure 1108.4.1.5). The lectern can be adjustable so that it can work for lawyers seated in wheelchairs as well as those standing.

1108.4.2 Holding cells. Central holding cells and court-floor holding cells shall comply with Sections 1108.4.2.1 and 1108.4.2.2.

❖ If holding cells are provided, Sections 1108.4.2.1 and 1108.4.2.2 indicate which cells shall be accessible.

Figure 1108.4.1.5
COURTROOM WELL WORK STATIONS

1108.4.2.1 Central holding cells. Where separate central holding cells are provided for adult males, juvenile males, adult females or juvenile females, one of each type shall be *accessible*. Where central holding cells are provided and are not separated by age or sex, at least one *accessible* cell shall be provided.

❖ Some courthouse facilities have a central holding area for detainees that are in the courthouse for judicial proceedings. At least one central holding cell is required to be accessible. If separate holding cells are provided for males and females or to separate juvenile offenders from the adult offenders, at least one of each type is required to be accessible.

1108.4.2.2 Court-floor holding cells. Where separate court-floor holding cells are provided for adult males, juvenile males, adult females or juvenile females, each courtroom shall be served by one *accessible* cell of each type. Where court-floor holding cells are provided and are not separated by age or sex, courtrooms shall be served by at least one *accessible* cell. *Accessible* cells shall be permitted to serve more than one courtroom.

❖ Some courthouse facilities have a holding cell located in the area of the courtroom for detainees who are in the courthouse for judicial proceedings. For security reasons, these holding cells may be provided on each floor of the facility in order to have the detainees as close to the courtrooms they are to appear in as possible. At least one holding cell per floor is required to be accessible. One accessible holding cell could serve all the courtrooms on one floor. If separate holding cells are provided for males and females or to separate juvenile offenders from the adult offenders, at least one of each type is required to be accessible.

1108.4.3 Visiting areas. Visiting areas shall comply with Sections 1108.4.3.1 and 1108.4.3.2.

❖ Persons appearing in court proceedings may need to talk with their lawyer, social worker, parole officer, etc. Typically, these visitation areas include cubicles or counters in supervised areas.

1108.4.3.1 Cubicles and counters. At least 5 percent but no fewer than one of the cubicles shall be *accessible* on both the visitor and detainee sides. Where counters are provided, at least one shall be *accessible* on both the visitor and detainee sides.

Exception: This requirement shall not apply to the detainee side of cubicles or counters at noncontact visiting areas not serving *accessible* holding cells.

❖ If detainee/visitor counters or cubicles are provided, at least 5 percent must be accessible. Since it is not known if the person needing the accessible counter is on the visitor side or the detainee side, at least one counter location shall be accessible on both sides. In accordance with the exception, visiting areas that do not serve accessible holding cells would still require 5 percent of the counters or cubicles to be accessible on the visitor's side (see Figure 1108.4.3.1). This is consistent with the exception to certain areas of jails in accordance with Section 1103.2.14.

Figure 1108.4.3.1
EXAMPLE OF ACCESSIBLE
VISITOR CUBICLE IN A COURTHOUSE

1108.4.3.2 Partitions. Where solid partitions or security glazing separate visitors from detainees, at least one of each type of cubicle or counter partition shall be *accessible*.

❖ Section 1108.4.3.1 requires 5 percent of cubicles or counters in courthouse visiting areas to be accessible in accordance with the built-in counter/work surface requirements. This section deals with the visiting situ-

ation where solid partitions of security glazing separate visitors from detainees. To facilitate communication, the system may include some type of handset, headphones or microphone. The system must consider in its design that either user may use a wheelchair or have difficulty bending or stooping. Any type of telephone or headphone system must have a volume control.

SECTION 1109
OTHER FEATURES AND FACILITIES

1109.1 General. *Accessible* building features and facilities shall be provided in accordance with Sections 1109.2 through 1109.15.

Exception: *Accessible units*, *Type A units* and *Type B units* shall comply with Chapter 10 of ICC A117.1.

❖ This section clarifies that the provisions of Section 1109 are applicable in addition to all other requirements of Chapter 11. For example, although Section 1109.2 sets forth accessibility requirements for toilet rooms and bathing facilities within a store, it is not intended to mean that these are the only accessibility requirements that are applicable to stores. The building features and facilities covered by this section are required to be accessible to the extent set forth herein. The exception is a reminder that Accessible Type A and Type B dwelling and sleeping units should comply with Chapter 10 of ICC A117.1 within the individual dwelling units. Common and public areas associated with Group R-2 and R-3 occupancies should comply with Section 1109.

1109.2 Toilet and bathing facilities. Each toilet room and bathing room shall be *accessible*. Where a floor level is not required to be connected by an *accessible route*, the only toilet rooms or bathing rooms provided within the facility shall not be located on the inaccessible floor. At least one of each type of fixture, element, control or dispenser in each *accessible* toilet room and bathing room shall be *accessible*.

Exceptions:

1. In toilet rooms or bathing rooms accessed only through a private office, not for *common* or *public use* and intended for use by a single occupant, any of the following alternatives are allowed:
   1.1. Doors are permitted to swing into the clear floor space, provided the door swing can be reversed to meet the requirements in ICC A117.1;
   1.2. The height requirements for the water closet in ICC A117.1 are not applicable;
   1.3. Grab bars are not required to be installed in a toilet room, provided that reinforcement has been installed in the walls and located so as to permit the installation of such grab bars; and
   1.4. The requirement for height, knee and toe clearance shall not apply to a lavatory.
2. This section is not applicable to toilet and bathing rooms that serve *dwelling units* or *sleeping units* that are not required to be *accessible* by Section 1107.
3. Where multiple single-user toilet rooms or bathing rooms are clustered at a single location, at least 50 percent but not less than one room for each use at each cluster shall be *accessible*.
4. Where no more than one urinal is provided in a toilet room or bathing room, the urinal is not required to be *accessible*.
5. Toilet rooms that are part of critical care or intensive care patient sleeping rooms are not required to be *accessible*.
6. Where toilet facilities are primarily for children's use, required *accessible* water closets, toilet compartments and lavatories shall be permitted to comply with the children's provisions of ICC A117.1.

❖ This section generally requires toilet rooms and bathing rooms to be accessible. A person using a wheelchair must be able to approach and enter the room. Within the toilet room and/or bathing room, a minimum of one of each element or fixture provided is required to be accessible. Elements and fixtures include such things as water closets, lavatories, mirrors, towel dispensers, hand dryers and any other device that is installed and intended for use by the occupants of the room. Showers and bathtubs are both considered bathing fixtures, but not as different types of bathing fixtures. If a shower and a bathtub are both provided in the same bathing room, only one is required to be accessible. The designer or owner can choose which one. Requirements for the total number of bathing and toilet rooms are in Chapter 29 of the code [which is duplicated from Section 403 of the *International Plumbing Code*® (IPC®)]. Large assembly and mercantile occupancies must also include a family or assisted use toilet room in addition to their other toilet facilities (see commentary, Section 1109.2.1).

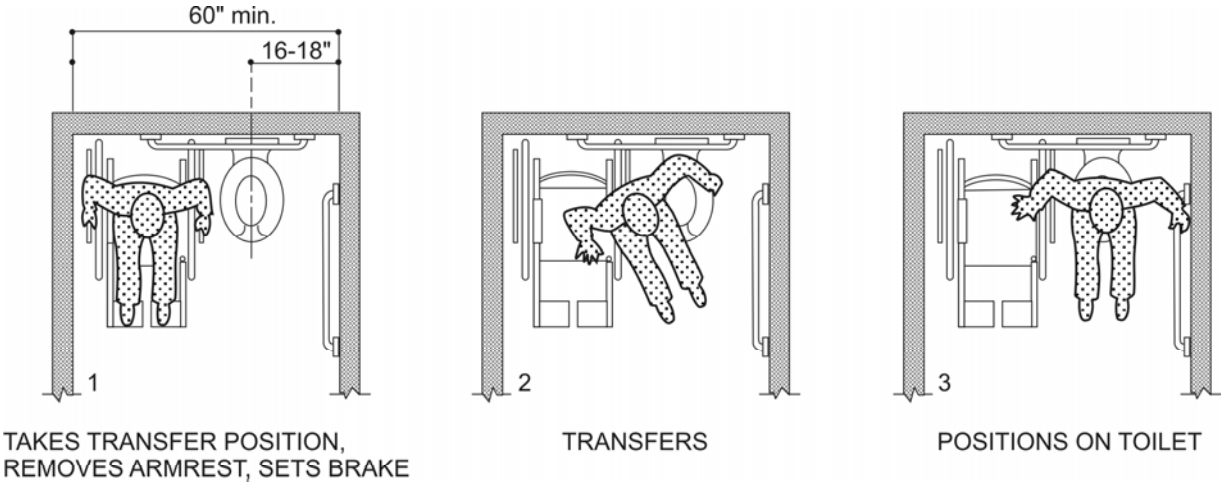
Provisions for accessible bathrooms are required even on levels that are not accessed by an accessible route. Many people benefit from the accessibility provisions in accessible bathrooms. For example, a person who is arthritic can use the grab bars to stand up and sit down, as well as finding the level handles on the lavatory easier to use. In addition, Title I of the ADA might require that level to be made accessible as part of an employee modification. If the bathroom is already accessible, it does not need to be modified, thus reducing the changes that need to be made to the building.

ICC A117.1 is the document referenced for all accessible toilet room requirements. The technical requirements in ICC A117.1 are based on allowing a

person in a wheelchair to perform a side transfer [see Figure 1109.2(1)]. Maintaining a clear floor space at each fixture is important [see Figure 1109.2(2) for possible configurations]. The single-occupant bathroom requirements in the 2010 Standard are now consistent with the provisions in ICC A117.1.

Exception 1 addresses a condition in which a toilet room or bathing room is permitted to be adaptable rather than fully accessible. The intent is that if a toilet room is part of an individual office and serves only the occupant of that office, the adaptable toilet room can be readily modified to be fully accessible based on that individual's needs. Preplanning during construction and design, such as installing blocking for grab bars and arranging plumbing fixtures to have adequate clear floor space, will facilitate future alterations.

Exception 2 is intended to correlate with the provisions of Section 1107, which establish the minimum number of facilities required to be Accessible, Type A or Type B units. Without this exception, the code would literally be requiring accessible fixtures in inaccessible dwelling and sleeping units. It is important to note that the bathrooms associated with required Accessible, Type A and Type B dwelling and sleeping units must comply with the requirements in Chapter 10 of ICC A117.1.



Exception 3 specifies that all toilet rooms that are clustered together need not be accessible. In such configurations, typically found in a doctor's office or drug test center, the requirement is reduced to a 50 percent minimum. If these toilet rooms are clustered in separate locations, such as in a multiclinic facility, the 50 percent minimum would be applied to each cluster. A single-occupant women's bathroom adjacent to a single-occupant men's bathroom is not considered a cluster since they each serve a different sex.

The IPC permits urinals to be substituted for water closets to a maximum of 67 percent in each toilet room (see Section 419.2 of the IPC). Exception 4 states that if only one urinal is provided within a toilet room, that urinal is not required to be accessible. This situation would typically only occur in toilet rooms with one water closet compartment.

While Exception 2 would exempt all the nonaccessible patient rooms in a hospital from accessible bathroom requirements, the intent of Exception 5 is also to exempt the Accessible units that may be provided within the critical-care or intensive-care units from requiring accessible bathrooms. In critical-care or intensive-care units the patients are often too ill to use the bathroom without assistance; therefore, assistance is offered and expected in these areas to all patients. In addition, critical-care and intensive-care rooms often must be designed to maximize free space for equipment and personnel in case of emergency care situations.

Exception 6 acknowledges the allowances in the ICC A117.1 for a toilet room and water closet compartment specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

1109.2.1 Family or assisted-use toilet and bathing rooms. In assembly and mercantile occupancies, an *accessible* family or assisted-use toilet room shall be provided where an aggregate of six or more male and female water closets is required. In buildings of mixed occupancy, only those water closets required for the assembly or mercantile occupancy shall be used to determine the family or assisted-use toilet room requirement. In recreational facilities where separate-sex bathing rooms are provided, an *accessible* family or assisted-

For SI: 1 inch = 25.4 mm.

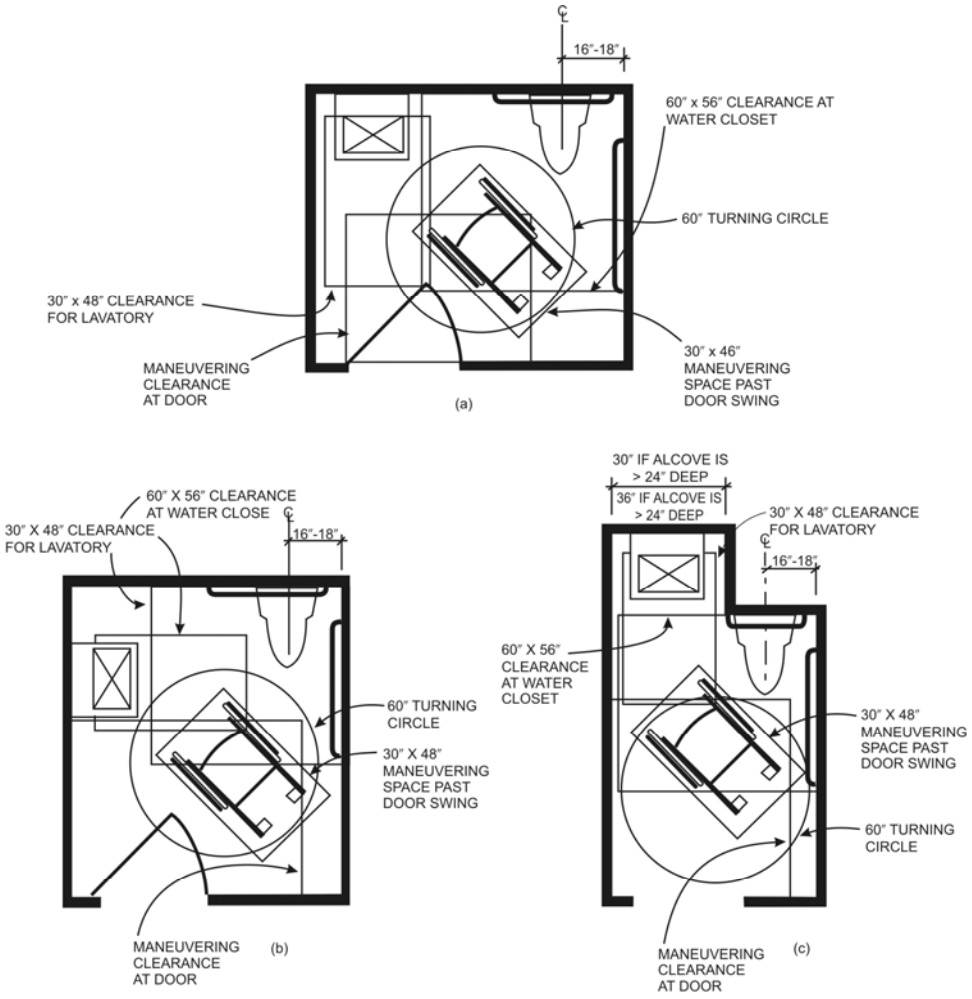


Figure 1109.2(1)
SIDE APPROACH WHEELCHAIR TRANSFER

use bathing room shall be provided. Fixtures located within family or assisted-use toilet and bathing rooms shall be included in determining the number of fixtures provided in an occupancy.

Exception: Where each separate-sex bathing room has only one shower or bathtub fixture, a family or assisted-use bathing room is not required.

❖ The requirements for family or assisted-use (referred to as "family" in the following commentary) toilet and bathing rooms were recommended for adoption into the codes by the BCMC, in conjunction with representatives of the Access Board. The primary issue relative to family toilet/bathing facilities is that some people with disabilities require assistance to utilize them. If that attendant is of the opposite sex, a toilet or bathing facility that can accommodate both persons is required. It is important to note that these provisions will typically not result in a substantial cost burden to the building owners, since the fixtures provided also count towards the minimum number required (see Section 2902.1.2 or Section 403.1.2 of the IPC).

The family or assisted-use bathing room requirements, although beneficial to all occupancies and building sizes, have been limited to those structures that typically have large transient occupant loads, namely assembly and mercantile. The section also identifies how mixed-occupancy buildings are to be addressed relative to the calculation. The fixtures provided in family toilet and bathing rooms count towards the number of required fixtures for the occupancy. The number of fixtures to be located in such rooms is limited, based on the premise that these rooms are securable (see commentary, Section 1109.2.1.2). The provision for bathing facilities is primarily geared towards recreational facilities. It is only required where the designer has chosen to provide separate-sex facilities for bathing and has provided more than one tub or shower for each sex. The exception acknowledges that smaller bathing rooms such as those described can be utilized by a disabled

For SI: 1 inch = 25.4 mm.

Figure 1109.2(2)
EXAMPLES OF TOILET ROOM PLANS WITH OVERLAP

person with assistance without much hardship to a nondisabled person.

Many facilities have been installing family bathrooms as part of their standard bathroom layouts prior to the code requirement, viewing them as "customer friendly." For example, a person requiring assistance can also be a small child or an elderly adult. A parent shopping or attending an event with a child of the opposite sex can utilize this facility as well as an adult who may need assistance from a spouse.

Note that the requirement for family bathrooms does not exempt separate-sex bathrooms from providing accessible or ambulatory stalls. For a discussion of family bathrooms in existing buildings, see Section 3411.8.11.

1109.2.1.1 Standard. Family or assisted-use toilet and bathing rooms shall comply with Sections 1109.2.1.2 through 1109.2.1.7.

❖ The facilities are required to comply with the accessible technical provisions for toilet rooms in ICC A117.1 as well as the additional criteria established in the following subsections. In smaller tenant spaces, the IPC now permits two family or assisted-use toilet rooms in place of two single-occupant separate-sex bathrooms (Section 2902.2.2 and Section 403.2.1 of the IPC).

1109.2.1.2 Family or assisted-use toilet rooms. Family or assisted-use toilet rooms shall include only one water closet and only one lavatory. A family or assisted-use bathing room in accordance with Section 1109.2.1.3 shall be considered a family or assisted-use toilet room.

Exception: A urinal is permitted to be provided in addition to the water closet in a family or assisted-use toilet room.

❖ A family toilet room must include a lavatory and a water closet. The exception permits a urinal to also be installed in the family toilet room if desired. If a family bathing room is provided within a facility, it can serve as the required family toilet room.

1109.2.1.3 Family or assisted-use bathing rooms. Family or assisted-use bathing rooms shall include only one shower or bathtub fixture. Family or assisted-use bathing rooms shall also include one water closet and one lavatory. Where storage facilities are provided for separate-sex bathing rooms, *accessible* storage facilities shall be provided for family or assisted-use bathing rooms.

❖ A family bathing facility is required to have one shower or tub, one water closet and one lavatory. The shower can be a transfer type, a roll-in type or a combination of the two. Accessible storage facilities, such as lockers, are also required if storage facilities are provided in the separate-sex bathing facilities. A family bathing room can also serve a dual purpose (bathing and toilet) as the required family toilet room (see commentary, Section 1109.2.1.2).

1109.2.1.4 Location. Family or assisted-use toilet and bathing rooms shall be located on an *accessible route*. Family or assisted-use toilet rooms shall be located not more than one *story* above or below separate-sex toilet rooms. The *accessible route* from any separate-sex toilet room to a family or assisted-use toilet room shall not exceed 500 feet (152 m).

❖ A one-story, 500-foot (1524 mm) limitation for access to customer toilet facilities is currently in Section 2902.3.2 (which is duplicated from Section 403.3.3 of the IPC). The distance to the customer toilet facilities is measured from the main entrance of a store or space to the toilet facility. The distance in this section is measured from the separate-sex facility to the family facility. The general travel distance requirement, in combination with this section, could result in a total travel distance for a family toilet room of two stories or 1,000 feet (3048 mm) maximum. The travel distance limitation is why there is more than one family bathroom in large facilities. An accessible route is required to provide access to the family facilities. Signage is required at both the separate-sex and family facilities in accordance with Sections 1110.1 and 1110.2.

1109.2.1.5 Prohibited location. In passenger transportation facilities and airports, the *accessible route* from separate-sex toilet rooms to a family or assisted-use toilet room shall not pass through security checkpoints.

❖ Security checkpoints in airports and similar facilities represent a potential delay, which may cause missed flights or connections. Due to security concerns, more and more facilities are adding security checkpoints. For example, many large sports facilities, courthouses and government buildings have checkpoints where the public move into certain portions of the facilities. While not required, due to the delay in moving through a security system, a designer might want to follow this same guidance for location of the family bathrooms in other types of facilities.

1109.2.1.6 Clear floor space. Where doors swing into a family or assisted-use toilet or bathing room, a clear floor space not less than 30 inches by 48 inches (762 mm by 1219 mm) shall be provided, within the room, beyond the area of the door swing.

❖ The clear floor space provisions are intended to provide a room that is large enough to allow a person in a wheelchair to enter and close the door before utilizing the fixtures. This requirement is also in ICC A117.1 [see Figure 1109.2(2)].

1109.2.1.7 Privacy. Doors to family or assisted-use toilet and bathing rooms shall be securable from within the room.

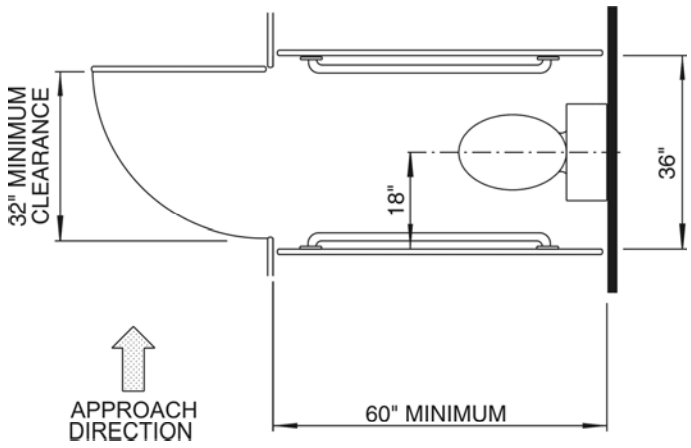
❖ Since privacy while utilizing bathing and toilet facilities is an issue, the door to the facility must be securable from the inside. The securing mechanism must be within reach and not require any tight pinching, grasping or sharp turning of the wrist to operate.

While it is not prohibited to lock bathrooms, this bathroom should be as easily accessed as the separate men's and women's bathroom. A person who needed this facility should not have to find someone with a key for the family bathroom if the men's and

women's bathrooms are readily available. This bathroom does count towards the required fixture count (see Section 2902.1.2) and as such must be available.

1109.2.2 Water closet compartment. Where water closet compartments are provided in a toilet room or bathing room, at least one wheelchair-accessible compartment shall be provided. Where the combined total water closet compartments and urinals provided in a toilet room or bathing room is six or more, at least one ambulatory-accessible water closet compartment shall be provided in addition to the wheelchair-accessible compartment.

❖ There are different configurations of water closet compartments that facilitate different degrees of physical disability. The provisions of ICC A117.1 establish the configuration and dimensional requirements for various types of water closet compartments. A wheelchair-accessible compartment is one in which sufficient space is provided for the wheelchair to enter completely the water closet compartment [see Figures 1109.2.2(2) and 1109.2.2(3)]. The wheelchair user then transfers from the wheelchair to the water closet in order to utilize the fixture. It is important that the required clear floor space be maintained. The configuration did not intend for a lavatory to be provided within the minimum-sized compartment. If a lavatory is located within a compartment, it must meet the same provisions as a single-occupant toilet room.

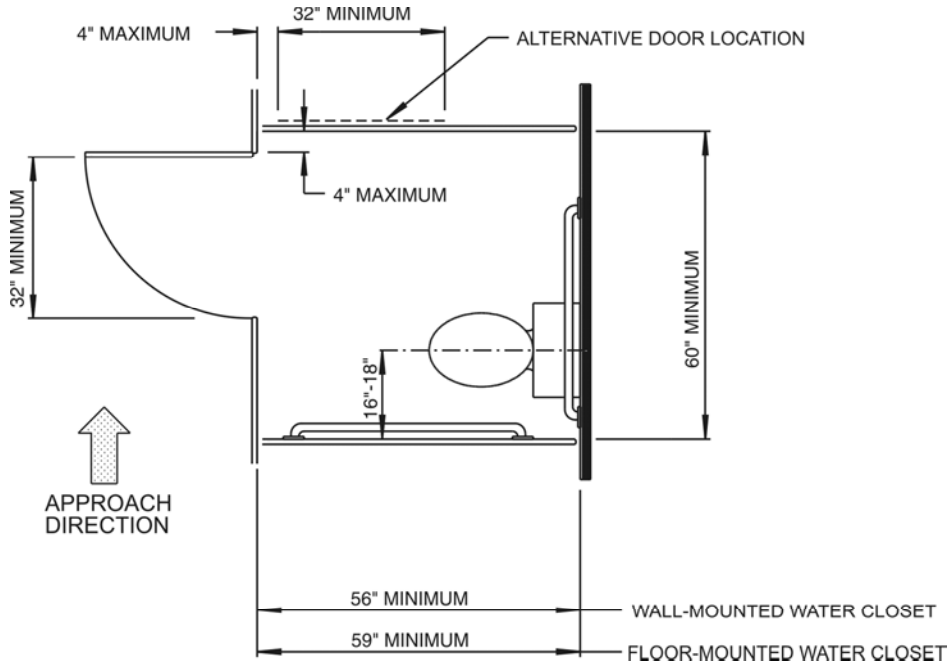


An ambulatory-accessible compartment is intended to facilitate use by a person with a mobility impairment that necessitates the use of a walking aid, such as a cane or walker [see Figure 1109.2.2(1)]. An ambulatory-accessible water closet compartment is not intended to be utilized by a person in a wheelchair. The 36-inch (914 mm) width is intended to allow standing persons to support themselves utilizing the grab bars on both sides. A wider compartment would not allow adequate bearing. Since these provisions are intended to address, within reason, the needs of both ranges of mobility impairment, this section requires a wheelchair-accessible compartment in all cases. In larger toilet rooms (i.e., those with a total of six or more water closet compartments and urinals), one ambulatory-accessible compartment is required in addition to the wheelchair-accessible compartment.

This section is not intended to increase the required number of fixtures beyond that required by the IPC. For example, if a toilet room contains 10 water closets, eight water closet compartments may be of conventional design, one water closet compartment must be wheelchair accessible and one must be ambulatory accessible.

1109.2.3 Lavatories. Where lavatories are provided, at least 5 percent, but not less than one, shall be accessible. Where the total lavatories provided in a toilet room or bathing facility is six or more, at least one lavatory with enhanced reach ranges shall be provided.

❖ A lavatory is a type of sink for which the primary purpose is hand washing. This section provides scoping requirements for lavatories located in spaces not specifically addressed or exempted by Section 1109.2. If a lavatory is provided in toilet and bathing rooms specifically exempted by Section 1109.2, it is not required to be accessible. Lavatories are not as commonly part of an employee work station as sinks are, however, if they are they are exempted under Section 1103.2.3. An example of a lavatory that was part of an employee's work area would be the lavatories found in the exam rooms. The lavatories are there for the nurses and doctors to wash their hands before examining a patient.



When lavatories are provided in other areas, a minimum of 5 percent, but not less than one, is required to be accessible via a front approach with appropriate knee and toe clearances.

For SI: 1 inch = 25.4 mm.

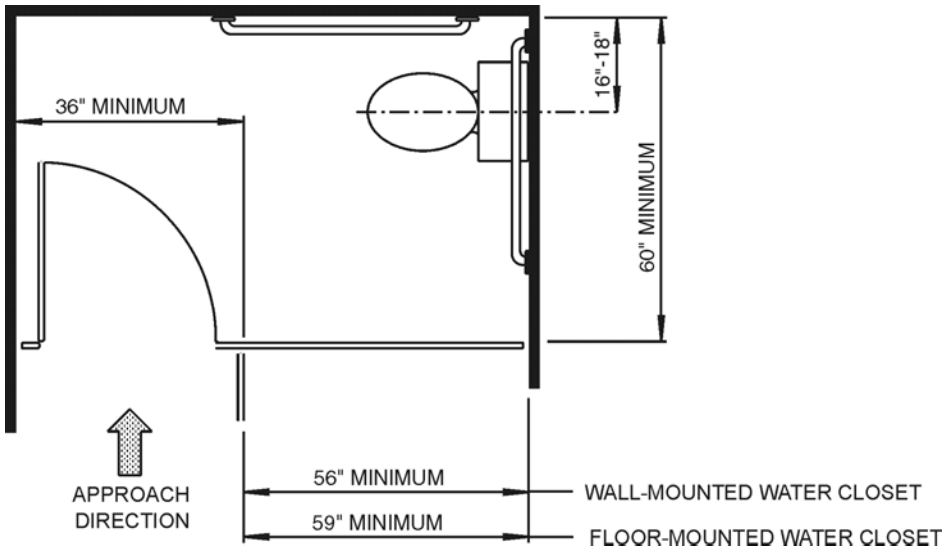


Figure 1109.2.2(1)
AMBULATORY-ACCESSIBLE COMPARTMENT

In large facilities, where the designer has located six or more lavatories within one toilet facility (similar to the ambulatory stall), one of the lavatories must also be provided with enhanced reach range for the faucet controls in accordance with Section 606.5 of ICC A117.1. This would require the faucets to be located on the side of the lavatory, or provide access to the side of one of the lavatories, or to have automatic controls. This is to address the needs of persons who may have a limited reach over the lavatory where they may have difficulty reaching the controls. The lavatory with enhanced reach range could be the

For SI: 1 inch = 25.4 mm.

Figure 1109.2.2(2)
WHEELCHAIR-ACCESSIBLE COMPARTMENT; OUT-SWINGING DOOR

For SI: 1 inch = 25.4 mm.

Figure 1109.2.2(3)
WHEELCHAIR-ACCESSIBLE COMPARTMENT; IN-SWINGING DOOR

same lavatory as the accessible lavatory, or it could be another lavatory.

There are allowances in ICC A117.1 for lavatories specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

1109.3 Sinks. Where sinks are provided, at least 5 percent but not less than one provided in *accessible* spaces shall be *accessible*.

Exception: Mop or service sinks are not required to be *accessible*.

❖ A sink may have numerous functions, unlike a lavatory which is primarily provided for hand washing. Sinks in kitchens, kitchenettes and classrooms are examples that may have scoping and accessibility requirements different than those for lavatories. When sinks are provided, a minimum of 5 percent, but not less than one, is required to be accessible via a front approach with knee and toe clearances. There is a specific exception here for mop or service-type sinks. Service sinks include a wide variety of specialized sinks manufactured for multiple or specific functions. Service sinks are sized and positioned for their function which usually renders them incapable of being accessible. Also, when a sink is part of an individual work station, that sink is not required to be accessible in accordance with Section 1103.2.3.

A forward approach to sinks, as required for a lavatory within a toilet room, is not always required (see commentary, Section 1109.4).

There are allowances in A117.1 for sinks specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

1109.4 Kitchens and kitchenettes. Where kitchens and kitchenettes are provided in *accessible* spaces or rooms, they shall be *accessible*.

❖ Kitchens, kitchenettes and wet bars in accessible spaces, other than within Type A and Type B dwelling units, must be accessible. An accessible kitchen would include clear floor spaces at all appliances, a sink with a front approach and a work surface with a front approach (see Section 804 of ICC A117.1 for specific details). Kitchenettes (where a cooktop or conventional range is not provided) allow a side approach to the sink (Section 606 of ICC A117.1) and do not require an accessible work surface. A common mistake is to forget that the sink must be set at a maximum height of 34 inches (864 mm) to allow for reach to the faucets (see Figure 1109.4).

1109.5 Drinking fountains. Where drinking fountains are provided on an exterior site, on a floor or within a secured area, the drinking fountains shall be provided in accordance with Sections 1109.5.1 and 1109.5.2.

❖ This section establishes a reasonable threshold for the required number of accessible drinking fountains. It should be noted that this section does not require the installation of drinking fountains where none are required or provided. Chapter 29 (which is duplicated from Section 403 of the IPC) contains criteria indicating the number of drinking fountains that are required based on occupancy. There are spaces that are not required to have drinking fountains. Examples are spaces with fewer than 15 occupants and spaces that serve water, like a restaurant.

Current requirements for plumbing fixtures (see Table 2902 and Table 403 of the IPC) stipulate only one drinking fountain per number of occupants for many facilities or tenant spaces. Through Note e, the provisions in Section 1109.5.1 and Section 410.2 of the IPC stipulate a minimum of two drinking fountains for these facilities and spaces in order to meet the high/low criteria. Additionally, the plumbing requirements would allow for 50 percent of the drinking fountains to be substituted with bottled water coolers (see Section 410.3 of the IPC). While the provisions in Sections 1109.5.1 and 1109.5.2 and Section 410.2 of the IPC would not prohibit the substitution, the requirement for two drinking fountains would effectively negate this substitution unless there were at least three drinking fountains required for a floor.

The IPC now includes provisions for travel distance to a drinking fountain (see Section 403.5 of the IPC), which is 500 feet (152 400 mm) and one-story maximum travel. In malls, the travel is reduced to 300 feet (91 440 mm).

1109.5.1 Minimum number. No fewer than two drinking fountains shall be provided. One drinking fountain shall comply with the requirements for people who use a wheelchair and one drinking fountain shall comply with the requirements for standing persons.

Exceptions:

1. A single drinking fountain that complies with the requirements for people who use a wheelchair and

Figure 1109.4
EXAMPLE OF KITCHENETTE

standing persons shall be permitted to be substituted for two separate drinking fountains.

2. Where drinking fountains are primarily for children's use, drinking fountains for people using wheelchairs shall be permitted to comply with the children's provisions in ICC A117.1 and drinking fountains for standing children shall be permitted to provide the spout at 30 inches (762 mm) minimum above the floor.

❖ Where a single drinking fountain is provided, this section mandates a minimum of two fixtures be provided: one for seated persons and one for standing persons. The seated and standing drinking fountains that serve a facility need not be provided at the same location in the facility. The exception allows the use of a single fixture that accommodates both seated and standing persons. Technical criteria for both wheelchair accessible fountains and standing person fountains are located in Section 602 of ICC A117.1 (see Figure 1109.5.1). The drinking fountains must be located so that they are not protruding objects (see Section 1003.3).

Exception 1 allows for a single drinking fountain to meet the requirements for both high and low heights; however, at this time, drinking fountains that can meet the two spout heights are very limited.

Exception 2 allows for both the high and low drinking fountains to be designed for children. There are technical criteria in A117.1 for wheelchair drinking fountains specifically designed for children who are age 12 and younger. This may be appropriate for facilities such as day care facilities and certain areas of elementary schools.

Figure 1109.5.1
EXAMPLE OF DRINKING FOUNTAINS FOR PERSONS USING WHEELCHAIR AND STANDING PERSONS

1109.5.2 More than the minimum number. Where more than the minimum number of drinking fountains specified in Section 1109.5.1 are provided, 50 percent of the total number of drinking fountains provided shall comply with the requirements for persons who use a wheelchair and 50 percent of the total number of drinking fountains provided shall comply with the requirements for standing persons.

Exceptions:

1. Where 50 percent of the drinking fountains yields a fraction, 50 percent shall be permitted to be rounded up or down, provided that the total number of drinking fountains complying with this section equals 100 percent of the drinking fountains.
2. Where drinking fountains are primarily for children's use, drinking fountains for people using wheelchairs shall be permitted to comply with the children's provisions in ICC A117.1 and drinking fountains for standing children shall be permitted to provide the spout at 30 inches (762 mm) minimum above the floor.

❖ When an even number of drinking fountains is provided, half must accommodate seated persons and half must accommodate standing persons. Exception 1 addresses when an odd number of drinking fountains is provided.

An example:

- Two drinking fountains are required by Section 1109.5.1 and Section 410.2 of the IPC.
- Seven drinking fountains are provided.
- Fifty percent of seven is three and one-half.
- Rounding up yields four; rounding down yields three.
- Therefore, there are two choices:
  - Provide four sitting and three standing fountains; or
  - Provide three sitting and four standing fountains.
- Both choices comply since the complying fixtures total 100 percent.

This logic applies whenever an odd number of three or more drinking fountains is provided, regardless of the total quantity. This is based on the number provided—not the number required. In accordance with Section 410.3 of the IPC, a designer/owner could switch out some of the required drinking fountains for bottled water.

Exception 2 is consistent with the same exception in Section 1109.5.2, allowing for both standing and seating drinking fountains to be designed for children. There are technical criteria in ICC A117.1 for wheelchair drinking fountains specifically designed for children who are age 12 and younger. This may be appropriate for day care facilities and certain areas of elementary schools.

1109.6 Saunas and steam rooms. Where provided, saunas and steam rooms shall be *accessible*.

Exception: Where saunas or steam rooms are clustered at a single location, at least 5 percent of the saunas and steam rooms, but not less than one, of each type in each cluster shall be *accessible*.

❖ The 2009 edition of the ICC A117.1 standard has included technical requirements for saunas and steam rooms. The scoping in the IBC is consistent with bathrooms and coordinates with the 2010 Standard. What constitutes a "cluster" is subjective; however, typically the rooms would have to have the entrances immediately adjacent or across the hall from one another to be considered "clustered."

The requirements within the standard provide for entering the room, closing the door and then transfering to the bench in the room. Removing the wheelchair from the space is not addressed, so perhaps a special chair might be utilized. Section 914 of the *International Mechanical Code*® (IMC®) addresses safety requirements for sauna rooms.

1109.7 Elevators. Passenger elevators on an *accessible route* shall be *accessible* and comply with Chapter 30.

❖ This section requires all passenger elevators on an accessible route to be accessible. The reference to Chapter 30 requires all passenger elevators to conform to general elevator safety standards as well as accessibility standards. It is not the intent of this section to prohibit service elevators, LULA elevators, private residence elevators or platform lifts (as permitted by Section 1109.7). Service, LULA and private residence elevators are recognized as types of passenger lifts by ASME A17.1/CSA B44.

Elevators are defined in ASME A17.1 as "a hoisting and lowering mechanism, equipped with a car, that moves within guides and serves two or more landings …" The limitations of use for the different types of elevators are controlled by the standard.

ASME limits the occupants in "freight elevators" to just the operator and the people needed to load and unload the freight. Also "construction elevators" are limited to construction purposes only. Only passenger-type elevators can serve as part of an accessible route; therefore, freight and construction types of elevators are not required to be accessible.

The term "service elevator" is not defined in ASME A17.1. This is a slang term used by building owners to separate the "back of the house" passenger elevator used by staff (and typically designed to accommodate a heavier load) from the passenger elevators used by the general public for circulation. As part of an accessible route to employee work areas, a service elevator is required to be accessible.

LULA elevators have a maximum vertical travel distance of 25 feet (7620 mm). Private residence elevators are limited to within or serving individual dwelling units.

It should also be noted that unlike plumbing fixtures, this section does not establish that a certain number of passenger elevators are required to be accessible while other passenger elevators may be of a design that is not fully accessible. All passenger elevators that are on an accessible route are required to be accessible. If a bank of passenger elevators is provided as part of an accessible route, all elevators in that bank must be accessible. See Section 3411.8.2 for existing elevators being altered.

The reference to an accessible route (see Sections 1104.3.1, 1004.4 and 1109.6) is important because some areas in certain buildings may not be required to be accessible (see Sections 1103.2 and 1104.4). For example, since an elevator penthouse is not required to be accessible (see Section 1103.2.9), the passenger elevator is not required to serve that level. Keep in mind that the penthouse must be accessed by a stairway (see Section 1009.17). In addition, certain types of elevators (e.g., freight elevators) may not be part of an accessible route.

Note that there are additional requirements for elevators depending on the building height:

- In buildings four stories and higher, at least one elevator must be sized in order to accommodate stretchers (see Section 3002.4).
- In buildings five stories and higher, an elevator must be available for serving as part of an accessible means of egress (see Section 1007.2.1).
- Buildings 120 feet (36 576 mm) or taller shall have fire service access elevators (see Sections 403 and 3007).
- Occupant evacuation elevators are also an option (see Section 3008).

1109.8 Lifts. Platform (wheelchair) lifts are permitted to be a part of a required *accessible route* in new construction where indicated in Items 1 through 10. Platform (wheelchair) lifts shall be installed in accordance with ASME A18.1.

1. An *accessible route* to a performing area and speaker platforms in Group A occupancies.
2. An *accessible route* to *wheelchair spaces* required to comply with the *wheelchair space* dispersion requirements of Sections 1108.2.2 through 1108.2.6.
3. An *accessible route* to spaces that are not open to the general public with an *occupant load* of not more than five.
4. An *accessible route* within a *dwelling* or *sleeping unit*.
5. An *accessible route* to wheelchair seating spaces located in outdoor dining terraces in Group A-5 occupancies where the *means of egress* from the dining terraces to a *public way* are open to the outdoors.
6. An *accessible route* to jury boxes and witness stands; raised courtroom stations including judges' benches,

clerks' stations, bailiffs' stations, deputy clerks' stations and court reporters' stations; and to depressed areas such as the well of the court.

7. An *accessible route* to load and unload areas serving amusement rides.
8. An *accessible route* to play components or soft contained play structures.
9. An *accessible route* to team or player seating areas serving areas of sport activity.
10. An *accessible route* where existing exterior *site* constraints make use of a ramp or elevator infeasible.

❖ This section indicates that platform (wheelchair) lifts are only permitted to be part of a required accessible route in new construction in limited situations. If a platform lift is permitted as part of the accessible route into a space, it can also serve as part of the accessible route used for means of egress out of the space (with the exception of Item 10) if it has standby power (see Section 1007.5). There are concerns about the potential for a large number of people needing to exit the building under the allowances for Item 10; therefore, an accessible means of egress must be via another route. Platform lifts may be used more extensively in existing construction (see Section 3411.8.3). This is in recognition that circumstances in existing buildings may make it impractical to accomplish accessibility by use of an elevator, in which case a platform lift is a reasonable alternative. Accessible means of egress is not required in existing buildings undergoing alterations (see Section 1007.1, Exception 1 or Section 3411.6, Exception 2); therefore, a platform lift as part of the accessible means of egress in these situations is not an issue.

A previous edition of the technical standard (i.e., ASME A17.1-1996) required key operation to platform lifts, which unnecessarily inhibited independent access by persons with physical disabilities. The requirements for platform lifts have been removed from the elevator standard and now have their own standard, ASME A18.1, *Safety Standard for Platform Lifts and Stairway Chairlifts*. This newer standard allows push-button operation of platform lifts, thus making independent access much easier.

The listed items indicate when a platform lift can be utilized as part of a required accessible route in new construction. Items 1 and 2 allow platform lifts to be utilized for access to performing (i.e., stages, orchestra pits) and viewing areas (i.e., wheelchair spaces in stepped seating areas) in assembly occupancies. Item 3 specifies that a platform lift may be used to provide access to a nonpublic area with five or less occupants, such as a projection booth. Item 4 allows for a platform lift within an individual dwelling or sleeping unit. Item 5 is intended to address an outdoor dining area in Group A-5, such as a picnic terrace in a baseball park.

Item 6 permits platform lifts to provide access to the raised or lowered areas typically found in courtroom settings. This is consistent with Section 1108.4.

Item 7 allows platform lifts for access to loading and unloading areas serving amusement rides. It does not attempt to address access to any other element of a ride. There are provisions for amusement rides in Chapter 11 of the 2009 ICC A117.1.

Item 8 identifies children's play spaces, the entry to which may be raised or depressed, as an appropriate place for a platform lift. Such spaces are often associated with restaurants, shopping malls and preschools. There are provisions for children's play areas in Chapter 11 of the 2009 ICC A117.1.

Item 9 acknowledges that team or player seating may be a small depressed area (ie., dugout) capable of being efficiently served by a wheelchair lift.

Item 10 recognizes that existing site constraints may make installation of a ramp or elevator infeasible. An example would be the situation of dealing with existing public sidewalks, easements and public ways in downtown urban areas. This situation would be most common in hilly areas where the street and sidewalk follows grade and the building's floor is level, resulting in steps up or down at entrances.

Note that a platform lift that was not part of the required accessible route could be used to facilitate access to any space. The governing factor in those situations would be the limitations of the product itself for capacity and travel distance. Item 4 permits platform lifts to be utilized within individual dwelling or sleeping units as part of a required accessible route. Single-family homes are not required to be accessible; however, persons with mobility impairments may choose to install stairway chairlifts in their private homes. Section 1009.1, Exception 4, specifies a minimum stairway width for platform lifts or chair lifts provided within dwelling units.

A platform lift is an electrically operated, mechanical device designed to transport a person who cannot use stairs over a short vertical distance. Platform lifts must be sized to accommodate a wheelchair user. Platform lifts can be used by wheelchair users and persons with limited mobility and are sometimes equipped with folding seats. A fold-down seat that moves up the stairway is not a platform lift, but rather a chair lift. A stairway chair lift is not suitable for a person using a wheelchair and cannot serve as part of a required accessible route. A platform lift is most suitable for changes of elevation of one story or less where the installation of a ramp is not feasible [see Figures 1109.7(1) and 1109.7(2)].

While new technologies are expanding current options, there are two basic types of platform lifts: vertical lifts and inclined lifts. Vertical lifts are similar to elevators in that they travel only up and down in a fixed vertical space. Inclined platform lifts are usually installed in conjunction with a stairway and travel

along the slope of the stairway. Inclined lifts are a design consideration for long flights of stairs where a vertical platform lift is not practical, where headroom is limited or where ceilings are low.

(Figure courtesy of Wheel-evator)

1109.9 Storage. Where fixed or built-in storage elements such as cabinets, coat hooks, shelves, medicine cabinets, lockers, closets and drawers are provided in required *accessible* spaces, at least 5 percent, but not less than one of each type shall be *accessible*.

❖ Fixed or built-in storage elements are common in many occupancies, including both residential and many nonresidential occupancies, such as office buildings, recreational facilities, etc. Examples would include mailboxes, coat closets, storage closets, lockers, etc. The code does not require storage facilities, but when such facilities are provided, this section requires at least 5 percent, but not less than one, of each type to contain storage space in accordance with ICC A117.1. This could be a portion of shelving or coat rods, a number of lockers, etc. Requirements would include a wheelchair space in front of the element, operable parts (if applicable) and elements within the 15- to 48-inch (381 to 1219 mm) reach ranges. Storage within kitchens and kitchenettes is more specifically addressed in Section 804 of ICC A117.1. Storage elements within Accessible, Type A and Type B units are specifically addressed under Chapter 10 of ICC A117.1.

1109.9.1 Equity. *Accessible* facilities and spaces shall be provided with the same storage elements as provided in the similar nonaccessible facilities and spaces.

❖ This section is really about the issue of equal access to amenities. This requirement is consistent with the requirements for family or assisted-use bathrooms to have the same lockers, hand dryers, baby-changing stations, etc., as provided in the men's and women's bathrooms. For example, hotel rooms commonly provide closets and dressers for guests. These same storage facilities must also be available in the Accessible sleeping units. They cannot be eliminated as an

Figure 1109.8.1(1)
EXAMPLE OF LOCKER AREA

option to providing an accessible route or turning space within the Accessible unit. For hotel rooms, ICC A117.1 has a requirement for providing equal bathroom counter space in similar Accessible and nonaccessible guestrooms.

Figure 1109.8.1(2)
EXAMPLE OF LOCKER ROOM

1109.9.2 Shelving and display units. Self-service shelves and display units shall be located on an *accessible route*. Such shelving and display units shall not be required to comply with reach-range provisions.

❖ The intent of this section is that persons who utilize wheelchairs can see items on shelves in stores and libraries, but someone may be required to assist them in reaching the items. Putting all items within the 15- to 48-inch (381 to 1219 mm) reach range would adversely affect the space allowed for products or information.

1109.10 Detectable warnings. Passenger transit platform edges bordering a drop-off and not protected by platform screens or *guards* shall have a *detectable warning*.

Exception: *Detectable warnings* are not required at bus stops.

❖ A detectable warning is a standardized feature built in or applied to walking surfaces to warn a visually impaired person of a hazard on or near his or her path of travel that may otherwise go unnoticed and could result in injury to that person. A typical example of the need for a detectable warning is at any walking surface where a significant drop-off occurs that, if unnoticed, has the potential to cause injury should a person fall.

This section requires a detectable warning at the edges of passenger transit platforms where they border a drop-off. For example, loading platforms in both light- and heavy-rail transit stations where passengers await the arrival of trains are a serious potential hazard to a person with a vision impairment when there is no train at the station. There have been incidents where people with severe vision impairments have fallen off the transit platform and been killed or seriously injured. The presence of a detectable warning at the platform edge where it borders the drop-off would be encountered and recognized by a person with a vision impairment either through detection by a long cane or by foot contact with the detectable warning surface.

The exception for bus stops is established so as not to require a detectable warning at the curb between a sidewalk and the street. Detectable warnings at curbs are contradictory to the envisioned application of detectable warnings in the built environment. The curb itself is a recognizable and well-known cue to people with vision impairments to proceed with caution.

There is a great deal of controversy and general disagreement as to the benefit or advisability of detectable warning surfaces throughout the built environment. The use of such warnings at transit stations is, to date, the only well documented use of detectable warnings, as discussed in studies such as "Tactile Warnings to Promote Safety in the Vicinity of Transit Platform Edges," conducted by the Urban Mass Transportation Administration, and "Pathfinder Tactile Tile Demonstration Test Project," conducted by the Metro-Dade Transit Agency. The Access Board will be looking into this issue as part of the development of the *Public Rights-of-Way Guidelines*.

ICC A117.1 prescribes the type of surface that constitutes a detectable warning in Section 705. One option for the detectable warning surface that is currently considered suitable consists of raised, truncated domes with a diameter between 0.9 inches (23 mm) and 1.4 inches (36 mm), a height of approximately 0.2 inch (5.1 mm) and center-to-center spacing of between 1.6 (41 mm) and 2.4 inches (61 mm). However, there is current and ongoing research into the use and application of truncated domes as a suitable detectable warning surface for various applications, including interior and exterior locations. ICC A117.1 requires that the type of detectable warning surface utilized must be standard throughout a building, facility, site or complex of buildings. If different types of detectable warning surfaces are utilized, their usefulness is diminished. The different messages they would convey to a person with a vision impairment would not be consistent and may be confusing and easily misinterpreted.

It is anticipated that future applications of detectable warnings will be considered when additional

research and documentation of their usefulness and suitability is available. One issue, among many, is the durability of a detectable warning surface in an exterior application and the potential difficulty that truncated domes may present to a person in a wheelchair, as well as to nondisabled persons who may have to negotiate the surface.

1109.11 Seating at tables, counters and work surfaces. Where seating or standing space at fixed or built-in tables, counters or work surfaces is provided in *accessible* spaces, at least 5 percent of the seating and standing spaces, but not less than one, shall be *accessible*. In Group I-3 occupancy visiting areas at least 5 percent, but not less than one, cubicle or counter shall be *accessible* on both the visitor and detainee sides.

Exceptions:

1. Check-writing surfaces at check-out aisles not required to comply with Section 1109.11.2 are not required to be *accessible*.
2. In Group I-3 occupancies, the counter or cubicle on the detainee side is not required to be *accessible* at noncontact visiting areas or in areas not serving *accessible* holding cells or *sleeping unit*s.

❖ Many occupancies, such as libraries, classrooms, restaurants and other public spaces, are equipped with fixed seating, tables or both (see Figure 1109.11). Correctional facilities often have cubicles or counters that are set up for visiting sessions between detainees and their lawyers or visitors. This section requires that at least 5 percent, but not less than one, be accessible. The threshold of 5 percent is consistent with the requirement for accessible seating in dining areas as specified in Section 1108.2.9.1. Fixed or built-in seating that is part of an individual work station is not required to be accessible (see Section 1103.2.3). These accessible table and work surfaces are expected to include adequate knee and toe clearances as specified in ICC A117.1. For requirements for points of sales or service that do not include a work station, see Section 1109.12.3. For example, the check-writing station in the center of the bank lobby is considered a work station; however, the teller window is typically considered a service counter. The accessible check-writing station would require knee and toe clearances, while the accessible teller window would not.

Figure 1109.11
EXAMPLE OF ACCESSIBLE WORK STATION

Note that the requirement addresses built-in counters, tables or work stations for standing or seating. Built-in surfaces where persons are typically standing are most often installed at a height of 36 to 48 inches (914 to 1219 mm). Depending on the overall configuration of the counters in the space, a portion of the counter for standing persons may need to be lowered to an accessible height of 28 to 34 inches (711 to 864 mm) and configured for forward approach.

The intent of Exception 1 is that if a check-writing surface is provided at a nonaccessible checkout aisle, this surface is not required to meet the counter and work surface requirements in ICC A117.1 (see Section 1109.12.2).

Exception 2 is consistent with the Group I-3 exception found in Section 1103.2.14. If Accessible units are not required by Section 1107.5.5, accessible elements are not required on the detainee side of the cubicles. Since the detainees may have a disabled person visiting them on the public side, at least 5 percent of the stations must be accessible.

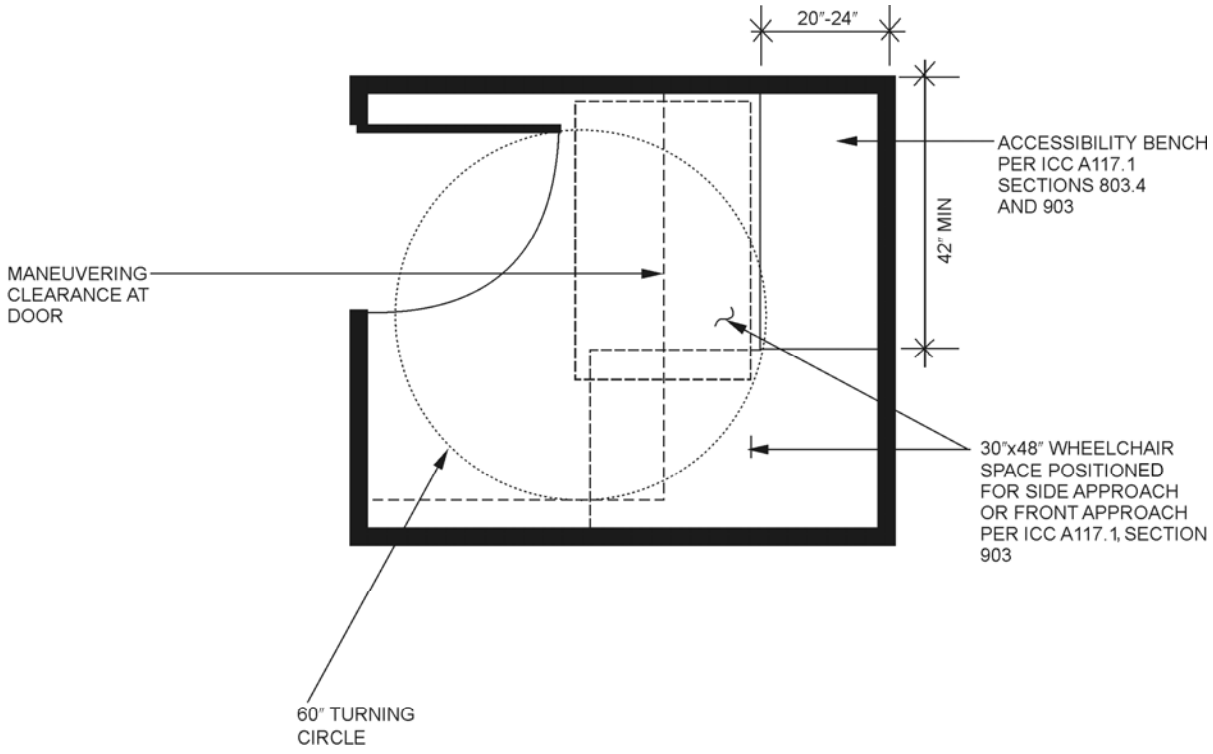
There are allowances in ICC A117.1 for work surfaces specifically designed for children's use. This may be appropriate in facilities such as day care facilities and certain areas of elementary schools, or areas frequented mostly by children, such as children's museums or the children's areas in libraries.

1109.11.1 Dispersion. *Accessible* fixed or built-in seating at tables, counters or work surfaces shall be distributed throughout the space or facility containing such elements and located on a level accessed by an *accessible route*.

❖ An appropriate distribution of seating and tables is required and is intended to be consistent with the distribution of all such seating and tables in the facility. For example, a library may contain several separate areas in which fixed seating or tables are installed. This provision would prohibit the location of all accessible seating and tables in a single specific area of the facility. However, this should not be construed to mean that every separate area in which fixed seating or tables are provided is required to contain an accessible seat or table. For example, if there are four areas in which fixed seating or tables are located, and two such seats or tables are required by this section to be accessible, the intent of this section is to require that one accessible seat or table be located in two of the four areas.

If the facility has floor levels exempted from an accessible route (see Section 1104.4), accessible

work surfaces are not required to be located on the nonaccessible level.



1109.12 Service facilities. Service facilities shall provide for *accessible* features in accordance with Sections 1109.12.1 through 1109.12.5.

❖ This section introduces five subsections that address accessibility of dressing rooms; service counters and windows; check-out aisles; food service; queues and waiting lines, etc. These types of elements are broadly termed "service facilities" and are intended to permit usage by persons with physical disabilities.

1109.12.1 Dressing, fitting and locker rooms. Where dressing rooms, fitting rooms or locker rooms are provided, at least 5 percent, but not less than one, of each type of use in each cluster provided shall be *accessible*.

❖ This section establishes a reasonable minimum threshold for accessible dressing, fitting and locker rooms. This section does not require that dressing, fitting and locker rooms be provided, but when such facilities are provided, at least 5 percent of each group of rooms is required to be accessible. This section also requires an appropriate distribution of accessible facilities based on distinct and different functions of each group of facilities provided. For example, a department store may have one group of fitting rooms serving the menswear department and a separate group of fitting rooms serving the women's wear department. This section would not permit the location of all accessible fitting rooms in one department and no accessible fitting rooms in another department. This may result in a number of accessible fitting rooms greater than 5 percent of the total number of all fitting rooms in the facility. For example, if there are two dressing rooms in each of three different departments in a retail store, a total of three accessible fitting rooms would be required: one in the three areas. Where amenities such as coat hooks, lockers or shelves are provided in inaccessible dressing, fitting or locker rooms, they must also be provided in the accessible rooms (see Section 1109.9). In accordance with Section 803.4 of ICC A117.1, an accessible bench must be provided in all accessible dressing, fitting and locker rooms (see Figure 1109.12.1).

1109.12.2 Check-out aisles. Where check-out aisles are provided, *accessible* check-out aisles shall be provided in accordance with Table 1109.12.2. Where check-out aisles serve different functions, at least one *accessible* check-out aisle shall be provided for each function. Where check-out aisles serve different functions, *accessible* check-out aisles shall be provided in accordance with Table 1109.12.2 for each function. Where check-out aisles are dispersed throughout the building or facility, *accessible* check-out aisles shall also be dispersed. Traffic control devices, security devices and turn-

For SI: 1 inch = 25.4 mm.

Figure 1109.12.1
EXAMPLE OF ACCESSIBLE DRESSING ROOM

stiles located in *accessible* check-out aisles or lanes shall be *accessible*.

❖ This section applies to sales locations configured as lanes or aisles, often designed to accommodate shopping carts, such as are typically found in supermarkets, drugstores, discount retail stores, etc. If check-out aisles serve different functions, at least one check-out aisle that serves each function shall be accessible. If a facility offers checkouts at a variety of locations, the accessible locations must also be dispersed. Where security devices such as turnstiles and automatically activated gates are provided, they are required to be accessible. The required number of check-out aisles for each function is set forth in Table 1109.12.2. Signage is required in accordance with Section 1110.1.

Providing a cash register at a location does not automatically create a check-out aisle. See Section 1109.12.3 for sales and service counters.

TABLE 1109.12.2
ACCESSIBLE CHECK-OUT AISLES

TOTAL CHECK-OUT AISLES OF EACH FUNCTION	MINIMUM NUMBER OF ACCESSIBLE CHECK-OUT AISLES OF EACH FUNCTION
1 to 4	1
5 to 8	2
9 to 15	3
Over 15	3, plus 20% of additional aisles

1109.12.3 Point of sale and service counters. Where counters are provided for sales or distribution of goods or services, at least one of each type provided shall be *accessible*. Where such counters are dispersed throughout the building or facility, *accessible* counters shall also be dispersed.

❖ Wherever sales or service counters or windows are provided, at least one window or a portion of a counter is required to be accessible. For example, most hotel registration and check-out functions occur at a counter. The intent of this section is to require that one portion of the counter area be accessible. Accessibility is accomplished by providing a lower counter height to accommodate a person using a wheelchair and locating that counter on an accessible route. This is not necessarily intended to require that multiple lower counter heights be provided based on the different types of services that are offered. For example, this is not intended to require two separate, lower counter heights: one for hotel registration and one for check-out. One lower counter height can be provided at which both functions are accomplished. In the above described situation, dispersion of the accessible counters would be required if the counters themselves were dispersed in separate locations.

The intent of the accessible service window is to permit the customer to interact with the service representative the same way they interact with the general public. An extra piece of counter stuck on the front of the high service counter [typically 42- to 48-inches (1067 to 1219 mm) high] may be appropriate as a temporary fix for barrier removal but is not acceptable in new construction. ICC A117.1 permits a maximum counter height of 36 inches (914 mm) at a service window (see commentary, Section 1109.11 and Figure 1109.12.3).

Figure 1109.12.3
SERVICE COUNTERS

1109.12.4 Food service lines. Food service lines shall be *accessible*. Where self-service shelves are provided, at least 50 percent, but not less than one, of each type provided shall be *accessible*.

❖ All lines that provide access to food service must meet the accessible route provisions in ICC A117.1. Where self-service shelves are utilized, such as in a cafeteria, at least half of each type must be on an accessible route and be located within reach ranges.

1109.12.5 Queue and waiting lines. Queue and waiting lines servicing *accessible* counters or check-out aisles shall be *accessible*.

❖ If patrons must form a line for service, then the waiting line must meet the accessible route provisions of ICC A117.1. When dealing with permanent crowd control barriers, special attention must be paid to turns around obstructions or dividers. Accessible waiting lines are required at locations where accessible counters, windows or check-out aisles are provided, such as banks, ticket counters, fast-food establishments and similar facilities. A separate waiting line for persons with disabilities is not a viable alternative.

1109.13 Controls, operating mechanisms and hardware. Controls, operating mechanisms and hardware intended for operation by the occupant, including switches that control lighting and ventilation and electrical convenience outlets, in

accessible spaces, along *accessible routes* or as parts of *accessible* elements shall be *accessible*.

Exceptions:

1. Operable parts that are intended for use only by service or maintenance personnel shall not be required to be *accessible*.
2. Electrical or communication receptacles serving a dedicated use shall not be required to be *accessible*.
3. Where two or more outlets are provided in a kitchen above a length of counter top that is uninterrupted by a sink or appliance, one outlet shall not be required to be *accessible*.
4. Floor electrical receptacles shall not be required to be *accessible*.
5. HVAC diffusers shall not be required to be *accessible*.
6. Except for light switches, where redundant controls are provided for a single element, one control in each space shall not be required to be *accessible*.
7. Access doors or gates in barrier walls and fences protecting pools, spas and hot tubs shall be permitted to have operable parts of the release of latch on self-latching devices at 54 inches (1370 mm) maximum and 48 inches minimum above the finished floor or ground, provided the self-latching devices are not also self-locking devices, operated by means of a key, electronic opener, or integral combination lock.

❖ This section requires that any controls intended to be utilized by the occupants of the space be accessible when such controls are located in an accessible space, along accessible routes or as part of an accessible element. For example, the switch controlling the general lighting of a room that is required to be accessible also must be accessible. This is also true for most of the electrical outlets that are located in the room. Thermostats that are intended to be adjustable by the occupants must also be accessible. Another example would be the button or switch that activates an automatic hand dryer in a toilet room. If the fixture is mounted such that the outlet for the air is at an accessible height, the purpose is defeated if the switch to activate the device is inaccessible.

The exceptions listed are similar to the exceptions already located in ICC A117.1 for Accessible, Type A and Type B dwelling and sleeping units. Since the same problems exist in nonresidential facilities, the exceptions are appropriate.

Exception 1 deals with items that are not intended for use by the general occupants of the space. This would include controls such as thermostats that are intended to be adjustable only by authorized personnel. Another example would be the controls restricted to use by authorized personnel for a public address system in a meeting room.

Exception 2 deals with connections for a dedicated use. For example, the outlet behind the refrigerator, where it plugs in, is not required to be accessible.

Exception 3 is for kitchens and kitchenettes. If more than one electrical outlet is provided over a portion of the countertop, only one is required to be accessible.

Exception 4 permits floor receptacles not to be accessible, since by being in the floor they are out of the reach range.

Exception 5 is for HVAC diffusers. The typical locations for these elements are most often in the floor, high up on the walls or on the ceiling.

Exception 6 allows for redundant controls for everything but lighting. For example, a ceiling fan could be operated by a wall switch as well as by the chain on the fan itself.

Exception 7 addresses the operable parts on safety gates and doors serving pools, spas and hot tubs. The operable parts are required to be higher than normal to be above the reach of young children (see Section 1008.1.9.2).

1109.13.1 Operable window. Where operable windows are provided in rooms that are required to be *accessible* in accordance with Sections 1107.5.1.1, 1107.5.2.1, 1107.5.3.1, 1107.5.4, 1107.6.1.1, 1107.6.2.1.1, 1107.6.2.2.1 and 1107.6.4.1, at least one window in each room shall be *accessible* and each required operable window shall be *accessible*.

Exception: *Accessible* windows are not required in bathrooms and kitchens.

❖ This section specifies when operable windows must be accessible, limiting the requirements to Accessible and Type A dwelling and sleeping units in Group I-1, I-2, R-1, R-2 and R-4 occupancies. There are no requirements for access to operable windows in Type B units. The concern is that such a requirement would force designers to opt for nonoperable windows when permitted by the code. Per ICC A117.1, if an operable window is required for natural ventilation, it is required to have a clear floor space in front and have operable parts within reach ranges. If the window is required for emergency escape then a clear floor space is required in front of the window. Due to their typical locations within the space (e.g., over the sink in a kitchen, raised in a bathroom for privacy), operable windows in kitchens or bathrooms are exempted.

1109.14 Fuel-dispensing systems. Fuel-dispensing systems shall be *accessible*.

❖ With the exceptions specific to fuel-dispensing systems (i.e, gas pumps) in ICC A117.1 under operable parts, this section asks for operable parts to be within the unobstructed reach range provisions in ICC A117.1, but due to safety concerns, they do not have to meet the 5-pounds-force (22.24 N) requirement. Basically, all the operable parts (e.g., pump controls, credit card readers, receipt dispenser, etc.) must be located between 15 inches and 48 inches (381 mm and 1219 mm) above the parking surface. Curbs must be considered when determining the height of

controls. The intent is to address the needs of persons with limited reach range. Fuel-dispensing systems that are part of a work station are exempted by Section 1103.2.3.

1109.15 Recreational and sports facilities. Recreational and sports facilities shall be provided with *accessible* features in accordance with Sections 1109.15.1 through 1109.15.4.

❖ Recreational and sports facilities such as tennis courts, swimming pools, baseball fields, etc., may be part of development on a site such as a school or apartment complex. Group R-2 and R-3 facilities are addressed in Sections 1109.14.1 and 1109.14.2 so that equitable opportunity for use by all occupants of a multibuilding site would be evaluated. All other occupancies must comply with Section 1109.15.3.

1109.15.1 Facilities serving a single building. In Group R-2 and R-3 occupancies where recreational facilities are provided serving a single building containing *Type A units* or *Type B units*, 25 percent, but not less than one, of each type of recreational facility shall be *accessible*. Every recreational facility of each type on a site shall be considered to determine the total number of each type that is required to be *accessible*.

❖ Many multiple-family developments include common recreational facilities, such as a swimming pool, community meeting room, tennis court, playground, etc., which are available for use by residents of the complex. In some cases, there may be more than one type of recreational facility located at different points within the development. This section establishes the criterion that 25 percent, but not less than one, of each type of recreational facility be accessible. For example, if two separate tennis court areas are provided, and one contains two tennis courts and another contains seven tennis courts, then a total of three tennis courts must be accessible. In a single building site, the three accessible tennis courts could all be in one area or divided between the two areas. This satisfies the requirement that at least 25 percent of the total number of courts be made accessible.

1109.15.2 Facilities serving multiple buildings. In Group R-2 and R-3 occupancies on a single *site* where multiple buildings containing *Type A units* or *Type B units* are served by recreational facilities, 25 percent, but not less than one, of each type of recreational facility serving each building shall be *accessible*. The total number of each type of recreational facility that is required to be *accessible* shall be determined by considering every recreational facility of each type serving each building on the site.

❖ In a multibuilding site, the same criteria applies as for single building sites; however, in addition, if certain facilities only serve certain buildings, at least 25 percent of them in each area must be accessible. For example, if two separate tennis court areas are provided, each serving a specific building, and one contains two tennis courts and another contains seven tennis courts, then 25 percent at each location, for a total of three tennis courts, must be accessible. While the number is the same for the single building, the distribution requirement is different. In this case, one tennis court in the two-court area must be made accessible and two of the tennis courts in the seven-court area must be made accessible. This satisfies the requirement that at least 25 percent of the courts for each building are made accessible. If all tennis courts serve all the buildings, then the distribution could be the same as discussed in Section 1109.14.1.

1109.15.3 Other occupancies. All recreational and sports facilities not falling within the purview of Section 1109.15.1 or 1109.15.2 shall be *accessible*.

❖ When tennis courts, pools, baseball diamonds, playgrounds or other recreational facilities are provided in occupancies other than Group R-2 or R-3, all facilities must be accessible.

The Access Board has included requirements for many types of recreational facilities in the new 2010 Standard. The 2009 edition of ICC A117.1 does include a new chapter with technical information on accessibility for many types of recreational facilities. The new Chapter 11 in ICC A117.1 contains technical provisions for amusement rides; recreational boating facilities; exercise machinery and equipment; fishing piers and platforms; golf facilities; miniature golf facilities; play areas; swimming pools; wading pools; hot tubs; spas and shooting and firing positions.

1109.15.4 Recreational and sports facilities exceptions. Recreational and sports facilities required to be *accessible* shall be exempt from this chapter to the extent specified in this section.

❖ This section identifies requirements or exceptions for five specific types of recreational facilities and/or elements within those facilities. These items are intended to harmonize with the new 2010 Standard.

1109.15.4.1 Bowling lanes. An *accessible route* shall be provided to at least 5 percent, but no less than one, of each type of bowling lane.

❖ Bowling lanes are typically depressed from the circulation and viewing areas in bowling facilities for sightline purposes. As with multiples in many nonsport facilities, only a percentage are required to be served by an accessible route.

1109.15.4.2 Court sports. In court sports, at least one *accessible route* shall directly connect both sides of the court.

❖ It is not permissible to have the only access to, for example, the far side of a court pass through the near side of the court. This requirement eliminates the possibility of having to travel through ongoing play on

one side of a court to access the opposite side of the court.

1109.15.4.3 Raised boxing or wrestling rings. Raised boxing or wrestling rings are not required to be *accessible*.

❖ It is impractical and unnecessary for raised boxing and wrestling rings to be accessible. This exception recognizes a basic premise of accessibility in the built environment for reasonable and logical accommodation.

1109.15.4.4 Raised refereeing, judging and scoring areas. Raised structures used solely for refereeing, judging or scoring a sport are not required to be *accessible*.

❖ This exception is in step with several of the general exceptions in Section 1103.2 where small raised areas provided for specific purposes are exempted. As with any other exception, there is nothing that would prohibit the installation of specialized equipment to allow a disabled person to perform the particular function.

1109.15.4.5 Raised diving boards and diving platforms. Raised diving boards and diving platforms are not required to be *accessible*.

❖ As with boxing rings, it is impractical and unnecessary for diving boards and platforms to be accessible.

SECTION 1110
SIGNAGE

1110.1 Signs. Required *accessible* elements shall be identified by the International Symbol of Accessibility at the following locations:

1. *Accessible* parking spaces required by Section 1106.1 except where the total number of parking spaces provided is four or less.
2. *Accessible* passenger loading zones.
3. *Accessible* rooms where multiple single-user toilet or bathing rooms are clustered at a single location.
4. *Accessible* entrances where not all entrances are accessible.
5. *Accessible* check-out aisles where not all aisles are accessible. The sign, where provided, shall be above the check-out aisle in the same location as the check-out aisle number or type of check-out identification.
6. Family or assisted-use toilet and bathing rooms.
7. *Accessible* dressing, fitting and locker rooms where not all such rooms are *accessible*.
8. *Accessible areas of refuge* in accordance with Section 1007.9.
9. Exterior areas for assisted rescue in accordance with Section 1007.9.

❖ Identification of accessible elements can be accomplished by use of an International Symbol of Accessibility (see Figure 1110.1). These figures are international in that they are recognized throughout the world as that which identifies accessibility.

There are nine specific circumstances in which required accessible elements are to be identified, as indicated in Items 1 through 9 of this section. Generally, these are locations in which not all of the facilities provided are accessible and, therefore, it is necessary to identify those that are accessible so that they can be readily recognized by the intended user. For example, Section 1106.1 specifies the required number of accessible parking spaces. If these are not identified by signage, it would be difficult and unnecessarily inconvenient for one to identify their location. (Note that the requirement for parking signage is limited to when more than four total parking spaces are provided. To require an accessible space to be reserved when it involves 25 to 100 percent of the parking provided is an undue hardship to the building tenant.) One of the concepts embodied in the code is to mainstream accessibility in recognition that many of the features that make facilities and elements accessible are also useful and of benefit to people without disabilities. Part of this principle includes the idea that if an element is universally usable by people both with and without disabilities, there is no need for signage specifically identifying the element as being accessible. Hence, the signage requirements generally address circumstances in which not all of the elements will be accessible.

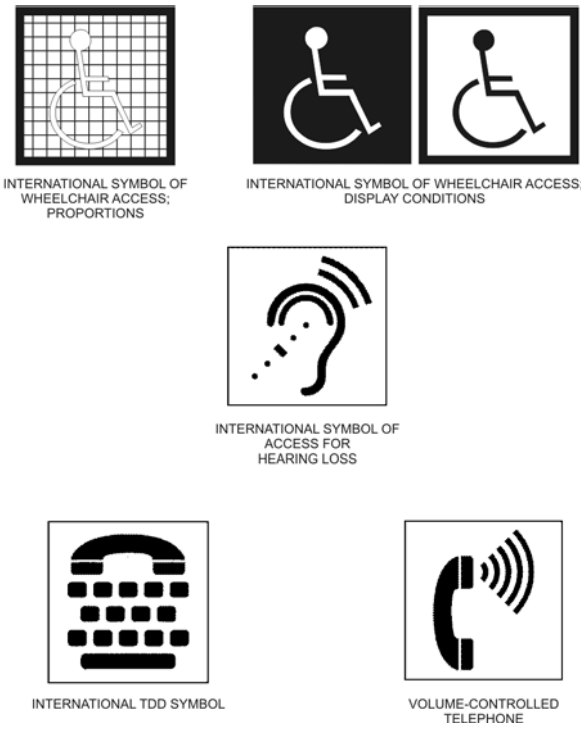


Figure 1110.1
INTERNATIONAL SYMBOLS OF ACCESSIBILITY

1110.2 Directional signage. Directional signage indicating the route to the nearest like *accessible* element shall be provided at the following locations. These directional signs shall include the International Symbol of Accessibility:

1. Inaccessible building entrances.
2. Inaccessible public toilets and bathing facilities.
3. Elevators not serving an *accessible route*.
4. At each separate-sex toilet and bathing room indicating the location of the nearest family or assisted-use toilet or bathing room where provided in accordance with Section 1109.2.1.
5. At *exits* and *exit stairways* serving a required *accessible* space, but not providing an *approved accessible means of egress*, signage shall be provided in accordance with Section 1007.10.

❖ There are circumstances in which it is useful and necessary to locate directional signage at certain inaccessible elements to indicate the route to the nearest like accessible element. For example, not all building entrances are required to be accessible (see Section 1105). Should a person in a wheelchair happen to approach an inaccessible building entrance at an unfamiliar facility, it is appropriate to provide direction indicating where the nearest accessible entrance is located. The same circumstance presents itself at inaccessible public toilet and bathing facilities, at elevators that do not serve an accessible route and in assembly and mercantile occupancies where family or assisted-use accessible toilet and bathing facilities are required.

This requirement for directional signage works in conjunction with the fact that everything is initially assumed to be accessible; therefore, items are not required to be identified by the International Symbols of Accessibility in the interest of mainstreaming. See the general comments to this chapter and the commentary to Section 1110.1 for a further discussion of main-streaming.

1110.3 Other signs. Signage indicating special accessibility provisions shall be provided as shown:

1. Each assembly area required to comply with Section 1108.2.7 shall provide a sign notifying patrons of the availability of assistive listening systems.

   Exception: Where ticket offices or windows are provided, signs are not required at each assembly area provided that signs are displayed at each ticket office or window informing patrons of the availability of assistive listening systems.
2. At each door to an *area of refuge*, an exterior area for assisted rescue, an egress *stairway*, *exit passageway* and *exit discharge*, signage shall be provided in accordance with Section 1011.4.
3. At *areas of refuge*, signage shall be provided in accordance with Section 1007.11.
4. At exterior areas for assisted rescue, signage shall be provided in accordance with Section 1007.11.
5. At two-way communication systems, signage shall be provided in accordance with Section 1007.8.2.
6. Within *interior exit stairways* and *ramps*, signage shall be provided in accordance with Section 1022.9.

❖ It is considered desirable that all the requirements for accessible signage be in one location. Item 1 requires signage indicating that assistive listening systems are provided when they are required by Section 1108.2.7. Items 2 through 6 are references to signage criteria in specific sections that have been mainstreamed in Chapter 10.

1110.4 Variable message signs. Where provided in the locations in Sections 1110.4.1 and 1110.4.2, variable message signs (VMS) shall comply with the VMS requirements of ICC A117.1.

❖ Variable Message Sign (VMS) requirements have been developed by the ICC A117.1 committee and added into the 2009 edition of the standard. The ICC A117.1 defines VMS as "Electronic signs that have a message with the capacity to change by means of scrolling, streaming, or paging across a background." Requirements vary depending on whether the sign resolution is high or low. Requirements for high-resolution signs are consistent with printed signs. The ICC A117.1 language modifies requirements for visual signs primarily by requiring increased character height and spacing for low-resolution VMS signs. Even for users with unimpaired vision, there is strong research evidence that character height in low-resolution VMS, such as the LED signs that are common in the transportation environment and elsewhere, must be approximately 30 percent greater than for equivalent print signs or VMS with high resolution. The requirements for increased character height, etc., for low-resolution VMS are not applicable to high-resolution VMS, such as video (see Figure 1110.4).

The section does not "require" that VMS signage be installed in any facility type, but instead requires

Figure 1110.4
VARIABLE MESSAGE SIGNAGE

that "where provided" within transportation facilities and emergency shelters, VMS comply with the standard and are usable by most of the population.

1110.4.1 Transportation facilities. Where provided in transportation facilities, variable message signs conveying transportation-related information shall comply with Section 1110.4.

❖ The phrasing "conveying transportation-related information" was included to limit the application of the ICC A117.1 VMS requirements to signs that are necessary for the most effective use of transportation information. The intent of this text is that signs that present information that is not necessary for transportation would be exempt. For example, neither a VMS that advertised what dining options in an airport would be required to comply with the standard's VMS provisions, nor a television set in the waiting area that had closed captioning of a news program. However any VMS that indicated what flight was departing from what gate or the time of the flight would be regulated.

Signage in transportation facilities is important for several reasons. Riders with reduced vision are especially dependent on public transportation for travel and are required by the ADA to have information that is equivalent to that provided to riders having unimpaired vision. This section coordinates the code requirements with those of the ADA. Currently, Sections E109 and E110 in Appendix E address some signage requirements within transportation facilities and stations and airports. The VMS signs are often used within transportation facilities (see Sections E109.2.2.2, E109.2.2.3, E109.2.7, E110.3) as a primary means of conveying information to riders. Since the ICC A117 committee has provided specific regulations for these signs, it is appropriate to reference these provisions so that designers and building officials know exactly what the technical requirements for the signs are. As noted earlier, this section does not "require" VMS signs, but "where provided" is intended to ensure that VMS comply with the requirements established by the ICC A117.1 committee.

The exception for equivalent audible information (see Section 1110.4.2) is not included in this section. This is done not only to coordinate with the ADA, but, also based upon the fact that in many such facilities the audible information is simply not easily understood. Anyone who has stood on a subway or train platform and tried to understand an audible message at the same time that the train is pulling up to the platform will understand this exclusion. Because of the problems with hearing messages in many transportation facilities, the audible message delivery is simply not considered as being adequate to replace or eliminate the clear visual sign information.

1110.4.2 Emergency shelters. Where provided in buildings that are designated as emergency shelters, variable message signs conveying emergency-related information shall comply with Section 1110.4.

Exception: Where equivalent information is provided in an audible manner, VMS signs are not required to comply with ICC A117.1.

❖ The phrasing "conveying emergency-related information" was included in the sections to limit the application of ICC A117.1 VMS requirements to signs that are necessary for the most-effective use of information in emergency shelters. The intent of this text is that signs that present information that is not necessary for the emergency use of facilities would be exempt. For example, in the case of an emergency shelter located at a school, only the signage related to shelter would be covered. The signage dealing with the school and what school activities were occurring that week would not be expected to comply with the VMS requirements.

Emergency shelters are typically identified by a jurisdiction when they are studying emergency planning or working with the Federal Emergency Management Agency (FEMA) to develop community plans. Although any building could ultimately be pressed into service as an emergency shelter in some circumstances, the intent of this text is to apply the requirement only to those facilities that are designated in advance or during that planning stage as an intended shelter. In many communities, this may include certain schools, civic administration buildings or even large convention facilities. Emergency-related information provided by VMS in emergency shelters is most likely to be information or instructions regarding additional problems or the recovery process.

The emergency shelter provisions contain an exception that would eliminate the requirement to meet the VMS provisions of the standard. Where audible information is conveyed that is either the same or equivalent to the information provided by the sign, compliance with ICC A117.1's VMS requirements is not needed. The VMS provides the information in a visual method and ICC A117.1 provisions ensure that the information is clearly visible and legible to both the general population and to people with some level of visual impairment. Providing the equivalent information in an audible manner makes the information accessible to people with severe visual impairment or who are blind.

Chapter 12: Interior Environment

General Comments

Chapter 12 contains provisions governing the interior environment requirements of all buildings and structures intended for human occupancy.

Section 1201 identifies the scope of the chapter. Section 1202 provides definitions applicable to terms used in this chapter.

Section 1203 identifies special enclosed spaces where accumulated moisture must be removed by ventilation and establishes criteria (minimum openable area) for the only method of measuring compliance with the natural ventilation requirements for occupied spaces.

Section 1204 identifies the minimum space-heating requirement for interior spaces intended for human occupancy.

Section 1205 requires light for every room or space intended for human occupancy. The method of compliance is the choice of the designer, who may elect to provide artificial instead of natural light. Prescriptive requirements for stairway lighting in dwelling units are also included.

Section 1206 specifies the minimum requirements for courts and yards, including area width, accessibility for cleaning and the location of air intakes when natural light or natural ventilation is the chosen design option.

Section 1207 establishes the sound transmission control requirements for air-borne and structure-borne sound in residential buildings.

Section 1208 addresses the minimum ceiling height for all habitable and occupiable spaces along with other spaces as specified (i.e., toilet rooms and bathrooms). The minimum floor area for rooms in dwelling units is also specified.

Section 1209 provides minimal opening requirements for access to crawl spaces and attics.

Section 1210 contains requirements for toilet room surfaces and fixture surrounds.

The environmental and physiological justification for the code requirements relevant to light and ventilation of occupiable spaces is based on knowledge, technology and practices developed over centuries of building structures in which humans live and work. These design practices have been further validated by studies during the 19th and 20th centuries.

The greatest impact on these provisions, and those that have resulted in changes during the past 30 years, has been from the interest in energy conservation through construction practices, including the minimization of exterior wall openings.

The requirements related to interior sound transmission and control are considered an important aspect of human comfort in residential occupancies.

Purpose

The purpose of Chapter 12 is to establish minimum conditions for the interior environment of a building. The size of spaces, light, ventilation and noise intrusion are all addressed in order to define the acceptable conditions to which any occupant may be exposed. Design options of natural and mechanical systems are introduced and the criteria for performance are specified.

Even though it was not completely understood, the need for "fresh air" had been recognized for centuries. Designers of centuries-old adobe buildings in the southwestern United States, hide-covered Native American tepees of the plains and frame houses of early settlers in the eastern United States all relied upon the buoyancy of warm air, enabling it to rise and cooler air to flow in to replace it. Whether the design relied on solar energy, thermal mass or even wind velocity to cause the movement, it still reflected a natural movement and, as a result, has been termed "natural ventilation." Only recently have we begun to recognize the reasons for ventilation and the implications of failing to provide an adequate quantity and acceptable quality of air for all occupants. The expression "sick building syndrome" has crept into our vocabulary and reflects the increased understanding of the relationship between interior environment requirements and the physiological well-being of the occupants.

The other purpose of regulating the interior environment is psychological. Merely providing adequate conditions is not sufficient if the occupant does not perceive them as adequate. Minimum space requirements (floor area, yard dimensions or ceiling height) address the need to perceive adequate light, ventilation and space to promote psychological well-being. Regulation of sound transmission also bears directly on the psychological and long-term physical well-being of the occupant.

Finally, adequate lighting from natural sources also meets the physical and psychological needs of the occupants and contributes directly to their overall safety. Safe use of any building under ordinary and emergency conditions depends greatly on proper illumination of the space. This chapter references the *International Mechanical Code*® (IMC®) as the performance standard to which ventilation must be compared and the installation standard for mechanical systems used in buildings regulated by the code.

SECTION 1201
GENERAL

1201.1 Scope. The provisions of this chapter shall govern ventilation, temperature control, lighting, *yards* and *courts*, sound transmission, room dimensions, surrounding materials and rodent proofing associated with the interior spaces of buildings.

❖ This section identifies the scope of Chapter 12. The requirements of this chapter are intended to govern and regulate the need for light, ventilation, sound transmission control, interior space dimensions and materials surrounding plumbing fixtures in all buildings. It is the intent of the code that the user must comply with these regulations for all newly constructed buildings and structures and for all buildings and structures, or portions thereof, when there is to be a change of occupancy or within any additions to a building.

SECTION 1202
DEFINITIONS

1202.1 General. The following terms are defined in Chapter 2:

❖ Definitions of terms that are associated with the content of this section are contained herein. These definitions can help in the understanding and application of the code requirements. It is important to emphasize that these terms are not exclusively related to this section but are applicable everywhere the term is used in the code. The purpose for including these definitions within this section is to provide more convenient access to them without having to refer back to Chapter 2. For convenience, these terms are also listed in Chapter 2 with a cross reference to this section. The use and application of all defined terms, including those defined herein, are set forth in Section 201.

SUNROOM.

❖ This terminology is provided in order to address separate requirements for sunrooms with regard to ventilation of adjoining spaces (see Section 1203.4.1.1). For the 2009 code the term "sunroom addition" was simplified to "sunroom." Provisions later in the chapter that still say sunroom addition. Those provisions are applicable regardless of whether the sunroom is an addition to an existing structure or is part of the original design and construction.

THERMAL ISOLATION.

❖ This terminology is required for the same reason provided in the definition of "Sunroom" (see above). Although the exact phrase "thermal isolation" is not used in the code, the phrase "thermally isolated" is found in a number of provisions. This definition provides guidance in applying this variation on the defined term.

SECTION 1203
VENTILATION

1203.1 General. Buildings shall be provided with natural ventilation in accordance with Section 1203.4, or mechanical ventilation in accordance with the *International Mechanical Code*.

Where the air infiltration rate in a *dwelling unit* is less than 5 air changes per hour when tested with a blower door at a pressure 0.2 inch w.c. (50 Pa) in accordance with Section R402.4.1.2 of the *International Energy Conservation Code*, the *dwelling unit* shall be ventilated by mechanical means in accordance with Section 403 of the *International Mechanical Code*.

❖ Every room or space must be provided with ventilation. The selection of natural versus mechanical ventilation on a room-by-room or space-by-space basis is the designer's prerogative. Certain conditions require mechanical exhaust even though natural ventilation systems have been selected by the designer. Section 1203.4.2 of the code, and Sections 401.6 and 403 of the IMC direct the treatment of those special situations. Existence of these conditions, however, does not require providing mechanical ventilation other than to address the specific condition. Other rooms or spaces not affected by those conditions may be served by natural systems.

The second paragraph requires mechanical ventilation for residences when the building has been sealed very tightly against air infiltration. The measure will be 5 air changes per hour (ACH) at 50 pascals when tested in accordance with the *International Energy Conservation Code®* (IECC®), which requires air leakage testing for all new residences.

Indoor air quality has direct impact on the health of building occupants. Poor indoor air quality is listed by the Enviranmental Protection Agency (EPA) as being the fourth largest environmental threat to our country. A 2007 California study revealed formaldehyde exposure in most new homes is beyond limits recommended by the California Air Resources Board. Multiple studies have shown that relying on window operation to provide ventilation is not sufficient enough for the health of occupants. If unchecked, pollutants from cleaning chemicals, finishes, furniture and occupant activities can cause serious health effects on building occupants. Whole-house mechanical ventilation reduces occupant exposure to such pollutants.

Traditionally, 0.35 natural air changes per hour has been the consensus ventilation rate to provide sufficient fresh air to building occupants. This ventilation rate was typically achieved without mechanical ventilation because homes were built without an effective air barrier. As building practices have improved, homes have become tighter, and as homes become tighter, mechanical ventilation must be introduced to provide sufficient levels of ventilation.

ASHRAE 136 was developed to enable calculation of natural air changes per hour as a function of air changes at various pressures. By following the calculation procedures in this standard, it can be shown that a natural infiltration rate of 0.35 is equivalent to somewhere between 7 air changes per hour to 10 air changes per hour at 50 pascals (7 ACH 50 to 10 ACH 50) depending on the local climatic conditions of the home. Because most dwellings are built this tight, ASHRAE 62.2 requires mechanical ventilation for all homes, with few exceptions. However, based on ASHRAE 136, a conservative code might prescribe whole-house mechanical ventilation for any home with an infiltration leakage rate of 10 ACH 50 or less.

As a second point of reference, Chapter 6 of California's 2005 Title 24 requires that, "Continuous mechanical ventilation (either exhaust or supply ventilation) must be installed when the target specific leakage area (SLA) is below 3.0." California's SLA of 3.0 is roughly equivalent to 6 ACH 50. As a third point of reference, National Association of Home Builders (NAHB) National Green Building Standard requires whole-house mechanical ventilation when the infiltration rate falls below 5.0 ACH 50. This requirement provides clear recognition from a consensus standard that whole-house mechanical ventilation should be provided for all homes that meet this threshold.

Based on the previous references, there is broad consensus across states and within consensus standards that whole-house mechanical ventilation should be required when a dwelling's infiltration falls below 5.0 ACH 50.

1203.2 Attic spaces. Enclosed *attics* and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof framing members shall have cross ventilation for each separate space by ventilation openings protected against the entrance of rain and snow. Blocking and bridging shall be arranged so as not to interfere with the movement of air. An airspace of not less than 1 inch (25 mm) shall be provided between the insulation and the roof sheathing. The net free ventilating area shall not be less than $1/150^{th}$ of the area of the space ventilated.

Exceptions:

1. The net free cross-ventilation area shall be permitted to be reduced to $^1/_{300}$ provided that not less than 50 percent and not more than 80 percent of the required ventilating area provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above eave or cornice vents with the balance of the required *ventilation* provided by eave or cornice vents.
2. The net free cross-ventilation area shall be permitted to be reduced to $^1/_{300}$ where a Class I or II vapor barrier is installed on the warm-in-winter side of the ceiling.
3. *Attic* ventilation shall not be required when determined not necessary by the *building official* due to atmospheric or climatic conditions.

❖ All attic spaces and each separate space formed between solid roof rafters are required to be cross ventilated where the ceiling is applied directly to the underside of the roof rafters. Care must be taken, however, to provide cross ventilation in a manner that does not introduce moisture to the attic area.

Snow infiltration can occur when the attic ventilation openings are not sufficiently protected against the entrance of snow or rain, or when more than 50 percent of the ventilation openings are located along the ridge or gable wall of the roof rather than at the eave. When the wind blows perpendicular to a roof ridge vent, a negative pressure builds up across the ridge that draws air out of the attic space through the attic vents. Cross flow of air through the attic can be achieved when outside air is drawn into the attic through the eave or cornice and exits through the ridge or gable vents. In order for this to occur, eave or cornice vents must be greater than or equal to the area of the ridge or gable vents.

Vents that permit snow or rain to infiltrate the attic are not permitted. While there is no specific test standard for this performance aspect of vents, snow infiltration through roof vents can be addressed by what is referred to as "balanced" venting. Balanced venting is providing at least 50 percent of the required ventilating area in the upper third of the space being ventilated (e.g., through ridge or gable vents). The balance of the required ventilation is provided by eave or cornice vents that are greater than or equal to the ventilation area provided by the ridge or gable vents. Most ridge vent manufacturers require slightly more ventilation area in the eaves than provided in the ridge vent to help prevent snow infiltration. If insufficient eave or cornice ventilation is provided, air will be drawn through the ridge or gable vents. Snow-laden air can enter the attic space through a ridge or gable vent; therefore, it is preferable to have both eave and ridge vents, with the eave vent area being greater than or equal to the ridge vent area (i.e., "balanced" venting).

If an adequate amount of ventilation area in the upper portion of the space is not provided and the ventilation area is provided mainly at the eave or cornice vents, then air will enter and leave the attic space at the eave, and very little cross flow of air will occur.

A test method that has been devised for ridge vent manufacturers involves the use of a 13-foot, 6-inch-diameter (4115 mm) propeller of a 2,650-horsepower aircraft engine wind generator. Snow is simulated with fine, soft wood sawdust, added to the airstream at about 5 pounds (2 kg) per minute. Using this

method, the wind speed is varied, because it is not known at what speed the most snow infiltration will occur or the factors that will determine that each wind speed was sustained for a period of 5 minutes. The entire roof system, with all vents, must be installed in the test set-up in order to get a true measure of the potential (or lack thereof) for snow infiltration.

Attic ventilation openings cannot be placed in roof areas subject to snow drifts. These roof areas are subject to greater concentrations of snow, which could increase the chances of snow entering the attic through the ventilation openings. In addition, the ventilation openings are required to be covered with corrosion-resistant mesh or similar material in accordance with Section 1203.2.1. If roof spaces are not created (e.g., solid concrete roof sections), ventilation is not required, as there is no concealed space for condensation to accumulate.

The amount of area needed for ventilating a roof space is also established in this section.

The following example illustrates the calculation of required ventilation areas for an attic space [see Figure 1203.2(1)]:

Note: The area of the attic must include the area of the eave or soffit.

Attic ventilation area = $^{1}/_{150}$ of area

Required ventilating area = $^{1,100}/_{150}$
= 7.33 sq. ft.
= 1056 sq. in.

For application of Exception 1:

Attic ventilation area = $^{1}/_{300}$ of area

Required ventilating area = $^{1,100}/_{150}$
3.67 sq. ft.
528 sq. in.

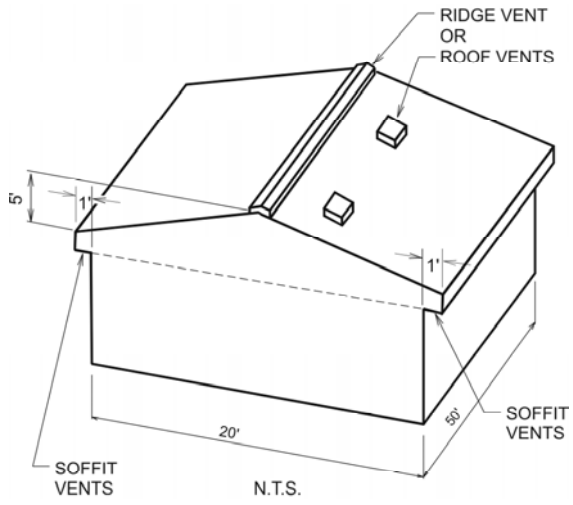
Provide 50% by = 528 x 0.5 ridge or roof vent
= 264 sq. in.

Provide soffit ventilation = 264 sq. in. total or 264/2(50)
= 2.64 sq. in./ft.

Area of attic = 1,100 sq. ft.

For SI: 1 square inch = 0.000645 m^2,
1 square foot = 0.0929 m^2.

Common methods used to provide soffit ventilation include manufactured units, strips or soffit panels and holes or slots (with screening) that meet the criteria and are approved.



It is important to note that the distribution of ventilation openings should be uniform along the length of the soffits and ridge.

Common methods used to provide roof ridge ventilation include manufactured roof units, ridge vents and gable louvers.

Common methods used to provide soffit ventilation include manufactured units, strips or soffit panels and holes or slots (with screening) that meet the criteria and are approved.

Note that the net-free ventilation area of equipment used for soffit, roof and gable ventilation must be determined. One cannot simply calculate the ventilation area based on the opening created in the roof, wall or soffit. Products vary by manufacturer, and a review of the listing and specifications is necessary to verify actual or net-free ventilation areas.

Where an attic space is not created, but the ceiling membrane is applied directly to the bottom of the solid roof rafters, each rafter space is to be ventilated separately. In this type of installation, it is particularly important that cross ventilation is developed between each rafter space by providing vents at the ridge and eave [see Figure 1203.2(2)]. For small sections of roofs such as above dormers and for roofs that are flat or of very low slope, the 30-inch (762 mm) height difference between the highest and lowest vent locations may not be readily achievable. The designer and building official need to ensure that the ventilation openings for such roofs will result in adequate ventilation.

For SI: 1 foot = 304.8 mm.

Figure 1203.2(1)
COMBINATION OF SOFFIT AND RIDGE VENTS

1203.2.1 Openings into attic. Exterior openings into the *attic* space of any building intended for human occupancy shall be protected to prevent the entry of birds, squirrels, rodents, snakes and other similar creatures. Openings for ventilation having a least dimension of not less than $^{1}/_{16}$ inch (1.6 mm) and not more than $^{1}/_{4}$ inch (6.4 mm) shall be permitted. Openings for ventilation having a least dimension larger than $^{1}/_{4}$ inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth, perforated vinyl or similar material with openings having a least dimension of not less than $^{1}/_{16}$ inch (1.6 mm) and not more than $^{1}/_{4}$ inch (6.4 mm).

Where combustion air is obtained from an *attic* area, it shall be in accordance with Chapter 7 of the *International Mechanical Code*.

❖ Ventilation openings that would permit the entrance of small animals into the structure must be protected in accordance with this section. Hardware cloth is a particular kind of metal wire cloth screening, and perforated vinyl is a plastic screening or grid with openings of similar dimensions. Metal or vinyl are specified because of their resistance to deterioration over time; therefore, whatever material is used, it must be nondeteriorating in addition to having the least dimension of the minimum and maximum openings of $^1/_{16}$ and $^1/_4$ inches (3.2 and 6.4 mm), respectively.

Combustion air is air supplied to the room where a fuel-burning appliance is located in order that combustion of the fuel can take place in a safe and complete manner. Chapter 7 of the IMC permits combustion air to be taken from an attic space that is ventilated by openings to the exterior, under certain conditions. Those conditions are based on the configuration of the attic space and the ventilation openings themselves (see Chapter 7 of the IMC and commentary for more information).

1203.3 Under-floor ventilation. The space between the bottom of the floor joists and the earth under any building except spaces occupied by basements or cellars shall be provided with ventilation openings through foundation walls or *exterior walls*. Such openings shall be placed so as to provide cross ventilation of the under-floor space.

❖ The intent of this section is to create an adequate flow of air through crawl spaces to achieve the ventilation goals of controlling temperature, humidity and accumulation of gases. The entire space must be properly ventilated by openings that are distributed to effect cross flow and include corner areas. Although the code does not specify the exact location of openings, an equal distribution of openings on at least three sides of a building, with at least one opening near each corner of the building, is typically sufficient.

Mechanical ventilating devices also can be installed to force air movement and ventilate the space, in which case the location and number of ventilation openings are less critical (see Section 1203.3.2, Exception 3). The amount of ventilation openings required can be drastically reduced if a vapor retarder is used on the ground surface in the crawl space, in accordance with Section 1203.3.2, Exception 2. Also, in accordance with Exception 3 of that section, when a vapor retarder is used, the installation of operable louvers (to close the openings in the coldest times of the year) is permitted.

1203.3.1 Openings for under-floor ventilation. The net area of ventilation openings shall not be less than 1 square foot for each 150 square feet (0.67 m^2 for each 100 m^2) of crawl-space area. Ventilation openings shall be covered for their height and width with any of the following materials, provided that the least dimension of the covering shall be not greater than $^1/_4$ inch (6 mm):

1. Perforated sheet metal plates not less than 0.070 inch (1.8 mm) thick.
2. Expanded sheet metal plates not less than 0.047 inch (1.2 mm) thick.
3. Cast-iron grilles or gratings.
4. Extruded load-bearing vents.
5. Hardware cloth of 0.035 inch (0.89 mm) wire or heavier.
6. Corrosion-resistant wire mesh, with the least dimension not greater than $^1/_8$ inch (3.2 mm).

❖ The following is an example of the area calculation: A rectangular building that is 60 feet (18 288 mm) long

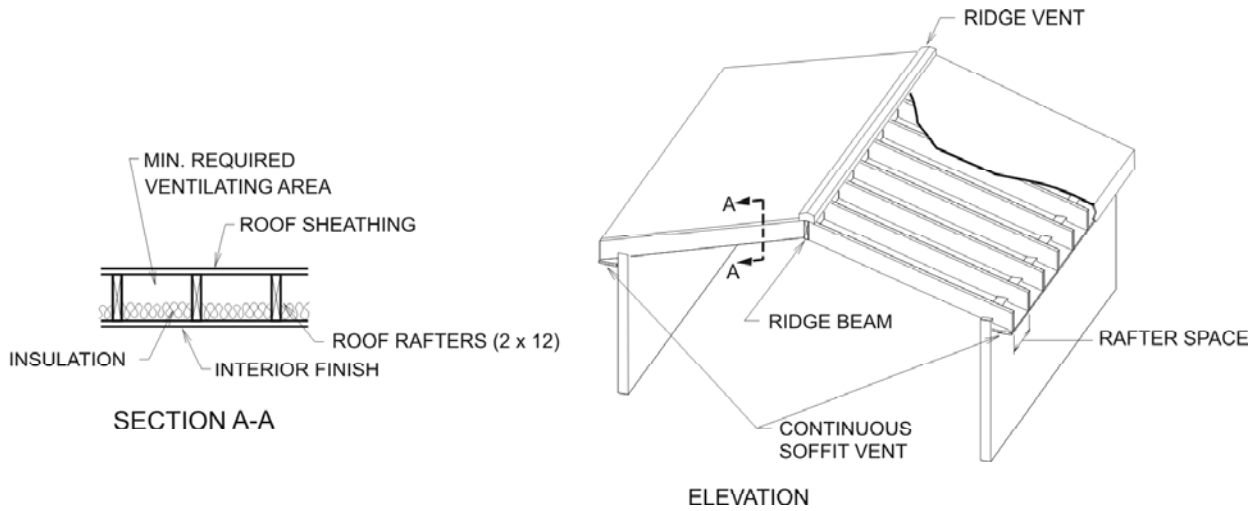


Figure 1203.2(2)
VENTILATION OF RAFTER SPACE

and 20 feet (6096 mm) wide has a plan area of 1,200 square feet (111.5 m^2). The amount of ventilation opening required is $^{1,200}/_{150}$ = 8 square feet (0.74 m^2) by 144 square inches (92 903 mm^2) per square foot = 1,152 square inches (0.74 m^2). This is the total (aggregate) amount of ventilation opening that must be distributed among all the openings. This required amount of openings may be reduced by a factor of 10 if a vapor retarder is used on the ground surface in accordance with Section 1203.3.2, Exception 2.

The requirement for covering the openings with perforated plates, corrosion-resistant wire mesh or other covering is to keep small animals out. Six alternatives are given for this covering, and they all must have openings that have no dimension exceeding $^1/_4$ inch (6.4 mm).

1203.3.2 Exceptions. The following are exceptions to Sections 1203.3 and 1203.3.1:

1. Where warranted by climatic conditions, ventilation openings to the outdoors are not required if ventilation openings to the interior are provided.
2. The total area of ventilation openings is permitted to be reduced to $^1/_{1,500}$ of the under-floor area where the ground surface is covered with a Class I vapor retarder material and the required openings are placed so as to provide cross ventilation of the space. The installation of operable louvers shall not be prohibited.
3. Ventilation openings are not required where continuously operated mechanical ventilation is provided at a rate of 1.0 cubic foot per minute (cfm) for each 50 square feet (1.02 L/s for each 10 m^2) of crawl space floor area and the ground surface is covered with a Class I vapor retarder.
4. Ventilation openings are not required where the ground surface is covered with a Class I vapor retarder, the perimeter walls are insulated and the space is conditioned in accordance with the *International Energy Conservation Code*.
5. For buildings in flood hazard areas as established in Section 1612.3, the openings for under-floor ventilation shall be deemed as meeting the flood opening requirements of ASCE 24 provided that the ventilation openings are designed and installed in accordance with ASCE 24.

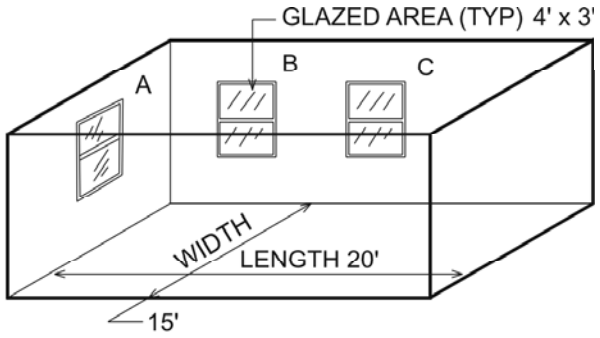
❖ This section lists the locations and conditions where ventilation openings can be omitted entirely or the area of required openings can be reduced. Exception 1 could be used in extremely cold climates, where ventilation openings are a serious breach of the structure in terms of energy usage. It provides for ventilating the crawl space to the interior conditioned space of the building, which is heated and can accept moisture from the underground space without detrimental effects on the building structure.

The use of a Class I vapor retarder material on the ground surface inhibits the flow of moisture from the ground surface into the crawl space and thus reduces, if not virtually eliminates, the need for ventilation. Therefore, Exception 2 provides for a drastic reduction in the amount of ventilation openings required. While the vapor retarder may significantly reduce the moisture accumulation, ventilation openings are still required but may be equipped with manual dampers to permit them to be closed during the coldest weeks of the year in northern climates.

Exception 3 provides for the use of mechanical ventilation, such as an exhaust fan similar to a bathroom exhaust fan, to keep air moving through the crawl space. A Class I vapor retarder on the ground surface is also required when using Exception 3.

When a crawl space is provided with a Class I vapor retarder on the ground surface and is mechanically conditioned and insulated, it becomes like any other space in the conditioned structure and ventilation openings are not required in accordance with Exception 4. Requirements for insulating structures are found in the IECC.

Section 1612 of the code requires buildings located in flood hazard areas to be constructed in accordance with ASCE 24. Exception 5 is necessary to coordinate the requirements for openings in ASCE 24 with this section. In most cases, the ventilation requirements of Section 1203.3 are not satisfied by installation of the flood openings because the requirements in ASCE 24 specify that flood openings are to be no more than 1 foot (305 mm) above the adjacent grade, while most airflow vents that meet the requirements of Section 1203.3 are installed immediately below the elevated floor. If there are a sufficient number of airflow vents located within 1 foot (305 mm) of the adjacent grade, they may satisfy both requirements. In either case, both airflow ventilation and flood opening requirements must be met for buildings and structures located in flood hazard areas. For further guidance, refer to FEMA FIA-TB-1, *Openings in Foundation Walls for Buildings Located in Special Flood Hazard Areas*.



1203.4 Natural ventilation. Natural *ventilation* of an occupied space shall be through windows, doors, louvers or other openings to the outdoors. The operating mechanism for such openings shall be provided with ready access so that the openings are readily controllable by the building occupants.

❖ This section provides the standard of natural ventilation for all occupied spaces. Openings to the outdoor air, such as doors, windows and louvers, provide natural ventilation. The section does not, however, state or intend that the doors, windows or openings actually be constantly open. The intent is that they be maintained in an operable condition so that they are available for use at the discretion of the occupant.

1203.4.1 Ventilation area required. The openable area of the openings to the outdoors shall be not less than 4 percent of the floor area being ventilated.

❖ This section specifies the ratio of openable doors, windows or openings to the floor space being venti-

lated but does not address the distribution around the space or location of these openings. It is the designer's prerogative to distribute openings in such a manner as to accomplish the natural ventilation of the space. When inadequate natural ventilation is provided, mechanical ventilation can supplement any inadequacy (see Chapter 4 of the IMC). The plan reviewer can determine compliance with this section. For example, in Figure 1203.4.1, the combined openable area (the net-free area of a door, window, louver, vent or skylight, etc., when fully open) of double-hung windows B and C is equal to 4 percent of the floor area [300 × 0.04 = 12 square feet (1 m^2)]. The openable area of window A is not required and need not open onto a court or yard complying with Section 1206.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m^2.

Figure 1203.4.1
NATURAL LIGHT AND VENTILATION WINDOWS

1203.4.1.1 Adjoining spaces. Where rooms and spaces without openings to the outdoors are ventilated through an adjoining room, the opening to the adjoining room shall be unobstructed and shall have an area of not less than 8 percent of the floor area of the interior room or space, but not less than 25 square feet (2.3 m^2). The openable area of the openings to the outdoors shall be based on the total floor area being ventilated.

Exception: Exterior openings required for *ventilation* shall be permitted to open into a sunroom with *thermal isolation* or a patio cover provided that the openable area between the sunroom addition or patio cover and the interior room shall have an area of not less than 8 percent of the floor area of the interior room or space, but not less than 20 square feet (1.86 m^2). The openable area of the openings to the outdoors shall be based on the total floor area being ventilated.

❖ Adjacent spaces with large connecting openings may share sources of light and ventilation. This section deals with the natural ventilation of connecting interior spaces, and it is the designer's obligation to place openings between rooms with exterior openings and connecting spaces without exterior openings in such a manner as to accomplish natural ventilation of the connected space. For purposes of ventilation, this section establishes a minimum openness requirement for the common wall between a room with openings to the exterior and an interior room without openings to the exterior. The minimum amount of openness required in that common wall is 8 percent of the floor area of the interior room or 25 square feet (2.33 m^2), whichever is greater. The openable area of the exterior openings in the "outer" room is required to be equal to or greater than 4 percent (in accordance with Section 1203.4.1) of the total combined floor areas served.

Figure 1203.4.1.1 shows a cut-away of an interior room (Space A) adjacent to a room with openings to the exterior (Space B). The openable area of exterior

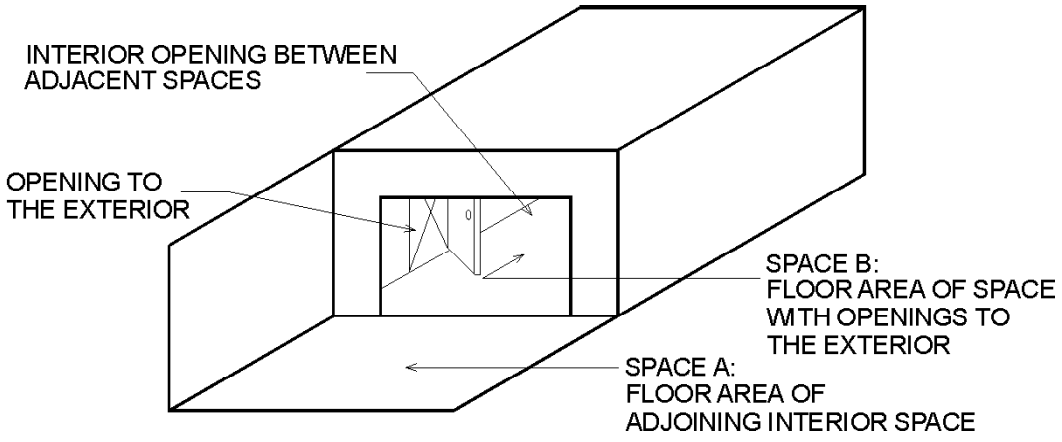


Figure 1203.4.1.1
NATURAL VENTILATION FROM ADJOINING SPACE

openings in Space B is required to be equal to or greater than 0.04 times the area of the entire space (floor area of Space A plus floor area of interior Space B). The opening in the wall between adjacent spaces must be a minimum of 25 square feet (2.33 m^2), but not less than 0.08 times the floor area of interior Space A. Since the opening between the adjacent spaces must be unobstructed in accordance with this section, a door cannot be installed in the opening.

The exception deals with a very common circumstance, especially in residential construction. As long as the sunroom is large enough and is thermally isolated, the building owner need not move ventilation openings when installing an addition that falls within the definition of "Sunroom." Sunrooms can be part of initial construction.

1203.4.1.2 Openings below grade. Where openings below grade provide required natural *ventilation*, the outside horizontal clear space measured perpendicular to the opening shall be one and one-half times the depth of the opening. The depth of the opening shall be measured from the average adjoining ground level to the bottom of the opening.

❖ This section is applicable whenever occupied spaces below grade are dependent upon natural ventilation through structures like window wells. In order to provide adequate ventilation, this section sets the minimum horizontal clear space adjacent to the opening used for natural ventilation. Without this minimum horizontal area, there will be inadequate air movement through the opening.

As illustrated in Figure 1203.4.1.2, the opening area required for the story below grade intended for human occupancy is:

$$A = 0.04 (L \times W)$$

The area of the window in the vertical plane (w × h) must equal or exceed the required opening area. Additionally, the horizontal dimension from the window to the well wall must equal one and one-half times the depth of the openable portion of the window at the lowest point. If the story below grade is not intended for human occupancy, ventilation is required to be provided in accordance with Section 1203.3 for under-floor spaces.

1203.4.2 Contaminants exhausted. Contaminant sources in naturally ventilated spaces shall be removed in accordance with the *International Mechanical Code* and the *International Fire Code*.

❖ Contaminants in the air are to be collected and exhausted by special means. Chapters 4 and 5 of the IMC specify areas or conditions that must be separately addressed. For example, there are many operations listed in Chapter 5 of the IMC that produce contaminants that cannot be properly or safely treated by natural means. Natural ventilation only anticipates normal occupancy by people and not the extra heat loads, dust, vapors and other contaminants generated by some activities.

1203.4.2.1 Bathrooms. Rooms containing bathtubs, showers, spas and similar bathing fixtures shall be mechanically ventilated in accordance with the *International Mechanical Code*.

❖ Chapter 4 of the IMC contains provisions for bathroom ventilation, requiring mechanical exhaust without recirculation of air at specific rates that depend on the occupancy group.

1203.4.3 Openings on yards or courts. Where natural *ventilation* is to be provided by openings onto *yards* or *courts*, such *yards* or *courts* shall comply with Section 1206.

❖ In order that adequate air movement will be provided through openings to naturally ventilated rooms, the openings must directly connect to yards or courts with the minimum dimensions specified in Section 1206.

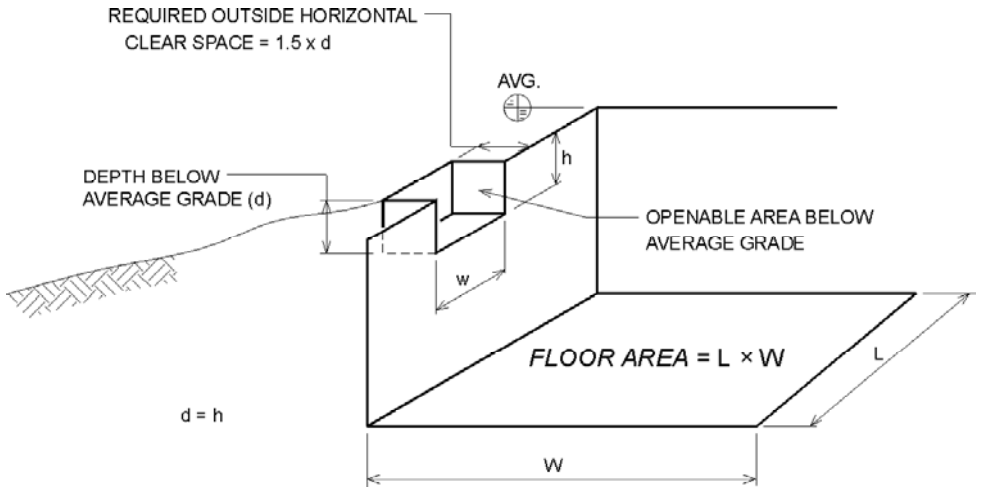

Figure 1203.4.1.2
VENTILATION OPENINGS BELOW GRADE

1203.5 Other ventilation and exhaust systems. *Ventilation* and exhaust systems for occupancies and operations involving flammable or combustible hazards or other contaminant sources as covered in the *International Mechanical Code* or the *International Fire Code* shall be provided as required by both codes.

❖ Chapter 5 of the IMC contains specific provisions for hazardous exhaust systems in occupancies such as vehicle repair garages, aircraft fueling stations, dry cleaning plants, spray painting operations and hazardous production materials (HPM) facilities. Many of these provisions are duplicated from the *International Fire Code*® (IFC®), which also contains provisions for the handling and storage of hazardous materials.

SECTION 1204
TEMPERATURE CONTROL

1204.1 Equipment and systems. Interior spaces intended for human occupancy shall be provided with active or passive space-heating systems capable of maintaining an indoor temperature of not less than 68°F (20°C) at a point 3 feet (914 mm) above the floor on the design heating day.

Exception: Space heating systems are not required for interior spaces where the primary purpose of the space is not associated with human comfort.

❖ Heating facilities are required for comfort in all new construction. The systems may be either active (such as a forced-air furnace) or passive (such as solar systems), as long as the specified performance is achieved.

The outdoor design temperatures are taken from the ASHRAE *Handbook of Fundamentals* and are listed in Appendix D of the *International Plumbing Code*® (IPC®). Outdoor design temperatures provide a baseline from which heat load calculations are made. Heating system capacity is dependent upon the predicted outdoor temperatures during the heating season. As the outdoor temperature falls, the heat input to a building must increase to offset the increasing heat losses through the building envelope. Heating systems are designed to have the capacity to maintain the desired indoor temperature when the outdoor temperature is at or above the outdoor design temperature. When the outdoor temperatures are below the outdoor design temperature, the heating system will not be able to maintain a desired indoor temperature. It would be impractical, for example, to design a heating system based on the assumption that someday it might be -20°F (-29°C) outdoors if the outdoor temperature in that region rarely, if ever, dropped that low. In such a case, the heating system would be oversized and, thereby, less efficient and economical.

The winter outdoor design temperature is defined as follows: For 97.5 percent of the total hours in the northern hemisphere heating season, from December through February, the predicted outdoor temperatures will be at or above the values given in Appendix D of the IPC. It would be unreasonable to expect any heating system to maintain a desired indoor temperature when the outdoor temperature is below the design temperature. When the 97.5-percent column in Appendix D of the IPC is used, it can be assumed that the actual outdoor temperature will be at or below the design temperature for roughly 54 hours of the total of 2,160 hours in the months of December through February (2.5 percent of 2,160 hours = 54).

The exception recognizes that not all interior spaces are associated with human comfort by the nature of their uses, such as a commercial cooler or freezer. These and similar spaces would not require heating systems.

SECTION 1205
LIGHTING

1205.1 General. Every space intended for human occupancy shall be provided with natural light by means of exterior glazed openings in accordance with Section 1205.2 or shall be provided with artificial light in accordance with Section 1205.3. Exterior glazed openings shall open directly onto a *public way* or onto a *yard* or *court* in accordance with Section 1206.

❖ This section establishes that an option can be exercised on a room-by-room or space-by-space basis. The option allows the designer to provide either natural light in accordance with this chapter or equivalent levels of artificial lighting.

1205.2 Natural light. The minimum net glazed area shall be not less than 8 percent of the floor area of the room served.

❖ This section establishes the minimum glazed area required based on the floor area served by the window. This is required only for spaces that are not provided with artificial light in accordance with Section 1205.3. It is the intent of the code to establish this ratio as the minimum glazed opening onto yards or courts, in accordance with Section 1205.1.

Early codes set this standard at 10 percent of the floor area served. This ratio was derived from certain architectural styles that yielded adequate light and ventilation; however, this is a more than adequate amount and has been reduced to the current levels because of energy conservation issues. Openings in excess of that minimum area are permitted to open onto areas other than a complying court or yard. In Figure 1203.4.1, the room dimensions are 15 feet by 20 feet (4572 mm by 6096 mm), or 300 square feet (27.9 m^2) of area. If windows B and C are double hung, with a combined glazed area of 24 square feet (2.23 m^2), they provide the minimum area required of 8 percent of the floor area (24/300 = 0.08). In this example, glazing unit A is not required for natural light; therefore, it need not face onto a required yard or court.

1205.2.1 Adjoining spaces. For the purpose of natural lighting, any room is permitted to be considered as a portion of an adjoining room where one-half of the area of the common

wall is open and unobstructed and provides an opening of not less than one-tenth of the floor area of the interior room or 25 square feet (2.32 m^2), whichever is greater.

Exception: Openings required for natural light shall be permitted to open into a sunroom with *thermal isolation* or a patio cover where the common wall provides a glazed area of not less than one-tenth of the floor area of the interior room or 20 square feet (1.86 m^2), whichever is greater.

❖ In a case where a space (or room) has no glazed area open to the required courts or yards but is adjacent to one that does, it may "borrow" natural lighting from the adjacent space if: (1) the wall between the adjoining spaces is at least one-half open and unobstructed; (2) the opening equals at least 10 percent of the floor area of the interior space and (3) the opening is not less than 25 square feet (2.33 m^2). The required glazed area facing the required court or yard must not be less than 8 percent of the total floor area of all rooms served. For example, in Figure 1205.2.1, the glazed area in Space B is required to be equal to or greater than 0.08 (floor area of Space A + floor area of Space B).

In the figure, the opening between the adjacent spaces must meet all three criteria: the wall must be at least half open and unobstructed, it must be a minimum of 25 square feet (2.33 m^2) and it must be not less than one-tenth of the floor area of space A.

The exception deals with a very common circumstance, especially in residential construction. As long as the sunroom is large enough and is thermally isolated, the building owner need not move openings for lighting when installing an addition that falls within the definition of "Sunroom." Note that sunrooms can also be part of the initial construction of a building.

1205.2.2 Exterior openings. Exterior openings required by Section 1205.2 for natural light shall open directly onto a *public way*, *yard* or *court*, as set forth in Section 1206.

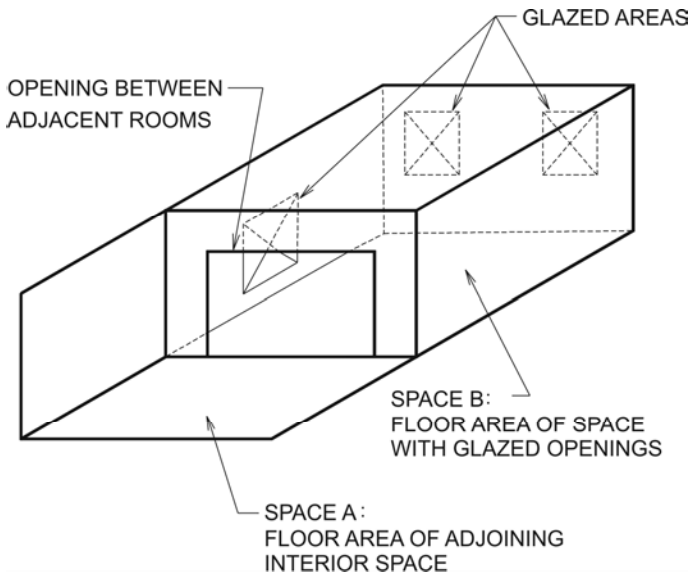
Exceptions:

1. Required exterior openings are permitted to open into a roofed porch where the porch:
   1.1. Abuts a *public way*, *yard* or *court*;
   1.2. Has a ceiling height of not less than 7 feet (2134 mm); and
   1.3. Has a longer side at least 65 percent open and unobstructed.
2. Skylights are not required to open directly onto a *public way*, *yard* or *court*.

❖ In order that enough light will be provided through openings to naturally lit rooms, the openings must open onto yards or courts with the minimum dimensions specified in Section 1206. Skylights admit light directly from above and, therefore, are not required to face a court or yard in accordance with Exception 2. Exception 1 gives the criteria by which a roofed porch may be located directly outside required openings without significantly obstructing the entrance of light to the space.

1205.3 Artificial light. Artificial light shall be provided that is adequate to provide an average illumination of 10 footcandles (107 lux) over the area of the room at a height of 30 inches (762 mm) above the floor level.

❖ The section establishes the minimum required illumination for rooms without the minimum required natural light (see Figure 1205.3). Please note that Section 1006.2 requires 1 footcandle (11 lux) of light at the walking surface of all means of egress.



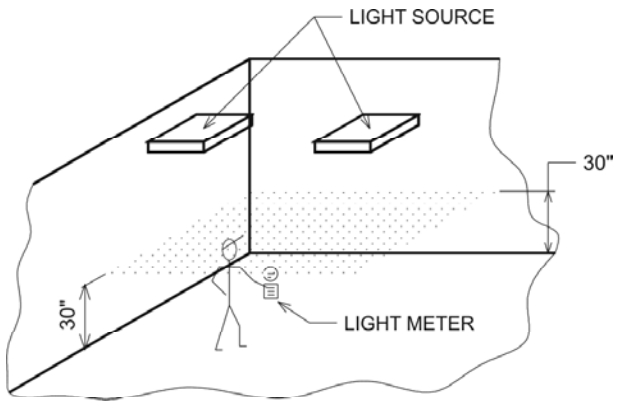


Figure 1205.2.1
NATURAL LIGHT FROM ADJACENT SPACE

For SI: 1 inch = 25.4 mm.

Figure 1205.3
ARTIFICIAL LIGHTING IN A ROOM

1205.4 Stairway illumination. *Stairways* within *dwelling units* and *exterior stairways* serving a *dwelling unit* shall have an illumination level on tread runs of not less than 1 footcandle (11 lux). *Stairs* in other occupancies shall be governed by Chapter 10.

❖ Illumination is essential for stairway safety during normal use, as well as during egress in an emergency. The lighting must be operable by switches in the vicinity of the stairway, located as required by the *National Electrical Code*® (NEC). Emergency egress lighting, also referred to as "means of egress illumination," is required in occupancies other than dwelling units at a lower rate of illumination (see commentary, Sections 1006 and 1205.5).

1205.4.1 Controls. The control for activation of the required *stairway* lighting shall be in accordance with NFPA 70.

❖ The NEC provides for controls at the top and bottom of stairways within dwelling units, allowing an occupant to illuminate the stairways before traversing any stairways, regardless of the direction of travel. Illuminated switches, where required, allow an occupant to quickly find the switches when the stairways are dark.

Illumination controls for exterior stairways that are operable from the inside of a dwelling unit allow an occupant to safely egress by activating exterior stairway illumination prior to leaving the building. Exterior stairways must be provided with the minimum illumination level specified in Section 1205.4.

1205.5 Emergency egress lighting. The *means of egress* shall be illuminated in accordance with Section 1006.1.

❖ Means of egress illumination is required in all buildings to allow occupants enough light to negotiate the exit access (such as corridors) and exits (such as enclosed stairways) at all times the building is occupied (see commentary, Section 1006.1).

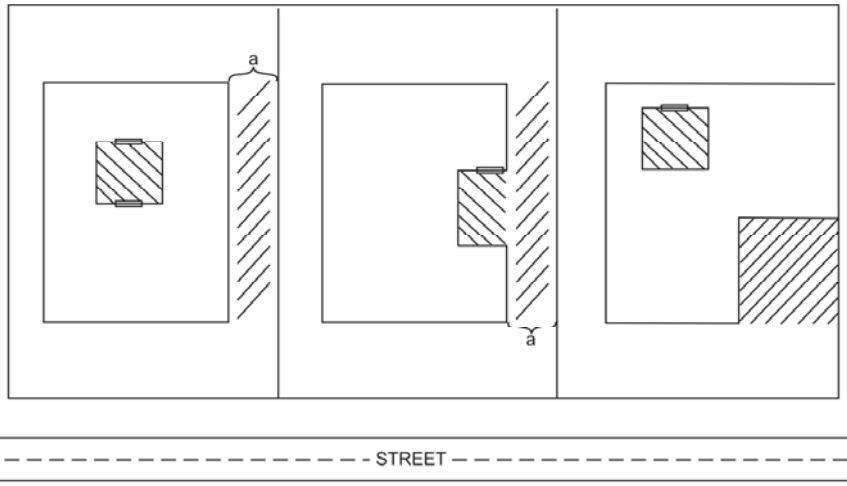
SECTION 1206
YARDS OR COURTS

1206.1 General. This section shall apply to *yards* and *courts* adjacent to exterior openings that provide natural light or ventilation. Such *yards* and *courts* shall be on the same *lot* as the building.

❖ These provisions are intended to regulate those exterior areas of a building or structure that are supposed to supply required natural light or ventilation to interior spaces. These requirements are intended to increase the likelihood that the exterior walls are provided with enough adjacent open space to allow the required light and ventilating air to freely enter the exterior wall openings. These exterior areas are defined as "Courts" and "Yards." Courts and yards must be open, uncovered and on the same lot as the building. They may be either partly or wholly enclosed by the building. Requirements are provided in Section 1206, which regulates the minimum width, area, air intake and drainage of courts and yards. The requirements of Sections 1206.2 through 1206.3.3 do not apply if artificial ventilation and lighting is provided for the spaces opening onto the court or yard in accordance with Section 1203.1 or 1205.1. See Figure 1206.1 for examples of courts and yards.

1206.2 Yards. *Yards* shall be not less than 3 feet (914 mm) in width for buildings two *stories* or less above *grade plane*. For buildings more than two *stories above grade plane*, the minimum width of the *yard* shall be increased at the rate of 1 foot (305 mm) for each additional *story*. For buildings exceeding 14 *stories above grade plane*, the required width of the *yard* shall be computed on the basis of 14 *stories above grade plane*.

❖ A yard is distinguished from a court by the definitions in Chapter 2 (see commentary, Chapter 2). A court is bounded on at least three sides by exterior building walls or similar enclosing devices, whereas a yard is typically located between a building and a lot line and is open on at least two sides or ends (see Figure 1206.1).



The required width of a yard is measured perpendicular from the face of the wall to the opposing wall on the other side of the yard. A five-story building would be required to have a yard at least 6 feet (1829 mm) in width [3 feet (914 mm) plus 1 foot (305 mm) each for stories three through five]. A 20-story building is required to have a yard at least 15 feet (4572 mm) [3 feet (914 mm) plus 1 foot (305 mm) each for stories three through 14]. The last sentence of the section simply requires a minimum yard width of 15 feet (4572 mm) for all buildings over 14 stories in height. If the building is adjacent to a court rather than a yard, the requirements of Section 1206.3 apply. Neither Section 1206.2 nor 1206.3 is applicable if artificial lighting and ventilation is provided for spaces facing the yard or court in accordance with Sections 1203.1 and 1205.1. Note that the stories are measured above grade plane.

1206.3 Courts. *Courts* shall be not less than 3 feet (914 mm) in width. *Courts* having windows opening on opposite sides shall be not less than 6 feet (1829 mm) in width. *Courts* shall be not less than 10 feet (3048 mm) in length unless bounded on one end by a *public way* or *yard*. For buildings more than two *stories above grade plane*, the *court* shall be increased 1 foot (305 mm) in width and 2 feet (610 mm) in length for each additional *story*. For buildings exceeding 14 *stories above grade plane*, the required dimensions shall be computed on the basis of 14 *stories above grade plane*.

❖ "Courts" are defined in Chapter 2 as being bounded on no less than three sides by walls or other enclosing construction. A court adjacent to a five-story building would be required to have a width measured perpendicular from the wall facing the court of at least 6 feet (1829 mm) when required openings are on one wall and 9 feet (2743 mm) when required openings are on opposing walls [3 feet (914 mm) plus 1 foot (305 mm) each for stories three through five, or 6 feet (1829 mm) plus 1 foot (305 mm) each for stories three through five]. If the same court is bounded on all sides, the required minimum length would be 16 feet (4877 mm) [10 feet (3048 mm) plus 2 feet (610 mm) each for stories three through five]. The last sentence simply requires all buildings higher than 14 stories to have a minimum court width of 15 feet (4572 mm) without opposing required openings, a minimum width of 18 feet (5486 mm) where required openings oppose each other and a minimum length of 34 feet (10 363 mm) if bounded on all sides [width equals 3 feet (914 mm) or 6 feet (1829 mm) plus 1 foot (305 mm) each for stories three through 14, and length equals 10 feet (3048 mm) plus 2 feet (610 mm) each for stories three through 14]. The requirements of this section are not applicable if artificial lighting and ventilation are provided for spaces facing the court in accordance with Sections 1203.1 and 1205.1. Note that the stories are measured above grade plane. See Figure 1206.3 for examples of court dimensions.

1206.3.1 Court access. Access shall be provided to the bottom of *courts* for cleaning purposes.

❖ Courts must be accessed for maintenance. Clearly, a court intended to be a source of ventilation air must be maintained in a manner conducive to its purpose.

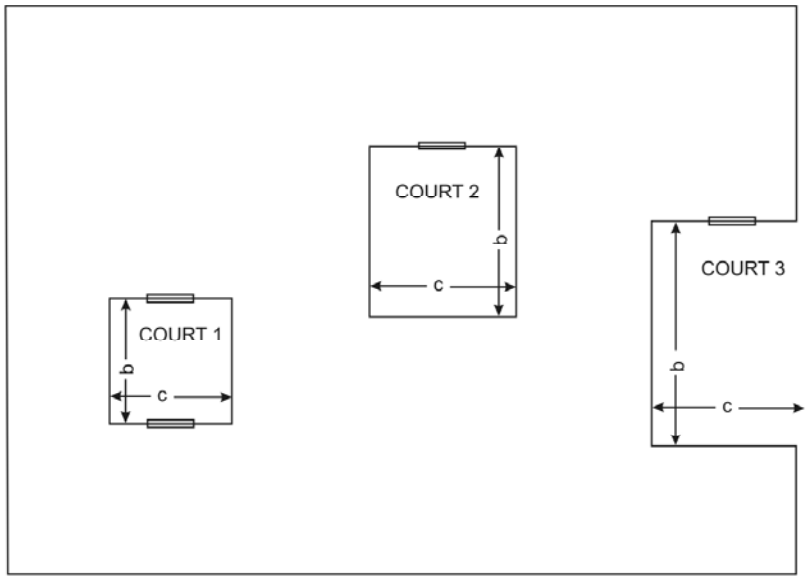

Figure 1206.1
YARDS AND COURTS

1206.3.2 Air intake. *Courts* more than two *stories* in height shall be provided with a horizontal air intake at the bottom not less than 10 square feet (0.93 m^2) in area and leading to the exterior of the building unless abutting a *yard* or *public way*.

❖ This section is applicable only to courts that are bounded on all four sides by walls or other construction. A fully bounded court takes on characteristics similar to a chimney during summer weather when the building mass is heated from the daytime sun. In order for a fully bounded court to function as an efficient source of natural ventilation, the bottom of the court must have a source of fresh air (similar to a chimney). This source of fresh air is supplied through the required opening of 10 square feet (0.93 m^2) connected directly to a street or yard. The requirements of this section are not applicable if artificial lighting and ventilation are provided for spaces facing the court in accordance with Sections 1203.1 and 1206.1.

1206.3.3 Court drainage. The bottom of every *court* shall be properly graded and drained to a public sewer or other *approved* disposal system complying with the *International Plumbing Code*.

❖ A court is an inherent water trap. A court that is not both graded and drained will accumulate water and remain in a saturated condition, which will promote an insanitary condition, including odors. Stagnant water is often a breeding ground for disease-carrying insects. Based on the design and nature of the soil after construction, paving the court may be the best solution to eliminate a problem.

SECTION 1207
SOUND TRANSMISSION

1207.1 Scope. This section shall apply to common interior walls, partitions and floor/ceiling assemblies between adjacent *dwelling units* or between *dwelling units* and adjacent public areas such as halls, *corridors*, *stairs* or service areas.

❖ Since noise transmission can be quantified and affects the quality of life, the code incorporates regulations that address noise transmission in multiple-family residential construction, wherein the occupants may have no control over noise. The regulated components of construction are those through which noise is primarily transmitted.

1207.2 Air-borne sound. Walls, partitions and floor/ceiling assemblies separating *dwelling units* from each other or from public or service areas shall have a sound transmission class (STC) of not less than 50 (45 if field tested) for air-borne noise when tested in accordance with ASTM E 90. Penetrations or openings in construction assemblies for piping; electrical devices; recessed cabinets; bathtubs; soffits; or heating, ventilating or exhaust ducts shall be sealed, lined, insulated or otherwise treated to maintain the required ratings. This requirement shall not apply to *dwelling unit* entrance doors; however, such doors shall be tight fitting to the frame and sill.

❖ The code requires common walls between dwelling units and between dwelling units and public areas to have a minimum sound transmission class (STC) of 50. The STC is a measure of an assembly's ability to resist sound transmission. The higher the number (rating), the higher the resistance (less sound transmission). Standard architectural wall construction assemblies have been tested for sound transmission ratings, and reference to the construction specifications will yield such information. Air-borne noise originates in the air, such as voice or music. For structure-borne sound, see the commentary to Section 1207.3.

As a rule, vertical assemblies meeting the requirements of this section consist of double walls or walls containing insulation similar to exterior walls.

1207.2.1 Masonry. The sound transmission class of concrete masonry and clay masonry assemblies shall be calculated in accordance with TMS 0302 or determined through testing in accordance with ASTM E 90.

❖ The STC values found in the referenced standard TMS 0302 are derived from laboratory testing of masonry assemblies in accordance with ASTM E 90. This reference provides a quicker alternative for compliance with the STC ratings required by Section 1207.2 of the code for masonry and clay masonry assemblies.

1207.3 Structure-borne sound. Floor/ceiling assemblies between *dwelling units* or between a *dwelling unit* and a public or service area within the structure shall have an impact insulation class (IIC) rating of not less than 50 (45 if field tested) when tested in accordance with ASTM E 492.

❖ The impact insulation class (IIC) is a measure of an assembly's ability to resist sound transmission. The higher the number (rating), the higher the resistance (less sound transmission). Floors between dwelling units and those between dwelling units and public areas are required to have a minimum IIC rating of 50.

Usually, floor assemblies that are carpeted meet the minimum requirement for an IIC rating of 50. Other areas with hard-surfaced finishes may require additional treatment or insulation to comply with these requirements.

There are various resource documents containing STC ratings and IIC ratings, including the following: GA 600, *Fire Resistance Design Manual*, by the Gypsum Association; NCMA TEK 69A, *New Data on Sound Reduction with Concrete Masonry Walls*, by the National Concrete Masonry Association; and BIA TN 5A, *Sound Insulation—Clay Masonry Walls*, by the Brick Institute of America. These or any other similar sources can be submitted as a basis for approval once it is demonstrated to the building official that the data are based on ASTM E 90 and E 492.

SECTION 1208
INTERIOR SPACE DIMENSIONS

1208.1 Minimum room widths. *Habitable spaces*, other than a kitchen, shall be not less than 7 feet (2134 mm) in any plan dimension. Kitchens shall have a clear passageway of not less than 3 feet (914 mm) between counter fronts and appliances or counter fronts and walls.

❖ This provision specifies the minimum horizontal dimensions required for all habitable rooms. Any room that functions as a living room, bedroom, dining room or any other similar habitable room must be sized such that a cylinder with a diameter of 7 feet (2134 mm) may be placed in it. Only kitchens are exempt from this requirement. This code provision allows the circulation of ventilation air through the space while maintaining reasonably sized living quarters for the occupants. "Habitable space" is defined in Chapter 2. Smaller spaces, such as bathrooms and hallways, do not need to meet the minimum room width requirements because they are not considered habitable rooms.

1208.2 Minimum ceiling heights. Occupiable spaces, *habitable spaces* and *corridors* shall have a ceiling height of not less than 7 feet 6 inches (2286 mm). Bathrooms, toilet rooms, kitchens, storage rooms and laundry rooms shall be permitted to have a ceiling height of not less than 7 feet (2134 mm).

Exceptions:

1. In one- and two-family *dwellings*, beams or girders spaced not less than 4 feet (1219 mm) on center shall be permitted to project not more than 6 inches (152 mm) below the required ceiling height.
2. If any room in a building has a sloped ceiling, the prescribed ceiling height for the room is required in one-half the area thereof. Any portion of the room

measuring less than 5 feet (1524 mm) from the finished floor to the ceiling shall not be included in any computation of the minimum area thereof.

3. The height of *mezzanines* and spaces below m*ezzanines* shall be in accordance with Section 505.1.

❖ Occupiable spaces or rooms (including habitable spaces) are required to have a specific minimum ceiling height. Bathrooms, toilet rooms, kitchens, storage rooms and laundry rooms are permitted to have a lower minimum ceiling height in accordance with this section. Ceiling height is one of the variables that affects the circulation of air in a space. Additionally, there is a psychological need for spaciousness in a living space or in one of the accessory spaces.

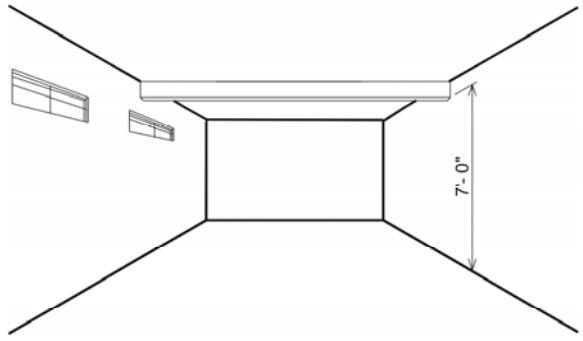

Figure 1208.2(1) illustrates the application of Exception 1 for beams and girders spaced no more than 4 feet (1219 mm) on center in one- and two-family dwellings.

Figure 1208.2(2) illustrates the application of Exception 2. Rooms with sloped ceilings are required to meet two distinct conditions. First, the area of the room having a floor-to-ceiling clearance of less than 5 feet (1524 mm) does not contribute to the minimum floor area required by Section 1208.3. Second, at least one-half of the actual total area of the room must meet the minimum ceiling height requirements of Section 1208.2 [see Figure 1208.2(2)].

Finally, Exception 3 is consistent with Section 505.1, which establishes the minimum ceiling height for mezzanines at 7 feet (2134 mm). In accordance with Section 505.2, mezzanines cannot exceed one-third of the area of the room in which they are located.

1208.2.1 Furred ceiling. Any room with a furred ceiling shall be required to have the minimum ceiling height in two-thirds of the area thereof, but in no case shall the height of the furred ceiling be less than 7 feet (2134 mm).

❖ This section only applies to rooms required to have a ceiling height of no less than 7 feet, 6 inches (2286 mm). In Figure 1208.2.1, floor area A_1 must be greater than or equal to two-thirds (length times width). Note that only those ceiling heights furred to a height of less than 7 feet, 6 inches (2286 mm) affect area A_1.

For SI: 1 foot = 304.8 mm.

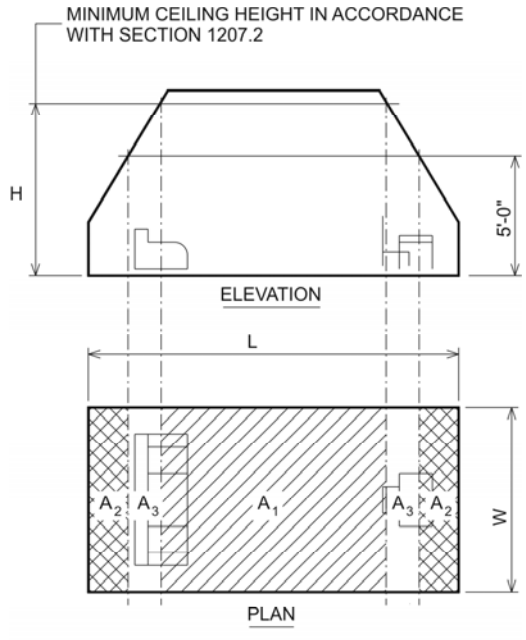

Figure 1208.2(1)
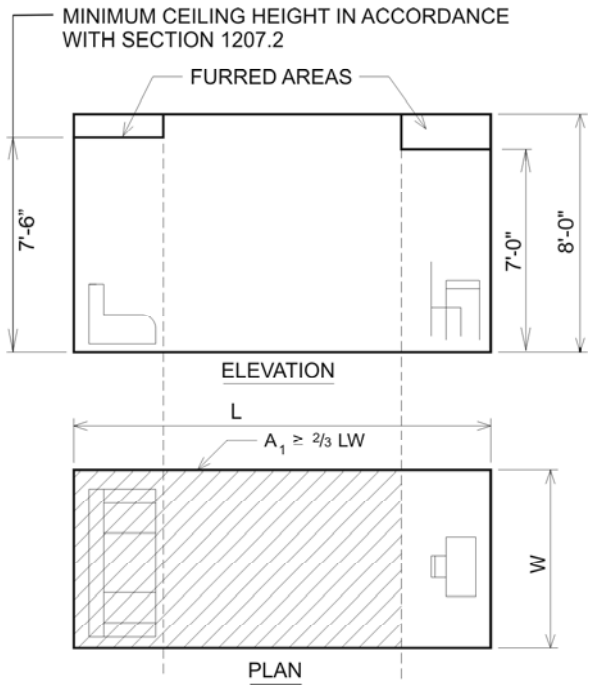
MINIMUM CEILING HEIGHT—
ALLOWABLE PROJECTIONS IN
ONE- AND TWO-FAMILY DWELLINGS

1208.3 Room area. Every *dwelling unit* shall have no fewer than one room that shall have not less than 120 square feet (13.9 m^2) of *net floor area*. Other habitable rooms shall have a *net floor area* of not less than 70 square feet (6.5 m^2).

Exception: Kitchens are not required to be of a minimum floor area.



❖ This section applies only to dwelling units. A minimum area of 120 square feet (13.9 m^2) for at least one room of each dwelling unit and a minimum of 70 square feet (6.5 m^2) for all other habitable rooms, except kitchens, are the minimum standards for habitable rooms. These minimums reflect the physiological requirements of light and ventilation and also preserve the individual's perception of space and the elements necessary for a psychological sense of well-being. The code does not regulate the minimum area of rooms and spaces in other than residential occupancies.

The exception permits smaller kitchens in dwelling units built under the code. There is no minimum area or dimension required for kitchens.

For SI: 1 foot = 304.8 mm.

Figure 1208.2(2)
SLOPED CEILING HEIGHTS

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1208.2.1
FURRED CEILING HEIGHTS

1208.4 Efficiency dwelling units. An efficiency living unit shall conform to the requirements of the code except as modified herein:

1. The unit shall have a living room of not less than 220 square feet (20.4 m^2) of floor area. An additional 100 square feet (9.3 m^2) of floor area shall be provided for each occupant of such unit in excess of two.
2. The unit shall be provided with a separate closet.
3. The unit shall be provided with a kitchen sink, cooking appliance and refrigeration facilities, each having a clear working space of not less than 30 inches (762 mm) in front. Light and *ventilation* conforming to this code shall be provided.
4. The unit shall be provided with a separate bathroom containing a water closet, lavatory and bathtub or shower.

❖ Efficiency units are very small apartments consisting of one or two rooms and a bathroom. Efficiency units that comply with this section are not required to comply with the minimum area requirements in Section 1208.3; however, the total allowable number of occupants in the dwelling is limited, depending on the area of the unit in accordance with Item 1. The purpose of both efficiency units and this section is to provide for combined use of spaces in an economical or "efficient" manner without jeopardizing health or comfort. This is possible because of the occupant limitation.

In addition to the living room, the apartment must have a separate closet and bathroom. There are no minimum area requirements for these spaces; however, the fixture clearances in the bathroom must be as required in the IPC. There is not a requirement for a separate kitchen, but if the required sink and appliances are located in the living room, they cannot encroach on the required minimum floor space.

SECTION 1209
ACCESS TO UNOCCUPIED SPACES

1209.1 Crawl spaces. Crawl spaces shall be provided with no fewer than one access opening which shall be not less than 18 inches by 24 inches (457 mm by 610 mm).

❖ The requirements of this section establish 18 inches by 24 inches (457 mm by 610 mm) as the minimum size opening for crawl spaces. If access is through a wall, the 18-inch (457 mm) minimum would be the height and the 24-inch (610 mm) minimum would be the width.

Items such as plumbing and wiring installations pass through crawl spaces at times. Required initial and periodic inspections, and repairs cannot be carried out without access to such crawl spaces.

1209.2 Attic spaces. An opening not less than 20 inches by 30 inches (559 mm by 762 mm) shall be provided to any *attic* area having a clear height of over 30 inches (762 mm). Clear headroom of not less than 30 inches (762 mm) shall be provided in the *attic* space at or above the access opening.

❖ Access to the attic provides a convenient and nondestructive means for fire department personnel to visually check for an attic fire and, if need be, gain entry to the concealed spaces and suppress a fire. Access to attic spaces can be provided through the ceiling within each compartment that is created by draftstops or through openings within the draftstops themselves. Openings located within the draftstop are required to be self-closing and the opening protective must provide structural fire integrity (the ability to remain in place) similar to the draftstop. Access is required when the attic space has a clear height greater than 30 inches (762 mm) measured from the top of the ceiling joists (or top of the floor sheathing, if present) to the underside of the roof rafters.

1209.3 Mechanical appliances. Access to mechanical appliances installed in under-floor areas, in *attic* spaces and on roofs or elevated structures shall be in accordance with the *International Mechanical Code*.

❖ Access to mechanical appliances is needed to maintain and service the equipment. See Section 306 in the IMC for detailed requirements.

SECTION 1210
TOILET AND BATHROOM REQUIREMENTS

[P] 1210.1 Required fixtures. The number and type of plumbing fixtures provided in any occupancy shall comply with Chapter 29.

❖ The minimum number of plumbing fixtures depends upon the occupant load and use of the building. Chapter 29 contains a table for determination of the number of facilities.

1210.2 Finish materials. Walls, floors and partitions in toilet and bathrooms shall comply with Sections 1210.2.1 through 1210.2.4.

1210.2.1 Floors and wall bases. In other than *dwelling units*, toilet, bathing and shower room floor finish materials shall have a smooth, hard, nonabsorbent surface. The intersections of such floors with walls shall have a smooth, hard, nonabsorbent vertical base that extends upward onto the walls not less than 4 inches (102 mm).

❖ The purpose of this requirement is to provide nonabsorbent surfaces that can be maintained in a sanitary condition. The 4-inch (152 mm) extension of the surface up the surrounding walls is so that the wall will not absorb moisture during cleaning and, thus, will be left in a clean condition. This provision does not require that the same material that is on the floor be extended up the wall. As long as the wall material is smooth, hard and nonabsorbent, and there is adequate seal between the materials to restrict moisture from getting behind the surface material and into the wall construction, the intent of the requirement should be met.

1210.2.2 Walls and partitions. Walls and partitions within 2 feet (610 mm) of service sinks, urinals and water closets shall have a smooth, hard, nonabsorbent surface, to a height of not less than 4 feet (1219 mm) above the floor, and except for structural elements, the materials used in such walls shall be of a type that is not adversely affected by moisture.

Exception: This section does not apply to the following buildings and spaces:

1. Dwelling units and sleeping units.
2. Toilet rooms that are not accessible to the public and which have not more than one water closet.

Accessories such as grab bars, towel bars, paper dispensers and soap dishes, provided on or within walls, shall be installed and sealed to protect structural elements from moisture.

❖ The walls and partitions near urinals and water closets need to have the surface specified in this section since they are subject to moisture. Exception 1 recognizes that water closet facilities in dwelling units and sleeping units are not exposed to as much use as those that serve the public and, thus, are easier to maintain. Exception 2 acknowledges that toilet fixtures that do not serve the public are also subject to less use. This section requires protection of the structural supports for accessories so that they will maintain their strength.

1210.2.3 Showers. Shower compartments and walls above bathtubs with installed shower heads shall be finished with a smooth, nonabsorbent surface to a height not less than 70 inches (1778 mm) above the drain inlet.

❖ The 70-inch (1778 mm) requirement in this section is based on the height of the shower compartment and walls that are exposed to significant moisture that would cause the surface to become insanitary over a long period of time.

1210.2.4 Waterproof joints. Built-in tubs with showers shall have waterproof joints between the tub and adjacent wall.

❖ The joint between the tub and wall must be sealed to prevent moisture from getting into the supporting floor and framing. Waterproof joints are also needed to keep the concealed area of the wall in a sanitary condition.

[P] 1210.3 Privacy. Privacy at water closets and urinals shall be provided in accordance with Sections 1210.3.1 and 1210.3.2.

❖ For most people, a certain amount of privacy in public facilities is desirable. For some, it is imperative. This section provides requirements for water-closet compartments and urinal dividers.

[P] 1210.3.1 Water closet compartment. Each water closet utilized by the public or employees shall occupy a separate compartment with walls or partitions and a door enclosing the fixtures to ensure privacy.

Exceptions:

1. Water closet compartments shall not be required in a single-occupant toilet room with a lockable door.
2. Toilet rooms located in child day care facilities and containing two or more water closets shall be permitted to have one water closet without an enclosing compartment.
3. This provision is not applicable to toilet areas located within Group I-3 occupancy housing areas.

❖ Psychological studies have proven that lack of privacy places a burden on an individual's physical ability to use bathroom facilities. This is caused by uneasiness, inhibition or indignation. A partitioned compartment can provide the necessary privacy. Also, a single-occupant toilet room with a lockable door can provide the required privacy as stated in Exception 1. Exception 2, allowing an unenclosed water closet in a child care facility, recognizes the need for people to be able to assist children. Exception 3 was added in the 2009 code edition to allow for security personal to better monitor for illicit activities of inmates in Group 1-3 occupancies.

[P] 1210.3.2 Urinal partitions. Each urinal utilized by the public or employees shall occupy a separate area with walls or partitions to provide privacy. The walls or partitions shall

begin at a height not more than 12 inches (305 mm) from and extend not less than 60 inches (1524 mm) above the finished floor surface. The walls or partitions shall extend from the wall surface at each side of the urinal not less than 18 inches (457 mm) or to a point not less than 6 inches (152 mm) beyond the outermost front lip of the urinal measured from the finished backwall surface, whichever is greater.

Exceptions:

1. Urinal partitions shall not be required in a single-occupant or family or assisted-use toilet room with a lockable door.
2. Toilet rooms located in child day care facilities and containing two or more urinals shall be permitted to have one urinal without partitions.

❖ Users of urinals in a public toilet room need to be afforded a level of privacy for the reasons stated in the commentary for Section 1210.3.1. In addition, partitions aid in protecting adjacent users from splash. Because of the likelihood of splashing, the partition surfaces must be designed so that they can be easily cleaned and sanitized during normal restroom maintenance. Exception 1 assumes that in a single-occupant toilet room or a family/assisted-use toilet room privacy is afforded by locking the door. Exception 2 allows day care and child care centers to have one urinal out of two or more urinals in a toilet room to be without partitions. This affords care providers the ability to assist or supervise certain children with use of the urinal (e.g., those just learning to use a urinal or those with difficult clothing arrangements). Where urinal partitions are provided, occupants are more inclined to use a urinal rather than a water closet for urination. This will result in less soiling of water closet seats and surrounding surfaces. Note that where partitions are used, the distance from the center of the urinal to the face of the partition must be at least 15 inches (381 mm).The thickness of partitions cannot encroach into the required spaces for fixtures.

1210.4 Toilet room location. Toilet rooms shall not open directly into a room used for the preparation of food for service to the public.

❖ The requirement that toilet rooms not open directly into rooms where food is prepared for the public is necessary to keep the food preparation area in a sanitary condition.

Chapter 13: Energy Efficiency

General Comments

Chapter 13 provides for the design and construction of energy-efficient buildings and structures or portions thereof intended primarily for human occupancy by direct reference to the *International Energy Conservation Code*® (IECC®).

Purpose

The purpose of Chapter 13 is to provide minimum design requirements that will promote efficient utilization of energy in building construction. The requirements are directed toward the design of building envelopes with adequate thermal resistance and low air leakage, and toward the design and selection of mechanical, service water heating, electrical and illumination systems that will promote the effective use of depletable energy resources and encourage the use of nondepletable energy resources.

SECTION 1301 GENERAL

[E] 1301.1 Scope. This chapter governs the design and construction of buildings for energy efficiency.

❖ The scope of Chapter 13 is applicable to all buildings and structures, as well as their components and systems that are regulated by the IECC. The IECC thereby addresses the design of energy-efficient building envelopes, and the selection and installation of energy-efficient mechanical, service-water heating, electrical distribution and illumination systems and equipment for the effective use of energy in both residential and commercial buildings.

[E] 1301.1.1 Criteria. Buildings shall be designed and constructed in accordance with the *International Energy Conservation Code*.

❖ The energy conservation requirements of this chapter rely exclusively on the technical provisions of the IECC. Compliance with the IECC is the sole means of demonstrating compliance with the technical provisions of Chapter 13.

The climate basis for the 2012 IECC is derived from geographical zones that are based on multiple climate variables (so that both heating and cooling considerations are accommodated). Further, within the U.S., the zones are completely defined by political boundaries (county lines) so that code users will never have to choose from disparate climate data sources to determine local requirements. The climate zones were developed in an open process, in consultation with relevant standards committees of the American Society of Heating, Refrigerating and Air-conditioning Engineers (ASHRAE). The zones are designed to be an appropriate foundation for both residential and commercial codes, and may be useful in other contexts as well.

The IECC is designed to increase consumer awareness of a home's energy features by making baseline requirements uniform within a jurisdiction and by requiring a disclosure of each house's *R*-values, *U*-factors and heating, ventilating and air-conditioning (HVAC) efficiencies.

The IECC is designed, to the extent practicable, to incorporate aspects of the latest building science regarding energy efficiency and its effects on moisture control and durability. For example, the IECC contains provisions related to unvented crawl spaces, modifies vapor retarder requirements, requires sealing of air handlers in garages and limits worst-case glazing *U*-factors in locations where moisture condensation can be a serious problem.

Bibliography

Chapter 14: Exterior Walls

General Comments

Chapter 14 provides requirements for the materials and construction creating finished exterior surfaces of a building or structure. The chapter provides requirements resulting in minimum permitted weather resistance and fire performance.

In the past, there were relatively few materials available for application to exterior walls for protection against weather and exposure to other outside elements. With the development of new methods and materials over the years, architects and builders began to use a variety of materials for different appearances, improved insulating quality, sound transmission control and fire resistance. The code has developed prescriptive and performance regulations to control these aspects and the types and thickness of exterior wall coverings.

Purpose

The purpose of Chapter 14 is to provide the minimum requirements for exterior wall coverings. This chapter also includes the minimum regulations for materials, and the minimum thicknesses and installation requirements for exterior weather coverings and various wall veneers. Limitations on the use of combustible exterior wall finishes are also included.

SECTION 1401 GENERAL

1401.1 Scope. The provisions of this chapter shall establish the minimum requirements for exterior walls; *exterior wall* coverings; *exterior wall* openings; exterior windows and doors; architectural *trim*; balconies and similar projections; and bay and oriel windows.

❖ The requirements for exterior wall construction, including components such as openings, doors, windows, trim and balconies, are specified herein. Also specified are provisions intended to prevent damage to a building from the effects of weather and from moisture intrusion into or through the exterior walls.

SECTION 1402 DEFINITIONS

1402.1 Definitions. The following terms are defined in Chapter 2:

ADHERED MASONRY VENEER.

ANCHORED MASONRY VENEER.

BACKING.

EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS).

EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS) WITH DRAINAGE.

EXTERIOR WALL.

EXTERIOR WALL COVERING.

EXTERIOR WALL ENVELOPE.

FIBER-CEMENT SIDING.

HIGH-PRESSURE DECORATIVE EXTERIOR-GRADE COMPACT LAMINATE (HPL).

HIGH-PRESSURE DECORATIVE EXTERIOR-GRADE COMPACT LAMINATE (HPL) SYSTEM.

METAL COMPOSITE MATERIAL (MCM).

METAL COMPOSITE MATERIAL (MCM) SYSTEM.

POLYPROPYLENE SIDING.

PORCELAIN TILE.

VENEER.

VINYL SIDING.

WATER-RESISTIVE BARRIER.

❖ Definitions facilitate the understanding of code provisions and minimize potential confusion. To that end, this section lists definitions of terms associated with roof assemblies, roof coverings and rooftop structures. Note that these definitions are found in Chapter 2. The use and application of defined terms, as well as undefined terms, are set forth in Section 201.

SECTION 1403 PERFORMANCE REQUIREMENTS

1403.1 General. The provisions of this section shall apply to exterior walls, wall coverings and components thereof.

❖ The exterior walls of buildings provide support for the floor and roof systems; act as barriers against the outside environment; reduce heat loss from the interior and, in some instances, provide the sole resistance to such destructive forces as earthquakes and floods. This section provides references to other

applicable sections of the code that are intended to detail specific requirements to accomplish these objectives. Additionally, this chapter contains detailed requirements related to the performance of exterior wall coverings and the exterior wall envelope.

1403.2 Weather protection. Exterior walls shall provide the building with a weather-resistant *exterior wall envelope*. The *exterior wall envelope* shall include flashing, as described in Section 1405.4. The *exterior wall envelope* shall be designed and constructed in such a manner as to prevent the accumulation of water within the wall assembly by providing a *water-resistive barrier* behind the exterior veneer, as described in Section 1404.2, and a means for draining water that enters the assembly to the exterior. Protection against condensation in the *exterior wall* assembly shall be provided in accordance with Section 1405.3.

Exceptions:

1. A weather-resistant *exterior wall envelope* shall not be required over concrete or masonry walls designed in accordance with Chapters 19 and 21, respectively.
2. Compliance with the requirements for a means of drainage, and the requirements of Sections 1404.2 and 1405.4, shall not be required for an *exterior wall envelope* that has been demonstrated through testing to resist wind-driven rain, including joints, penetrations and intersections with dissimilar materials, in accordance with ASTM E 331 under the following conditions:
   2.1. *Exterior wall envelope* test assemblies shall include at least one opening, one control joint, one wall/eave interface and one wall sill. All tested openings and penetrations shall be representative of the intended end-use configuration.
   2.2. *Exterior wall envelope* test assemblies shall be at least 4 feet by 8 feet (1219 mm by 2438 mm) in size.
   2.3. *Exterior wall envelope* assemblies shall be tested at a minimum differential pressure of 6.24 pounds per square foot (psf) (0.297 kN/m^2).
   2.4. *Exterior wall envelope* assemblies shall be subjected to a minimum test exposure duration of 2 hours.

   The *exterior wall envelope* design shall be considered to resist wind-driven rain where the results of testing indicate that water did not penetrate control joints in the *exterior wall* envelope, joints at the perimeter of openings or intersections of terminations with dissimilar materials.
3. Exterior insulation and finish systems (EIFS) complying with Section 1408.4.1.

❖ All exterior walls of buildings must be protected against damage caused by precipitation, wind and other weather conditions.

The main text of this section prescribes three basic components of a weather-resistive exterior wall assembly: a water-resistive barrier installed over the building substrate; flashings at penetrations and terminations of the exterior wall finish and a means of draining moisture that may penetrate behind the finish back to the exterior.

Section 1404.2 is referenced for the requirements of the water-resistive barrier and Section 1405.3 is referenced for requirements for the flashings (see commentary, Sections 1404.2 and 1405.3). This section does not, however, contain a prescriptive requirement for the means of drainage to be provided. The method to provide the means of drainage is a performance criterion and must be evaluated based upon the ability to allow moisture that may penetrate behind the exterior wall covering to drain back to the exterior. This may be as complicated as a rain-screen, pressure-equalized type of exterior assembly or as simple as providing discontinuities or gaps between the surface of the substrate and the back side of the finish, such as through the use of noncorrodible furring.

For common types of construction, such as vinyl siding or brick veneer, the typical practice of installing building paper and weeps will comply with the intent of this section. Discontinuities between the exterior covering and substrate must be such that they encourage the flow of moisture via gravity or capillary action to a location where the water may exit, such as at flashings and weeps. The absence of a means of drainage may result in the accumulation of moisture that becomes trapped between the finish and the substrate. Over time, extended exposure to moisture may contribute to the degradation of the finish, building substrate or even the structural elements of the exterior wall.

Exception 1 states that where the exterior wall envelope is designed and constructed of concrete or masonry materials in accordance with the requirements of Chapters 19 and 21, respectively, the water-resistive barrier and means of drainage may be omitted. This is because the penetration of moisture behind the exterior wall finish is not detrimental to concrete and masonry substrates.

Exception 2 permits the use of exterior wall finishes that do not meet the prescriptive requirements of Section 1403.2, provided that the system, with penetration details, is tested for wind-driven rain resistance. The test specimen(s) must incorporate those penetration and termination details intended for use and the system will be limited to use with those details that successfully pass the test. The minimum panel size specified represents that which is commonly used in testing to ASTM E 331; however, this does not preclude the testing of larger panels if desired. The modifications to the test pressure differential and test duration are intended to represent more closely conditions that will be encountered in service. The pass/fail criteria is based upon the visual observation of moisture on the rear side of the wall assembly. In cavity-type assemblies, such as stud walls, this requires

the observation of locations such as the rear face of the exterior wall sheathing and wall framing members for the presence of moisture. The test method is intended to assess the performance of the method(s) intended for use in sealing the interface between the termination of the exterior wall finish and the penetration items or abutting construction. The method is not necessarily intended to test the performance of the penetrating item.

Exception 3 relates to exterior insulation and finish (EIFS) that is constructed in accordance with Section 1408.2. This material does not have the means for draining water that is called out in this section.

Walls designed and constructed in accordance with this chapter must also comply with the requirements of the *International Energy Conservation Code*® (IECC®).

1403.3 Structural. *Exterior walls*, and the associated openings, shall be designed and constructed to resist safely the superimposed loads required by Chapter 16.

❖ Exterior walls and their associated openings are required to resist all structural loads in accordance with the provisions of Chapter 16. This section is a correlative cross reference to emphasize the applicability of Chapter 16.

1403.4 Fire resistance. *Exterior walls* shall be fire-resistance rated as required by other sections of this code with opening protection as required by Chapter 7.

❖ The required fire-resistance rating of exterior walls is set forth in Tables 601 and 602. Table 602 is applicable to both load-bearing and nonload-bearing walls, since it addresses the prevention of fire spread from one building to an adjacent building. Load-bearing walls must comply with the greater of the requirements in Tables 601 and 602, based on the type of construction of the building. The size of openings in exterior walls is limited to prevent the spread of fire to other buildings. The commentary to Section 705 should also be reviewed when designing exterior walls. Trim on exterior walls is regulated by Section 1406.

The allowable size of openings in exterior walls is tabulated in Table 705.8. Section 715.4 specifies the required fire protection rating for opening protectives when required by Table 705.8. Where a fire-resistance rating is not required for the wall and unprotected openings are allowed, the glazing and the sash or frame may be of any material permitted by the code.

1403.5 Vertical and lateral flame propagation. Exterior walls on buildings of Type I, II, III or IV construction that are greater than 40 feet (12 192 mm) in height above grade plane and contain a combustible water-resistive barrier shall be tested in accordance with and comply with the acceptance criteria of NFPA 285.

❖ This section addresses the potential vertical and lateral flame spread that can occur either on or within exterior wall assemblies that contain combustible materials.

Construction practices, such as the addition of combustible water-resistant barriers, allow significant amounts of combustible materials/products (other than foam plastics) to be installed on or in exterior walls. This section requires testing in accordance with NFPA 285 for exterior walls that contain these types of combustible materials. This requirement is already in place for any exterior walls that contain foam plastic insulation or use metal composite material (MCM) exterior veneers. Small-scale testing has shown that these types of materials can provide significant amounts of combustible fuel loading to a wall assembly.

With the advent of newer exterior wall technologies, such as "rainscreen" systems, the openings in the exterior veneer will allow flames and heat to readily impact and ignite the barrier material. Due to the built-in standoffs of these systems, the barrier materials could then exhibit significant vertical or lateral flame propagation.

The testing requirements are applicable for exterior walls on Type I, II, III or IV construction since these types of construction allow either none or limited combustibles in the exterior walls. The 40-foot (12 192 mm) height limit is consistent with the code provisions for combustible exterior wall coverings.

1403.6 Flood resistance. For buildings in flood hazard areas as established in Section 1612.3, *exterior walls* extending below the elevation required by Section 1612 shall be constructed with flood-damage-resistant materials. Wood shall be pressure-preservative treated in accordance with AWPA U1 for the species, product and end use using a preservative *listed* in Section 4 of AWPA U1 or decay-resistant heartwood of redwood, black locust or cedar.

❖ Flood-resistant construction of exterior walls requires special consideration. Construction materials used in exterior walls of buildings that are located in flood hazard areas must be resistant to the effects of flooding. Some of the properties these materials must possess include resistance to prolonged contact with water, the ability to be cleaned and disinfected after the water recedes and negligible loss of physical properties after exposure to water. Additionally, systems must possess structural strength to resist the hydrodynamic and impact forces related to flooding. Wood construction materials in locations below the base flood elevation are required to be resistant to decay and exposure to water (see the commentary to Section 2303.1.8 for more discussion on preservative treatment of wood). Appendix G contains requirements specific to construction within areas that are prone to flooding.

1403.7 Flood resistance for high-velocity wave action areas. For buildings in flood hazard areas subject to high-velocity wave action as established in Section 1612.3, electrical, mechanical and plumbing system components shall not

be mounted on or penetrate through exterior walls that are designed to break away under flood loads.

❖ ASCE 24 and Section 1612.3 provide for the option to design exterior walls to break away under flood loads. This section prohibits the installation of penetrations for electrical, plumbing or mechanical systems through such exterior walls. The breakaway provisions are a method of protecting the remaining building frame and building system. Installation of penetrations through these walls could serve in part to defeat that purpose or to reduce the ability of the breakaway system to perform as designed.

SECTION 1404
MATERIALS

1404.1 General. Materials used for the construction of exterior walls shall comply with the provisions of this section. Materials not prescribed herein shall be permitted, provided that any such alternative has been *approved*.

❖ Section 1404 contains performance requirements and detailed installation specifications for a number of common materials used in or on exterior walls of buildings. Reference is made to the applicable chapters that contain additional requirements. These chapters should be reviewed by the reader.

It is not the intent of the code to prevent the use of any material that is equivalent in performance to those specified in Section 1404.

1404.2 Water-resistive barrier. A minimum of one layer of No.15 asphalt felt, complying with ASTM D 226 for Type 1 felt or other *approved* materials, shall be attached to the studs or sheathing, with flashing as described in Section 1405.4, in such a manner as to provide a continuous *water-resistive barrier* behind the *exterior wall* veneer.

❖ Many exterior veneers provide weather resistance but may allow either penetration of water through joints or seams or the development of condensation to occur behind the veneer. To increase the weather resistance of the wall, a layer of asphalt felt or other approved material is required to be installed over the wall backing. The felt layer and the flashing provide a water-resistive barrier behind the exterior veneer. The water-resistive membrane must be attached to the studs or sheathing in a way that will not allow the penetration of water as a result of the attachment method.

1404.3 Wood. Exterior walls of wood construction shall be designed and constructed in accordance with Chapter 23.

❖ Chapter 23 contains general requirements regulating the use of wood in buildings; however, this section contains specific provisions for the minimum thicknesses of wood siding, wood backing surfaces and hardboard siding, as well as installation and nailing requirements for wood used as weatherboarding or a wall covering.

1404.3.1 Basic hardboard. Basic hardboard shall conform to the requirements of AHA A135.4.

❖ Basic hardboard is required to comply with AHA A135.4. This material is not intended for use as exposed siding or as a weather covering, but it is often a component of veneered wall construction.

1404.3.2 Hardboard siding. Hardboard siding shall conform to the requirements of AHA A135.6 and, where used structurally, shall be so identified by the *label* of an *approved* agency.

❖ Hardboard conforming to AHA A135.6 is manufactured in panels that are usually 4 feet by 8 feet (1219 mm by 2438 mm) in size or in sizes simulating drop siding where the material is to be applied horizontally over structural sheathing. When used as a panel, hardboard siding is applied directly to the wood-framing members as a backing material. Hardboard panels are not adequate to serve as a nailing base (spanning between studs) for coverings. Coverings are fastened directly at framing locations, through the panels.

1404.4 Masonry. Exterior walls of masonry construction shall be designed and constructed in accordance with this section and Chapter 21. Masonry units, mortar and metal accessories used in anchored and adhered veneer shall meet the physical requirements of Chapter 21. The backing of anchored and adhered veneer shall be of concrete, masonry, steel framing or wood framing.

❖ Chapter 21 contains the general requirements for the use of masonry in buildings. The material classification of masonry in this section includes materials such as concrete masonry; bricks of clay, shale or calcium silicate; clay-tile units; glazed masonry units; terra cotta; natural or cast stone and ceramic tile. Chapter 21 and this section contain provisions for the minimum thickness of masonry units, limitations on loading, heights of veneers, backing and attachment.

1404.5 Metal. Exterior walls of formed steel construction, structural steel or lightweight metal alloys shall be designed in accordance with Chapters 22 and 20, respectively.

❖ Chapters 20 and 22 contain the general requirements for use of metal in buildings. Chapters 20 and 22 as well as this section contain provisions for the minimum thickness of metal weather coverings, and requirements for protection from corrosion, installation and grounding.

1404.5.1 Aluminum siding. Aluminum siding shall conform to the requirements of AAMA 1402.

❖ Although aluminum siding is addressed in Chapter 20, it is more specifically addressed here as an exterior wall covering. Aluminum siding is required to conform to the referenced standard. The thickness, installation and protection provisions of this section are also applicable (see commentary, Sections 1405.11, 1405.11.1, 1405.11.2, 1405.11.3 and 1405.11.4).

1404.5.2 Cold-rolled copper. Copper shall conform to the requirements of ASTM B 370.

❖ This material is commonly used for roofing, flashing, gutters, downspouts and general sheet metal work. ASTM B 370 provides the specification for both copper sheet and copper strip materials.

1404.5.3 Lead-coated copper. Lead-coated copper shall conform to the requirements of ASTM B 101.

❖ This material is commonly used for roofing, flashing, gutters, downspouts and general sheet metal work. The lead coating is applied by a hot-dipped method. ASTM B 101 specifies that the lead must uniformly coat both surfaces, edges and ends of the copper.

1404.6 Concrete. Exterior walls of concrete construction shall be designed and constructed in accordance with Chapter 19.

❖ Chapter 19 contains the general requirements for use of concrete in buildings, including provisions for the minimum thickness of concrete units used as veneers and wall coverings and their installation and protection.

1404.7 Glass-unit masonry. Exterior walls of glass-unit masonry shall be designed and constructed in accordance with Chapter 21.

❖ Structural glass block is generally regulated by the provisions of Sections 2103 and 2104; however, structural glass veneers used as wall coverings must comply with the thickness requirement of Table 1405.2.

1404.8 Plastics. Plastic panel, apron or spandrel walls as defined in this code shall not be limited in thickness, provided that such plastics and their assemblies conform to the requirements of Chapter 26 and are constructed of *approved* weather-resistant materials of adequate strength to resist the wind loads for cladding specified in Chapter 16.

❖ This section provides for the use of plastic panels for exterior walls. The code uses the term "light-transmitting plastic" to apply to plastics used for exterior wall panels and roof panels, as well as for glazing and skylights. The panels must meet the requirements of Chapter 26, as well as certain requirements of Chapter 14 for weather resistance and Chapter 16 for structural capabilities.

1404.9 Vinyl siding. Vinyl siding shall be certified and labeled as conforming to the requirements of ASTM D 3679 by an *approved* quality control agency.

❖ Plastics are addressed in Chapter 26; however, polyvinyl chloride (PVC) siding is specifically addressed here as an exterior wall covering. PVC siding is required to conform to the provisions of ASTM D 3679. Installation of vinyl siding is prescribed by Section 1405.14 (see the commentary to Section 1405.14 for additional discussion on the installation of vinyl siding). Note that the product must be certified and labeled, which means that the manufacturer must have regular inspections by an approved quality control agency.

1404.10 Fiber-cement siding. Fiber-cement siding shall conform to the requirements of ASTM C 1186, Type A, and shall be so identified on labeling listing an *approved* quality control agency.

❖ Fiber-cement siding is also a material used for weather-resistant siding. It is manufactured from fiber-reinforced cement, and the code permits its use as either panel siding or horizontal lap siding. The material standard is ASTM C 1186. Note that the product is required to bear a label, which means that the manufacturer must have regular inspections by a third-party inspection quality control agency.

1404.11 Exterior insulation and finish systems. Exterior insulation and finish systems (EIFS) and exterior insulation and finish systems (EIFS) with drainage shall comply with Section 1408.

❖ EIFS and EIFS with drainage are relatively complex exterior veneers that require great care and attention regarding the materials used and the installation details. This exterior veneer is now dealt with in Section 1408. All of the performance criteria, installation and design are covered in this section.

1404.12 Polypropylene siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of ASTM D 7254 and those of Section 1404.12.1 or 1404.12.2 by an approved quality control agency. Polypropylene siding shall be installed in accordance with the requirements of Section 1405.18 and in accordance with the manufacturer's installation instructions. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

❖ The requirements for polypropylene siding are similar to the requirements for vinyl siding, except for the fire testing. The required standard for polypropylene siding is ASTM D 7254. This specification addresses many of the key requirements for the material.

1404.12.1 Flame spread index. The certification of the flame spread index shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E 84 or UL 723.

❖ The fire-test requirement in ASTM D 7254 does not require that, when fire testing is conducted in the Steiner tunnel (ASTM E 84), the test specimen remain in place during the test and that flaming drips and falling test specimens do not occur during the test. This requirement is critical for exposed materials that are used so that the flame spread index assesses actual surface flame spread on the material surface; therefore, this section requires that the certification of compliance with ASTM D 7254 indicates that the specimen remained in place during the test procedure.

1404.12.2 Fire separation distance. The fire separation distance between a building with polypropylene siding and the adjacent building shall be no less than 10 feet (3048 mm).

❖ Based on the heat-release rate exhibited by polypropylene material, a minimum distance of 10 feet (3048 mm) is required between the structure with the polypropylene siding and any adjacent structure.

SECTION 1405
INSTALLATION OF WALL COVERINGS

1405.1 General. *Exterior wall coverings* shall be designed and constructed in accordance with the applicable provisions of this section.

❖ Exterior wall coverings used to provide weather protection to the structure are required to comply with all the applicable provisions contained in Section 1405.

1405.2 Weather protection. *Exterior walls* shall provide weather protection for the building. The materials of the minimum nominal thickness specified in Table 1405.2 shall be acceptable as *approved* weather coverings.

❖ The exterior walls of a structure must be designed and constructed to provide for the health and safety of the occupants and to protect the structure from the detrimental effects of weather exposure.

This section introduces Table 1405.2, which is a tabulation of the minimum acceptable nominal thicknesses for a number of common weather coverings.

TABLE 1405.2. See next column.

❖ This table should be used in addition to all other applicable chapters and requirements of the code for the specific material listed. Testing and experience have determined that the minimum tabulated thicknesses will be durable and protect the building against the elements for relatively long periods of time when attached and maintained as required.

Note a of Table 1405.2 allows material less than 0.5-inch-thick (12.7 mm) wood siding to be used, provided that it is installed over an approved sheathing conforming to the requirements of Section 2304.6.1 (see commentary, Section 2304.6.1).

Note b of Table 1405.2 establishes that the minimum permitted nominal thickness is based on the narrowest solid thickness of material, exclusive of texture.

Section 2304.6.1 allows fiberboard and particleboard for sheathing. Although permitted as sheathing, fiberboard and particleboard materials, and other similar materials, do not provide a nailing base for weatherboarding. When used over such materials, 0.5-inch (12.7 mm) wood siding is to be fastened to the wood-framing members or otherwise adequately secured. Wood siding having a thickness of less than 0.5 inch (12.7 mm) is not permitted to be fastened to foam plastic and other sheathing materials not having adequate strength as a nailing base spanning between studs or framing members.

TABLE 1405.2
MINIMUM THICKNESS OF WEATHER COVERINGS

COVERING TYPE	MINIMUM THICKNESS (inches)
Adhered masonry veneer	0.25
Aluminum siding	0.019
Anchored masonry veneer	2.625
Asbestos-cement boards	0.125
Asbestos shingles	0.156
Cold-rolled copper[d]	0.0216 nominal
Copper shingles[d]	0.0162 nominal
Exterior plywood (with sheathing)	0.313
Exterior plywood (without sheathing)	See Section 2304.6
Fiber cement lap siding	0.25[c]
Fiber cement panel siding	0.25[c]
Fiberboard siding	0.5
Glass-fiber reinforced concrete panels	0.375
Hardboard siding[c]	0.25
High-yield copper[d]	0.0162 nominal
Lead-coated copper[d]	0.0216 nominal
Lead-coated high-yield copper	0.0162 nominal
Marble slabs	1
Particleboard (with sheathing)	See Section 2304.6
Particleboard (without sheathing)	See Section 2304.6
Porcelain tile	.025
Precast stone facing[e]	0.625
Steel (approved corrosion resistant)	0.0149
Stone (cast artificial, anchored)	1.5
Stone (natural)	2
Structural glass	0.344
Stucco or exterior cement plaster	
Three-coat work over:	
Metal plaster base	0.875[b]
Unit masonry	0.625[b]
Cast-in-place or precast concrete	0.625[b]
Two-coat work over:	
Unit masonry	0.5[b]
Cast-in-place or precast concrete	0.375[b]
Terra cotta (anchored)	1
Terra cotta (adhered)	0.25
Vinyl siding	0.035
Wood shingles	0.375
Wood siding (without sheathing)[a]	0.5

For SI: 1 inch = 25.4 mm.

a. Wood siding of thicknesses less than 0.5 inch shall be placed over sheathing that conforms to Section 2304.6.

b. Exclusive of texture.

c. As measured at the bottom of decorative grooves.

d. 16 ounces per square foot for cold-rolled copper and lead-coated copper, 12 ounces per square foot for copper shingles, high-yield copper and lead-coated high-yield copper.

e. Includes scratch coat, setting bed, and precast stone.

1405.3 Vapor retarders. Class I or II vapor retarders shall be provided on the interior side of frame walls in Zones 5, 6, 7, 8 and Marine 4. The appropriate zone shall be selected in accordance with Chapter 3 of the *International Energy Conservation Code*.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.

❖ The purpose of these requirements is to provide prescriptive methods for moisture control. The code prescribes three different vapor retarder classes, based upon the vapor permeability of the material. These are defined in Chapter 2. The basic requirement is for Class I or II vapor retarders to be installed on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4. These climate zones are defined in the IECC. Figure 301.1 and Table 301.1 of the IECC provide information regarding the climate zones for all geographic locations in the United States. These are reproduced here for convenience (see Figure 1405.3 and Table 1405.3). Also, Tables 301.3(1) and 301.3(2) of the IECC define international climate zones outside of the United States. These are reprinted in this commentary as well [see Tables 1405.3(1) and 1405.3(2)]. As can be seen by studying Figure 301.1, Climate Zones 5, 6, 7, 8 and Marine 4 are in the middle to northern portions of the continental United States and Alaska. These are areas where colder temperatures can be expected in winter months, which cause moisture from the interior of the building to condensate in the exterior walls of the building. A Class I or II vapor retarder is therefore called for on the interior side of the exterior wall.

1405.3.1 Class III vapor retarders. Class III vapor retarders shall be permitted where any one of the conditions in Table 1405.3.1 is met.

❖ Wall assemblies can be designed and constructed to dry inwards, outwards and to both sides in all climate zones. This section allows more flexibility in the design and construction of moisture forgiving wall systems. These requirements recognize that many common materials function to various degrees to slow the passage of moisture. In many situations common materials such as the kraft facing on a fiberglass batt or latex paint may serve to retard moisture sufficiently. In particular, the "standard" sheet of polyethylene is usually not required as a vapor retarder in walls. This section therefore allows the use of Class III vapor retarders in lieu of the Class I or II otherwise called out in Section 1405.3. Classes of vapor retarders are defined in Chapter 2.

The Class III vapor retarders allow more moisture vapor to pass through them. These are allowed to be used with exterior wall assemblies described in Table 1405.3.1 that can be expected to dry. Section 1405.3.2 describes materials that are deemed to be Class III vapor retarders, and Section 1405.3.3 describes the attributes of cladding that make it "vented" as called out in Table 1405.3.1.

TABLE 1405.3.1
CLASS III VAPOR RETARDERS

ZONE	CLASS III VAPOR RETARDERS PERMITTED FOR:[a]
Marine 4	Vented cladding over wood structural panels Vented cladding over fiberboard Vented cladding over gypsum Insulated sheathing with *R*-value ≥ R2.5 over 2 × 4 wall Insulated sheathing with *R*-value ≥ R3.75 over 2 × 6 wall
5	Vented cladding over wood structural panels Vented cladding over fiberboard Vented cladding over gypsum Insulated sheathing with *R*-value ≥ R5 over 2 × 4 wall Insulated sheathing with *R*-value ≥ R7.5 over 2 × 6 wall
6	Vented cladding over fiberboard Vented cladding over gypsum Insulated sheathing with *R*-value ≥ R7.5 over 2 × 4 wall Insulated sheathing with *R*-value ≥ R11.25 over 2 × 6 wall
7 and 8	Insulated sheathing with *R*-value ≥ R10 over 2 × 4 wall Insulated sheathing with *R*-value ≥ R15 over 2 × 6 wall

For SI: 1 pound per cubic foot = 16 kg/m^3.

a. Spray foam with a minimum density of 2 lbs/ft^3 applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the insulating sheathing requirement where the spray foam *R*-value meets or exceeds the specified insulating sheathing *R*-value.

❖ This table describes the situations where it is permissible to use Class III vapor retarders instead of Class I or II. Class III vapor retarders allow more moisture vapor to pass through them. These are allowed to be used with exterior wall assemblies described in Table 1405.3.1 that can be expected to dry. The table provides types of wall assemblies that can be used with Class III vapor retarders in different climate zones. The climate zones are determined based upon Chapter 3 of the IECC.

1405.3.2 Material vapor retarder class. The *vapor retarder class* shall be based on the manufacturer's certified testing or a tested assembly.

The following shall be deemed to meet the class specified:

Class I: Sheet polyethylene, nonperforated aluminum foil.

Class II: Kraft-faced fiberglass batts or paint with a perm rating greater than 0.1 and less than or equal to 1.0.

Class III: Latex or enamel paint.

❖ The vapor retarder class is defined in Section 202 of the code in terms of vapor permeability. The test method called out for determination of the perm value is ASTM E 96. However, this section provides a list of materials that can be used for each class of vapor retarder and deemed to comply with the test standard. No testing is required for these materials. All other materials are required to be tested.

TABLE C301(1)
INTERNATIONAL CLIMATE ZONE DEFINITIONS

MAJOR CLIMATE TYPE DEFINITIONS
Marine (C) Definition—Locations meeting all four criteria: 1. Mean temperature of coldest month between -3°C (27°F) and 18°C (65°F). 2. Warmest month mean < 22°C (72°F). 3. At least four months with mean temperatures over 10°C (50°F). 4. Dry season in summer. The month with the heaviest precipitation in the cold season has at least three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.
Dry (B) Definition—Locations meeting the following criteria: Not marine and $P_{in} < 0.44 \times (TF - 19.5)$ [$P_{cm} < 2.0 \times (TC + 7)$ in SI units] where: P_{in} = Annual precipitation in inches (cm) T = Annual mean temperature in °F (°C)
Moist (A) Definition—Locations that are not marine and not dry.
Warm-humid Definition—Moist (A) locations where either of the following wet-bulb temperature conditions shall occur during the warmest six consecutive months of the year: 1. 67°F (19.4°C) or higher for 3,000 or more hours; or 2. 73°F (22.8°C) or higher for 1,500 or more hours.

For SI: °C = [(°F)-32]/1.8, 1 inch = 2.54 cm.

FIGURE 1405.3(1) FROM TABLE C301.3(1) OF THE IECC

TABLE 1405.3(2)
INTERNATIONAL CLIMATE ZONE DEFINITIONS

ZONE NUMBER	THERMAL CRITERIA	
	IP Units	SI Units
1	9000 < CDD50°F	5000 < CDD10°C
2	6300 < CDD50°F ≤ 9000	3500 < CDD10°C ≤ 5000
3A and 3B	4500 < CDD50°F ≤ 6300 AND HDD65°F ≤ 5400	2500 < CDD10°C ≤ 3500 AND HDD18°C ≤ 3000
4A and 4B	CDD50°F ≤ 4500 AND HDD65°F ≤ 5400	CDD10°C ≤ 2500 AND HDD18°C ≤ 3000
3C	HDD65°F ≤ 3600	HDD18°C ≤ 2000
4C	3600 < HDD65°F ≤ 5400	2000 < HDD18°C ≤ 3000
5	5400 < HDD65°F ≤ 7200	3000 < HDD18°C ≤ 4000
6	7200 < HDD65°F ≤ 9000	4000 < HDD18°C ≤ 5000
7	9000 < HDD65°F ≤ 12600	5000 < HDD18°C ≤ 7000
8	12600 < HDD65°F	7000 < HDD18°C

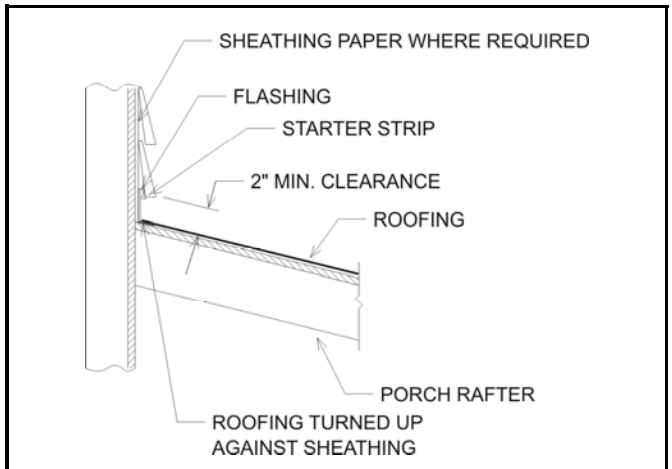
For SI: °C = [(°F)-32]/1.8.

FIGURE 1405.3(2) FROM TABLE C301.3(2) OF THE IECC

1405.3.3 Minimum clear airspaces and vented openings for vented cladding. For the purposes of this section, vented cladding shall include the following minimum clear airspaces.

1. Vinyl lap or horizontal aluminum siding applied over a weather-resistive barrier as specified in this chapter.
2. Brick veneer with a clear airspace as specified in this code.
3. Other *approved* vented claddings.

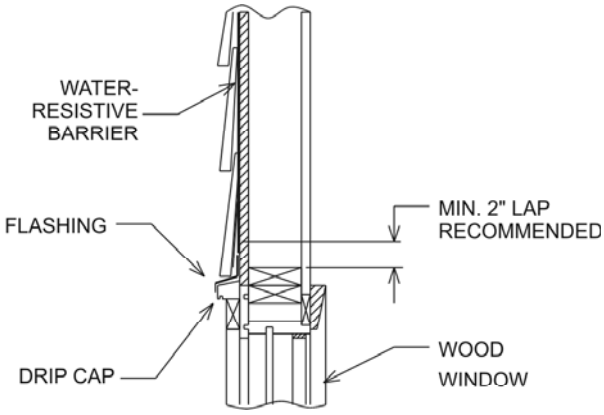
❖ This section is intended to define what is intended by "vented cladding" called out in Table 1405.3.1. As can be seen, vented cladding is material commonly used in the code, including vinyl siding, aluminum siding, and brick with a clear airspace.



By "other approved vented claddings," the code intends materials that can be shown to allow drying of

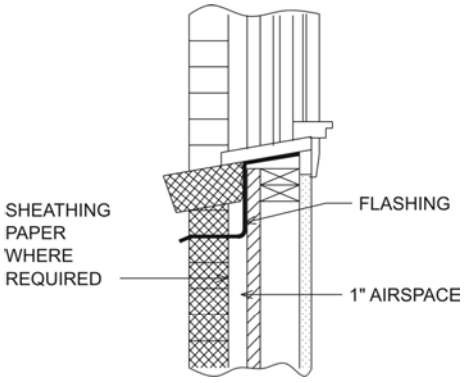
the components behind them in the same manner and at the same rate as the specific materials in Items 1 or 2.

1405.4 Flashing. Flashing shall be installed in such a manner so as to prevent moisture from entering the wall or to redirect it to the exterior. Flashing shall be installed at the perimeters of exterior door and window assemblies, penetrations and terminations of *exterior wall* assemblies, *exterior wall* intersections with roofs, chimneys, porches, decks, balconies and similar projections and at built-in gutters and similar locations where moisture could enter the wall. Flashing with projecting flanges shall be installed on both sides and the ends of copings, under sills and continuously above projecting *trim*.



❖ Water that enters the exterior wall can lead to the decay of wood and the degradation of other building materials that are sensitive to moisture. Some of the most common points of moisture penetration in an exterior wall are at intersections of windows, doors, chimneys and roof lines with other framing These potential points of moisture intrusion must be closed by corrosion-resistant flashings or by other acceptable practices [see Figures 1405.4(1) through 1405.4(5)]. Materials such as asphalt-saturated felt or building paper are not acceptable for flashing at required locations, in part due to the fact that these materials have a limited ability to resist water penetration. The flashing installation locations stated in this section represent those that are most commonly encountered. As an alternative to the installation of flashings, testing of the specific penetrations, terminations and intersections of the exterior wall finish must be performed in accordance with Section 1403.2 (see commentary, Section 1403.2).

Improperly sloped flashings may enable the accumulation of moisture in the wall assembly, which may result in eventual degradation of the wall finish, building substrate or even the flashing material. Without the extension of the flashing beyond the face of the exterior wall finish, moisture may reenter the wall assembly directly below the flashing through capillary action as indicated in Figure 1405.4(5).



For SI: 1 inch = 25.4 mm.

Figure 1405.4(1)
FLASHING AT SIDING ROOF INTERFACE

For SI: 1 inch = 25.4 mm.

Figure 1405.4(2)
FLASHING AT SIDING/WINDOW INTERFACE

For SI: 1 inch = 25.4 mm.

Figure 1405.4(3)
FLASHING UNDER WINDOW IN EXTERIOR WALL

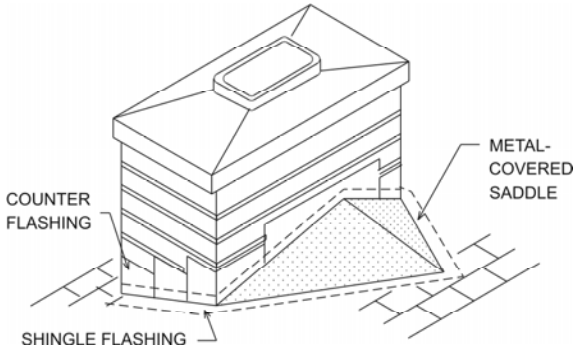


Figure 1405.4(4)
FLASHING AT VARIOUS POINTS

1405.4.1 Exterior wall pockets. In exterior walls of buildings or structures, wall pockets or crevices in which moisture can accumulate shall be avoided or protected with caps or drips, or other *approved* means shall be provided to prevent water damage.

❖ Changes in building lines and elevations, materials and tops of walls, etc., can produce wall pockets, crevices and other openings that allow the entry of rain, snow, ice and other sources of moisture. Where these openings are present, additional covers, caps, flashings, etc., must be provided to prevent the entry of moisture.

1405.4.2 Masonry. Flashing and weep holes in anchored veneer shall be located in the first course of masonry above finished ground level above the foundation wall or slab, and other points of support, including structural floors, shelf angles and lintels where anchored veneers are designed in accordance with Section 1405.6.

❖ Water can penetrate walls constructed of masonry materials from a number of sources. Some of the most common causes of water penetration are: the porous nature of many masonry materials; openings such as small cracks, that may occur between the masonry unit and mortar joint due to expansion and contraction of the wall over time; and the interface between the masonry and penetrations or dissimilar materials.

Walls constructed of anchored masonry veneer must be designed to accommodate water penetration and to provide a means to both stop the moisture penetration and for the moisture to leave the wall. This section stipulates the use of flashing to stop moisture penetration into the wall backing and small openings (weepholes) to allow the moisture to exit the wall. In order for these two components to function as intended, the weepholes must be installed immediately above the flashing so that moisture collected by the flashing can exit the wall, preventing the accumulation of water at the flashing location.

1405.5 Wood veneers. Wood veneers on exterior walls of buildings of Type I, II, III and IV construction shall be not

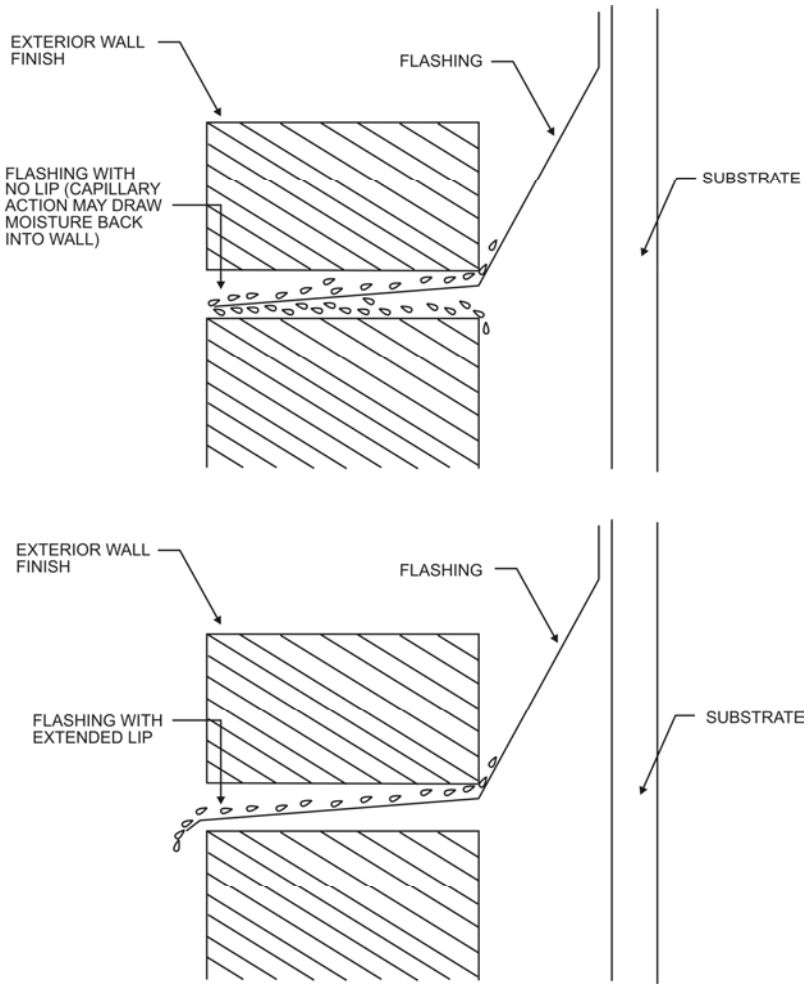

Figure 1405.4(5)
FLASHING EXTENSION

less than 1 inch (25 mm) nominal thickness, 0.438-inch (11.1 mm) exterior hardboard siding or 0.375-inch (9.5 mm) exterior-type wood structural panels or particleboard and shall conform to the following:

1. The veneer shall not exceed 40 feet (12 190 mm) in height above grade. Where fire-retardant-treated wood is used, the height shall not exceed 60 feet (18 290 mm) in height above grade.
2. The veneer is attached to or furred from a noncombustible backing that is fire-resistance rated as required by other provisions of this code.
3. Where open or spaced wood veneers (without concealed spaces) are used, they shall not project more than 24 inches (610 mm) from the building wall.

❖ Wood veneers, which are combustible exterior materials, are permitted for use on buildings of other than combustible (Type V) construction where the minimum thickness requirements of this section and three construction criteria are met (see the commentary to Section 1406.2.1.1 for more discussion on wood veneers as a combustible material on exterior walls).

Item 1 limits the maximum height of the installation of the wood veneer and is coordinated with the provisions of Section 1406.2.1 (see the commentary to Section 1406.2.1 for more discussion on the limitations of use of combustible exterior materials). The increase of one additional story is permitted due to the limited combustible nature of fire-retardant-treated wood (FRTW) siding (see commentary, Section 2303.2). Item 2 requires the backing to be noncombustible, which is consistent with requirements of Chapter 6 for buildings of Type I, II, III and IV construction. The backing must also have the fire-resistance rating required by other provisions of the code, such as in Tables 601 and 602. Item 3 limits the maximum distance that wood veneers may project from the face of the building.

1405.6 Anchored masonry veneer. Anchored masonry veneer shall comply with the provisions of Sections 1405.6, 1405.7, 1405.8 and 1405.9 and Sections 6.1 and 6.2 of TMS 402/ACI 530/ASCE 5.

❖ Sections 6.1 and 6.2 of ACI 530/ASCE 5/TMS 402 are to be used for the design and detailing requirements for anchored masonry veneers. See the commentary for ACI 530/ASCE 5/TMS 402 for an explanation of the anchored masonry veneer requirements.

1405.6.1 Tolerances. Anchored masonry veneers in accordance with Chapter 14 are not required to meet the tolerances in Article 3.3 F1 of TMS 602/ACI 530.1/ASCE 6.

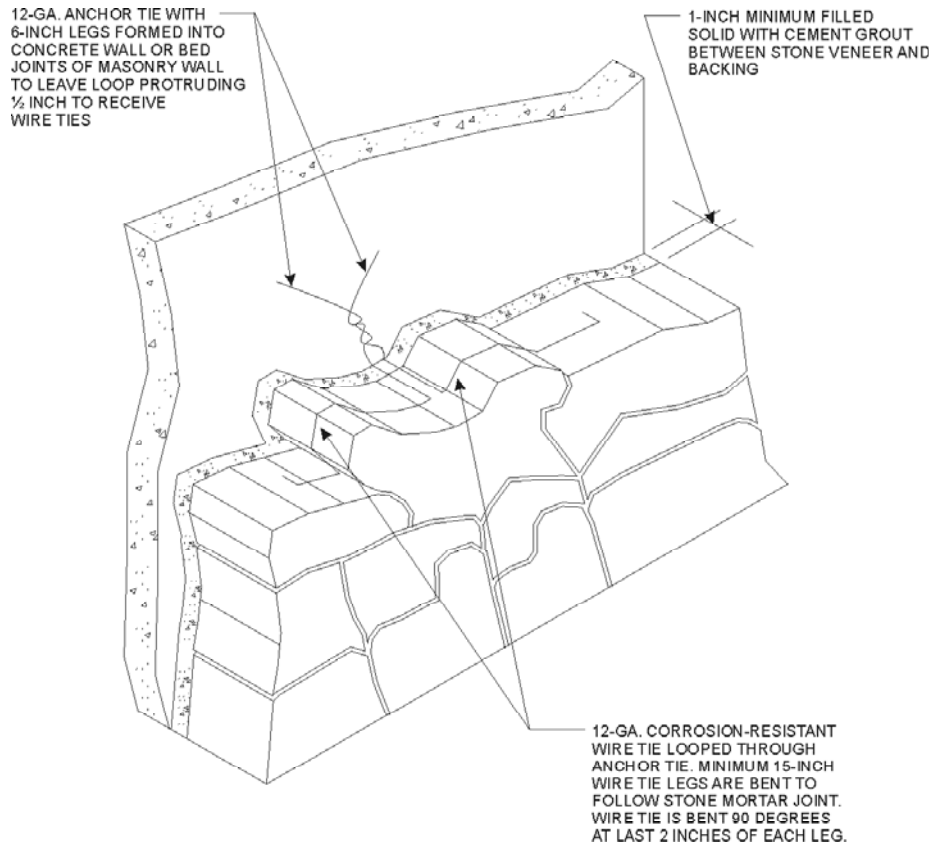
❖ The tolerances in the referenced standard apply to masonry units that are utilized in masonry wall construction and are not intended to be applied to masonry veneers.

1405.6.2 Seismic requirements. Anchored masonry veneer located in Seismic Design Category C, D, E or F shall conform to the requirements of Section 6.2.2.10 of TMS 402/ACI 530/ASCE 5.

❖ This section requires that the seismic design and detailing of anchored masonry veneer be performed in accordance with referenced standard ACI 530 for veneers located in Seismic Design Categories C, D, E and F (see Chapter 16 for more information on seismic design categories). Section 6.2.2.10 of ACI 530 contains criteria for components such as masonry anchor spacing, joint reinforcement bedding and splicing.

1405.7 Stone veneer. Stone veneer units not exceeding 10 inches (254 mm) in thickness shall be anchored directly to masonry, concrete or to stud construction by one of the following methods:

1. With concrete or masonry backing, anchor ties shall be not less than 0.1055-inch (2.68 mm) corrosion-resistant wire, or *approved* equal, formed beyond the base of the backing. The legs of the loops shall be not less than 6 inches (152 mm) in length bent at right angles and laid in the mortar joint, and spaced so that the eyes or loops are 12 inches (305 mm) maximum on center (o.c.) in both directions. There shall be provided not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire tie, or *approved* equal, threaded through the exposed loops for every 2 square feet (0.2 m^2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length bent so that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.
2. With wood stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) zinc-coated or non-metallic coated wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to wood studs spaced a maximum of 16 inches (406 mm) o.c. On studs, the mesh shall be attached with 2-inch long (51 mm) corrosion-resistant steel wire furring nails at 4 inches (102 mm) o.c. providing a minimum 1.125-inch (29 mm) penetration into each stud and with 8d annular threaded nails at 8 inches (203 mm) o.c. into top and bottom plates or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm zinc-coated or nonmetallic coated wire, or approved equal, attached to the stud with a minimum of an 8d (0.120 in. diameter) annular threaded nail for every 2 square feet (0.2 m^2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.
3. With cold-formed steel stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) zinc-coated or nonmetallic coated wire mesh with two layers of water-



resistive barrier in accordance with Section 1404.2 shall be applied directly to steel studs spaced a maximum of 16 inches (406 mm) o.c. The mesh shall be attached with corrosion-resistant #8 self-drilling, tapping screws at 4 inches (102 mm) o.c., and at 8 inches (203 mm) o.c. into top and bottom tracks or with equivalent wire ties. All screws shall extend through the steel connection a minimum of three exposed threads. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, attached to the stud with a minimum of a #8 self-drilling, tapping screw extending through the steel framing a minimum of three exposed threads for every 2 square feet (0.2 m^2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer. The cold-formed steel framing members shall have a minimum bare steel thickness of 0.0428 inches (1.087 mm).

❖ This section permits direct anchorage of stone veneers to the wall backing by one of three specified methods. It should be noted that support from below is required to be provided in accordance with Section 1405.6. Since the framing is providing only lateral anchorage, thicknesses of up to 10 inches (254 mm) are permitted.

There are three methods of anchorage prescribed in this section, based upon the construction of the wall backing. The first method specifies the anchor type, size and spacing for concrete and masonry backing (see Figure 1405.7). The second method specifies the anchorage requirements for wood-frame walls. The third method specifies the anchorage requirements for cold-formed steel stud-framed walls.

All methods require that the anchorage ties be of corrosion-resistant material, such as zinc or nonmetallic coated material. Corrosion-resistant ties are necessary because of the potential for corrosion caused by both water penetration and an adverse reaction of the metal with the mortar or other masonry material.

According to the first method, the specified tie spacings, in conjunction with the cement grout, are intended to achieve lateral support points of the veneer at adequate spacings. Where lateral ties are not installed at the required locations, buckling of the masonry veneer under vertical dead loads and lateral loads is possible. It should be noted that the required

For SI: 1 inch = 25.4 mm, 90 degrees = 1.57 rad.

Figure 1405.7
STONE VENEER WITH CONCRETE BACKING

1 inch (25 mm) of mortar grout creates walls that are not considered cavity wall construction.

The second and third methods require that two layers of a water-resistive barrier be installed over the wood-stud construction to provide protection from moisture penetration.

1405.8 Slab-type veneer. Slab-type veneer units not exceeding 2 inches (51 mm) in thickness shall be anchored directly to masonry, concrete or stud construction. For veneer units of marble, travertine, granite or other stone units of slab form ties of corrosion-resistant dowels in drilled holes shall be located in the middle third of the edge of the units, spaced a maximum of 24 inches (610 mm) apart around the periphery of each unit with not less than four ties per veneer unit. Units shall not exceed 20 square feet (1.9 m^2) in area. If the dowels are not tight fitting, the holes shall be drilled not more than 0.063 inch (1.6 mm) larger in diameter than the dowel, with the hole countersunk to a diameter and depth equal to twice the diameter of the dowel in order to provide a tight-fitting key of cement mortar at the dowel locations when the mortar in the joint has set. Veneer ties shall be corrosion-resistant metal capable of resisting, in tension or compression, a force equal to two times the weight of the attached veneer. If made of sheet metal, veneer ties shall be not smaller in area than 0.0336 by 1 inch (0.853 by 25 mm) or, if made of wire, not smaller in diameter than 0.1483-inch (3.76 mm) wire.

❖ Slab-type veneer refers to thin stone masonry veneers that are individually supported. These units do not bear on the successive units below, but are anchored to and supported vertically by the backup construction with corrosion-resistant dowels located at the edges of each unit. This type of veneer anchorage applies to the use of thin stone units that are typically not set in mortar, but are made water tight at the edges through the use of sealant materials. The strength of the veneer ties is required to be adequate to support twice the weight of the veneer in tension to provide for an adequate margin of safety, such that the veneer will remain in place in case it works loose of the grout and backing.

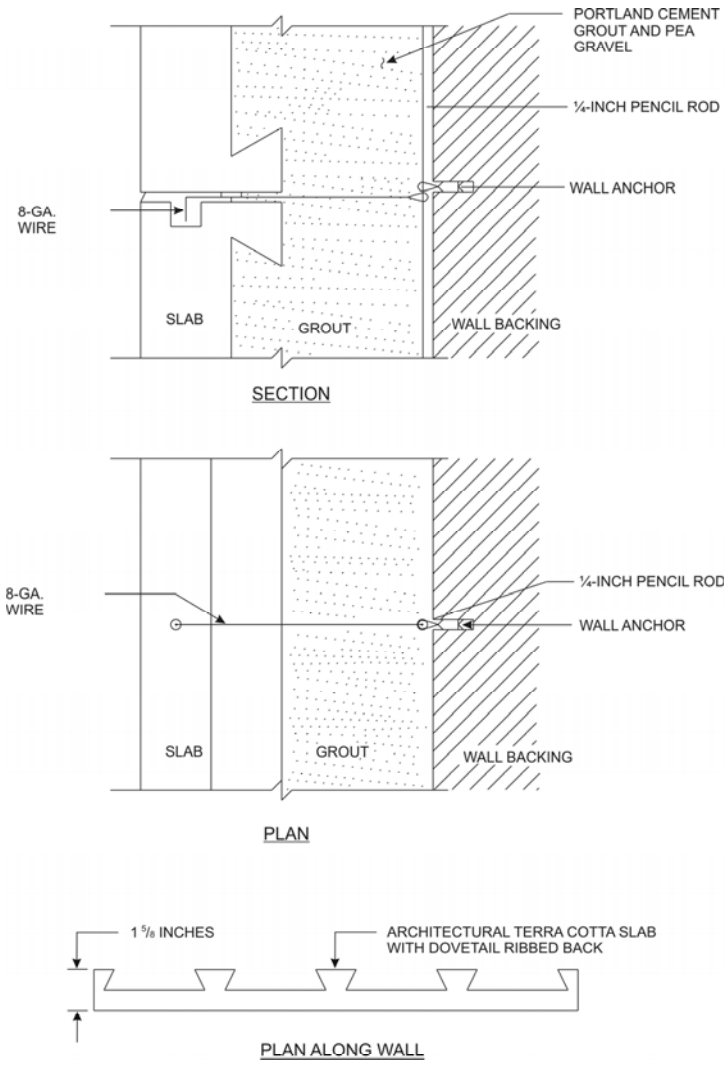
1405.9 Terra cotta. Anchored terra cotta or ceramic units not less than $1^5/_8$ inches (41 mm) thick shall be anchored directly to masonry, concrete or stud construction. Tied terra cotta or ceramic veneer units shall be not less than $1^5/_8$ inches (41 mm) thick with projecting dovetail webs on the back surface spaced approximately 8 inches (203 mm) o.c. The facing shall be tied to the backing wall with corrosion-resistant metal anchors of not less than No. 8 gage wire installed at the top of each piece in horizontal bed joints not less than 12 inches (305 mm) nor more than 18 inches (457 mm) o.c.; these anchors shall be secured to $^1/_4$-inch (6.4 mm) corrosion-resistant pencil rods that pass through the vertical aligned loop anchors in the backing wall. The veneer ties shall have sufficient strength to support the full weight of the veneer in tension. The facing shall be set with not less than a 2-inch (51 mm) space from the backing wall and the space shall be filled solidly with Portland cement grout and pea gravel. Immediately prior to setting, the backing wall and the facing shall be drenched with clean water and shall be distinctly damp when the grout is poured.

❖ The minimum permitted $1^5/_8$-inch (41 mm) thickness for terra cotta units is necessary in order for each unit to have an inherent level of structural integrity. In order to increase the mechanical anchorage of the backing, dovetail webs are required and are embedded in the 2-inch (51 mm) cement grout space. The strength of the veneer ties is required to be adequate to support the full weight of the veneer in tension in order to achieve an adequate margin of safety, such that the veneer will remain in place in case it works loose of the grout and backing (see Figure 1405.9).

1405.10 Adhered masonry veneer. Adhered masonry veneer shall comply with the applicable requirements in Section 1405.10 and Sections 6.1 and 6.3 of TMS 402/ACI 530/ASCE 5.

❖ Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS 402 are to be used for the design and detailing requirements for adhered masonry veneers. See the commentary for ACI 530/ASCE 5/TMS 402 for an explanation of the adhered masonry veneer requirements. Figures 1405.10(1) and 1405.10(2) illustrate two examples of an adhered masonry veneer.

1405.10.1 Exterior adhered masonry veneer. Exterior adhered masonry veneer shall be installed in accordance with Section 1405.10 and in accordance with the manufacturer's instructions.



❖ This section sets out the requirements for exterior adhered masonry veneer by reference to Section 1405.10 as a whole. Additionally, this section requires the installation to comply with the specific manufacturer's instructions.

1405.10.1.1 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section 2510.6.

❖ Requirements for water-resistive barriers refer to Section 2510.6 (stucco). Wall preparation for stucco and for exterior adhered masonry veneer is very similar, so referring to Section 2510.6 provides consistency in the code for water-resistive barrier requirements.

1405.10.1.2 Flashing at foundation. A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26 gauge galvanized or plastic with a minimum vertical attachment flange of $3^1/_2$ inches (89 mm) shall be installed to extend a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section 1405.4. The water-resistive barrier shall lap over the exterior of the attachment flange of the screed or flashing.

❖ This section contains requirements for the flashing at the foundation, which are similar to the weep-screed requirements for stucco, while at the same time allowing for alternatives to the stucco-specific weep screed.

For SI: 1 inch = 25.4 mm.

Figure 1405.9
TERRA COTTA VENEER

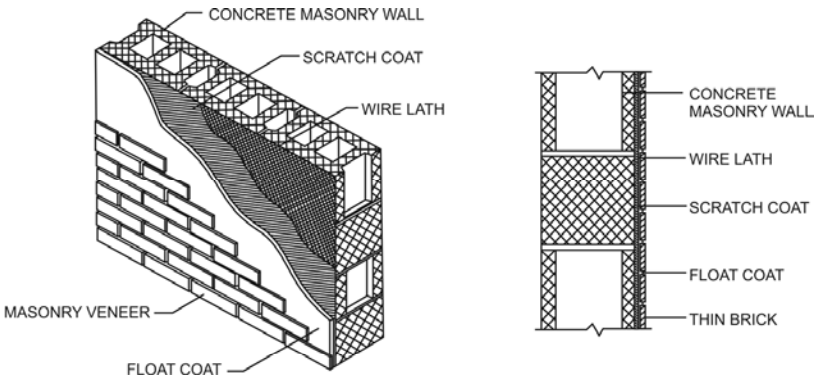


Figure 1405.10(1)
MASONRY VENEER ADHERED TO MASONRY BACKING
(Courtesy of Brick Industry)

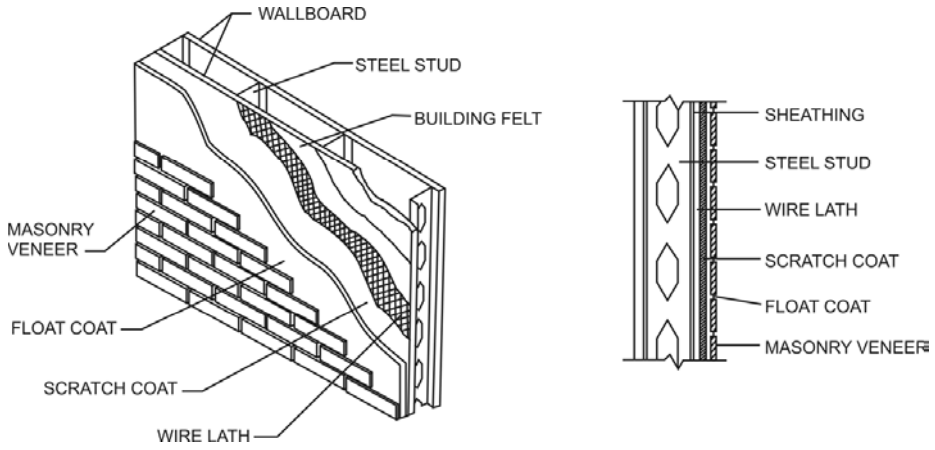

Figure 1405.10(2)
MASONRY VENEER ADHERED TO STEEL-FRAME BACKING
(Courtesy of Brick Industry)

1405.10.1.3 Clearances. On exterior stud walls, adhered masonry veneer shall be installed a minimum of 4 inches (102 mm) above the earth, or a minimum of 2 inches (51 mm) above paved areas, or a minimum of $^1/_2$ inch (12 mm) above exterior walking surfaces which are supported by the same foundation that supports the exterior wall.

❖ The clearance requirements within this section are consistent with stucco applications; however they go one step further by specifying a minimum $^1/_2$-inch (12 mm) clearance to exterior walking surfaces that are supported by the same foundation that supports the wall to which the exterior veneer is adhered. This $^1/_2$-inch (12 mm) clearance requirement allows for architectural and aesthetic improvements in the installation of adhered masonry veneer.

1405.10.2 Exterior adhered masonry veneers—porcelain tile. Adhered units shall not exceed $^5/_8$ inch (15.8 mm) thickness and a maximum of 24 inches (610 mm) in any face dimension nor more than 3 square feet (0.28 m^2) in total face area and shall not weigh more than 9 pounds psf (0.43 kN/m^2). Porcelain tile shall be adhered to an approved backing system.

❖ To ensure proper installation, this section limits the thickness, size and weight of porcelain tile units. These limitations are consistent with current construction practices and current adhesive capabilities.

1405.10.3 Interior adhered masonry veneers. Interior adhered masonry veneers shall have a maximum weight of 20 psf (0.958 kg/m^2) and shall be installed in accordance with Section 1405.10. Where the interior adhered masonry veneer is supported by wood construction, the supporting members shall be designed to limit deflection to $^1/_{600}$ of the span of the supporting members.

❖ This section addresses masonry veneer that is supported on wood members. The provisions of Section 2104.1.6 are not intended to preclude masonry veneer on wood supports. In fact, Section 2304.12 contains provisions for the support of interior masonry veneer on wood-frame construction. The deflection limit is to minimize cracking of the veneer.

1405.11 Metal veneers. Veneers of metal shall be fabricated from *approved* corrosion-resistant materials or shall be protected front and back with porcelain enamel, or otherwise be treated to render the metal resistant to corrosion. Such veneers shall not be less than 0.0149-inch (0.378 mm) nominal thickness sheet steel mounted on wood or metal furring strips or approved sheathing on the wood construction.

❖ All metal veneers used as exterior weather coverings are required to be manufactured from materials that are inherently corrosion resistant or to be protected with other materials, such as coatings, to prevent corrosion.

For sheet steel, the minimum nominal thickness is 0.0149 inches (0.38 mm), not including the thickness of the corrosion-resistant coating. For aluminum siding, a 0.019-inch-thick (0.48 mm) value is the minimum. Aluminum siding must also conform to AAMA 1402. The minimum thicknesses for other weather coverings are obtained from Table 1405.2.

1405.11.1 Attachment. Exterior metal veneer shall be securely attached to the supporting masonry or framing members with corrosion-resistant fastenings, metal ties or by other *approved* devices or methods. The spacing of the fastenings or ties shall not exceed 24 inches (610 mm) either vertically or horizontally, but where units exceed 4 square feet (0.4 m^2) in area there shall be not less than four attachments per unit. The metal attachments shall have a cross-sectional area not less than provided by W 1.7 wire. Such attachments and their supports shall be capable of resisting a horizontal force in accordance with the wind loads specified in Section 1609, but in no case less than 20 psf (0.958 kg/m^2).

❖ This section prescribes minimum requirements for the attachment of metal veneers to the exterior wall

construction. The attachment of the veneer may be accomplished through the use of fasteners, metal ties, clips or other means. The means of attaching the panels and supporting members to which the metal veneer is fastened must be able to resist the design wind loads determined in accordance with Chapter 16, but in no case a horizontal load of less than 20 psf (0.958 kg/m^2).

1405.11.2 Weather protection. Metal supports for exterior metal veneer shall be protected by painting, galvanizing or by other equivalent coating or treatment. Wood studs, furring strips or other wood supports for exterior metal veneer shall be *approved* pressure-treated wood or protected as required in Section 1403.2. Joints and edges exposed to the weather shall be caulked with *approved* durable waterproofing material or by other *approved* means to prevent penetration of moisture.

❖ Supports for metal veneers are required to be protected from corrosion induced by moisture. The corrosion resistance may be provided through a surface treatment applied to the metal or through the use of materials that are inherently corrosion resistant. Where wood supports are used, they must be protected through pressure treatment or covered with a minimum of one layer of water-resistive barrier as specified in Section 1404.2. Protection of joints and edges must be provided to prevent the entrance of moisture that may result in damage to the veneer, supports or building framing.

1405.11.3 Backup. Masonry backup shall not be required for metal veneer except as is necessary to meet the fire-resistance requirements of this code.

❖ The type of substrate that metal veneers may be installed over is not limited, except in cases where the wall is required to have a fire-resistance rating in accordance with other sections of the code.

1405.11.4 Grounding. Grounding of metal veneers on buildings shall comply with the requirements of Chapter 27 of this code.

❖ The need to provide electrical grounding for metal veneers has been widely discussed for more than 30 years. Examples of hazards have been demonstrated where electric services have been violated. Most metal-siding manufacturers have made provisions in their designs for grounding. This section references Chapter 27 without providing additional specifics regarding grounding of siding.

1405.12 Glass veneer. The area of a single section of thin exterior structural glass veneer shall not exceed 10 square feet (0.93 m^2) where it is not more than 15 feet (4572 mm) above the level of the sidewalk or grade level directly below, and shall not exceed 6 square feet (0.56 m^2) where it is more than 15 feet (4572 mm) above that level.

❖ Structural glass veneer is produced in the same manner as plate glass (see commentary, Chapter 24), with the addition of metallic oxides that are blended into the glass to provide opacity and color. To accommodate the forces due to expansion and contraction of differing materials in exterior installations, the maximum area of structural glass veneer is limited based upon the height above grade.

1405.12.1 Length and height. The length or height of any section of thin exterior structural glass veneer shall not exceed 48 inches (1219 mm).

❖ Where Section 1405.11 regulates the maximum area of any single section of structural glass veneer, this section limits the maximum dimension of any single section to 48 inches (1219 mm) when used in exterior application.

1405.12.2 Thickness. The thickness of thin exterior structural glass veneer shall be not less than 0.344 inch (8.7 mm).

❖ Structural glass veneers are produced in a range of thicknesses; however, the minimum thickness permitted for use as an exterior veneer is limited to $1^1/_{32}$ inch (8.7 mm).

1405.12.3 Application. Thin exterior structural glass veneer shall be set only after backing is thoroughly dry and after application of an *approved* bond coat uniformly over the entire surface of the backing so as to effectively seal the surface. Glass shall be set in place with an *approved* mastic cement in sufficient quantity so that at least 50 percent of the area of each glass unit is directly bonded to the backing by mastic not less than $^1/_4$ inch (6.4 mm) thick and not more than $^5/_8$ inch (15.9 mm) thick. The bond coat and mastic shall be evaluated for compatibility and shall bond firmly together.

❖ Structural glass veneer is bonded to a solid backing, such as masonry, through the use of a mastic adhesive. The backing must be provided with a coating that will serve to seal it from moisture absorption, provide a uniform surface to which the mastic can adhere and provide a relatively level surface. The bond coat must be compatible for use with the backing material so that debonding will not occur over time. Some common types of bond coats are a float coat of cement mortar and portland cement stucco.

The glass veneer is attached to the bond coat by applying mastic adhesives. Mastics are characterized by their ability to remain pliable over time, rather than harden. The minimum and maximum thicknesses permitted for the mastic application are specified, since an application that is too thin would not provide an adequate bond and one that is too thick could sag over time. To minimize the possibility of debonding, it is necessary to determine that the materials intended for use as a mastic and as a bond coat are compatible with one another.

1405.12.4 Installation at sidewalk level. Where glass extends to a sidewalk surface, each section shall rest in an *approved* metal molding, and be set at least $^1/_4$ inch (6.4 mm) above the highest point of the sidewalk. The space between the molding and the sidewalk shall be thoroughly caulked and made water tight.

❖ To protect glass veneer from breakage when installed at sidewalk level, the veneer is required to

be supported by a metal molding. The molding must be protected from corrosion and be constructed of a material that is compatible for contact with the glass. The molding is to be located a minimum of $^1/_4$ inch (6.4 mm) above the sidewalk to minimize the potential for cracking of the veneer due to expansion and contraction.

1405.12.4.1 Installation above sidewalk level. Where thin exterior structural glass veneer is installed above the level of the top of a bulkhead facing, or at a level more than 36 inches (914 mm) above the sidewalk level, the mastic cement binding shall be supplemented with *approved* nonferrous metal shelf angles located in the horizontal joints in every course. Such shelf angles shall be not less than 0.0478-inch (1.2 mm) thick and not less than 2 inches (51 mm) long and shall be spaced at *approved* intervals, with not less than two angles for each glass unit. Shelf angles shall be secured to the wall or backing with expansion bolts, toggle bolts or by other *approved* methods.

❖ Structural glass veneer installed more than 36 inches (914 mm) above sidewalk level is subject to impact from pedestrians and can pose a hazard if the veneer were to become dislodged from the backing. To minimize the potential for this occurring, it is necessary to provide additional supports that are attached to the backing. The supports are intended to supplement the mastic.

1405.12.5 Joints. Unless otherwise specifically *approved* by the *building official*, abutting edges of thin exterior structural glass veneer shall be ground square. Mitered joints shall not be used except where specifically *approved* for wide angles. Joints shall be uniformly buttered with an *approved* jointing compound and horizontal joints shall be held to not less than 0.063 inch (1.6 mm) by an *approved* nonrigid substance or device. Where thin exterior structural glass veneer abuts nonresilient material at sides or top, expansion joints not less than $^1/_4$ inch (6.4 mm) wide shall be provided.

❖ Glass has an expansion coefficient of roughly 4.5, which is less than most metals. To minimize the potential for cracking or chipping of the glass panels and the development of sharp edges due to differential movement, this section stipulates both the requirements for factory finishing of the glass veneer panel edges and the minimum requirements for joints between sections.

1405.12.6 Mechanical fastenings. Thin exterior structural glass veneer installed above the level of the heads of show windows and veneer installed more than 12 feet (3658 mm) above sidewalk level shall, in addition to the mastic cement and shelf angles, be held in place by the use of fastenings at each vertical or horizontal edge, or at the four corners of each glass unit. Fastenings shall be secured to the wall or backing with expansion bolts, toggle bolts or by other methods. Fastenings shall be so designed as to hold the glass veneer in a vertical plane independent of the mastic cement. Shelf angles providing both support and fastenings shall be permitted.

❖ While Section 1405.12.4.1 addresses the requirements for protection of pedestrians for installations of veneer that exceed 3 feet (914 mm) above sidewalk level, this section address installations that exceed 12 feet (3658 mm) above sidewalk level. Installations above 12 feet (3658 mm) are not subject to impact from pedestrians but are subject to wind loads. Therefore, each veneer section must be secured in place by mechanical means, in addition to the mastic and shelf angles specified in Sections 1405.12.3 and 1405.12.6, respectively.

1405.12.7 Flashing. Exposed edges of thin exterior structural glass veneer shall be flashed with overlapping corrosion-resistant metal flashing and caulked with a waterproof compound in a manner to effectively prevent the entrance of moisture between the glass veneer and the backing.

❖ The presence of moisture behind the glass veneer can result in loss of strength of either the mastic, the bond coat or both. In addition, corrosion of the supports or fasteners can occur. This can increase the potential for failure of the structural glass veneer. This section addresses the requirements for flashing of structural glass veneers to prevent the penetration of moisture behind the veneers.

1405.13 Exterior windows and doors. Windows and doors installed in exterior walls shall conform to the testing and performance requirements of Section 1710.5.

❖ Windows and doors that are part of the exterior building envelope are to be tested for wind-load resistance in accordance with the methods specified in Section 1710.5.2 (see commentary, Section 1710.5.2).

1405.13.1 Installation. Windows and doors shall be installed in accordance with *approved* manufacturer's instructions. Fastener size and spacing shall be provided in such instructions and shall be calculated based on maximum loads and spacing used in the tests.

❖ Windows and doors that are part of the exterior envelope are to be installed in accordance with the method in which they were tested (see Section 1405.13) and the window or door manufacturer's installation instructions.

1405.14 Vinyl siding. Vinyl siding conforming to the requirements of this section and complying with ASTM D 3679 shall be permitted on exterior walls of buildings located in areas where V_{asd} as determined in accordance with Section 1609.3.1 does not exceed 100 miles per hour (45 m/s) and the *building height* is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where V_{asd} as determined in accordance with Section 1609.3.1 exceeds 100 miles per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Vinyl siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

❖ The installation of vinyl siding on Type V buildings is limited based upon the basic wind speed for a given location. For areas where the basic wind speed is greater than 100 miles per hour (44 m/s), wind load resistance testing and structural calculations support-

ing the ability of the siding to withstand the basic wind speed must be provided.

1405.14.1 Application. The siding shall be applied over sheathing or materials listed in Section 2304.6. Siding shall be applied to conform with the *water-resistive barrier* requirements in Section 1403. Siding and accessories shall be installed in accordance with *approved* manufacturer's instructions. Unless otherwise specified in the *approved* manufacturer's instructions, nails used to fasten the siding and accessories shall have a minimum 0.313-inch (7.9 mm) head diameter and $^1/_8$-inch (3.18 mm) shank diameter. The nails shall be corrosion resistant and shall be long enough to penetrate the studs or nailing strip at least $^3/_4$ inch (19 mm). Where the siding is installed horizontally, the fastener spacing shall not exceed 16 inches (406 mm) horizontally and 12 inches (305 mm) vertically. Where the siding is installed vertically, the fastener spacing shall not exceed 12 inches (305 mm) horizontally and 12 inches (305 mm) vertically.

❖ This section prescribes requirements for the installation of vinyl siding. The installation must also comply with ASTM D 4756, which is referenced in ASTM D 3679 (see commentary, Section 1404.9) and the manufacturer's instructions. These instructions are necessary for compliance with the performance requirements of this chapter. The prescriptive fastener requirements of this section correspond with the requirements contained in ASTM D 4756.

1405.15 Cement plaster. Cement plaster applied to exterior walls shall conform to the requirements specified in Chapter 25.

❖ The materials and installation of cement plaster (sometimes referred to as "stucco") are governed by the requirements of Chapter 25. It should be noted that cement plaster is the only plaster type that is permitted for exterior use. Gypsum plaster, which is also governed by Chapter 25, is generally subject to deterioration in the presence of moisture and is therefore not permitted for use in exterior applications.

1405.16 Fiber-cement siding. Fiber-cement siding complying with Section 1404.10 shall be permitted on exterior walls of Type I, II, III, IV and V construction for wind pressure resistance or wind speed exposures as indicated by the manufacturer's listing and *label* and *approved* installation instructions. Where specified, the siding shall be installed over sheathing or materials *listed* in Section 2304.6 and shall be installed to conform to the *water-resistive barrier* requirements in Section 1403. Siding and accessories shall be installed in accordance with *approved* manufacturer's instructions. Unless otherwise specified in the *approved* manufacturer's instructions, nails used to fasten the siding to wood studs shall be corrosion-resistant round head smooth shank and shall be long enough to penetrate the studs at least 1 inch (25 mm). For metal framing, all-weather screws shall be used and shall penetrate the metal framing at least three full threads.

❖ Fiber cement siding is also a material used for weather-resistant siding. It is manufactured from fiber-reinforced cement, and the code permits its use as either panel siding or horizontal lap siding. Sections 1405.16.1 and 1405.16.2 states that the applicable material standard is ASTM C 1186. Note that the product is required to bear a label, which means that the manufacturer must have regular inspections by a third-party control agency.

1405.16.1 Panel siding. Fiber-cement panels shall comply with the requirements of ASTM C 1186, Type A, minimum Grade II. Panels shall be installed with the long dimension either parallel or perpendicular to framing. Vertical and horizontal joints shall occur over framing members and shall be sealed with caulking, covered with battens or shall be designed to comply with Section 1403.2. Panel siding shall be installed with fasteners in accordance with the *approved* manufacturer's instructions.

❖ This section specifies the material standard and type of material required for fiber cement siding used in a panel configuration. In addition specific details of installation necessary for fiber cement siding are called out.

1405.16.2 Lap siding. Fiber-cement lap siding having a maximum width of 12 inches (305 mm) shall comply with the requirements of ASTM C 1186, Type A, minimum Grade II. Lap siding shall be lapped a minimum of $1^1/_4$ inches (32 mm) and lap siding not having tongue-and- groove end joints shall have the ends sealed with caulking, covered with an H-section joint cover, located over a strip of flashing or shall be designed to comply with Section 1403.2. Lap siding courses shall be installed with the fastener heads exposed or concealed in accordance with the *approved* manufacturer's instructions.

❖ This section specifies the material standard and type of material required for fiber cement siding used in a lap configuration. In addition specific details of installation necessary for fiber cement siding are called out.

1405.17 Fastening. Weather boarding and wall coverings shall be securely fastened with aluminum, copper, zinc, zinc-coated or other *approved* corrosion-resistant fasteners in accordance with the nailing schedule in Table 2304.9.1 or the *approved* manufacturer's installation instructions. Shingles and other weather coverings shall be attached with appropriate standard-shingle nails to furring strips securely nailed to studs, or with *approved* mechanically bonding nails, except where sheathing is of wood not less than 1-inch (25 mm) nominal thickness or of wood structural panels as specified in Table 2308.9.3(3).

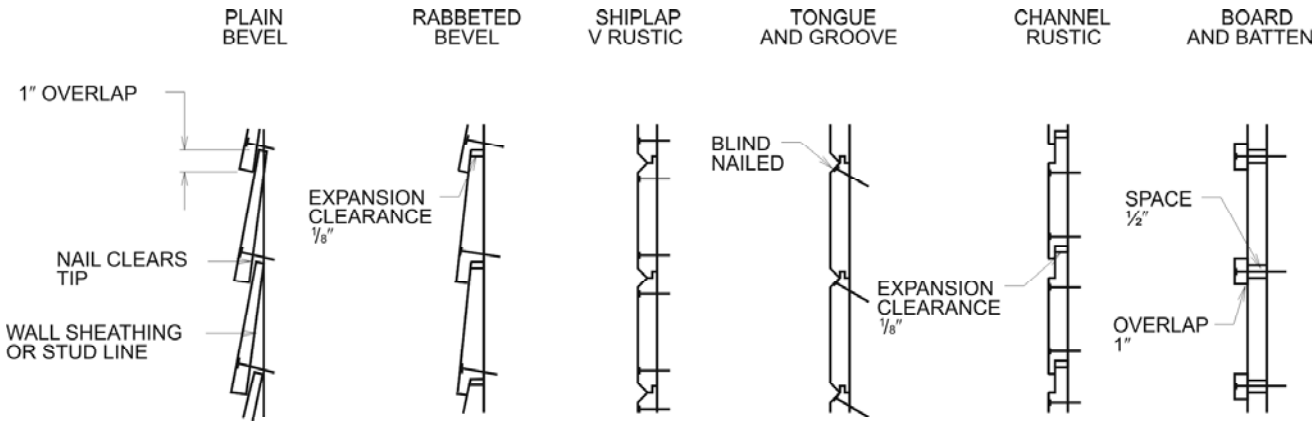
❖ The proper attachment of exterior weatherboard or cladding is critical in order for them to remain durable and stay in place under anticipated weather conditions. This section requires noncorrodible nails and other con-nectors. The requirements of Table 2304.9.1 address the attachment of wood structural panels and panels of particleboard and fiberboard. Lapped siding products of these materials are to be attached in accordance with the manufacturer's installation instructions.

The relatively narrow and variable widths of wood

shingles and shakes make it necessary to provide a continuous nailing base. This is permitted to be wood sheathing, wood structural panels not less than $^{5}/_{16}$-inch (7.9 mm) thick or horizontal furring strips. Dimension lumber furring strips are required to be 1-inch (25 mm) minimum nominal thickness. Shingles are attached with special mechanically bonding nails.

Wood shingles and shakes are required to be fastened with at least No. 14 B&S-gage corrosion-resistant nails in accordance with Table 2304.9.1. The nail must be long enough to penetrate the framing, sheathing or furring strip at least $^{3}/_{4}$ inch (19.1 mm). In accordance with Sections 1507.8.6 (shingles) and 1507.9.7 (shakes), shingles and shakes must be fastened with not more than two fasteners per shingle or shake.

Wood siding must be attached to the sheathing or framing in accordance with Table 2304.9.1. The method of nailing for the various siding patterns is illustrated in Figure 1405.17. Wood siding, especially plain bevel siding, applied over foam plastic sheathing, requires special attention to nailing. Cooperative research by the lumber and plastic industries has shown that poor performance may be expected if the nailing is inadequate. Since the foam plastic sheathing is not an adequate nail base, the siding is required to be nailed through the sheathing to the wood-framing members. Condensation can occur on the sheathing and the back of the siding, keeping the back wet. The weather face will remain dry. This differential moisture condition will cause the siding to "curl" or warp and pull improperly installed nails out of the framing members.



1405.18 Polypropylene siding. Polypropylene siding conforming to the requirements of this section and complying with Section 1404.12 shall be limited to exterior walls of Type VB construction located in areas where the wind speed specified in Chapter 16 does not exceed 100 miles per hour (45 m/s) and the building height is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceeds 100 miles per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

❖ The installation of polypropylene siding is limited to Type VB buildings and is further limited based upon the basic wind speed, building height and exposure category for a given location. For areas where the basic wind speed is greater than 100 miles per hour (44 m/s), wind-load-resistance testing and structural calculations supporting the ability of the siding to withstand the basic wind speed must be provided.

SECTION 1406
COMBUSTIBLE MATERIALS ON THE EXTERIOR SIDE OF EXTERIOR WALLS

1406.1 General. Section 1406 shall apply to *exterior wall coverings*; balconies and similar projections; and bay and oriel windows constructed of combustible materials.

❖ The requirements given in this section apply to exterior elements of combustible construction. The elements included are exterior wall veneers such as vinyl or wood siding, architectural trim, gutters, half-timbering, balconies, bay and oriel windows, plastic panels and foam plastics. The code requires walls to be noncombustible for buildings of construction Types I, II, III and IV, in order to limit the fuel load. Many common types of materials used for architectural enhancement of exterior walls are combustible. Therefore, the code provides limitations as well as requirements for flame spread and radiant heat exposure testing in order to mitigate the hazards associ-

For SI: 1 inch = 25.4 mm.

Figure 1405.17
WOOD WEATHERBOARD ATTACHMENT

ated with combustible materials as permitted elements of noncombustible construction.

1406.2 Combustible exterior wall coverings. Combustible *exterior wall coverings* shall comply with this section.

Exception: Plastics complying with Chapter 26.

❖ The specific requirements relating to the combustible exterior wall finish include resistance to ignition through radiant heat-exposure testing (see Section 1406.2.1.1) and limitations on the height and the amount of combustible materials.

The exception is provided for plastic materials that comply with the requirements of Chapter 26 for limitations on flame spread, ignition properties and amount of plastic.

1406.2.1 Type I, II, III and IV construction. On buildings of Type I, II, III and IV construction, exterior wall coverings shall be permitted to be constructed of combustible materials, complying with the following limitations:

1. Combustible exterior wall coverings shall not exceed 10 percent of an exterior wall surface area where the fire separation distance is 5 feet (1524 mm) or less.
2. Combustible exterior wall coverings shall be limited to 40 feet (12 192 mm) in height above grade plane.
3. Combustible exterior wall coverings constructed of fire-retardant-treated wood complying with Section 2303.2 for exterior installation shall not be limited in wall surface area where the fire separation distance is 5 feet (1524 mm) or less and shall be permitted up to 60 feet (18 288 mm) in height above grade plane regardless of the fire separation distance.
4. Wood veneers shall comply with Section 1405.5.

❖ The purpose of this section is to address the hazards associated with combustible material used on exterior walls of building and structures (i.e., "Exterior wall coverings" as defined in Chapter 2). This section allows combustible exterior wall coverings under specific limitations. The first limitation addresses fire exposure from adjacent structures by limiting the area of the combustible covering when the fire separation distance is 5 feet (1524 mm) or less. When applying the second limitation, all architectural trim and exterior veneers on buildings of Type I, II, III and IV construction that are more than 40 feet (12 192 mm) above grade are required to be noncombustible. This is primarily because of the difficulties associated with fire-fighter access to higher portions of a building and to minimize potential injury from flying brands at high elevation. Combustible architectural trim and exterior veneers are permitted below the 40-foot (12 192 mm) height even when the overall building height exceeds 40 feet (12 192 mm). The third limitation addresses the FRTW. FRTW used as an exterior wall covering is unlimited in area regardless of the fire separation distance. The only qualification is that the material is limited to 60 feet (18 288 mm) in height above grade. FRTW is pressure treated with chemicals that make the wood more resistant to flame spread; therefore, it can be expected to perform better than other combustible materials in the resistance to flame. The fourth limitation requires wood materials to comply with Section 1405.5, which contains limitations specific to wood veneers. Lastly, combustible exterior wall coverings are permitted on buildings of Type V construction without limitation. It should be noted that although Table 503 limits buildings of Type V construction to 40 feet (12 192 mm) in height, such buildings may be increased in height when protected with an automatic sprinkler system in accordance with Section 504.2.

1406.2.1.1 Ignition resistance. Where permitted by Section 1406.2.1, combustible exterior wall coverings shall be tested in accordance with NFPA 268.

Exceptions:

1. Wood or wood-based products.
2. Other combustible materials covered with an exterior covering other than vinyl sidings listed in Table 1405.2.
3. Aluminum having a minimum thickness of 0.019 inch (0.48 mm).

❖ In order to continue to provide the level of safety for adjoining property that is consistent with the fire-safety provisions for opening limitations in exterior walls, radiant-heat testing is required for combustible materials other than wood, using 1.25 W/cm^2 as a baseline exposure criterion.

This section requires that testing be performed in accordance with the NFPA 268 test method to measure the incident radiant heat that will cause a given exterior finish material to ignite.

There are three exceptions to the test requirements. Exception 1 is given because wood or wood-based products have been chosen as the baseline criterion for evaluation of other combustible materials. Testing in accordance with this section would be redundant since such materials are in compliance by virtue of being the baseline material.

Exception 2 relates to materials covered by one of the veneers listed in Table 1405.2. For example, the exception would apply to the building paper under vinyl siding, not the vinyl siding itself. Again, this is an exception to eliminate any confusion that might result from the presence of combustible components within a wall assembly that are not the exposed exterior finish.

Exception 3 is provided because, although most aluminum alloys are combustible, aluminum has a higher ignition temperature than wood. Although not tested, it is anticipated that the critical radiant heat flux would therefore also be higher.

1406.2.1.1.1 Fire separation 5 feet or less. Where installed on exterior walls having a fire separation distance of 5 feet (1524 mm) or less, combustible exterior wall coverings shall not exhibit sustained flaming as defined in NFPA 268.

❖ In order to qualify for use one walls with a fire seperation distance as little as 5 feet (1524 mm), the material must not flame when exposed to a 12.5 kW/m^2 exposure.

1406.2.1.1.2 Fire separation greater than 5 feet. For fire separation distances greater than 5 feet (1524 mm), any exterior wall covering shall be permitted that has been exposed to a reduced level of incident radiant heat flux in accordance with the NFPA 268 test method without exhibiting sustained flaming. The minimum fire separation distance required for the exterior wall covering shall be determined from Table 1406.2.1.1.2 based on the maximum tolerable level of incident radiant heat flux that does not cause sustained flaming of the exterior wall covering.

❖ Exterior wall coverings with a lower tolerance to radiant heat (less than 12.5 kW/m^2) can be used, but the trade-off is an increased fire separation distance to reduce the potential of ignition from radiant heat.

TABLE 1406.2.1.1.2
MINIMUM FIRE SEPARATION FOR COMBUSTIBLE EXTERIOR WALL COVERINGS

FIRE SEPARATION DISTANCE (feet)	TOLERABLE LEVEL INCIDENT RADIANT HEAT ENERGY(kW/m^2)	FIRE SEPARATION DISTANCE (feet)	TOLERABLE LEVEL INCIDENT RADIANT HEAT ENERGY(kW/m^2)
5	12.5	16	5.9
6	11.8	17	5.5
7	11.0	18	5.2
8	10.3	19	4.9
9	9.6	20	4.6
10	8.9	21	4.4
11	8.3	22	4.1
12	7.7	23	3.9
13	7.2	24	3.7
14	6.7	25	3.5
15	6.3		

For SI: 1 foot = 304.8 mm, 1 Btu/H^2 × °F = 0.0057 kW/m^2 × K.

❖ The table provides an increased minimum fire separation distance when the resistance of a material to radiant heat is less than 12.5 kW/m^2 required for veneers on walls with a separation distance of 5 feet (1524 mm). The required resistance to radiant heat decreases with increasing separation distances. It is not anticipated that interpolation will be involved, since fire separation distances are not enforced in fractions of feet. For example, if testing indicated a tolerable level of radiant heat energy of 9.5 kW/m^2, the required minimum fire separation distance would be 10 feet (30 480 mm).

1406.2.2 Location. Combustible exterior wall coverings located along the top of exterior walls shall be completely backed up by the exterior wall and shall not extend over or above the top of the exterior wall.

❖ Combustible trim is not permitted to extend above the exterior wall to which it is attached. This is intended to limit the overall potential involvement of exterior combustible materials in a fire and to reduce the risk of fire spreading to or from such materials from the interior limits of the building. A typical example of architectural trim in this instance is a wood canopy attached to the exterior wall of a strip shopping center, with the canopy fully backed up by the wall.

1406.2.3 Fireblocking. Where the combustible exterior wall covering is furred out from the exterior wall and forms a solid surface, the distance between the back of the exterior wall covering and the exterior wall shall not exceed $1^5/_8$ inches (41 mm). The concealed space thereby created shall be fireblocked in accordance with Section 718.

Exception: The distance between the back of the exterior wall covering and the exterior wall shall be permitted to exceed $1^5/_8$ inches (41 mm) where the concealed space is not required to be fireblocked by Section 718.

❖ This section limits the area of concealed space behind combustible veneers installed on the exterior of buildings of Type I, II, III or IV construction. The intent of fireblocking is to limit the potential for fire to spread through the concealed spaces formed by combustible veneers or architectural trim. Fireblocking materials and methods are regulated by Section 718.

The exception allows for larger distances between the exterior wall covering and the exterior wall, provided that firestopping in accordance with Section 718 is not required. The applicable exception in Section 718.2.6 is Exception 2, which allows the fireblocking to be omitted when the face of the combustible exterior wall covering exposed to the concealed space is covered by the noncombustible materials listed in that exception. Furthermore, Exception 3 to Section 718.2.6 allows the omission of fireblocking in these concealed spaces when the exterior wall covering has been tested in accordance with NFPA 285 and has successfully met the acceptance criteria therein. In both those cases, there will be little opportunity for a fire in the concealed space to spread via the materials in the concealed space because of their noncombustible coverings or because they successfully passed NFPA 285 to show limited fire and flame spread over the face of, as well as within the interior of, the exterior wall system.

1406.3 Balconies and similar projections. Balconies and similar projections of combustible construction other than fire-retardant-treated wood shall be fire-resistance rated where required by Table 601 for floor construction or shall be

of Type IV construction in accordance with Section 602.4. The aggregate length of the projections shall not exceed 50 percent of the building's perimeter on each floor.

Exceptions:

1. On buildings of Type I and II construction, three stories or less above *grade plane*, *fire-retardant-treated wood* shall be permitted for balconies, porches, decks and exterior stairways not used as required exits.
2. Untreated wood is permitted for pickets and rails or similar guardrail devices that are limited to 42 inches (1067 mm) in height.
3. Balconies and similar projections on buildings of Type III, IV and V construction shall be permitted to be of Type V construction, and shall not be required to have a *fire-resistance rating* where sprinkler protection is extended to these areas.
4. Where sprinkler protection is extended to the balcony areas, the aggregate length of the balcony on each floor shall not be limited.

❖ Because these elements are, in a sense, an extension of floor construction, combustible appendages are required to afford the same required fire-resistance rating as required for floor construction in Table 602, unless the appendage is of FRTW or heavy timber construction (Type IV construction). As an additional safeguard against exterior fire spread, the aggregate length of combustible appendages must not exceed 50 percent of the building perimeter on each floor. Balconies, porches, decks, supplemental exterior stairs and similar appendages in buildings of Types I and II construction are required to be constructed of noncombustible materials in order to prevent fire involvement and fire spread up or along the exterior of a noncombustible building. In buildings of Types III, IV and V construction, the use of combustible materials for these elements is permitted.

Exception 1 permits balconies and similar appendages to be constructed of FRTW where buildings of Types I and II construction do not exceed three stories in height. This is due to limited combustibility of FRTW. The three-story limitation is similar to the provisions contained in Section 1406.2.1 for combustible trim.

Exception 2 permits the use of combustible guardrails and handrails for all types of construction in an attempt to alleviate the warping and maintenance problems associated with thin lumber members used for pickets and rails. These items need not be constructed of FRTW.

Exception 3 is applicable to buildings of Types III, IV and V construction. Balconies and similar projections need not be constructed of FRTW nor have a fire-resistance rating when the appendages are protected with an automatic sprinkler system. The presence of sprinkler protection, such as a dry pendent sprinkler, will also serve to limit fire spread from floor to floor.

Balconies, porches, decks and supplemental exterior stairways that are not attached to or supported by the building are separate structures and are to be built accordingly. Although the structural support may be independent, such structures could serve to assist vertical fire spread depending on the construction of the exterior wall and the presence or lack of opening protectives.

1406.4 Bay and oriel windows. Bay and oriel windows shall conform to the type of construction required for the building to which they are attached.

Exception: *Fire-retardant-treated wood* shall be permitted on buildings three stories or less above grade plane of Type I, II, III or IV construction.

❖ In all buildings of other than Type V construction, bay windows and similar appendages are required to be constructed of noncombustible materials (see Figure 1406.4). This is consistent with the requirements for exterior walls in Type I, II, III or IV construction in Sections 602.2 through 602.4. Based upon the limited combustibility of these elements of FRTW, the exception permits their use on buildings of Type I, II, III or IV construction when the elements are constructed of FRTW and the building does not exceed three stories.

SECTION 1407
METAL COMPOSITE MATERIALS (MCM)

1407.1 General. The provisions of this section shall govern the materials, construction and quality of metal composite materials (MCM) for use as *exterior wall coverings* in addition to other applicable requirements of Chapters 14 and 16.

❖ MCMs are panels with a solid plastic core that is encapsulated with an aluminum facer on both sides. MCMs are typically used in exterior applications as a weather covering; however, they do not provide insulation. Section 1407 regulates MCMs that are used as exterior wall coverings. MCM used in a specific assembly, including joints and structure attachments and attachment members, are MCM systems. Figures 1407.1(1), 1407.1(2) and 1407.1(3) illustrate the details of some types of MCM systems.

1407.1.1 Plastic core. The plastic core of the MCM shall not contain foam plastic insulation as defined in Section 2602.1.

❖ MCMs are intended to consist of metal skins covering a thin plastic core. The core is not intended to consist of foam plastic that is regulated under Section 2603. MCM panels are unique and perform significantly different from foam plastic insulation under fire conditions.

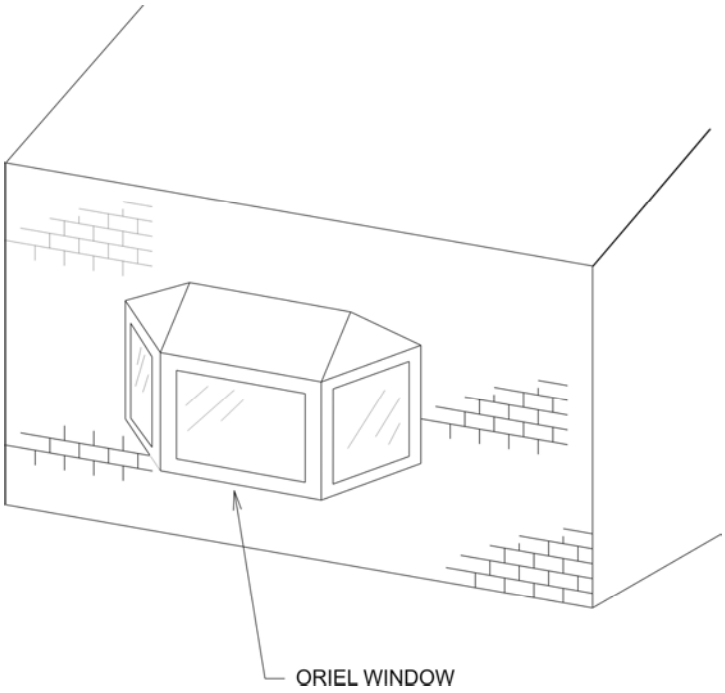


Figure 1406.4
ORIEL WINDOW

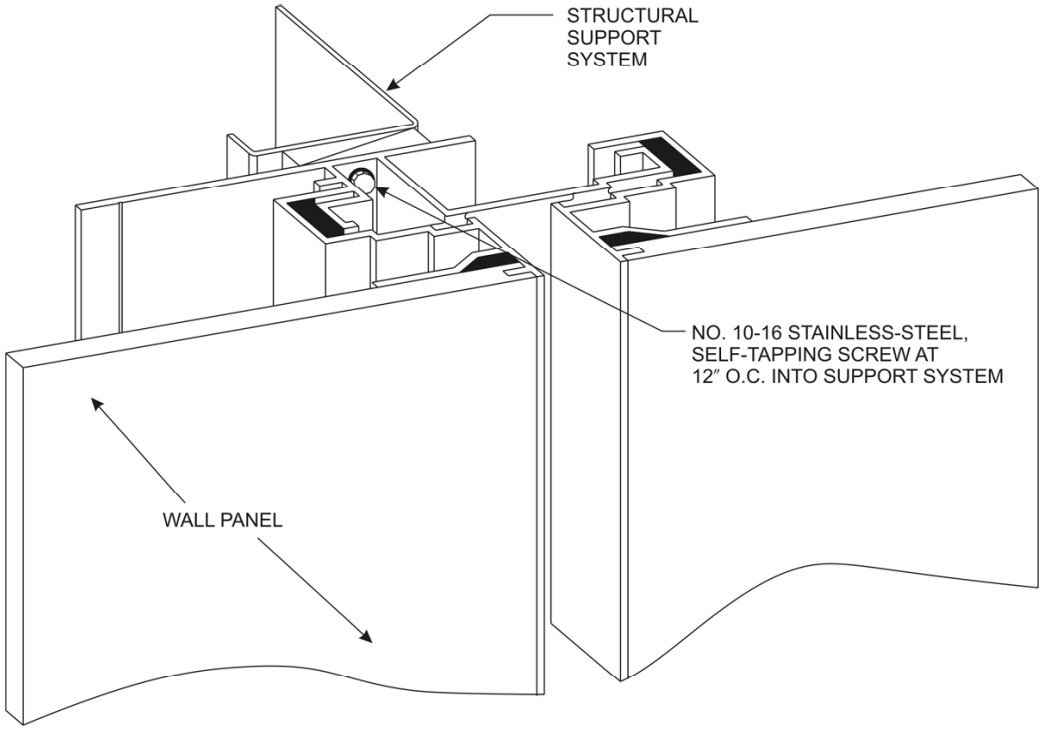

Figure 1407.1(1)
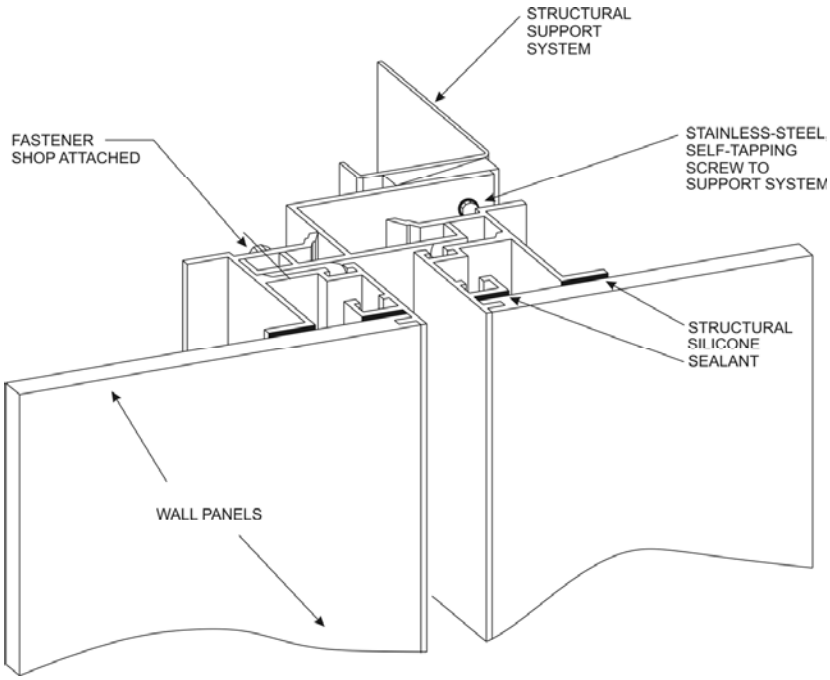
CONTINUOUS EDGE GRIP SYSTEM



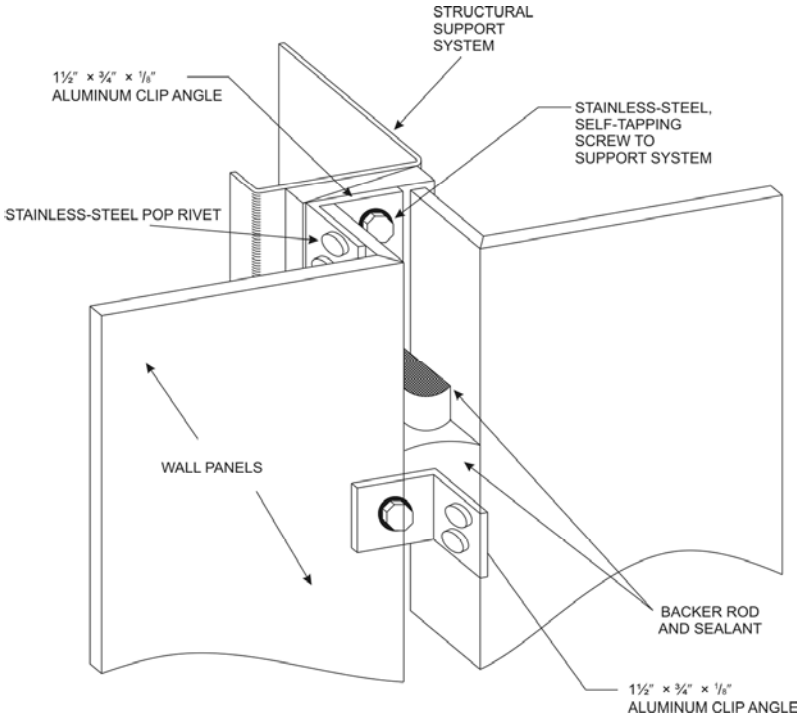


Figure 1407.1(2)
SECTION THROUGH VERTICAL JOINT (HORIZONTAL JOINT SIMILAR)

For SI: 1 inch = 25.4 mm.

Figure 1407.1(3)
TYPICAL RUT AND RETURN SYSTEM SECTION THROUGH VERTICAL JOINT (HORIZONTAL JOINT SIMILAR)

1407.2 Exterior wall finish. MCM used as *exterior wall* finish or as elements of balconies and similar projections and bay and oriel windows to provide cladding or weather resistance shall comply with Sections 1407.4 through 1407.14.

❖ The plastic core of aluminum composite materials is a combustible material. This section provides a correlation with Sections 1406.2, 1406.3 and 1406.4 regulating the use of combustible materials on the exterior of buildings.

1407.3 Architectural trim and embellishments. MCM used as architectural *trim* or embellishments shall comply with Sections 1407.7 through 1407.14.

❖ In a manner similar to Section 1407.2, the provisions of this section provide a correlation with Section 1406.2.1, which regulates the use of combustible trim on the exterior of buildings.

1407.4 Structural design. MCM systems shall be designed and constructed to resist wind loads as required by Chapter 16 for components and cladding.

❖ As previously stated in numerous locations throughout this chapter, exterior weather coverings must be designed and installed to resist the design wind loads required by Chapter 16. These provisions apply to the MCM panels, the supporting elements that are part of the MCM system and the attachment of the system to the building frame.

1407.5 Approval. Results of *approved* tests or an engineering analysis shall be submitted to the *building official* to verify compliance with the requirements of Chapter 16 for wind loads.

❖ The determination that an MCM system will be able to resist a specific wind load may be accomplished through wind load testing, structural engineering calculations or a combination of both. In all instances, documentation substantiating the system's ability to resist the design wind loads is required to be submitted to the building official.

1407.6 Weather resistance. MCM systems shall comply with Section 1403 and shall be designed and constructed to resist wind and rain in accordance with this section and the manufacturer's installation instructions.

❖ As with other exterior weather coverings, MCM systems must comply with the requirements of Section 1403 to prevent the entry of moisture into the building or structure. The manufacturer's installation instructions contain details that are specific to a weathertight installation.

1407.7 Durability. MCM systems shall be constructed of *approved* materials that maintain the performance characteristics required in Section 1407 for the duration of use.

❖ All materials used as weather coverings are required to exhibit a certain level of durability to be effective in providing protection to the structure and its occupants. MCM panels are a composite construction and the bond between the aluminum facing and plastic core must be maintained for the material to maintain the performance characteristics specified in Section 1407. For example, if the bond between the panel and core is not durable, debonding could occur. This could result in detrimental performance, such as possible water intrusion.

1407.8 Fire-resistance rating. Where MCM systems are used on exterior walls required to have a *fire-resistance rating* in accordance with Section 705, evidence shall be submitted to the *building official* that the required *fire-resistance rating* is maintained.

Exception: MCM systems not containing foam plastic insulation, which are installed on the outer surface of a fire-resistance-rated *exterior wall* in a manner such that the attachments do not penetrate through the entire *exterior wall* assembly, shall not be required to comply with this section.

❖ Evidence must be submitted to confirm that the installation of MCM systems will not reduce the fire-resistance rating of exterior walls that are required by Section 704.5 to have a rating. This data may consist of testing performed in accordance with ASTM E 119 of the MCM applied to the fire-resistance-rated wall assembly, as provided for in Section 703.2, or an alternative method, such as engineering analysis, as provided for in Section 703.3, respectively (see commentary, Sections 703.2 and 703.3).

1407.9 Surface-burning characteristics. Unless otherwise specified, MCM shall have a *flame spread index* of 75 or less and a smoke-developed index of 450 or less when tested in the maximum thickness intended for use in accordance with ASTM E 84 or UL 723.

❖ MCMs are required to have a basic flame spread index of 75 and a smoke-developed index of 450. This is consistent with the requirements for other types of plastics intended for use in building construction, in-cluding foam plastics. As indicated in Section 1407.10.1, the flame spread rating required is more restrictive (less that 25) when MCMs are installed on buildings of Type I, II, Ill and IV construction.

1407.10 Type I, II, III and IV construction. Where installed on buildings of Type I, II, III and IV construction, MCM systems shall comply with Sections 1407.10.1 through 1407.10.4, or Section 1407.11.

❖ Due to the combustible core of MCM panels, the fire performance of these panels is regulated. Sections 1407.10.1 through 1407.10.4 stipulate the fire testing that is required to permit the use of these materials on buildings of other than Type V construction. It should be noted that the requirements of these sections are similar to the provisions contained in Chapter 26 for foam plastic materials. Where fire testing is specified, the panels are required to be tested in the maximum thickness intended for use. This is because the maximum thickness represents the greatest potential fuel load in a fire condition.

It should be noted that since MCM panels have an aluminum facing with a minimum thickness of 0.019

inch (0.48 mm), these materials are not required to undergo the ignition-resistance testing required by Section 1406.2.1.

1407.10.1 Surface-burning characteristics. MCM shall have a *flame spread index* of not more than 25 and a smoke-developed index of not more than 450 when tested as an assembly in the maximum thickness intended for use in accordance with ASTM E 84 or UL 723.

❖ The limitations on the maximum flame spread and smoke-developed indexes correspond with the requirements of Section 2603.5.4 for foam plastic materials used on the exterior of buildings of other than Type V construction (see commentary, Section 2603.5.4).

1407.10.2 Thermal barriers. MCM shall be separated from the interior of a building by an approved thermal barrier consisting of $^1/_2$ -inch (12.7 mm) gypsum wallboard or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

❖ The requirements for the installation of a thermal barrier to separate the MCM from the interior of the building are similar to the requirements contained in Section 2603.5.2. Before 1975, experience had shown that foam plastics covered with plaster or $^1/_2$-inch (12.7 mm) gypsum wallboard had performed satisfactorily in building fires. For this reason, $^1/_2$-inch (12.7 mm) gypsum wallboard was included in the code as a minimum requirement. It was recognized that specifying a single material would not be desirable in a performance code; therefore, testing in accordance with NFPA 275 is allowed to qualify other materials. This test method was developed to specifically address the testing of materials to qualify as a thermal barrier. The test method provides specific construction samples, fire exposures and acceptance criteria to qualify a material to be a 15-minute thermal barrier. The test method address both the capability of the material to retard heat transfer via a fire-resistance test and to remain in place via a full-scale fire test.

1407.10.3 Thermal barrier not required. The thermal barrier specified for MCM in Section 1407.10.2 is not required where:

1. The MCM system is specifically approved based on tests conducted in accordance with NFPA 286 and with the acceptance criteria of Section 803.1.2.1, UL 1040 or UL 1715. Such testing shall be performed with the MCM in the maximum thickness intended for use. The MCM system shall include seams, joints and other typical details used in the installation and shall be tested in the manner intended for use.
2. The MCM is used as elements of balconies and similar projections, architectural *trim* or embellishments.

❖ The exemption of the installation of the thermal barrier required by Section 1407.10.2 may be accomplished in two ways. The first is through the use of large-scale fire testing of the MCM system. The system must be tested in a configuration that incorporates details that are representative of a typical installation. The second provision of this section exempts the installation of a thermal barrier where the MCM is limited to use as a component of balconies and similar projections or as architectural trim and embellishments.

1407.10.4 Full-scale tests. The MCM system shall be tested in accordance with, and comply with, the acceptance criteria of NFPA 285. Such testing shall be performed on the MCM system with the MCM in the maximum thickness intended for use.

❖ The final data required to permit the use of MCM systems on buildings of Type I, II, III and IV construction are the result of full-scale testing of the system. This testing is intended to determine that the system will not have the tendency to propagate the spread of fire over the surface of the panels or through the panel core.

1407.11 Alternate conditions. MCM and MCM systems shall not be required to comply with Sections 1407.10.1 through 1407.10.4 provided such systems comply with Sections 1407.11.1, 1407.11.2, 1407.11.3, or 1407.11.4.

❖ Section 1407.11 provides an alternative to compliance with the requirements of Section 1407.10, based upon a specific set of criteria. These criteria limit the amount and height of MCM above grade on buildings of Type I, II, III and IV construction in a manner similar to the provisions of Section 1406 for combustible materials.

1407.11.1 Installations up to 40 feet in height. MCM shall not be installed more than 40 feet (12 190 mm) in height above grade where installed in accordance with Sections 1407.11.1.1 and 1407.11.1.2.

❖ The height limitation of 40 feet (12 192 mm) corresponds to the limitations of Section 1406.2.1 for architectural trim. In addition to the height limitation, the material must comply with the requirements of Sections 1407.11.1.1 and 1407.11.1.2.

1407.11.1.1 Fire separation distance of 5 feet or less. Where the *fire separation distance* is 5 feet (1524 mm) or less, the area of MCM shall not exceed 10 percent of the *exterior wall* surface.

❖ To limit the potential for the spread of fire between buildings that are in close proximity to one another, the maximum amount of combustible exterior veneer is limited in size. These limitations are identical to those of Section 1406.2.1 for combustible veneers.

1407.11.1.2 Fire separation distance greater than 5 feet. Where the *fire separation distance* is greater than 5 feet (1524 mm), there shall be no limit on the area of *exterior wall* surface coverage using MCM.

❖ Based on the decreased potential for the spread of fire between buildings with greater fire separation distances, there is no limit on the area of the MCM on

such exterior walls. It is important to remember that the height of the MCM installation is also limited to 40 feet (12 190 mm). This is also a factor as it further limits the area of the MCM.

1407.11.2 Installations up to 50 feet in height. MCM shall not be installed more than 50 feet (15 240 mm) in height above grade where installed in accordance with Sections 1407.11.2.1 and 1407.11.2.2.

❖ The maximum installed height of MCM on buildings of Type I, II, III and IV construction may be increased up to 50 feet (15 240 mm) when the requirements of Sections 1407.11.2.1 and 1407.11.2.2 are complied with.

1407.11.2.1 Self-ignition temperature. MCM shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929.

❖ Keeping with the requirements in Chapter 26 for other plastic materials, the flame spread of the MCM is not permitted to exceed 75 and the smoke-developed index may not exceed 450. In addition to the limitations on flame spread and smoke development, the MCM must be tested for self-ignition in accordance with ASTM D 1929. These requirements are identical to those contained in Section 2606.4 for light-transmitting plastics (see commentary, Section 2606.4).

1407.11.2.2 Limitations. Sections of MCM shall not exceed 300 square feet (27.9 m^2) in area and shall be separated by a minimum of 4 feet (1219 mm) vertically.

❖ The size limitations of this section are consistent with the provisions of Section 2605.2, Item 3 and Section 2606.7.3. The area limitation is intended to minimize the amount of concentrated combustible materials on the exterior of noncombustible buildings. The separation requirement is intended to minimize the potential for extensive flame propagation over the face of the wall.

1407.11.3 Installations up to 75 feet in height (Option 1). MCM shall not be installed more than 75 feet (22 860 mm) in height above grade plane where installed in accordance with Sections 1407.11.3.1 through 1407.11.3.5.

Exception: Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 shall be exempt from the height limitation.

❖ The maximum installed height of MCM on buildings of Type I, II, III and IV construction may be increased up to 75 feet (22 860 mm) when the requirements of Sections 1407.11.3.1 through 1407.11.3.5 are complied with. The exception allows for installations over 75 feet (22 860 mm) in recognition of the protection provided by the installation of an automatic sprinkler system throughout the building.

1407.11.3.1 Prohibited occupancies. MCM shall not be permitted on buildings classified as Group A-1, A-2, H, I-2 or I-3 occupancies.

❖ Consistent with the requirements for plastic wall panels in accordance with Section 2607.1, MCM is permitted to be installed to a maximum height of 75 feet (22 860 mm) only in occupancies classified as Groups A-3, A-4, A-5, B, E, F-1, F-2, 1-1, M, R-1, R-2, R-3, R-4, S-1, S-2 and U. MCM is not allowed for these installations in occupancies where the generated products of combustion would significantly impair the egress of the impaired, confined or crowded occupants.

1407.11.3.2 Nonfire-resistance-rated exterior walls. MCM shall not be permitted on exterior walls required to have a *fire-resistance rating* by other provisions of this code.

❖ Consistent with the requirements for plastic wall panels in accordance with Section 2607.1, MCM is not permitted where the exterior walls are required to be fire-resistance rated when installed to heights of 75 feet (22 860 mm).

1407.11.3.3 Specifications. MCM shall be required to comply with all of the following:

1. MCM shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929.
2. MCM shall conform to one of the following combustibility classifications when tested in accordance with ASTM D 635:

   Class CC1: Materials that have a burning extent of 1 inch (25 mm) or less when tested at a nominal thickness of 0.060 inch (1.5 mm) or in the thickness intended for use.

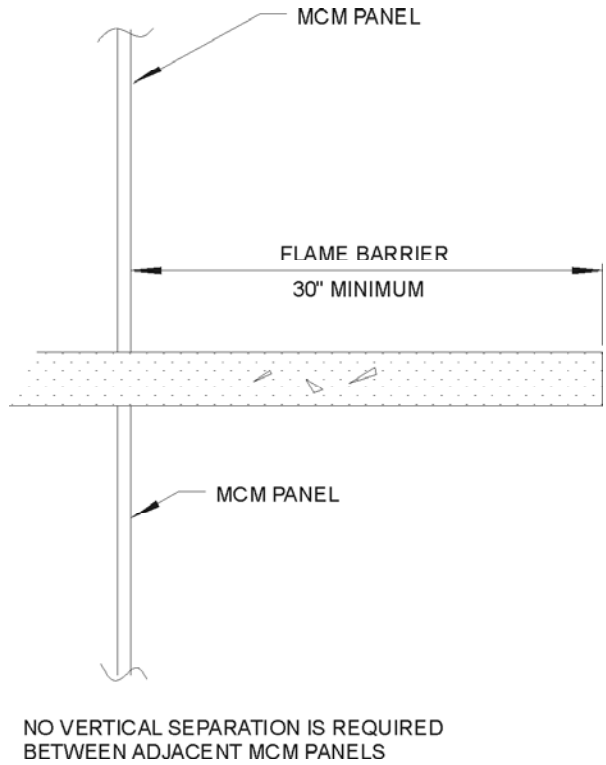
   Class CC2: Materials that have a burning rate of $2^1/_2$ inches per minute (1.06 mm/s) or less when tested at a nominal thickness of 0.060 inch (1.5 mm) or in the thickness intended for use.

❖ For installations up to 75 feet (22 860 mm) above grade plane, MCMs require a minimum self-ignition temperature of 650°F (343°C) when tested in accordance with ASTM D 1929. This temperature excludes the use of easily ignited materials. For comparative purposes, untreated wood and paper ignite at about 500°F (260°C).

In order for an MCM to be approved for these installations, its smoke-development index or smoke-density rating is limited and must be evaluated by one of two test methods prescribed (smoke-developed index limited to 450 by ASTM E 84 or UL 263, or a maximum average smoke-density rating of 75 by ASTM D 2843). For comparative purposes, these smoke-developed values are the maximum that can be expected from some wood products tested under similar conditions; however, there is no intent to indicate a correlation between the results from the two test methods.

MCMs are also to be tested in accordance with ASTM D 635 and be of combustibility Class CC1 or CC2. Class CC1 plastic materials burn at a slower rate than Class CC2 plastics. The above requirements are consistent with the requirements for plastic materials in Chapter 26.

1407.11.3.4 Area limitation and separation. The maximum area of a single MCM panel and the minimum vertical and horizontal separation requirements for MCM panels shall be as provided for in Table 1407.11.3.4. The maximum percentage of exterior wall area of any story covered with MCM panels shall not exceed that indicated in Table 1407.11.3.4 or the percentage of unprotected openings permitted by Section 705.8, whichever is smaller.



Exception: In buildings provided with flame barriers complying with Section 705.8.5 and extending 30 inches (760 mm) beyond the exterior wall in the plane of the floor, a vertical separation shall not be required at the floor other than that provided by the vertical thickness of the flame barrier.

❖ Refer to Table 1407.11.3.4 for area limitations of single MCM panels and the minimum separation requirements (vertical and horizontal) between adjacent panels. The maximum percentage of wall area faced with MCM panels is limited by Table 1407.11.3.4, as well as by the allowable percentage of unprotected openings in accordance with Section 705.8. At all times, the most restrictive requirement prevails.

Vertical separation of panels (see Table 1407.11.3.4) is not required where continuous architectural projections create at least a 30-inch (762 mm) barrier (called a flame barrier) between adjacent panels. Under most conditions, this flame barrier will delay or prevent vertical fire spread from one story to the next. This horizontal barrier is seen as protection equivalent to the vertical separation typically required by Table 1407.11.3.4 (see Figure 1407.11.3.4).

TABLE 1407.11.3.4. See below.

❖ This table establishes size and separation limitations for exterior MCM panels. The requirements are determined by the combustibility class of the MCM (Class CC1 or CC2) and fire separation distance. MCM panels are only permitted where a minimum fire separation distance of 6 feet (1829 mm) is provided. The vertical separation requirements can be modified by Section 1407.11.3.4 (see Table 1407.11.3.4, Note a). The maximum area limitations of a single panel and the maximum percentage area of an exterior wall can be doubled when the structure is sprinklered throughout in accordance with NFPA 13 (see Section 1407.11.3.4).

For SI: 1 inch = 25.4 mm.

Figure 1407.11.3.4
FLAME BARRIER

TABLE 1407.11.3.4
AREA LIMITATION AND SEPARATION REQUIREMENTS FOR MCM PANELS

FIRE SEPARATION DISTANCE (feet)	COMBUSTIBILITY CLASS OF MCM	MAXIMUM PERCENTAGE AREA OF EXTERIOR WALL COVERED WITH MCM PANELS	MAXIMUM SINGLE AREA OF MCM PANELS (square feet)	MINIMUM SEPARATION OF MCM PANELS (feet)	
				Vertical	Horizontal
Less than 6	—	Not Permitted	Not Permitted	—	—
6 or more but less than 11	CC1	10	50	8	4
	CC2	Not Permitted	Not Permitted	—	—
11 or more but less than or equal to 30	CC1	25	90	6	4
	CC2	15	70	8	4
More than 30	CC1	50	Not Permitted	3[a]	0
	CC2	50	100	6[a]	3

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m^2.
a. For reductions in the minimum vertical separation, see Section 1407.11.3.4.

1407.11.3.5 Automatic sprinkler system increases. Where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, the maximum percentage area of exterior wall of any story covered with MCM panels and the maximum square footage of a single area of MCM panels in Table 1407.11.3.4 shall be increased 100 percent. The area of MCM panels shall not exceed 50 percent of the exterior wall area of any story or the area permitted by Section 704.8 for unprotected openings, whichever is smaller.

❖ The extra protection provided by a complete NFPA 13 automatic fire sprinkler system enables the limitations placed on MCM panels to be reduced. In order for these modifications to apply, the structure must be sprinklered throughout. When this protection is achieved, the height to which plastic wall panels can be installed is not limited. Furthermore, the single panel size and exterior wall area limitations can be doubled. At no time, however, can the area of wall panels per story exceed 50 percent of the wall area of that story. The percentage limitation of Section 705.8 for unprotected openings is also applicable and the most restrictive area shall apply.

1407.11.4 Installations up to 75 feet in height (Option 2). MCM shall not be installed more than 75 feet (22 860 mm) in height above grade plane where installed in accordance with Sections 1407.11.4.1 through 1407.11.4.4.

Exception: Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 shall be exempt from the height limitation.

❖ The maximum installed height of MCM on buildings of Type I, II, III and IV construction may be increased up to 75 feet (22 860 mm) when the requirements of Sections 1407.11.4.1 through 1407.11.4.4 are complied with. The exception allows for installations over 75 feet (22 860 mm) in recognition of the protection provided by the installation of an automatic sprinkler system throughout the building. These provisions are intended as an alternative to the requirements in Section 1407.11.3. This option relies on more restrictive fire separation distances and area and size limitations to achieve a level of safety equivalent to that of Section 1407.11.3. This option also allows for installation of MCM on buildings of any occupancy and on walls that are fire-resistance rated.

1407.11.4.1 Minimum fire separation distance. MCM shall not be installed on any wall with a fire separation distance less than 30 feet (9 144 mm).

Exception: Where the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, the fire separation distance shall be permitted to be reduced to not less than 20 feet (6096 mm).

❖ This section requires a minimum fire separation distance of 30 feet (9144 mm), which greatly decreases the threat of fire to or from adjacent structures. The exception allows this distance to be reduced to 20 feet (6096 mm) in recognition of the protection provided by the installation of an automatic sprinkler system throughout the building.

1407.11.4.2 Specifications. MCM shall be required to comply with all of the following:

1. MCM shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929.
2. MCM shall conform to one of the following combustibility classifications when tested in accordance with ASTM D 635:

   Class CC1: Materials that have a burning extent of 1 inch (25 mm) or less when tested at a nominal thickness of 0.060 inch (1.5 mm), or in the thickness intended for use.

   Class CC2: Materials that have a burning rate of $2^{1}/_{2}$ inches per minute (1.06 mm/s) or less when tested at a nominal thickness of 0.060 inch (1.5 mm), or in the thickness intended for use.

❖ The minimum specifications for MCM used in Option 2 are identical to those required in Option 1. However, for Option 2 the combustibility classification of the MCM does not relate to differing requirements as with Option 1. These specifications, therefore, are a minimum benchmark for the MCM.

1407.11.4.3 Area and size limitations. The aggregate area of MCM panels shall not exceed 25 percent of the area of any exterior wall face of the story on which it is installed. The area of a single MCM panel installed above the first story above grade plane shall not exceed 16 square feet (1.5 m^2) and the vertical dimension of a single MCM panel shall not exceed 4 feet (1219 mm).

Exception: Where the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, the maximum aggregate area of MCM panels shall be increased to 50 percent of the exterior wall face of the story on which it is installed and there shall not be a limit on the maximum dimension or area of a single MCM panel.

❖ This section sets forth the maximum area and size limitations for MCM under Option 2. These limitations are much more restrictive than those in Option 1; however, as indicated in the commentary to Section 1407.11.4, this option is applicable to buildings of any occupancy and on walls that are fire-resistance rated. The exception recognizes the extra protection provided by a complete NFPA 13 automatic fire sprinkler system and allows the limitations placed on MCM panels to be reduced. In order for these modifications to apply, the structure must be sprinklered throughout. When this protection is achieved, the single panel size (dimension and area) is not limited and exterior wall area limitations can be increased by 50 percent.

1407.11.4.4 Vertical separations. Flame barriers complying with Section 705.8 and extending 30 inches (762 mm) beyond the exterior wall or a vertical separation of not less

than 4 feet (1219 mm) in height shall be provided to separate MCM panels located on the exterior walls at one story intervals.

Exception: Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ Consistent with other provisions to limit fire spread, this section places restrictions on the size and vertical separation of MCM panels. The 4-foot (1219 mm) vertical separation is widely accepted as adequate for spandrels and other intervening construction between floors. Vertical separation of panels is not required where continuous projections create at least a 30-inch (762 mm) barrier (called a flame barrier) between adjacent panels. Under most conditions, this flame barrier will delay or prevent vertical fire spread from one story to the next. This horizontal barrier is seen as protection equivalent to the vertical separation required by this section (see Figure 1407.11.3.4).

1407.12 Type V construction. MCM shall be permitted to be installed on buildings of Type V construction.

❖ Because of the combustible nature of Type V construction, the fire testing requirements for MCM used as exterior veneers on these buildings is less severe than for other construction types. This is similar in concept to the provisions of Section 1406.

1407.13 Foam plastic insulation. MCM systems containing foam plastic insulation shall also comply with the requirements of Section 2603.

❖ The purpose of this section is to simply point the user of the code to Section 2603 for foam plastics when the MCM contains foam plastic components. The common use of foam plastic in MCM insulation would be the core of the material.

1407.14 Labeling. MCM shall be labeled in accordance with Section 1703.5.

❖ Because of the composite nature of MCMs and the proprietary nature of the panel cores, the fabrication of the panels must be subject to independent third-party verification. The verification of this inspection is evidenced by labeling of the product by the third-party agency (refer to Section 1703.5 for more discussion on the labeling of products).

SECTION 1408
EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS)

1408.1 General. The provisions of this section shall govern the materials, construction and quality of exterior insulation and finish systems (EIFS) for use as *exterior wall coverings* in addition to other applicable requirements of Chapters 7, 14, 16, 17 and 26.

❖ EIFS and EIFS with drainage are relatively complex exterior veneers that require great care and attention in the materials used and the installation details. This exterior veneer is now dealt with in this separate section. All of the performance criteria, installation, and design are covered in this section. EIFS is defined in Section 1402 of this code as wall cladding systems consisting of a foam plastic insulation material covered by a plastic reinforced portland cement base coat and a textured finish coat. The complexity of this material comes in the installation details. For the material to be able to perform as a watertight barrier, the various layers must be carefully applied to strict specifications.

1408.2 Performance characteristics. EIFS shall be constructed such that it meets the performance characteristics required in ASTM E 2568.

❖ ASTM E 2568 defines the necessary performance of EIFS systems. This standard contains basic test criteria for the materials and the entire system. These are generally tests that provide minimum performance levels for the system, including salt spray, accelerated weathering, ignition resistance, fire endurance and wind resistance.

1408.3 Structural design. The underlying structural framing and substrate shall be designed and constructed to resist loads as required by Chapter 16.

❖ This section addresses the structural design of the supporting members. The section underscores the fact that Section 1408 does not obviate the need to support the EIFS with a structural support system.

1408.4 Weather resistance. EIFS shall comply with Section 1403 and shall be designed and constructed to resist wind and rain in accordance with this section and the manufacturer's application instructions.

❖ The important aspect of this section is that, like all other exterior cladding materials, EIFS must be weather resistant as well. Section 1403 provides the performance criteria for exterior cladding.

1408.4.1 EIFS with drainage. EIFS with drainage shall have an average minimum drainage efficiency of 90 percent when tested in accordance the requirements of ASTM E 2273 and is required on framed walls of Type V construction, Group R1, R2, R3 and R4 occupancies.

❖ For wood-framed walls or any light-frame construction using wood sheathing or other water soluble type of material, it is essential to protect the supporting substrate from moisture. The EIFS system, like all other exterior veneers, must be able to allow water that gets behind the cladding to drain.

1408.4.1.1 Water-resistive barrier. For EIFS with drainage, the *water-resistive barrier* shall comply with Section 1404.2 or ASTM E 2570.

❖ The EIFS systems with drainage are required to have a barrier behind the cladding that serves as the "drainage plane" where all water penetration is stopped and directed downward and out of the wall.

The section or referenced standard provide basic test criteria for the materials that would be used behind an EIFS system with drainage.

1408.5 Installation. Installation of the EIFS and EIFS with drainage shall be in accordance with the EIFS manufacturer's instructions.

❖ Manufacturers' instructions provide the proper installation parameters for these materials, including the proper mix proportions for the cement-based substrate, the correct sequence for installation and setting times, among others. The manufacturer's instructions form the job specification for this material.

1408.6 Special inspections. EIFS installations shall comply with the provisions of Sections 1704.2 and 1705.15.

❖ The installation of EIFS systems require attention to detail because the performance of the system can only be assured if the system is installed correctly. This sensitivity requires that special inspections be performed to ensure that ambient conditions were within acceptable range, installation sequences were followed, and all components meet the manufacturer's requirements.

SECTION 1409
HIGH-PRESSURE DECORATIVE EXTERIOR-GRADE COMPACT LAMINATES (HPL)

1409.1 General. The provisions of this section shall govern the materials, construction and quality of High-Pressure Decorative Exterior-Grade Compact Laminates (HPL) for use as exterior wall coverings in addition to other applicable requirements of Chapters 14 and 16.

❖ High-pressure decorative exterior-grade compact laminates (HPL) are panels with a cellulose fibrous material bonded with a thermosetting resin by a high-pressure process. HPL are typically used in exterior applications as a weather covering; however, they do not provide insulation.

1409.2 Exterior wall finish. HPL used as exterior wall covering or as elements of balconies and similar projections and bay and oriel windows to provide cladding or weather resistance shall comply with Sections 1409.4 and 1409.14.

❖ The plastic core of aluminum composite materials is a combustible material. This section provides a correlation with Sections 1406.2, 1406.3 and 1406.4, which regulate the use of combustible materials on the exterior of buildings.

1409.3 Architectural trim and embellishments. HPL used as architectural trim or embellishments shall comply with Sections 1409.7 through 1409.14.

❖ In a manner similar to Section 1409.2, the provisions of this section provide a correlation with Section 1406.2.1, which regulates the use of combustible trim on the exterior of buildings.

1409.4 Structural design. HPL systems shall be designed and constructed to resist wind loads as required by Chapter 16 for components and cladding.

❖ As previously stated in numerous locations throughout this chapter, exterior weather coverings must be designed and installed to resist the design wind loads required by Chapter 16. These provisions apply to the HPL panels, the supporting elements that are part of the HPL system and the attachment of the system to the building frame.

1409.5 Approval. Results of approved tests or an engineering analysis shall be submitted to the building official to verify compliance with the requirements of Chapter 16 for wind loads.

❖ The determination that an HPL system will be able to resist a specific wind load may be accomplished through wind-load testing, structural engineering calculations or a combination of both. In all instances, documentation substantiating the system's ability to resist the design wind loads is required to be submitted to the building official.

1409.6 Weather resistance. HPL systems shall comply with Section 1403 and shall be designed and constructed to resist wind and rain in accordance with this section and the manufacturer's installation instructions.

❖ As with other exterior weather coverings, HPL systems must comply with the requirements of Section 1403 to prevent the entry of moisture into the building or structure. The manufacturer's installation instructions contain details that are specific to a weather-tight installation.

1409.7 Durability. HPL systems shall be constructed of approved materials that maintain the performance characteristics required in Section 1409 for the duration of use.

❖ All materials used as weather coverings are required to exhibit a certain level of durability to be effective in providing protection to the structure and its occupants.

1409.8 Fire-resistance rating. Where HPL systems are used on exterior walls required to have a *fire-resistance rating* in accordance with Section 705, evidence shall be submitted to the building official that the required *fire-resistance rating* is maintained.

Exception: HPL systems not containing foam plastic insulation, which are installed on the outer surface of a fire-resistance-rated exterior wall in a manner such that the attachments do not penetrate through the entire exterior wall assembly, shall not be required to comply with this section.

❖ Evidence must be submitted to confirm that the installation of HCL systems will not reduce the fire-resistance rating of exterior walls that is required by Section 705.5. This data may consist of testing performed in accordance with ASTM E 119 of the HCL applied to the fire-resistance-rated wall assembly, as

provided for in Section 703.2, or an alternative method, such as engineering analysis, as provided for in Section 703.3 (see commentary, Sections 703.2 and 703.3).

1409.9 Surface-burning characteristics. Unless otherwise specified, HPL shall have a flame spread index of 75 or less and a smoke-developed index of 450 or less when tested in the minimum and maximum thicknesses intended for use in accordance with ASTM E 84 or UL 723.

❖ HCL are required to have a basic flame spread index of 75 and a smoke-developed index of 450. This is consistent with the requirements for other types of plastics intended for use in building construction, including foam plastics. As indicated in Section 1407.10.1, the flame spread rating required is more restrictive (not more than 25) when HCL are installed on buildings of Type I, II, III and IV construction.

1409.10 Type I, II, III and IV construction. Where installed on buildings of Type I, II, III and IV construction, HPL systems shall comply with Sections 1409.10.1 through 1409.10.4, or Section 1409.11.

❖ Due to the combustible core of HCL panels, the fire performance of these panels is regulated. Sections 1407.10.1 through 1407.10.4 stipulate the fire testing that is required to permit the use of these materials on buildings of other than Type V construction. It should be noted that the requirements of these sections are similar to the provisions contained in Chapter 26 for foam plastic materials. Where fire testing is specified, the panels are required to be tested in the maximum thickness intended for use. This is because the maximum thickness represents the greatest potential fuel load in a fire condition.

1409.10.1 Surface-burning characteristics. HPL shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450 when tested in the minimum and maximum thicknesses intended for use in accordance with ASTM E 84 or UL 723.

❖ The limitations on the maximum flame spread and smoke-developed indexes of the HCL used in this application correspond with the requirements of Section 2603.5.4 for foam plastic materials used on the exterior of buildings of other than Type V construction (see commentary, Section 2603.5.4).

1409.10.2 Thermal barriers. HPL shall be separated from the interior of a building by an approved thermal barrier consisting of $^1/_2$-inch (12.7 mm) gypsum wallboard or equivalent thermal barrier material that will limit the average temperature rise of the unexposed surface to not more than 250°F (121°C) after 15 minutes of fire exposure in accordance with the standard time-temperature curve of ASTM E 119 or UL 263. The thermal barrier shall be installed in such a manner that it will remain in place for not less than 15 minutes based on a test conducted in accordance with UL 1715.

❖ The requirements for the installation of a thermal barrier to separate the HCL from the interior of the building are similar to the requirements contained in Section 2603.5.2. Before 1975, experience had shown that foam plastics covered with plaster or $^1/_2$-inch (12.7 mm) gypsum wallboard had performed satisfactorily in building fires. For this reason, $^1/_2$-inch (12.7 mm) gypsum wallboard was included in the code as a minimum requirement. Alternative materials are allowed when tested to, and meeting, the criteria stated.

1409.10.3 Thermal barrier not required. The thermal barrier specified for HPL in Section 1409.10.2 is not required where:

1. The HPL system is specifically approved based on tests conducted in accordance with UL 1040 or UL 1715. Such testing shall be performed with the HPL in the minimum and maximum thicknesses intended for use. The HPL system shall include seams, joints and other typical details used in the installation and shall be tested in the manner intended for use.
2. The HPL is used as elements of balconies and similar projections, architectural trim or embellishments.

❖ The exemption of the installation of the thermal barrier required by Section 1407.10.2 may be accomplished in two ways. The first is through the use of large-scale fire testing of the HCL system. The system must be tested in a configuration that incorporates details that are representative of a typical installation. The second provision of this section exempts the installation of a thermal barrier where the use of HCL is limited to a component of balconies and similar projections or as architectural trim and embellishments.

1409.10.4 Full-scale tests. The HPL system shall be tested in accordance with, and comply with, the acceptance criteria of NFPA 285. Such testing shall be performed on the HPL system with the HPL in the minimum and maximum thicknesses intended for use.

❖ The final data required to permit the use of HCL systems on buildings of Type I, II, III and IV construction are the result of full-scale testing of the system. This testing is intended to determine that the system will not have the tendency to propagate the spread of fire over the surface of the panels or through the panel core.

1409.11 Alternate conditions. HPL and HPL systems shall not be required to comply with Sections 1409.10.1 through 1409.10.4 provided such systems comply with Section 1409.11.1 or 1409.11.2.

❖ Section 1407.11 provides an alternative to compliance with the requirements of Section 1407.10, based upon a specific set of criteria. These criteria limit the amount of material and height above grade in a manner similar to the provisions of Section 1406 for combustible materials.

1409.11.1 Installations up to 40 feet in height. HPL shall not be installed more than 40 feet (12 190 mm) in height

above grade plane where installed in accordance with Sections 1409.11.1.1 and 1409.11.1.2.

❖ The height limitation of 40 feet (12 192 mm) corresponds to the limitations of Section 1406.2.2 for architectural trim. In addition to the height limitation, the material must comply with the requirements of Sections 1407.11.1 and 1407.11.2.

1409.11.1.1 Fire separation distance of 5 feet or less. Where the fire separation distance is 5 feet (1524 mm) or less, the area of HPL shall not exceed 10 percent of the exterior wall surface.

❖ To limit the potential for the spread of fire between buildings that are in close proximity to one another, the maximum amount of combustible exterior veneer is limited in size. These limitations are identical to those of Section 1406.2.1 for combustible veneers.

1409.11.1.2 Fire separation distance greater than 5 feet. Where the fire separation distance is greater than 5 feet (1524 mm), there shall be no limit on the area of exterior wall surface coverage using HPL.

❖ Based on the decreased potential for the spread of fire between buildings with greater fire separation distances, there is no limit on the area of the HCL on such exterior walls. It is important to remember that the height of the HCL installation is also limited to 40 feet (12 192 mm). This is also a factor as it further limits the area of the HCL.

1409.11.2 Installations up to 50 feet in height. HPL shall not be installed more than 50 feet (15 240 mm) in height above grade plane where installed in accordance with Sections 1409.11.2.1 and 1409.11.2.2.

❖ The maximum installed height of HCL on buildings of Type I, II, III and IV construction may be increased up to 50 feet (15 240 mm) when the requirements of Sections 1407.11.2.1 and 1407.11.2.2 are complied with.

1409.11.2.1 Self-ignition temperature. HPL shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929.

❖ In addition to the limitations on flame spread and smoke development, the HCL must be tested for self-ignition in accordance with ASTM D 1929. These requirements are identical to those contained in Section 2606.4 for light-transmitting plastics (see commentary, Section 2606.4).

1409.11.2.2 Limitations. Sections of HPL shall not exceed 300 square feet (27.9 m^2) in area and shall be separated by a minimum 4 feet (1219 mm) vertically.

❖ The size limitations of this section are consistent with the provisions of Section 2605.2, Item 3, and Section 2606.7.3. The area limitation is intended to minimize the amount of concentrated combustible materials on the exterior of noncombustible buildings. The separation requirement is intended to minimize the potential for extensive flame propagation over the face of the wall.

1409.12 Type V construction. HPL shall be permitted to be installed on buildings of Type V construction.

❖ Because of the combustible nature of Type V construction, the fire-testing requirements for HCL used as exterior veneers on these buildings is less severe than for other construction types. This is similar in concept to the provisions of Section 1406.

1409.13 Foam plastic insulation. HPL systems containing foam plastic insulation shall also comply with the requirements of Section 2603.

❖ The purpose of this section is to simply point the code user to Section 2603 for foam plastics when the HCL contains foam plastic components. The common use of foam plastic in HCL insulation would be the core of the material.

1409.14 Labeling. HPL shall be labeled in accordance with Section 1703.5.

❖ Because of the composite nature of HCL and the proprietary nature of the panel cores, the fabrication of the panels must be subject to independent third-party verification. The verification of this inspection is evidenced by labeling of the product by the third-party agency (refer to Section 1703.5 for more discussion on the labeling of products).

Chapter 15: Roof Assemblies and Rooftop Structures

General Comments

Chapter 15 regulates the materials, design, construction and quality of roofs and roof structures for all buildings and structures. Requirements for weather protection, fire classification, flashings and insulation are provided to govern the roof slab or deck and its supporting members, in addition to the covering that is applied to the roof for weather resistance, fire resistance or appearance. Specific installation requirements for certain steep-slope and low-slope roof coverings are provided.

Section 1502 lists the defined terms that are most closely associated with the provisions in this chapter.

Section 1503 provides requirements for roof coverings to protect against the effects of weather.

Section 1504 provides performance requirements including referenced standards for evaluating the performance of new and innovative roof coverings.

Section 1505 provides a classification system to determine a roof covering's effectiveness against certain fire test exposures. Specific classifications of roof coverings are required based on the type of construction classification of the structure.

Section 1506 provides requirements for the application of roof covering materials.

Section 1507 provides requirements for the installation of roof coverings.

Section 1508 establishes requirements for the use of combustible roof insulation in all types of construction.

Section 1509 establishes minimum requirements for specific structures that can be constructed on and above the roof.

Section 1510 provides requirements for reroofing, including adequate structural supports, recovering of existing roof materials and replacement.

Section 1511 provides references to roof and structural roof-frame requirements necessary for solar energy systems.

Purpose

The provisions in Chapter 15 for roof construction and coverings are intended to provide a weather-protective barrier at the roof and, in most circumstances, a fire-retardant barrier to prevent flaming combustible materials, such as flying brands from nearby fires, from penetrating the roof construction. The chapter is essentially prescriptive in nature and is based on decades of experience with various traditional roofing materials. These prescriptive rules are very important for satisfactory performance of the roof covering even though the reasoning behind particular requirements may be lost. The provisions are based on preventing a repeat of past unsatisfactory performance of the various roofing materials and components.

SECTION 1501 GENERAL

1501.1 Scope. The provisions of this chapter shall govern the design, materials, construction and quality of roof assemblies, and rooftop structures.

❖ This section specifies the scope and applicability of the code for all roofs, roof assemblies and roof structures. Requirements are provided to regulate the materials, design and construction of roofs and rooftop structures such as penthouses, water tanks and other structures. See also the definition of "Roof assembly" in Section 202. Other roof assemblies addressed elsewhere in the code and not addressed in this chapter include membrane structures (see Section 3102) and light-transmitting plastics (see Section 2606).

SECTION 1502 DEFINITIONS

1502.1 Definitions. The following terms are defined in Chapter 2:

AGGREGATE.

BALLAST.

BUILT-UP ROOF COVERING.

INTERLAYMENT.

MECHANICAL EQUIPMENT SCREEN.

METAL ROOF PANEL.

METAL ROOF SHINGLE.

MODIFIED BITUMEN ROOF COVERING.

PENTHOUSE.

PHOTOVOLTAIC MODULES/SHINGLES.

POSITIVE ROOF DRAINAGE.

REROOFING.

ROOF ASSEMBLY.

ROOF COVERING.

ROOF COVERING SYSTEM.

ROOF DECK.

ROOF RECOVER.

ROOF REPAIR.

ROOF REPLACEMENT.

ROOF VENTILATION.

ROOFTOP STRUCTURE.

SCUPPER.

SINGLE-PLY MEMBRANE.

UNDERLAYMENT.

❖ Definitions facilitate the understanding of code provisions and minimize potential confusion. To that end, this section lists definitions of terms associated with roof assemblies, roof coverings and rooftop structures. Note that these definitions are found in Chapter 2. The use and application of defined terms, as well as undefined terms, are set forth in Section 201.

SECTION 1503
WEATHER PROTECTION

1503.1 General. Roof decks shall be covered with *approved* roof coverings secured to the building or structure in accordance with the provisions of this chapter. Roof coverings shall be designed and installed in accordance with this code and the *approved* manufacturer's instructions such that the roof covering shall serve to protect the building or structure.

❖ The roof covering provides protection from water intrusion into a building. The roofing system has historically been one of the most problematic areas of a building. Without a properly constructed roof assembly, water may infiltrate the building causing damage to building materials and contents. A roof assembly, for the purposes of this chapter, is defined as including the roof deck and components above that make up the roof covering. For a roof covering to perform the way it must to protect the building, it must meet certain requirements. The code provides basic requirements for the construction of roof assemblies. The designer will typically include in his or her roof specification compatibility of materials, deck type, weather conditions, roof slope, structural loads, roof drainage, roof penetrations and future reroofing.

1503.2 Flashing. Flashing shall be installed in such a manner so as to prevent moisture entering the wall and roof through joints in copings, through moisture-permeable materials and at intersections with parapet walls and other penetrations through the roof plane.

❖ Water that penetrates the building envelope can lead to the degradation of building materials that are sensitive to moisture. Flashing must be installed in a very specific manner so that moisture does not enter the building construction or get under the roof covering. As indicated, the flashing is required anywhere the roof covering is interrupted or terminated.

1503.2.1 Locations. Flashing shall be installed at wall and roof intersections, at gutters, wherever there is a change in roof slope or direction and around roof openings. Where flashing is of metal, the metal shall be corrosion resistant with a thickness of not less than 0.019 inch (0.483 mm) (No. 26 galvanized sheet).

❖ Flashing consists of components that weatherproof or seal the roof system at discontinuities, such as perimeters, penetrations, walls [see commentary Figure 1405.4(1)], expansion joints, valleys, drains and other places, where the roof covering is interrupted or terminated. For example, membrane base flashing covers the edge of the field membrane and cap flashings or counterflashings shield the upper edges of the base flashing.

Metal flashing must be no less than the specified minimum thickness and be corrosion resistant. "Corrosion resistance" is defined in Section 202 as "The ability of a material to withstand deterioration of its surface or its properties when exposed to its environment." This definition includes metallic and nonmetallic materials.

1503.3 Coping. Parapet walls shall be properly coped with noncombustible, weatherproof materials of a width no less than the thickness of the parapet wall.

❖ Coping is the covering piece on top of a wall which is exposed to the weather, usually made of metal, masonry or stone. It is typically sloped to shed water back onto the roof.

[P] 1503.4 Roof drainage. Design and installation of roof drainage systems shall comply with Section 1503 of this code and Sections 1106 and 1108, as applicable, of and the *International Plumbing Code*.

❖ The purpose of this section is to call attention to the need for providing roof drainage as well as the requirements for sizing and locating secondary drains. Positive roof drainage is required for essentially two reasons: to prevent excessive ponding of water and the consequent rapid deterioration of the roof-covering material, including the potential for early failure of the roof covering; and to prevent excessive ponding and the resulting failure of the roof structure or, alternatively, the need for increased strength of the roof system to support ponding. Section 1611.2 requires the structural design calculations to consider ponding and preclude a progressive deflection of the structural roof members.

[P] 1503.4.1 Secondary (emergency overflow) drains or scuppers. Where roof drains are required, secondary (emer-

gency overflow) roof drains or scuppers shall be provided where the roof perimeter construction extends above the roof in such a manner that water will be entrapped if the primary drains allow buildup for any reason. The installation and sizing of secondary emergency overflow drains, leaders and conductors shall comply with Sections 1106 and 1108, as applicable, of the *International Plumbing Code.*

❖ These requirements alert the roofer to the need for providing properly sized secondary drains or scuppers. A secondary drainage system is required where the building has parapet walls or other construction that could restrict drainage at the roof's perimeter. This section requires all buildings to have some method for preventing the accumulation of unplanned excessive rainwater.

The intent here is to limit the amount of ponding water that will be placed on the roof by rainfall. If the building is designed so water cannot pond on the roof, such as roofs sloped toward the edge of the building, secondary drainage is not required. This simple concept should be carried to all portions of the roof, so that if any portion is designed so water can pond, secondary drains would be required.

Bear in mind that a roof could be intentionally designed to allow ponding to some design depth such as for a rainwater harvesting system.

1503.4.2 Scuppers. When scuppers are used for secondary (emergency overflow) roof drainage, the quantity, size, location and inlet elevation of the scuppers shall be sized to prevent the depth of ponding water from exceeding that for which the roof was designed as determined by Section 1611.1. Scuppers shall not have an opening dimension of less than 4 inches (102 mm). The flow through the primary system shall not be considered when locating and sizing scuppers.

❖ Scuppers allow water to drain at the perimeter of a roof. These devices are commonly larger than the roof drain. This section provides performance requirements for roofs using wall scuppers as a means of secondary roof drainage. This section also provides minimum prescriptive opening dimensions for scuppers regardless of the results of the performance design. The performance design typically takes into account the flow rate, the length of the scupper opening and the water pressure (head) on the scupper.

1503.4.3 Gutters. Gutters and leaders placed on the outside of buildings, other than Group R-3, private garages and buildings of Type V construction, shall be of noncombustible material or a minimum of Schedule 40 plastic pipe.

❖ All roofs are required to be designed and built with positive drainage (see Section 1507.10.1 for the slope requirements of built-up roofs). "Positive roof drainage" is defined in Section 202. Ponding water has detrimental effects on a roof system, including roof surface and membrane deterioration due to debris accumulation; vegetation and fungal growth; deck deflections which can lead to structural damage; ice formation; tensile splitting; and the possibility of water entering the building.

1503.5 Roof ventilation. Intake and exhaust vents shall be provided in accordance with Section 1203.2 and the manufacturer's installation instructions.

❖ During cold weather, condensation is deposited on cold surfaces when, for example, warm, moist air rising from the interior of a building and through the attic comes in contact with the roof deck. Ventilation prevents moisture condensation on the cold surfaces and, therefore, will reduce or prevent dry rot on the bottom surface of shingles or wood roof decks.

1503.6 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration greater than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

Exception: Unit skylights installed in accordance with Section 2405.5 and flashed in accordance with the manufacturer's instructions shall be permitted to be installed without a cricket or saddle.

❖ A cricket or saddle is a raised roof substrate or structure constructed to channel or direct surface water around a chimney or other similar roof penetration. The exception recognizes the use of engineered skylight systems that are designed to prevent water infiltration without the use of a cricket. It applies to unit skylights that are installed in accordance with Section 2405.5.

SECTION 1504
PERFORMANCE REQUIREMENTS

1504.1 Wind resistance of roofs. Roof decks and roof coverings shall be designed for wind loads in accordance with Chapter 16 and Sections 1504.2, 1504.3 and 1504.4.

❖ It is important that roof coverings and roof decks remain intact and in place when subjected to high winds. Without an intact roof system, the building would be subjected either to water damage, which would reduce its structural stability, or to higher wind pressures for which the building is not designed. The following sections specify requirements for different roof coverings regarding wind loads. The roof decks are included in the requirements of Chapter 16.

1504.1.1 Wind resistance of asphalt shingles. Asphalt shingles shall comply with Section 1507.2.7.

❖ For the installation of asphalt shingles related to wind-resistance performance, this section refers to Section 1507.2.7 (see commentary, Section 1507.2.7).

1504.2 Wind resistance of clay and concrete tile. Wind loads on clay and concrete tile roof coverings shall be in accordance with Section 1609.5.

❖ To determine the minimum wind loads to use in the design and installation of clay and concrete roof tile,

this section refers to Section 1609.5. When required by Table 1507.3.7, the tiles must be installed to resist the wind loads as calculated in accordance with Section 1609.5.

1504.3 Wind resistance of nonballasted **roofs.** Roof coverings installed on roofs in accordance with Section 1507 that are mechanically attached or adhered to the roof deck shall be designed to resist the design wind load pressures for components and cladding in accordance with Section 1609.

❖ This section addresses wind resistance of steep-slope systems that are mechanically attached by fasteners or adhered to the roof slab or deck by adhesives. Steep-slope roof coverings are those described in Section 1507 with a roof slope of 2:12 or greater. The basic wind speed as obtained from Chapter 16 for the building's location must be modified for the building's overall height above grade and exposure category, wind gust effect and wind importance factor. A structural design is required to demonstrate that the proposed fastening schedule will resist the wind uplift loads.

1504.3.1 Other roof systems. Roof systems with built-up, modified bitumen, fully adhered or mechanically attached single-ply through fastened metal panel roof systems, and other types of membrane roof coverings shall also be tested in accordance with FM 4474, UL 580 or UL 1897.

❖ Minimum requirements addressing the wind resistance of low-slope roof systems (typically less than 2:12) are established in this section. Besides compliance with the requirements of Section 1504.3, membrane-type roof coverings are required to be physically tested for compliance with one of three standards: FM 4474, UL 580 or UL 1897.

1504.3.2 Metal panel roof systems. Metal panel roof systems through fastened or standing seam shall be tested in accordance with UL 580 or ASTM E 1592.

Exception: Metal roofs constructed of cold-formed steel, where the roof deck acts as the roof covering and provides both weather protection and support for structural loads, shall be permitted to be designed and tested in accordance with the applicable referenced structural design standard in Section 2210.1.

❖ This section specifies the test that metal panel roof systems are required to pass before installation. Standards and test methods have been established for the proper installation of metal panel roof systems whether fastened or standing seamed.

The exception recognizes metal decks that provide both weather protection and support for structural loads, including wind and live loads. Many of these metal decks are structural elements where stresses can be calculated just like the design approach used for the roof-framing members that support the roof deck. The American Iron and Steel Institute (AISI) specification referenced in Section 2210.1 recognizes a wide variety of roofing profiles where calculations are applicable. For roofing profiles that cannot be directly calculated, the specification requires additional testing, including many of the tests currently referenced by the code for wind resistance. In addition, unlike many of the wind tests, the specification gives guidance on the selection of appropriate safety factors.

1504.4 Ballasted low-slope roof systems. Ballasted low-slope (roof slope < 2:12) single-ply roof system coverings installed in accordance with Sections 1507.12 and 1507.13 shall be designed in accordance with Section 1504.8 and ANSI/SPRI RP-4.

❖ Sections 1507.12 and 1507.13 prescribe the installation for ballasted low-slope, single-ply roof system coverings. These coverings are to be designed in accordance with Section 1504.8 and ANSI/SPRI RP-4, which is listed in Chapter 35.

1504.5 Edge securement **for low-slope roofs.** Low-slope built-up, modified bitumen and single-ply roof system metal edge securement, except gutters, shall be designed and installed for wind loads in accordance with Chapter 16 and tested for resistance in accordance with Test Methods RE-1, RE-2 and RE-3 of ANSI/SPRI ES-1, except V_{ult} wind speed shall be determined from Figure 1609A, 1609B, or 1609C as applicable.

❖ These requirements are specific to low-slope membrane roofs, namely built-up, modified bitumen and single-ply roofs. This section references the appropriate standard for low-slope roofs, which is ANSI/SPRI ES-1. This standard is important in preventing failures of the edge attachment on low-slope roof systems. ANSI/SPRI ES-1 consists of two primary parts. In the portion of ANSI/SPRI ES-1 that is included in the scope of reference, the edge metal flashings' wind resistance is determined according to RE-1, RE-2 and RE-3 test methods. By specifically referencing those test methods in ANSI/SPRI ES-1, any confusion with the determination of wind loads should be avoided since other portions of the standard can be used to determine the wind loads at a roof edge. Also, by referring the code user to code Figures 1609A, 1609B and 1609C, the intent that wind speeds must be determined using Chapter 16 is reinforced.

1504.6 Physical properties. Roof coverings installed on low-slope roofs (roof slope < 2:12) in accordance with Section 1507 shall demonstrate physical integrity over the working life of the roof based upon 2,000 hours of exposure to accelerated weathering tests conducted in accordance with ASTM G 152, ASTM G 155 or ASTM G 154. Those roof coverings that are subject to cyclical flexural response due to wind loads shall not demonstrate any significant loss of tensile strength for unreinforced membranes or breaking strength for reinforced membranes when tested as herein required.

❖ This section, which addresses the effects of weather on the performance of the roof covering, requires that

weather testing be performed and includes performance criteria for those roof coverings that will have to perform while subjected to wind loads.

The ASTM International (ASTM) test methods that are referenced cover exposure to carbon-arc-type or xenon-arc-type light (with or without water), fluorescent ultraviolet-condensation-type rays and concentrated natural sunlight. In conjunction with these tests, roofing materials must not show any significant signs of failure caused by cyclical wind conditions. The tensile strength in unreinforced membranes and the breaking strength in reinforced membranes must endure such conditions without any significant strength reduction.

1504.7 Impact resistance. Roof coverings installed on low-slope roofs (roof slope < 2:12) in accordance with Section 1507 shall resist impact damage based on the results of tests conducted in accordance with ASTM D 3746, ASTM D 4272, CGSB 37-GP-52M or the "Resistance to Foot Traffic Test" in Section 5.5 of FM 4470.

❖ All roof-covering materials must withstand impact loads, such as hail and driving rainstorms. The referenced standards set criteria for the testing of certain roofing materials on low-slope roofs, such as plastic film and bituminous roofing systems. Each test uses similar devices to test the material. The tests consist of dropping a dart or missile, which weighs from $2^1/_2$ to 5 pounds (1.1 to 2.3 kg), approximately 4 to 5 feet (1219 to 1524 mm) and then evaluating the material for failure.

1504.8 Aggregate. Aggregate used as surfacing for roof coverings and aggregate, gravel or stone used as ballast shall not be used on the roof of a building located in a hurricane-prone region as defined in Section 202, or on any other building with a mean roof height exceeding that permitted by Table 1504.8 based on the exposure category and basic wind speed at the site.

❖ This section recognizes that aggregate, gravel and stone used on roofs can be blown off when subjected to hurricane-strength winds or higher wind effects due to the roof height on a taller building. Field assessments of damage to buildings caused by high-wind events have shown that gravel or stone blown from the roofs of buildings has exacerbated damage to neighboring buildings due to breakage of glass. Once glass is broken, higher internal pressures are created within the building, which can result in structural damage to interior walls, and to the cladding of walls and roof surface subjected to negative external pressures. Even where the higher internal pressure is considered and the building is designed accordingly, the breakage of windows will generally result in substantial wind and water damage to the building's interior and contents.

TABLE 1504.8
MAXIMUM ALLOWABLE MEAN ROOF HEIGHT PERMITTED FOR BUILDINGS WITH AGGREGATE ON THE ROOF IN AREAS OUTSIDE A HURRICANE-PRONE REGION

NOMINAL DESIGN WIND SPEED, V_{asd} (mph)[b, d]	MAXIMUM MEAN ROOF HEIGHT (ft)[a, c]		
	Exposure category		
	B	C	D
85	170	60	30
90	110	35	15
95	75	20	NP
100	55	15	NP
105	40	NP	NP
110	30	NP	NP
115	20	NP	NP
120	15	NP	NP
Greater than 120	NP	NP	NP

For SI: 1 foot = 304.8 mm; 1 mile per hour = 0.447 m/s.

a. Mean roof height as defined in ASCE 7.

b. For intermediate values of V_{asd}, the height associated with the next higher value of V_{asd} shall be used, or direct interpolation is permitted.

c. NP = gravel and stone not permitted for any roof height.

d. V_{asd} shall be determined in accordance with Section 1609.3.1.

❖ This table establishes maximum roof heights where aggregate can be used on roofs of buildings outside a hurricane-prone region. The heights are a function of basic wind speed and exposure category.

SECTION 1505
FIRE CLASSIFICATION

1505.1 General. Roof assemblies shall be divided into the classes defined below. Class A, B and C roof assemblies and roof coverings required to be listed by this section shall be tested in accordance with ASTM E 108 or UL 790. In addition, *fire-retardant-treated wood* roof coverings shall be tested in accordance with ASTM D 2898. The minimum roof coverings installed on buildings shall comply with Table 1505.1 based on the type of construction of the building.

Exception: Skylights and sloped glazing that comply with Chapter 24 or Section 2610.

❖ The code designates the use of any particular classification of roof coverings based on the type of construction of the building. A minimum Class B roof covering is required for all roofs that have a minimum 1-hour fire-resistance rating in accordance with Table 602. Roofs without a required fire-resistance rating require a minimum Class C roof covering.

The exception clarifies that skylights and sloped glazing are not required to be tested for fire classification as are roof coverings. Skylights and sloped glazing are considered to be individual assemblies that are required to meet specific requirements listed in other portions of the code. For example, the fire requirements for light-transmitting plastic skylights are covered in Section 2610 and the material and

curbing requirements for glass skylights and sloped glazing are given in Chapter 24.

TABLE 1505.1[a, b]
MINIMUM ROOF COVERING CLASSIFICATION FOR TYPES OF CONSTRUCTION

IA	IB	IIA	IIB	IIIA	IIIB	IV	VA	VB
B	B	B	C[c]	B	C[c]	B	B	C[c]

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m^2.

a. Unless otherwise required in accordance with the *International* Wildland-*Urban Interface Code* or due to the location of the building within a fire district in accordance with Appendix D.

b. Nonclassified roof coverings shall be permitted on buildings of Group R-3 and Group U occupancies, where there is a minimum fire-separation distance of 6 feet measured from the leading edge of the roof.

c. Buildings that are not more than two stories above grade plane and having not more than 6,000 square feet of projected roof area and where there is a minimum 10-foot fire-separation distance from the leading edge of the roof to a lot line on all sides of the building, except for street fronts or public ways, shall be permitted to have roofs of No. 1 cedar or redwood shakes and No. 1 shingles.

❖ See the commentary to Section 1505.1.

1505.2 Class A roof assemblies. Class A roof assemblies are those that are effective against severe fire test exposure. Class A roof assemblies and roof coverings shall be *listed* and identified as Class A by an *approved* testing agency. Class A roof assemblies shall be permitted for use in buildings or structures of all types of construction.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry or an exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile or slate installed on noncombustible decks or ferrous, copper or metal sheets installed without a roof deck on noncombustible framing.
3. Class A roof assemblies include minimum 16 oz/sq. ft. (0.0416 kg/m^2) copper sheets installed over combustible decks.

❖ Roof coverings that are effective against the severe fire-test exposure of ASTM E 108 are classified as Class A. Exception 1 prescribes roof-covering materials that are identified as Class A without having to be tested in accordance with ASTM E 108, based on the past performance of these materials. These include the following noncombustible coverings: brick, masonry or exposed concrete. Any assembly that is tested in accordance with ASTM E 108 requirements for severe fire exposure, and that is listed and labeled by an approved testing agency as a Class A roof covering, is allowed as a roof covering on any type of construction designated in the code. Similarly, Exception 2 prescribes roof-covering materials that are identified as Class A as long as they are installed over a noncombustible deck or, in some cases, without a deck but over noncombustible framing. Exception 3 allows copper sheets over combustible decking to serve as a Class A roof covering. Lastly, note that the materials and specific installations in all three exceptions do not require listing or labeling by an approved agency.

1505.3 Class B roof assemblies. Class B roof assemblies are those that are effective against moderate fire-test exposure. Class B roof assemblies and roof coverings shall be *listed* and identified as Class B by an *approved* testing agency.

❖ Roof coverings that are effective against the moderate fire test exposure of ASTM E 108 are classified as Class B. Those roof coverings listed and identified as Class A by an approved testing agency are also allowed to be used where Class B is required. For buildings and structures of any type of construction designated in the code, Class A or B roof coverings are allowed.

1505.4 Class C roof assemblies. Class C roof assemblies are those that are effective against light fire-test exposure. Class C roof assemblies and roof coverings shall be *listed* and identified as Class C by an *approved* testing agency.

❖ Roof coverings that are effective against the light fire test exposure of ASTM E 108 are classified as Class C. There are no specific materials or products that automatically qualify as Class C roof coverings. However, note that those roof coverings listed and identified as Class A or B are allowed to be used where a Class C is required. Class C roof coverings that are listed and labeled by an approved testing agency may only be used on Types IIB, IIIB and VB construction.

1505.5 Nonclassified roofing. Nonclassified roofing is *approved* material that is not *listed* as a Class A, B or C roof covering.

❖ Nonclassified roofing is a roofing material that is approved by the building official that is not otherwise classified (see the definition of "Approved" in Section 202).

1505.6 Fire-retardant-treated wood shingles and shakes. *Fire-retardant-treated wood* shakes and shingles shall be treated by impregnation with chemicals by the full-cell vacuum-pressure process, in accordance with AWPA C1. Each bundle shall be marked to identify the manufactured unit and the manufacturer, and shall also be labeled to identify the classification of the material in accordance with the testing required in Section 1505.1, the treating company and the quality control agency.

❖ This section specifically identifies the particular pressure-impregnation method to be used to treat wood shakes and shingles. This method consists of placing bundles of the roofing materials inside a retort, which is a huge cylindrical pressure container. A vacuum is then created inside the retort, which in turn draws the air and moisture from the millions of cells per square inch in western red cedar. The fire-retardant chemical mixture is then injected at pressures reaching 150 psi (1034 kPa). The chemical is forced into every cell of

the shakes and shingles—even the innermost layers. After the products are pressure treated, they are then placed in a special drying kiln where they undergo finishing with a thermal cure at temperatures of up to 2,000°F (1093°C). This section further identifies the test standard to be followed, the method of labeling and the information required per bundle of shingles in order for the building official to evaluate code compliance. This includes the testing requirements found in Section 1505.1.

1505.7 Special purpose roofs. Special purpose wood shingle or wood shake roofing shall conform with the grading and application requirements of Section 1507.8 or 1507.9. In addition, an underlayment of $^{5}/_{8}$-inch (15.9 mm) Type X water-resistant gypsum backing board or gypsum sheathing shall be placed under minimum nominal $^{1}/_{2}$-inch-thick (12.7 mm) wood structural panel solid sheathing or 1-inch (25 mm) nominal spaced sheathing.

❖ Informal tests of special purpose roofs have shown that they provide a significant increase in protection for combustible roof coverings, and again the protection offered is considered appropriate if applied in the manner stipulated.

1505.8 Photovoltaic systems. Rooftop installed photovoltaic systems that are adhered or attached to the roof covering or photovoltaic modules/shingles installed as roof coverings shall be labeled to identify their fire classification in accordance with the testing required in Section 1505.1.

❖ The minimum requirement set forth here establishes that the rooftop photovoltaic system should comply with the same minimum fire classification requirements as the underlying roof assembly.

SECTION 1506
MATERIALS

1506.1 Scope. The requirements set forth in this section shall apply to the application of roof-covering materials specified herein. Roof coverings shall be applied in accordance with this chapter and the manufacturer's installation instructions. Installation of roof coverings shall comply with the applicable provisions of Section 1507.

❖ This section establishes specifications and standards for materials and installation techniques in conjunction with recognized industry standards and acceptable roofing applications. By complying with the specified material requirements, slope limitations, underlayment requirements and fastening schedules, the proposed roof covering can be expected to perform as anticipated.

1506.2 Compatibility of materials. Roofs and roof coverings shall be of materials that are compatible with each other and with the building or structure to which the materials are applied.

❖ Material compatibility requires many considerations. For example, some roof coverings might not be compatible with certain roof deck material, certain sealants or solvents and oils. Additionally, it is necessary to have the correct combinations of materials to resist deleterious effects of moisture and humidity as well as to provide energy conservation for buildings of specific materials in given climates.

1506.3 Material specifications and physical characteristics. Roof-covering materials shall conform to the applicable standards *listed* in this chapter. In the absence of applicable standards or where materials are of questionable suitability, testing by an *approved* agency shall be required by the *building code official* to determine the character, quality and limitations of application of the materials.

❖ Where possible, this chapter references appropriate material standards; however, this section acknowledges that there may be materials on the market for which the code does not currently reference a test standard. In those cases, the building official will have to require testing by an approved lab to determine the character, quality and application limitations of the materials. The building official must also require testing when he or she questions the suitability of the materials.

1506.4 Product identification. Roof-covering materials shall be delivered in packages bearing the manufacturer's identifying marks and *approved* testing agency labels required in accordance with Section 1505. Bulk shipments of materials shall be accompanied with the same information issued in the form of a certificate or on a bill of lading by the manufacturer.

❖ Identification of the roofing materials is mandatory in order to verify that they comply with quality standards. In addition to bearing the manufacturer's label or identifying mark, prepared roofing and built-up roofing materials are required by the code to carry a label of an approved agency that inspects the material and finished products during manufacture.

SECTION 1507
REQUIREMENTS FOR ROOF COVERINGS

1507.1 Scope. Roof coverings shall be applied in accordance with the applicable provisions of this section and the manufacturer's installation instructions.

❖ Roof coverings serve as the membrane of the roof system, making it critical in providing weather protection. This section requires that the installation of roof coverings be in accordance with the code and the manufacturer's installation instructions. Often, other requirements must be met, such as UL or FM requirements. It is very possible that there will be times that these requirements conflict. Once adopted, the code is law. The other provisions are not law, and compliance with them does not necessarily mean that com-

pliance with the code has been achieved. In cases where conflicts arise, the code requirements govern.

1507.2 Asphalt shingles. The installation of asphalt shingles shall comply with the provisions of this section.

❖ This section establishes the criteria for asphalt shingle roofs. Two general types of asphalt shingles specifically apply to this section: strip shingles (e.g., three-tab shingles) and individual interlocking shingles (e.g., T-lock shingles). Asphalt strip shingles, which are the most common, are produced in a variety of finished appearances, including three-tab, random or multiple-tab, no-cutout and laminated architectural.

Asphalt shingles are typically classified as one of two types: cellulose felt reinforced (i.e., organic shingles) and fiberglass mat reinforced (i.e., fiberglass shingles).

Although it is not specifically addressed in this section, the roofing industry generally recommends the attic space below asphalt shingle roofs be properly ventilated (see Section 1503.5).

Additional information regarding asphalt shingle roofs is provided in the *NRCA Roofing Manual: Steep-slope Roof Systems* published by the National Roofing Contractors Association (NRCA).

1507.2.1 Deck requirements. Asphalt shingles shall be fastened to solidly sheathed decks.

❖ Solid sheathed roof decks typically include nominal 1-inch (25 mm) solid lumber or wood structural panels. It is recommended that solid sawn lumber, not more than 8 inches (203 mm) in width, be used. Wider pieces are more likely to warp and cup. The code is specific about the types of decking allowed depending on the material used. For example, wood roof decking is addressed in Chapter 23. Manufacturers may also require the application of their materials to specific roof deck materials for warranty of their products.

1507.2.2 Slope. Asphalt shingles shall only be used on roof slopes of two units vertical in 12 units horizontal (17-percent slope) or greater. For roof slopes from two units vertical in 12 units horizontal (17-percent slope) up to four units vertical in 12 units horizontal (33-percent slope), double underlayment application is required in accordance with Section 1507.2.8.

❖ Asphalt shingles are intended to be applied to a steep roof. A minimum slope is crucial in the performance of such shingles because it is a primary indicator of a roof's ability to shed water. Where the roof slope is less than four units vertical in 12 units horizontal (33-percent slope), water drainage from the roof is slower, which can cause it to back up under the roofing and cause leaks. Thus, this section also specifies double coverage of the underlayment where the slope is between two units vertical in 12 units horizontal (17-percent slope) and four units vertical in 12 units horizontal (33-percent slope). One layer of underlayment must be provided under asphalt shingle roof coverings with a slope greater than four units vertical in 12 units horizontal (33-percent slope). Also, the effect of ice dams at the eaves is more pronounced on low-sloped roofs and, as a result, special precautions are necessary for satisfactory performance of the roofing materials.

1507.2.3 Underlayment. Unless otherwise noted, required underlayment shall conform to ASTM D 226, Type I, ASTM D 4869, Type I, or ASTM D 6757.

❖ Asphalt shingle roofs are required to be installed with a felt underlayment. Underlayment serves as secondary protection against wind-driven rain and other moisture penetration when individual shingles become damaged or dislodged. Underlayment for asphalt shingle roofs is required to comply with ASTM D 226, Type I, or ASTM D 4869, Type I. Products complying with the "Type I" designation of these standards are commonly called "No. 15 asphalt felt." See application requirements for underlayment in Section 1507.2.8 as well as additional restrictions on underlayment applied in high-wind areas in Section 1507.2.8.1.

Underlayment also serves as a separator sheet between the shingles and deck. As a separator, the underlayment provides some protection to the shingles from uneven roof deck edges and deck fasteners. Underlayment also helps eliminate a rectangular pattern of ridges in the membrane over insulation or deck joints.

Underlayment offers protection from resins and other chemicals contained in wood board sheathing.

Using the appropriate underlayments, decking materials and shingles will help in meeting the fire classification ratings.

1507.2.4 Self-adhering polymer modified bitumen sheet. Self-adhering polymer modified bitumen sheet shall comply with ASTM D 1970.

❖ Self-adhering polymer modified bitumen sheets meeting ASTM D 1970 requirements are intended for use as underlayment for ice dam protection. These underlayments have an adhesive layer that is exposed by removal of a protective sheet. The top surface of the sheet is suitable to work on during the application of the exposed roofing.

1507.2.5 Asphalt shingles. Asphalt shingles shall comply with ASTM D 225 or ASTM D 3462.

❖ ASTM D 225 is a specification for asphalt roofing in shingle form, composed of single or multiple thicknesses of organic felt saturated and coated on both sides with asphalt and surfaced on the weather side with mineral granules. This standard is well established in the roofing industry. Generally, all organic shingles currently manufactured comply with this standard.

ASTM D 3462 is a specification for asphalt roofing in shingle form, composed of single or multiple thicknesses of glass felt impregnated and coated on both sides with asphalt, and surfaced on the weather side with mineral granules. The shingles may be either

locked together during installation, or have a factory-applied self-sealing adhesive. Additionally, asphalt shingles meeting this standard must pass the Class A fire exposure test requirements of ASTM E 108 and the wind-resistance test requirements of ASTM D 7158 (see also Section 1507.2.7.1).

Some "20-year warranted" shingles and "25-year warranted" shingles currently on the market may not necessarily comply with ASTM D 3462. Fiberglass shingles complying with ASTM D 3462 will typically be identified as such on the shingle bundle packaging or the manufacturer will supply a written certification of compliance with the standard.

1507.2.6 Fasteners. Fasteners for asphalt shingles shall be galvanized, stainless steel, aluminum or copper roofing nails, minimum 12 gage [0.105 inch (2.67 mm)] shank with a minimum $^3/_8$ inch-diameter (9.5 mm) head, of a length to penetrate through the roofing materials and a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing. Where the roof sheathing is less than $^3/_4$ inch (19.1 mm) thick, the nails shall penetrate through the sheathing. Fasteners shall comply with ASTM F 1667.

❖ The fasteners allowed are either of metal that is corrosion resistant or galvanized to be corrosion resistant. It is important to use fasteners that are long enough to penetrate the roof covering, flashing, underlayment and into the deck a minimum of $^3/_4$ inch (19.1 mm). When the deck is less than $^3/_4$ inch (19.1 mm) in thickness, the fastener must penetrate through the deck. It is recommended that the nail be at least $^1/_8$ inch (3.2 mm) through the deck.

1507.2.7 Attachment. Asphalt shingles shall have the minimum number of fasteners required by the manufacturer, but not less than four fasteners per strip shingle or two fasteners per individual shingle. Where the roof slope exceeds 21 units vertical in 12 units horizontal (21:12), shingles shall be installed as required by the manufacturer.

❖ This section clarifies that the manufacturers instructions must be consulted when installing asphalt shingles, unless the manufacturer's instructions contain fastening requirements less than those prescribed in this section. As a minimum, there needs to be four fasteners for each strip-type shingle and two fasteners for individual shingles.

For roof slopes greater than 21:12, the manufacturer should be consulted for installation requirements. Typically such an installation will include a 5-inch (127 mm) exposure, with each tab cemented in place using asphalt roofing cement compatible with the shingle.

1507.2.7.1 Wind resistance. Asphalt shingles shall be tested in accordance with ASTM D 7158. Asphalt shingles shall meet the classification requirements of Table 1507.2.7.1(1) for the appropriate maximum basic wind speed. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D 7158 and the required classification in Table 1507.2.7.1(1).

Exception: Asphalt shingles not included in the scope of ASTM D 7158 shall be tested and labeled to indicate compliance with ASTM D 3161 and the required classification in Table 1507.2.7.1(2).

❖ This section recognizes two test methods for the wind resistance of asphalt shingles: ASTM D 7158, which provides a method of testing that is appropriate for sealed asphalt shingles, and ASTM D 3161, which provides a method of testing that is appropriate for unsealed asphalt shingles. Each of these standards results in shingle "classification" based on the ability of the asphalt shingle installation to resist wind uplift. Tables 1507.2.7.1(1) and 1507.2.7.1(2) contain minimum classification requirements based on the nominal design wind speed as determined from Section 1609.3.1.

TABLE 1507.2.7.1(1)
CLASSIFICATION OF ASPHALT ROOF SHINGLES PER ASTM D 7158[a]

NOMINAL DESIGN WIND SPEED, V_{asd}[b] (mph)	CLASSIFICATION REQUIREMENT
85	D, G or H
90	D, G or H
100	G or H
110	G or H
120	G or H
130	H
140	H
150	H

For SI: 1 foot = 304.8 mm; 1 mph = 0.447 m/s.

a. The standard calculations contained in ASTM D 7158 assume exposure category B or C and building height of 60 feet or less. Additional calculations are required for conditions outside of these assumptions.

b. V_{asd} shall be determined in accordance with Section 1609.3.1.

❖ See the commentary for Table 1507.2.7.1(2).

TABLE 1507.2.7.1(2)
CLASSIFICATION OF ASPHALT SHINGLES PER ASTM D 3161

NOMINAL DESIGN WIND SPEED, V_{asd}[a] (mph)	CLASSIFICATION REQUIREMENT
85	A, D or F
90	A, D or F
100	A, D or F
110	F
120	F
130	F
140	F
150	F

For SI: 1 mph = 0.447 m/s.

a. V_{asd} shall be determined in accordance with Section 1609.3.1.

❖ Tables 1507.2.7.1(1) and 1507.2.7.1(2) contain minimum classification requirements based on the nominal design wind speed as determined from Section 1609.3.1 (see commentary, Section 1507.2.7.1).

1507.2.8 Underlayment application. For roof slopes from two units vertical in 12 units horizontal (17-percent slope) and up to four units vertical in 12 units horizontal (33-percent slope), underlayment shall be two layers applied in the following manner. Apply a minimum 19-inch-wide (483 mm) strip of underlayment felt parallel with and starting at the eaves, fastened sufficiently to hold in place. Starting at the eave, apply 36-inch-wide (914 mm) sheets of underlayment overlapping successive sheets 19 inches (483 mm), by fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seal. For roof slopes of four units vertical in 12 units horizontal (33-percent slope) or greater, underlayment shall be one layer applied in the following manner. Underlayment shall be applied shingle fashion, parallel to and starting from the eave and lapped 2 inches (51 mm), fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seal.

❖ Low-sloped roofs, 2:12 to 4:12, shed water more slowly than steeper roofs, therefore requiring greater protection from water backing up under the shingles. This is particularly important when considering wind-driven water and ice damming. For this reason, two layers of underlayment are required. For greater slopes, only one layer of underlayment is necessary, except at eaves where ice dams are potentially a problem.

Installation of underlayment material over a distorted surface can result in reduced wind and weather (moisture) resistance and poor aesthetics. Regardless of the slope, underlayment need only be fastened well enough to stay in place until the shingles are applied. The application of shingle fasteners will serve to fasten the underlayment.

1507.2.8.1 High wind attachment. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's instructions. Fasteners are to be applied along the overlap at a maximum spacing of 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section 1507.2.8 except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if shingles are lost due to a high-wind event. Where the nominal wind speed is greater than 110 mph (49 m/s), fasteners must be approved for asphalt shingle installation and should be flat headed and corrosion resistant.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal wind speed exceeds 120 mph (54 m/s). In laboratory tests, ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception specifically permits the use of a self-adhered underlayment in accordance with Section 1507.2.4 (ASTM D 1970).

1507.2.8.2 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the *exterior wall* line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The water will eventually leak causing damage to the structure, including the walls, ceilings and roof [see Commentary Figures 1507.8.4(1) and (2)]. In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section that exempts accessory buildings from such restrictions as they are unheated structures where the need for protection against ice dams is unnecessary. The same exception is found in Sections 1507.5.4, 1507.6.4, 1507.7.4, 1507.8.4 and 1507.9.4.

1507.2.9 Flashings. Flashing for asphalt shingles shall comply with this section. Flashing shall be applied in accordance

with this section and the asphalt shingle manufacturer's printed instructions.

❖ This section establishes the requirement for roof flashings for asphalt shingles to prevent leakage and further establishes performance criteria.

1507.2.9.1 Base and cap flashing. Base and cap flashing shall be installed in accordance with the manufacturer's instructions. Base flashing shall be of either corrosion-resistant metal of minimum nominal 0.019-inch (0.483 mm) thickness or mineral-surfaced roll roofing weighing a minimum of 77 pounds per 100 square feet (3.76 kg/m^2). Cap flashing shall be corrosion-resistant metal of minimum nominal 0.019-inch (0.483 mm) thickness.

❖ Roof system edges must be weatherproofed or sealed where they intersect with other vertical components, such as walls or chimneys. Flashing is composed of two parts: the base and cap. For a general discussion of roof flashings, see the commentary to Section 1503.2.

1507.2.9.2 Valleys. Valley linings shall be installed in accordance with the manufacturer's instructions before applying shingles. Valley linings of the following types shall be permitted:

1. For open valleys (valley lining exposed) lined with metal, the valley lining shall be at least 24 inches (610 mm) wide and of any of the corrosion-resistant metals in Table 1507.2.9.2.
2. For open valleys, valley lining of two plies of mineral-surfaced roll roofing complying with ASTM D 3909 or ASTM D 6380 shall be permitted. The bottom layer shall be 18 inches (457 mm) and the top layer a minimum of 36 inches (914 mm) wide.
3. For closed valleys (valleys covered with shingles), valley lining of one ply of smooth roll roofing complying with ASTM D 6380, and at least 36 inches (914 mm) wide or types as described in Item 1 or 2 above shall be permitted. Self-adhering polymer modified bitumen underlayment complying with ASTM D 1970 shall be permitted in lieu of the lining material.

❖ Valleys are the internal angle formed by the intersection of two sloping roof planes. For asphalt shingle roofs, the valley protection is categorized as open or closed. An open valley is a method of construction in which the steep-slope roofing on both sides is trimmed along each side of the valley, exposing the valley flashing.

Closed valleys are those that are covered with shingles, and include methods known as closed-cut valleys and woven valleys.

Closed-cut valleys are a method of valley construction in which shingles from one side of the valley extend across the valley, while shingles from the other side are trimmed back approximately 2 inches (51 mm) from the valley centerline.

Woven valley is a method of valley construction in which shingles from both sides of the valley extend across the valley and are woven together by overlapping alternate courses as they are applied.

TABLE 1507.2.9.2. See below.

❖ These corrosion-resistant metals may be used in open-valley construction as valley lining where the lining is exposed.

1507.2.9.3 Drip edge. Provide drip edge at eaves and gables of shingle roofs. Overlap to be a minimum of 2 inches (51 mm). Eave drip edges shall extend $^1/_4$ inch (6.4 mm) below sheathing and extend back on the roof a minimum of 2 inches (51 mm). Drip edge shall be mechanically fastened a maximum of 12 inches (305 mm) o.c.

❖ A drip edge is a metal flashing or other overhanging component applied at the roof edge that is intended to control the direction of dripping water and help protect the underlying building components. Drip edges have an outward projecting lower edge to direct the water away from the building. It is also used to break the continuity of contact between the roof perimeter

TABLE 1507.2.9.2
VALLEY LINING MATERIAL

MATERIAL	MINIMUM THICKNESS	GAGE	WEIGHT
Aluminum	0.024 in.	—	—
Cold-rolled copper	0.0216 in.	—	ASTM B 370, 16 oz. per square ft.
Copper	—	—	16 oz
Galvanized steel	0.0179 in.	26 (zinc-coated G90)	—
High-yield copper	0.0162 in.	—	ASTM B 370, 12 oz. per square ft.
Lead	—	—	2.5 pounds
Lead-coated copper	0.0216 in.	—	ASTM B 101, 16 oz. per square ft.
Lead-coated high-yield copper	0.0162 in.	—	ASTM B 101, 12 oz. per square ft.
Painted terne	—	—	20 pounds
Stainless steel	—	28	—
Zinc alloy	0.027 in.	—	—

For SI: 1 inch = 25.4 mm, 1 pound = 0.454 kg, 1 ounce = 28.35 g, 1 square foot = 0.093 m^2.

and the wall components to help prevent capillary action.

Metal drip edge is a formed metal flashing that extends back from, and bends down over, the roof edge. Along roof gables, rakes and the eave, the edge drip is applied over the underlayment.

1507.3 Clay and concrete tile. The installation of clay and concrete tile shall comply with the provisions of this section.

❖ Additional information regarding clay and concrete tile roofs is provided in the *NRCA Roofing Manual: Steep-slope Roof Systems* published by the NRCA.

1507.3.1 Deck requirements. Concrete and clay tile shall be installed only over solid sheathing or spaced structural sheathing boards.

❖ The choice of deck material is critical to the life of the roof system. Decks must be capable of withstanding loads such as the weight of the tile and associated roof components and accessories. The weight of tile can increase significantly due to water absorption, depending on its porosity. It is important for designers to note that some types of roof tiles may develop increased porosity with age.

1507.3.2 Deck slope. Clay and concrete roof tile shall be installed on roof slopes of $2^1/_2$ units vertical in 12 units horizontal (21-percent slope) or greater. For roof slopes from $2^1/_2$ units vertical in 12 units horizontal (21-percent slope) to four units vertical in 12 units horizontal (33-percent slope), double underlayment application is required in accordance with Section 1507.3.3.

❖ Along with the manufacturer's installation specifications, this section gives specific limitations on the application of concrete and clay tile. Thus, tile is not allowed to be installed on slopes less than $2^1/_2$:12 regardless of the manufacturer's literature. Additionally, for low-sloped roofs, double underlayment is required.

1507.3.3 Underlayment. Unless otherwise noted, required underlayment shall conform to: ASTM D 226, Type II; ASTM D 2626 or ASTM D 6380, Class M mineral-surfaced roll roofing.

❖ Because of the long service life of many tile roofs, an underlayment should be chosen that will provide protection for a comparable period of time. ASTM D 226 includes the physical requirements for Type II asphalt-saturated felt, which is commonly called No. 30 asphalt felt.

ASTM D 2626 covers the felt base sheet with fine mineral surfacing on the top side, with or without perforations. It is intended that nonperforated felt be used in this application. The *NRCA Roofing Manual: Steep-slope Roof Systems* has recommendations regarding the choice of underlayment for specific roof slopes and applications.

ASTM D 6380, Class M, designates mineral-surfaced roll-roofing products.

1507.3.3.1 Low-slope roofs. For roof slopes from $2^1/_2$ units vertical in 12 units horizontal (21-percent slope), up to four units vertical in 12 units horizontal (33-percent slope), underlayment shall be a minimum of two layers applied as follows:

1. Starting at the eave, a 19-inch (483 mm) strip of underlayment shall be applied parallel with the eave and fastened sufficiently in place.
2. Starting at the eave, 36-inch-wide (914 mm) strips of underlayment felt shall be applied overlapping successive sheets 19 inches (483 mm) and fastened sufficiently in place.

❖ The code requires that the underlayment be laid with two layers in a manner that provides two thicknesses at any point.

1507.3.3.2 High-slope roofs. For roof slopes of four units vertical in 12 units horizontal (33-percent slope) or greater, underlayment shall be a minimum of one layer of underlayment felt applied shingle fashion, parallel to, and starting from the eaves and lapped 2 inches (51 mm), fastened only as necessary to hold in place.

❖ A single layer of underlayment is required on all roof slopes of 4:12 or greater. Reinforced underlayment is required on all roofs with spaced sheathing in order to avoid breakthrough of the tiles.

1507.3.3.3 High wind attachment. Underlayment applied in areas subject to high wind [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Sections 1507.3.3.1 and 1507.3.3.2 except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if tiles are lost due to a high-wind event. Where the nominal design wind speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant in accordance with the manufacturer's instructions.

Where the nominal design wind speed exceeds

120 mph (54 m/s), the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception specifically permits the use of a self-adhered underlayment as an alternative in accordance with ASTM D 1970.

1507.3.4 Clay tile. Clay roof tile shall comply with ASTM C 1167.

❖ ASTM C 1167 specifies material characteristics and physical properties for clay tiles that are intended for use as a roof covering where durability and appearance are required to provide a weather-resistant surface of specified design. These tiles are made of clay, shale or other earthy substances and are heat treated at an elevated temperature. The process develops a fired bond between the particulate constituents to provide the strength and durability requirements of ASTM C 1167. The tiles are classified into three grades based on their resistance to weathering. Additionally, the standard covers performance characteristics, including durability; freezing and thawing; strength; efflorescence; permeability and reactive particulates.

1507.3.5 Concrete tile. Concrete roof tile shall comply with ASTM C 1492.

❖ ASTM C 1492 is the standard that covers the physical properties and material characteristics for concrete roof tiles. The water absorption requirement in ASTM C 1492 for normal roof weight tiles is $12^1/_2$ percent, which is lower than the 15 percent previously listed in the code. In addition, ASTM C 1492 adds clarity with regards to the water absorption requirements for medium- and lightweight roof tiles. ASTM C 140 is still referenced for the testing procedures in ASTM C 1492, even though it is no longer directly referenced by the code.

1507.3.6 Fasteners. Tile fasteners shall be corrosion resistant and not less than 11 gage, $^5/_{16}$-inch (8.0 mm) head, and of sufficient length to penetrate the deck a minimum of $^3/_4$ inch (19.1 mm) or through the thickness of the deck, whichever is less. Attaching wire for clay or concrete tile shall not be smaller than 0.083 inch (2.1 mm). Perimeter fastening areas include three tile courses but not less than 36 inches (914 mm) from either side of hips or ridges and edges of eaves and gable rakes.

❖ Fasteners are to be corrosion resistant, such as hot-dipped galvanized steel, aluminum or stainless steel, needle or diamond pointed, with large flat heads.

1507.3.7 Attachment. Clay and concrete roof tiles shall be fastened in accordance with Table 1507.3.7.

❖ Refer to the commentary to Section 1504.2 for other information in the code related to the wind resistance of clay and concrete roof tile.

TABLE 1507.3.7. See page 15-14.

❖ The tabulated requirements for fastener installation are based on wind speed, mean roof height and roof slope. It also covers interlocking requirements for specific areas and criteria for roofs.

1507.3.8 Application. Tile shall be applied according to the manufacturer's installation instructions, based on the following:

1. Climatic conditions.
2. Roof slope.
3. Underlayment system.
4. Type of tile being installed.

❖ Clay and concrete tiles come in two generic forms: roll tile and flat tile. Either one may be interlocking but must be applied according to the manufacturer's instructions.

1507.3.9 Flashing. At the juncture of the roof vertical surfaces, flashing and counterflashing shall be provided in accordance with the manufacturer's installation instructions, and where of metal, shall not be less than 0.019-inch (0.48 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend at least 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). For roof slopes of three units vertical in 12 units horizontal (25-percent slope) and over, the valley flashing shall have a 36-inch-wide (914 mm) underlayment of either one layer of Type I underlayment running the full length of the valley, or a self-adhering polymer-modified bitumen sheet complying with ASTM D 1970, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water, the metal valley flashing underlayment shall be solid cemented to the roofing underlayment for slopes under seven units vertical in 12 units horizontal (58-percent slope) or self-adhering polymer-modified bitumen sheet shall be installed.

❖ Flashings are required to maintain the integrity of weather-resistant roofs (see commentary, Section 1503.2).

TABLE 1507.3.7
CLAY AND CONCRETE TILE ATTACHMENT[a, b, c]

GENERAL - CLAY OR CONCRETE ROOF TILE				
Maximum Nominal Design Wind Speed, V_{asd}[f] (mph)	**Mean roof height (feet)**	**Roof slope < 3:12**	**Roof slope 3:12 and over**	
85	0-60	One fastener per tile. Flat tile without vertical laps, two fasteners per tile.	Two fasteners per tile. Only one fastener on slopes of 7:12 and less for tiles with installed weight exceeding 7.5 lbs./sq. ft. having a width no greater than 16 inches.	
100	0-40			
100	>40-60	The head of all tiles shall be nailed. The nose of all eave tiles shall be fastened with approved clips. All rake tiles shall be nailed with two nails. The nose of all ridge, hip and rake tiles shall be set in a bead of roofer's mastic.		
110	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
120	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
130	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
All	>60	The fastening system shall resist the wind forces in Section 1609.5.3.		
INTERLOCKING CLAY OR CONCRETE ROOF TILE WITH PROJECTING ANCHOR LUGS[d, e] (Installations on spaced/solid sheathing with battens or spaced sheathing)				
Maximum Nominal Design Wind Speed, V_{asd}[f] (mph)	**Mean roof height (feet)**	**Roof slope < 5:12**	**Roof slope 5:12 < 12:12**	**Roof slope 12:12 and over**
85	0-60	Fasteners are not required. Tiles with installed weight less than 9 lbs./sq. ft. require a minimum of one fastener per tile.	One fastener per tile every other row. All perimeter tiles require one fastener. Tiles with installed weight less than 9 lbs./sq. ft. require a minimum of one fastener per tile.	One fastener required for every tile. Tiles with installed weight less than 9 lbs./sq. ft. require a minimum of one fastener per tile.
100	0-40			
100	>40-60	The head of all tiles shall be nailed. The nose of all eave tiles shall be fastened with approved clips. All rake tiles shall be nailed with two nails The nose of all ridge, hip and rake tiles shall be set in a bead of roofer's mastic.		
110	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
120	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
130	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
All	>60	The fastening system shall resist the wind forces in Section 1609.5.3.		
INTERLOCKING CLAY OR CONCRETE ROOF TILE WITH PROJECTING ANCHOR LUGS (Installations on solid sheathing without battens)				
Maximum Nominal Design Wind Speed, V_{asd}[f] (mph)	**Mean roof height (feet)**	**All roof slopes**		
85	0-60	One fastener per tile.		
100	0-40	One fastener per tile.		
100	> 40-60	The head of all tiles shall be nailed. The nose of all eave tiles shall be fastened with approved clips. All rake tiles shall be nailed with two nails The nose of all ridge, hip and rake tiles shall be set in a bead of roofer's mastic.		
110	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
120	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
130	0-60	The fastening system shall resist the wind forces in Section 1609.5.3.		
All	> 60	The fastening system shall resist the wind forces in Section 1609.5.3.		

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound per square foot = 4.882 kg/m^2.

a. Minimum fastener size. Corrosion-resistant nails not less than No. 11 gage with $^5/_{16}$-inch head. Fasteners shall be long enough to penetrate into the sheathing $^3/_4$ inch or through the thickness of the sheathing, whichever is less. Attaching wire for clay and concrete tile shall not be smaller than 0.083 inch.

b. Snow areas. A minimum of two fasteners per tile are required or battens and one fastener.

c. Roof slopes greater than 24:12. The nose of all tiles shall be securely fastened.

d. Horizontal battens. Battens shall be not less than 1 inch by 2 inch nominal. Provisions shall be made for drainage by a minimum of $^1/_8$-inch riser at each nail or by 4-foot-long battens with at least a $^1/_2$-inch separation between battens. Horizontal battens are required for slopes over 7:12.

e. Perimeter fastening areas include three tile courses but not less than 36 inches from either side of hips or ridges and edges of eaves and gable rakes.

f. V_{asd} shall be determined in accordance with Section 1609.3.1.

1507.4 Metal roof panels. The installation of metal roof panels shall comply with the provisions of this section.

❖ There are two general categories of metal roofing systems: architectural metal roofing and structural metal roofing. Architectural metal roofs are generally water-shedding roof systems and structural metal roofs have hydrostatic (water barrier) characteristics.

Architectural metal roof systems are usually characterized by a flat pan with $^3/_4$- to $1^1/_2$-inch (19.1 to 38 mm) ribs on each side. The absence of intermediate ribs and massive side ribs gives a clean appearance, but does not provide the panels with the strength to be considered a structural panel. Architectural metal roofing systems are typically designed for steep slopes so that water will shed off the roof panels. This type of design does not require the seams to be water tight. Therefore, the slope for such nonwater-tight roof panels is required to be not less than 3:12. One exception is traditional flat seamed, soldered or welded metal roofing, which is acceptable on slopes less than 3:12. An example of roofing that has traditionally been used this way is copper. Architectural metal roofing systems require solid decking.

"Metal roof panels" are defined in Section 202 as an interlocking metal sheet having a minimum installed weather exposure of 3 square feet (0.28 m^2) per sheet. In contrast, metal roof shingles have less than 3 square feet (0.28 m^2) of exposure.

1507.4.1 Deck requirements. Metal roof panel roof coverings shall be applied to a solid or closely fitted deck, except where the roof covering is specifically designed to be applied to spaced supports.

❖ The deck for metal roofing is required to be solid or closely fitted, except where the panels are specifically designed to be applied to spaced supports. Structural standing seam metal panel roof systems possess strength characteristics that allow them to span between structural supports, as is commonly used on preengineered metal buildings. The metal panel ribs are not seamed or interlocked like a true standing seam metal roof system.

1507.4.2 Deck slope. Minimum slopes for metal roof panels shall comply with the following:

1. The minimum slope for lapped, nonsoldered seam metal roofs without applied lap sealant shall be three units vertical in 12 units horizontal (25-percent slope).
2. The minimum slope for lapped, nonsoldered seam metal roofs with applied lap sealant shall be one-half unit vertical in 12 units horizontal (4-percent slope). Lap sealants shall be applied in accordance with the *approved* manufacturer's installation instructions.
3. The minimum slope for standing seam of roof systems shall be one-quarter unit vertical in 12 units horizontal (2-percent slope).

❖ Typically, structural metal roofing systems are designed to resist water at laps and seams with sealants applied in the seams. It is usually recommended that these types of roof systems have a slope of not less than $^1/_2$:12, although some manufacturers allow slopes as low as $^1/_4$:12. While the code requires a minimum slope of 3:12, a lower slope is permitted on standing-seam-type roof systems, which require only $^1/_4$:12. The term "standing seam" is used to refer to almost any roof panel with a raised vertical rib. Strictly speaking, it only indicates those metal panels that interlock or are seamed together vertically above the panel's pan.

1507.4.3 Material standards. Metal-sheet roof covering systems that incorporate supporting structural members shall be designed in accordance with Chapter 22. Metal-sheet roof coverings installed over structural decking shall comply with Table 1507.4.3(1). The materials used for metal-sheet roof coverings shall be naturally corrosion resistant or provided with corrosion resistance in accordance with the standards and minimum thicknesses shown in Table 1507.4.3(2).

❖ The requirements for metal roof coverings that incorporate supporting structural members into their design are contained in Chapter 22. Other metal-sheet roof coverings are required to comply with Table 1507.4.3(1).

Many of the materials listed in Table 1507.4.3(1) are inherently corrosion resistant, such as aluminum, copper and lead. For these corrosion-resistant materials a material standard is listed for the base material; however, for steel roofing products, coatings are added to the base material to provide the necessary corrosion resistance.

TABLE 1507.4.3(1). See page 15-16.

❖ This table provides specific guidance and appropriate metal roof coverings. The requirements vary based upon the type of metal used, such as aluminum, steel, copper, lead and zinc. In some cases, standards are referenced; in other cases, basic criteria is provided.

TABLE 1507.4.3(2). See page 15-16.

❖ Steel coating standards are located in Table 1507.4.3(2). Having this table separate from Table 1507.4.3(1) helps to clarify that these standards only address the process necessary to provide corrosion resistance for the base steel. The coating descriptions in Table 1507.4.3(2) are consistent with the applicable coating standards.

TABLE 1507.4.3(1)
METAL ROOF COVERINGS

ROOF COVERING TYPE	STANDARD APPLICATION RATE/THICKNESS
Aluminum	ASTM B 209, 0.024 inch minimum thickness for roll-formed panels and 0.019 inch minimum thickness for press-formed shingles.
Aluminum-zinc alloy coated steel	ASTM A 792 AZ 50
Cold-rolled copper	ASTM B 370 minimum 16 oz./sq. ft. and 12 oz./sq. ft. high yield copper for metal-sheet roof covering systems: 12 oz./sq. ft. for preformed metal shingle systems.
Copper	16 oz./sq. ft. for metal-sheet roof-covering systems; 12 oz./sq. ft. for preformed metal shingle systems.
Galvanized steel	ASTM A 653 G-90 zinc-coated[a].
Hard lead	2 lbs./sq. ft.
Lead-coated copper	ASTM B 101
Prepainted steel	ASTM A 755
Soft lead	3 lbs./sq. ft.
Stainless steel	ASTM A 240, 300 Series Alloys
Steel	ASTM A 924
Terne and terne-coated stainless	Terne coating of 40 lbs. per double base box, field painted where applicable in accordance with manufacturer's installation instructions.
Zinc	0.027 inch minimum thickness; 99.995% electrolytic high grade zinc with alloy additives of copper (0.08% - 0.20%), titanium (0.07% - 0.12%) and aluminum (0.015%).

For SI: 1 ounce per square foot = 0.0026 kg/m^2,
1 pound per square foot = 4.882 kg/m^2,
1 inch = 25.4 mm, 1 pound = 0.454 kg.

a. For Group U buildings, the minimum coating thickness for ASTM A 653 galvanized steel roofing shall be G-60.

TABLE 1507.4.3(2)
MINIMUM CORROSION RESISTANCE

55% Aluminum-zinc alloy coated steel	ASTM A 792 AZ 50
5% Aluminum alloy-coated steel	ASTM A 875 GF60
Aluminum-coated steel	ASTM A 463 T2 65
Galvanized steel	ASTM A 653 G-90
Prepainted steel	ASTM A 755[a]

a. Paint systems in accordance with ASTM A 755 shall be applied over steel products with corrosion-resistant coatings complying with ASTM A 792, ASTM A 875, ASTM A 463 or ASTM A 653.

1507.4.4 Attachment. Metal roof panels shall be secured to the supports in accordance with the *approved* manufacturer's fasteners. In the absence of manufacturer recommendations, the following fasteners shall be used:

1. Galvanized fasteners shall be used for steel roofs.
2. Copper, brass, bronze, copper alloy or 300 series stainless-steel fasteners shall be used for copper roofs.
3. Stainless-steel fasteners are acceptable for all types of metal roofs.

❖ Fasteners used to attach metal roofing to their supporting construction are to have the manufacturer's approval for that purpose. If such approval is not provided, then galvanized fasteners are required for steel roofs; copper, brass, bronze, copper alloy or 300 series stainless steel fasteners are required for copper roofs and stainless-steel fasteners are permitted on any type of metal roof. The purpose of these provisions is to provide compatibility with roof materials and prevent corrosion.

1507.4.5 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 1970. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of roofs subjected to high winds particularly if the roof covering is lost due to a high-wind event. Where the nominal design wind speed is greater than 110 mph (49 m/s), underlayment is required to be applied with fasteners that are corrosion resistant and in accordance with the manufacturer's instructions.

Where the nominal design wind speed exceeds 120 mph (54 m/s), the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception recognizes that a self-adhered underlayment can be used as an alternative in accordance with ASTM D 1970.

1507.5 Metal roof shingles. The installation of metal roof shingles shall comply with the provisions of this section.

❖ See the commentary to Section 1507.4 for a general discussion about metal roof systems.

1507.5.1 Deck requirements. Metal roof shingles shall be applied to a solid or closely fitted deck, except where the roof covering is specifically designed to be applied to spaced sheathing.

❖ The manufacturer's instructions must be followed in addition to any restrictions required by the code.

1507.5.2 Deck slope. Metal roof shingles shall not be installed on roof slopes below three units vertical in 12 units horizontal (25-percent slope).

❖ Metal shingles cannot be installed on roof slopes less than 3:12.

1507.5.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.

❖ A single layer of underlayment is the minimum requirement under all metal shingles other than flat metal shingles. The underlayment must meet the performance criteria of ASTM D 226, Type I, or ASTM D 4869.

1507.5.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch spacing (152 mm) at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of ¾ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if shingles are lost due to a high-wind event. Where the design nominal wind speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant and in accordance with the manufacturer's instructions.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal design wind speed exceeds 120 mph (54 m/s). In laboratory tests, ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception recognizes the use of a self-adhered underlayment as an alernative in accordance with ASTM D 1970.

1507.5.4 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The roof will eventually leak, causing damage to the structure, including the walls, ceilings and roof [see Figures 1507.8.4(1) and (2)] (see Section 1507.8.4). In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section that exempts accessory buildings from such restrictions as they are unheated structures where the need for protection against ice dams is unnecessary.

1507.5.5 Material standards. Metal roof shingle roof coverings shall comply with Table 1507.4.3(1). The materials used for metal-roof shingle roof coverings shall be naturally corrosion resistant or provided with corrosion resistance in accordance with the standards and minimum thicknesses specified in the standards listed in Table 1507.4.3(2).

❖ ASTM A 653 regulates steel sheet for roofing and siding that is zinc coated on continuous lines and by the cut-length method. Material of this quality is furnished flat, in coils and cut lengths, and is formed in cut lengths. Roofing and siding includes corrugated, V-crimp, roll roofing and many special patterns. Corrugated roofing and siding sheet is produced in a number of corrugations, with variations of pitch and depth. ASTM A 755 covers steel sheet that is metallic coated by the hot-dipped process and prepainted by the coil-coating process with organic films for exterior-exposed building products of various qualities. Sheet material of this designation is furnished in coils, cut lengths and formed cut lengths. ASTM B 101 covers lead-coated copper sheets for architectural uses.

Many of the materials listed in Table 1507.4.3(1) are inherently corrosion resistant, such as aluminum, copper and lead. For these corrosion-resistant materials a material standard is listed for the base material; however, for steel roofing products, coatings are added to the base material to provide the necessary

corrosion resistance.

Steel coating standards are located in Table 1507.4.3(2). Having this table separate from Table 1507.4.3(1) helps to clarify that these standards only address the process necessary to provide corrosion resistance for the base steel. The coating descriptions in Table 1507.4.3(2) are consistent with the applicable coating standards.

1507.5.6 Attachment. Metal roof shingles shall be secured to the roof in accordance with the *approved* manufacturer's installation instructions.

❖ Fasteners used to attach metal roofing to the roof are to have the manufacturer's approval for that purpose.

1507.5.7 Flashing. Roof valley flashing shall be of corrosion-resistant metal of the same material as the roof covering or shall comply with the standards in Table 1507.4.3(1). The valley flashing shall extend at least 8 inches (203 mm) from the centerline each way and shall have a splash diverter rib not less than $^3/_4$ inch (19.1 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). In areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water, the metal valley flashing shall have a 36-inch-wide (914 mm) underlayment directly under it consisting of either one layer of underlayment running the full length of the valley or a self-adhering polymer-modified bitumen sheet complying with ASTM D 1970, in addition to underlayment required for metal roof shingles. The metal valley flashing underlayment shall be solidly cemented to the roofing underlayment for roof slopes under seven units vertical in 12 units horizontal (58-percent slope) or self-adhering polymer-modified bitumen sheet shall be installed.

❖ See the commentary to Section 1503.2.

1507.6 Mineral-surfaced roll roofing. The installation of mineral-surfaced roll roofing shall comply with this section.

❖ Mineral-surfaced roll roofing is an asphalt roll roofing material in some cases having a selvage edge, which is a specially defined edge (lined for demarcation) designed for some special purpose, such as overlapping or seaming. It is typically 36 inches (914 mm) in width and is surfaced with coarse mineral granules. In mineral-surfaced roll roofing, the selvage is not surfaced with coarse mineral granules to allow better adhesion of the overlapping sheet.

There are two general methods for applying roll roofing: the exposed nail method and the concealed nail method. Depending on the slope and nailing method used, roll roofing can be applied parallel (downslope roof edge) or perpendicular to the eave (parallel with the rake) (see Section 1507.6.1).

1507.6.1 Deck requirements. Mineral-surfaced roll roofing shall be fastened to solidly sheathed roofs.

❖ Prior to the application of the roll roofing on wood plank or plywood decks, the deck should be inspected for delamination of plywood, warped boards and proper nailing.

For roll roofing applied parallel to the eave, a minimum roof slope of 2:12 is recommended for application by the concealed-nail method, and 6:12 is recommended for application by the exposed-nail method.

For roll roofing applied parallel to the rake, a minimum roof slope of 3:12 is recommended for application by the concealed-nail method, and 4:12 is recommended for application by the exposed-nail method.

1507.6.2 Deck slope. Mineral-surfaced roll roofing shall not be applied on roof slopes below one unit vertical in 12 units horizontal (8-percent slope).

❖ It is not recommended that asphalt roll roofing be applied to deck slopes of less than 2:12, with one exception. Roll roofing with a 19-inch (483 mm) selvage edge (commonly referred to as double coverage or split-sheet) may be applied on a deck with a slope as low as 1:12; however, it should only be used on roofs that will drain by gravity. It is not recommended for decks that will allow puddling and require evaporation to dry the roof.

1507.6.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.

❖ A single layer of underlayment is the minimum requirement under mineral-surfaced rolled roofing. The underlayment must meet the performance criteria of ASTM D 226, Type I, or ASTM D 4869.

1507.6.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if the roof covering is lost due to a high-wind event. Where the nominal design wind speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant and in accordance with

the manufacturer's instructions.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal design wind speed exceeds 120 mph (54 m/s). In laboratory tests, ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception recognizes the use of a self-adhered underlayment as an alternative in accordance with ASTM D 1970.

1507.6.4 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The roof will eventually leak, causing damage to the structure, including the walls, ceilings and roof [see Figures 1507.8.4(1) and (2)]. In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section that exempts accessory buildings from such restrictions as they are unheated structures where the need for protection against ice dams is unnecessary.

1507.6.5 Material standards. Mineral-surfaced roll roofing shall conform to ASTM D 3909 or ASTM D 6380.

❖ ASTM D 6380 covers asphalt roll roofing (organic felt). ASTM D 3909 covers asphalt-impregnated and coated glass felt roll roofing surfaced on the weather side with mineral granules for use as a cap sheet in the construction of built-up roofs.

1507.7 Slate shingles. The installation of slate shingles shall comply with the provisions of this section.

❖ Slate is a dense, tough, durable natural rock or stone material that is practically nonabsorbent. This natural rock has cleavage planes that allow the slate to be easily split into relatively thin layers. Slate also possesses a natural grain that usually runs perpendicular to the cleavage. Slate is usually split so the length of the shingle runs in the direction of the grain.

Slate roofing has a long service life when consideration is given to all components of the roofing system. Some grades of slate combined with proper roof deck, underlayments, fastening and accessories have a service life in excess of 75 years.

1507.7.1 Deck requirements. Slate shingles shall be fastened to solidly sheathed roofs.

❖ Due to the long service life expected of a slate roof system, careful consideration should be given to the deck material. Deck material that can be expected to last as long as the service life of the roof should be chosen. Additionally, consideration should be given to the weight of the slate when choosing the deck. Slate is available in many different thicknesses and, therefore, the weight will vary.

1507.7.2 Deck slope. Slate shingles shall only be used on slopes of four units vertical in 12 units horizontal (4:12) or greater.

❖ This type of roof covering cannot be installed on roof slopes that are less than 4:12.

1507.7.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.

❖ A single layer of underlayment is the minimum requirement under mineral-surfaced rolled roofing. The underlayment must meet the performance criteria of ASTM D 226, Type I, or ASTM D 4869.

1507.7.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if the roof covering is lost due to a high-wind event. Where the nominal design wind

speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant and in accordance with the manufacturer's instructions.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal design wind speed exceeds 120 mph (54 m/s). In laboratory tests, ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception recognizes the use of a self-adhered underlayment as an alernative in accordance with ASTM D 1970.

1507.7.4 Ice barrier. In areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The roof will eventually leak, causing damage to the structure, including the walls, ceilings and roof [see Figures 1507.8.4(1) and (2)]. In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section that exempts accessory buildings from such restrictions as they are unheated structures where the need for protection against ice dams is unnecessary.

1507.7.5 Material standards. Slate shingles shall comply with ASTM C 406.

❖ ASTM C 406 covers the material characteristics, physical requirements and sampling appropriate for the selection of slate as a roofing material.

1507.7.6 Application. Minimum headlap for slate shingles shall be in accordance with Table 1507.7.6. Slate shingles shall be secured to the roof with two fasteners per slate.

❖ Slate shingles are drilled or punched with holes for fasteners with consideration for proper headlap. Fastener material should be chosen based on the expected service life. Copper slating nails, stainless steel, aluminum-alloy, bronze or cut-brass roofing nails are often specified, depending on the particular project. Unprotected black-iron, electroplated and hot-dipped galvanized fasteners are usually not recommended.

TABLE 1507.7.6
SLATE SHINGLE HEADLAP

SLOPE	HEADLAP (inches)
4:12 < slope < 8:12	4
8:12 < slope < 20:12	3
slope ≥ 20:12	2

For SI: 1 inch = 25.4 mm.

❖ Headlap is the distance of overlap measured from the uppermost ply or course to the point that it overlaps the undermost ply or course.

1507.7.7 Flashing. Flashing and counterflashing shall be made with sheet metal. Valley flashing shall be a minimum of 15 inches (381 mm) wide. Valley and flashing metal shall be a minimum uncoated thickness of 0.0179-inch (0.455 mm) zinc-coated G90. Chimneys, stucco or brick walls shall have a minimum of two plies of felt for a cap flashing consisting of a 4-inch-wide (102 mm) strip of felt set in plastic cement and extending 1 inch (25 mm) above the first felt and a top coating of plastic cement. The felt shall extend over the base flashing 2 inches (51 mm).

❖ Flashing is required at all intersections between exterior walls and roofs. These are areas where rainwater can easily penetrate the building envelope (see Section 1503.2).

1507.8 Wood shingles. The installation of wood shingles shall comply with the provisions of this section and Table 1507.8.

❖ "Wood shingles" are defined by the roofing industry as sawn wood products featuring a uniform butt thickness per individual length.

TABLE 1507.8. See page 15-21.

❖ Wood shingles cannot be installed on roof slopes below 3:12. Single-layer underlayment is required at eaves, ridges, hips, valleys and all other changes of roof slope or direction to protect the roof from leakage caused by water backup. Each shingle must be securely fastened to the roof deck with a maximum of two fasteners. Care should be taken so that the fasteners do not cause splitting of the wood shingle. Fasteners are to be specified in the manufacturer's installation instructions.

1507.8.1 Deck requirements. Wood shingles shall be installed on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall not be less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners.

❖ Spaced sheathing is usually of 1-inch by 4-inch (25 mm by 102 mm) or 1-inch by 6-inch (25 mm by 152 mm) softwood boards. Note that solid sheathing is required for certain locations by Section 1507.8.1.1.

1507.8.1.1 Solid sheathing required. Solid sheathing is required in areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water.

❖ Solid sheathing is usually softwood panels, which provide a smooth, even base for the roofing material and help stiffen the entire roof structure. Solid sheathing provides an extra degree of protection where ice damming is a possibility.

1507.8.2 Deck slope. Wood shingles shall be installed on slopes of three units vertical in 12 units horizontal (25-percent slope) or greater.

❖ Wood shingles cannot be installed on roof slopes below 3:12.

TABLE 1507.8
WOOD SHINGLE AND SHAKE INSTALLATION

ROOF ITEM	WOOD SHINGLES	WOOD SHAKES
1. Roof slope	Wood shingles shall be installed on slopes of three units vertical in 12 units horizontal (3:12) or greater.	Wood shakes shall be installed on slopes of four units vertical in 12 units horizontal (4:12) or greater.
2. Deck requirement		
Temperate climate	Shingles shall be applied to roofs with solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall not be less than 1″ × 4″ nominal dimensions and shall be spaced on center equal to the weather exposure to coincide with the placement of fasteners.	Shakes shall be applied to roofs with solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall not be less than 1″ × 4″ nominal dimensions and shall be spaced on center equal to the weather exposure to coincide with the placement of fasteners. When 1″ × 4″ spaced sheathing is installed at 10 inches, boards must be installed between the sheathing boards.
In areas where the average daily temperature in January is 25°F or less or where there is a possibility of ice forming along the eaves causing a backup of water.	Solid sheathing required.	Solid sheathing is required.
3. Interlayment	No requirements.	Interlayment shall comply with ASTM D 226, Type 1.
4. Underlayment		
Temperate climate	Underlayment shall comply with ASTM D 226, Type 1.	Underlayment shall comply with ASTM D 226, Type 1.
In areas where there is a possibility of ice forming along the eaves causing a backup of water.	An ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall extend from the eave's edge to a point at least 24 inches inside the exterior wall line of the building.	An ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall extend from the lowest edges of all roof surfaces to a point at least 24 inches inside the exterior wall line of the building.
5. Application		
Attachment	Fasteners for wood shingles shall be hot-dipped galvanized or Type 304 (Type 316 for coastal areas) stainless steel with a minimum penetration of 0.75 inch into the sheathing. For sheathing less than 0.5 inch thick, the fasteners shall extend through the sheathing.	Fasteners for wood shakes shall be hot-dipped galvanized or Type 304 (Type 316 for coastal areas) with a minimum penetration of 0.75 inch into the sheathing. For sheathing less than 0.5 inch thick, the fasteners shall extend through the sheathing.
No. of fasteners	Two per shingle.	Two per shake.
Exposure	Weather exposures shall not exceed those set forth in Table 1507.8.7.	Weather exposures shall not exceed those set forth in Table 1507.9.8.
Method	Shingles shall be laid with a side lap of not less than 1.5 inches between joints in courses, and no two joints in any three adjacent courses shall be in direct alignment. Spacing between shingles shall be 0.25 to 0.375 inch.	Shakes shall be laid with a side lap of not less than 1.5 inches between joints in adjacent courses. Spacing between shakes shall not be less than 0.375 inch or more than 0.625 inch for shakes and taper sawn shakes of naturally durable wood and shall be 0.25 to 0.375 inch for preservative-treated taper sawn shakes.
Flashing	In accordance with Section 1507.8.8.	In accordance with Section1507.9.9.

For SI: 1 inch = 25.4 mm, °C = [(°F) - 32]/1.8.

1507.8.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.

❖ A single layer of underlayment is the minimum required under wood shingles. The underlayment must meet the performance criteria of ASTM D 226, Type I, or ASTM D 4869.

1507.8.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of ¾ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if wood shingles are lost in a high-wind event. Where the nominal design wind speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant and in accordance with the manufacturer's instructions.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal design wind speed exceeds 120 mph (54 m/s). In laboratory tests, ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception specifically permits the use of a self-adhered underlayment as an alernative in accordance with ASTM D 1970.

1507.8.4 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The roof will eventually leak, causing damage to the structure, including the walls, ceilings and roof [see Figures 1507.8.4(1) and (2)]. In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section that exempts accessory buildings from such restrictions they are unheated structures where the need for protection against ice dams is unnecessary.

1507.8.5 Material standards. Wood shingles shall be of naturally durable wood and comply with the requirements of Table 1507.8.5.

❖ Information about the installation of wood shingles is available in the *Design and Application Manual for New Roof Construction* published by the Cedar Shake and Shingle Bureau (CSSB). Additional information regarding wood shingle roofs is provided in the wood roofing section of the *NRCA Roofing Manual: Steep-slope Roof Systems* published by the NRCA.

TABLE 1507.8.5
WOOD SHINGLE MATERIAL REQUIREMENTS

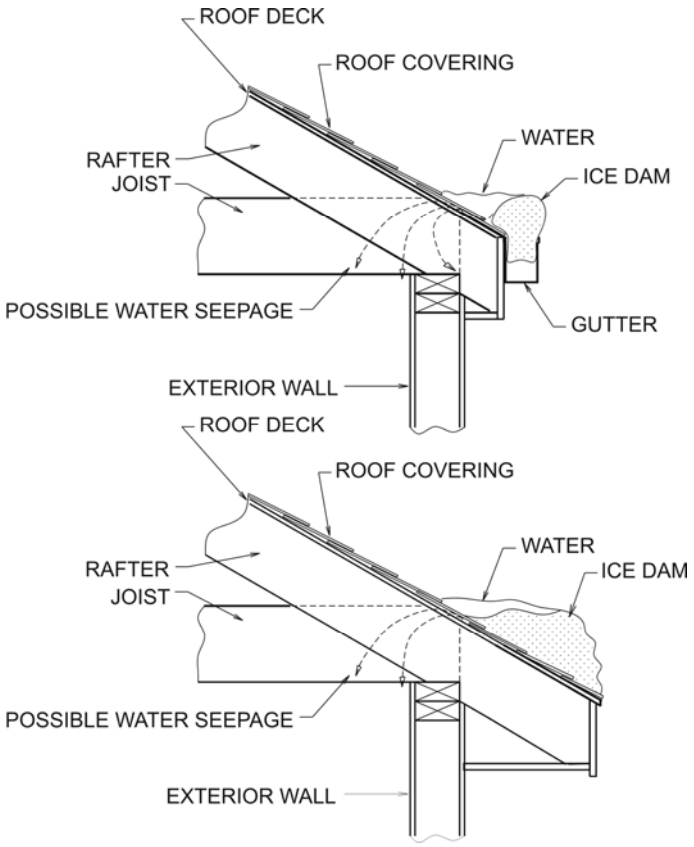
MATERIAL	APPLICABLE MINIMUM GRADES	GRADING RULES
Wood shingles of naturally durable wood	1, 2 or 3	CSSB

CSSB = Cedar Shake and Shingle Bureau

❖ The standards published by CSSB contain useful information on the grading rules for wood shingles. A third-party inspection agency's label is now required to document compliance of the shingle.

1507.8.6 Attachment. Fasteners for wood shingles shall be corrosion resistant with a minimum penetration of $^3/_4$ inch (19.1 mm) into the sheathing. For sheathing less than $^1/_2$ inch (12.7 mm) in thickness, the fasteners shall extend through the sheathing. Each shingle shall be attached with a minimum of two fasteners.

❖ Each shingle must be securely fastened to the roof deck with a minimum of two fasteners. Care should be taken so that the fasteners do not cause splitting of the wood shingle. Fasteners are to be as specified in the manufacturer's installation instructions.



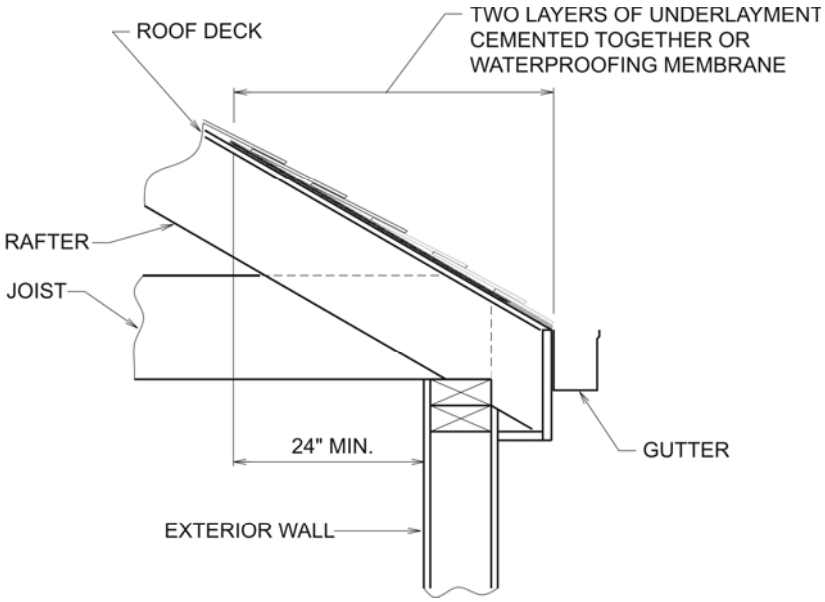


Figure 1507.8.4(1)
POSSIBLE WATER DAMAGE AT ICE DAMS

For SI: 1 inch = 25.4 mm.

Figure 1507.8.4(2)
PROTECTIVE ICE SHEILD

1507.8.7 Application. Wood shingles shall be laid with a side lap not less than $1^1/_2$ inches (38 mm) between joints in adjacent courses, and not be in direct alignment in alternate courses. Spacing between shingles shall be $^1/_4$ to $^3/_8$ inches (6.4 to 9.5 mm). Weather exposure for wood shingles shall not exceed that set in Table 1507.8.7.

❖ Wood shingle exposure is specified in Table 1507.8.7. Depending on the grade of the material, total shingle length and slope of the roof deck, the table specifies the maximum length of exposure for weathering purposes.

TABLE 1507.8.7
WOOD SHINGLE WEATHER EXPOSURE AND ROOF SLOPE

ROOFING MATERIAL	LENGTH (inches)	GRADE	EXPOSURE (inches)	
			3:12 pitch to < 4:12	4:12 pitch or steeper
Shingles of naturally durable wood	16	No. 1	3.75	5
		No. 2	3.5	4
		No. 3	3	3.5
	18	No. 1	4.25	5.5
		No. 2	4	4.5
		No. 3	3.5	4
	24	No. 1	5.75	7.5
		No. 2	5.5	6.5
		No. 3	5	5.5

For SI: 1 inch = 25.4 mm.

❖ The grade of the shingle will be listed on the label required for wood shingles. Each of the three different grades is available in three different lengths. For lower-sloped roofs (3:12 to 4:12), where wind uplift is more significant, the maximum weather exposure is always less than for steeper-sloped roofs (4:12 and greater).

1507.8.8 Flashing. At the juncture of the roof and vertical surfaces, flashing and counterflashing shall be provided in accordance with the manufacturer's installation instructions, and where of metal, shall not be less than 0.019-inch (0.48 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend at least 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). For roof slopes of three units vertical in 12 units horizontal (25-percent slope) and over, the valley flashing shall have a 36-inch-wide (914 mm) underlayment of either one layer of Type I underlayment running the full length of the valley or a self-adhering polymer-modified bitumen sheet complying with ASTM D 1970, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water, the metal valley flashing underlayment shall be solidly cemented to the roofing underlayment for slopes under seven units vertical in 12 units horizontal (58-percent slope) or self-adhering polymer-modified bitumen sheet shall be installed.

❖ Improper installation of flashing is the greatest cause of failures of roof covering systems. Whenever one plane of a roof intersects another plane, flashing is required where the planes intersect (see Section 1503.2).

1507.9 Wood shakes. The installation of wood shakes shall comply with the provisions of this section and Table 1507.8.

❖ This section establishes design and installation requirements for wood shakes, which are defined as roofing products split from logs and then shaped as required by the individual manufacturers. Wood shakes must be labeled by an approved third-party inspection agency. A quality control program is required to contain a set of grading rules.

Information about the installation of wood shakes is available in the *Design and Application Manual for New Roof Construction* published by the CSSB. Additional information is provided in the wood roofing section of the *NRCA Roofing Manual: Steep-slope Roof Systems* published by the NRCA.

1507.9.1 Deck requirements. Wood shakes shall only be used on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall not be less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners. Where 1-inch by 4-inch (25 mm by 102 mm) spaced sheathing is installed at 10 inches (254 mm) o.c., additional 1-inch by 4-inch (25 mm by 102 mm) boards shall be installed between the sheathing boards.

❖ See the commentary to Section 1507.8.1.

1507.9.1.1 Solid sheathing required. Solid sheathing is required in areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water.

❖ See the commentary to Section 1507.8.1.1.

1507.9.2 Deck slope. Wood shakes shall only be used on slopes of four units vertical in 12 units horizontal (33-percent slope) or greater.

❖ Wood shakes cannot be installed on roof slopes less than 4:12 to provide for adequate drainage of the roof.

1507.9.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.

❖ A single layer of underlayment is the minimum requirement under wood shakes. The underlayment

must meet the performance criteria of ASTM D 226, Type I, or ASTM D 4869.

1507.9.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [V_{asd} greater than 110 mph (49 m/s) as determined in accordance with Section 1609.3.1] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where V_{asd}, in accordance with Section 1609.3.1, equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all laps shall be a minimum of 4 inches (102 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thickness of at least 32-gauge [0.0134 inch (0.34 mm)] sheet metal. The cap nail shank shall be a minimum of 12 gauge [0.105 inch (2.67 mm)] with a length to penetrate through the roof sheathing or a minimum of $^3/_4$ inch (19.1 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

❖ These provisions are intended to improve the performance of underlayment on roofs subjected to high winds, particularly if wood shakes are lost in a high-wind event. Where the nominal design wind speed is greater than 110 mph (49 m/s), fasteners must be corrosion resistant and in accordance with the manufacturer's instructions.

Based on observations of roof underlayment performance both in the field following hurricanes as well as in laboratory tests, ASTM 226, Type I, underlayment is not permitted where the nominal design wind speed exceeds 120 mph (54 m/s). In laboratory tests ASTM 226, Types I and II, underlayment performed dramatically different, with the ASTM 226, Type II, material remaining in place and exhibiting fewer signs of distress. In addition, the attachment of the underlayment must be accomplished with cap nails. A 1-inch (25.4 mm) head diameter of the cap portion recognizes the type most commonly used in the field. The exception recognizes that a self-adhered underlayment can be used as an alternative in accordance with ASTM D 1970.

1507.9.4 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer-modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

❖ Ice dams form when snow melts over the warmer parts of a roof and refreezes over the colder eaves. This ice formation acts like a dam and causes water to back up beneath the roof covering. The roof will eventually leak, causing damage to the structure, including the walls, ceilings and roof [see Figures 1507.8.4(1) and (2)]. In areas where this is prevalent, the installation of an ice barrier is required in accordance with this section.

There is an exception to this section exempts accessory buildings from such restrictions as they are unheated structures where the need for protection against ice dams is unnecessary.

1507.9.5 Interlayment. Interlayment shall comply with ASTM D 226, Type I.

❖ A single layer of felt interlayment must be shingled between each course on all roof slopes.

1507.9.6 Material standards. Wood shakes shall comply with the requirements of Table 1507.9.6.

❖ Information about the installation of wood shingles is available in the *Design and Application Manual for New Roof Construction* published by CSSB. Additional information is provided in the wood roofing section of the *NRCA Roofing Manual: Steep-slope Roof Systems* published by the NRCA.

TABLE 1507.9.6
WOOD SHAKE MATERIAL REQUIREMENTS

MATERIAL	MINIMUM GRADES	APPLICABLE GRADING RULES
Wood shakes of naturally durable wood	1	CSSB
Taper sawn shakes of naturally durable wood	1 or 2	CSSB
Preservative-treated shakes and shingles of naturally durable wood	1	CSSB
Fire-retardant-treated shakes and shingles of naturally durable wood	1	CSSB
Preservative-treated taper sawn shakes of Southern pine treated in accordance with AWPA U1 (Commodity Specification A, Use Category 3B and Section 5.6)	1 or 2	TFS

CSSB = Cedar Shake and Shingle Bureau.
TFS = Forest Products Laboratory of the Texas Forest Services.

❖ Wood shakes must be labeled by an approved third-party inspection agency. A quality control program is required to contain a set of grading rules. Care must be taken to completely follow the manufacturer's installation instructions for each particular product. The building official must review and approve all

installations with special note of any application limitations.

1507.9.7 Attachment. Fasteners for wood shakes shall be corrosion resistant with a minimum penetration of $^3/_4$ inch (19.1 mm) into the sheathing. For sheathing less than $^1/_2$ inch (12.7 mm) in thickness, the fasteners shall extend through the sheathing. Each shake shall be attached with a minimum of two fasteners.

❖ Each shake must be secured with a minimum of two fasteners. Fasteners are to be as specified in the manufacturer's installation instructions.

1507.9.8 Application. Wood shakes shall be laid with a side lap not less than $1^1/_2$ inches (38 mm) between joints in adjacent courses. Spacing between shakes in the same course shall be $^3/_8$ to $^5/_8$ inches (9.5 to 15.9 mm) for shakes and taper sawn shakes of naturally durable wood and shall be $^1/_4$ to $^3/_8$ inch (6.4 to 9.5 mm) for preservative taper sawn shakes. Weather exposure for wood shakes shall not exceed those set in Table 1507.9.8.

❖ Care must be taken to follow completely the manufacturer's installation instructions for each particular product. The building official must review and approve all installations with special note of any application limitations.

TABLE 1507.9.8
WOOD SHAKE WEATHER EXPOSURE AND ROOF SLOPE

ROOFING MATERIAL	LENGTH (inches)	GRADE	EXPOSURE (inches) 4:12 PITCH OR STEEPER
Shakes of naturally durable wood	18 24	No. 1 No. 1	7.5 10a
Preservative-treated taper sawn shakes of Southern yellow pine	18 24	No. 1 No. 1	7.5 10
	18 24	No. 2 No. 2	5.5 7.5
Taper sawn shakes of naturally durable wood	18 24	No. 1 No. 1	7.5
	18 24	No. 2 No. 2	5.5 7.5

❖ The code provides specific weather exposure limitations for two different lengths of shakes. As with wood shingles, the longer the shake, the greater the exposure allowance, since wind uplift resistance is greater for the longer shakes. The reduced weather exposure enhances the wind uplift resistance that these wood shakes will be able to provide. The exposure limitations are applicable regardless of the roof slope since they are only permitted on steep slopes roofs (4:12 or greater).

1507.9.9 Flashing. At the juncture of the roof and vertical surfaces, flashing and counterflashing shall be provided in accordance with the manufacturer's installation instructions, and where of metal, shall not be less than 0.019-inch (0.48 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend at least 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). For roof slopes of three units vertical in 12 units horizontal (25-percent slope) and over, the valley flashing shall have a 36-inch-wide (914 mm) underlayment of either one layer of Type I underlayment running the full length of the valley or a self-adhering polymer-modified bitumen sheet complying with ASTM D 1970, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less or where there is a possibility of ice forming along the eaves causing a backup of water, the metal valley flashing underlayment shall be solidly cemented to the roofing underlayment for slopes under seven units vertical in 12 units horizontal (58-percent slope) or self-adhering polymer-modified bitumen sheet shall be installed.

❖ Improper installation of flashing is the greatest cause of failure of roof covering systems. Whenever one plane of a roof intersects another plane, flashing is required where the planes intersect [see commentary, Section 1503.2 and Figures 1507.8.4(1) and (2)].

1507.10 Built-up roofs. The installation of built-up roofs shall comply with the provisions of this section.

❖ A built-up roof membrane is a continuous, semiflexible multiple-ply roof membrane, consisting of plies or layers of saturated felts, coated felts, fabrics or mats between which alternate layers of bitumen are applied. Generally, built-up roof membranes are surfaced with mineral aggregate and bitumen, a liquid-applied coating or granule-surfaced cap sheet.

1507.10.1 Slope. Built-up roofs shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage, except for coal-tar built-up roofs that shall have a design slope of a minimum one-eighth unit vertical in 12 units horizontal (1-percent slope).

❖ Because of their low melting points and self-healing characteristics, coal tar membranes are permitted on lower slopes of one-eighth inch per foot (1 percent).

1507.10.2 Material standards. Built-up roof covering materials shall comply with the standards in Table 1507.10.2 or UL 55A.

❖ Asphalt and coal tar are the principal bitumens used for roofing purposes. As an alternative to the ASTM material standards that are referenced, the code also permits materials that are evaluated for compliance in accordance with UL 55A.

TABLE 1507.10.2. See page 15-27.

❖ The various types of materials permitted in typical built-up roofing must comply with applicable standards as noted in the table. The following discusses some of those standards and what they address. Note that the titles and specific editions of all the standards are located in Chapter 35 of the code.

ASTM D 1863 covers the quality and grading of crushed stone, crushed slag and water-worn gravel

suitable for use as aggregate surfacing on built-up roofs.

ASTM D 4601 covers asphalt-impregnated and coated glass fiber base sheet, with or without perforations, for use as the first ply of the built-up roofing. When not perforated, this sheet may be used as a vapor retarder under or between roof insulation with a solid top coating of asphaltic material.

ASTM D 2178 covers glass felt impregnated to varying degrees with asphalt, which may be used both with asphalts conforming to the requirements of ASTM D 312 in the construction of built-up roofs, and asphalts conforming to the requirements of ASTM D 449 in the membrane system of waterproofing.

ASTM D 2626 covers the base sheet with fine mineral surfacing on the top side, with or without perforations, for use as the first ply of a built-up roof. When not perforated, this sheet may be used as a vapor retarder under roof insulation.

ASTM D 226 covers asphalt-saturated organic felts, with perforations, that may be used with asphalts conforming to the requirements of ASTM D 312 in the construction of built-up roofs, and with asphalts conforming to the requirements of ASTM D 449 in the membrane system of waterproofing.

ASTM D 312 covers four types of asphalt intended for use in built-up roof construction. The specification is intended for general classification purposes only, and does not imply restrictions on the slope at which an asphalt must be used. There are four classification types. Type I includes asphalts that are relatively susceptible to flow at roof temperatures with good adhesive and self-sealing properties. Type II includes asphalts that are moderately susceptible to flow at roof temperatures. Type III includes asphalts that are relatively nonsusceptible to flow at roof temperatures for use in built-up roof construction on slope inclines from 8.3 to 25 percent. Type IV includes asphalts that are generally nonsusceptible to flow at roof temperatures for use in built-up roof construction on slope inclines from approximately 16.7 to 50 percent.

ASTM D 227 covers coal-tar saturated organic felt that may be used with coal-tar pitches conforming to the appropriate requirements of ASTM D 450 in the construction of built-up roofs and in the membrane system of waterproofing.

ASTM D 450 covers three types of coal-tar pitch suitable for use in the construction of built-up roofing, dampproofing and membrane waterproofing systems. Only Type I or III can be used in code-recognized roofing systems. Type I is suitable for use in built-up roofing systems with felts conforming to the requirements of ASTM D 227 or as specified by the manufacturer. Type III is suitable for use in built-up roofing systems, but has less volatile components than Type I.

ASTM D 3909 covers asphalt-impregnated and coated glass felt roll roofing surfaced on the weather side with mineral granules for use as a cap sheet in the construction of built-up roofs.

As noted, this list is not all-inclusive when compared to Table 1507.10.2, but includes materials commonly used as built-up roofing materials.

TABLE 1507.10.2
BUILT-UP ROOFING MATERIAL STANDARDS

MATERIAL STANDARD	STANDARD
Acrylic coatings used in roofing	ASTM D 6083
Aggregate surfacing	ASTM D 1863
Asphalt adhesive used in roofing	ASTM D 3747
Asphalt cements used in roofing	ASTM D 3019; D 2822; D 4586
Asphalt-coated glass fiber base sheet	ASTM D 4601
Asphalt coatings used in roofing	ASTM D 1227; D 2823; D 2824; D 4479
Asphalt glass felt	ASTM D 2178
Asphalt primer used in roofing	ASTM D 41
Asphalt-saturated and asphalt-coated organic felt base sheet	ASTM D 2626
Asphalt-saturated organic felt (perforated)	ASTM D 226
Asphalt used in roofing	ASTM D 312
Coal-tar cements used in roofing	ASTM D 4022; D 5643
Coal-tar saturated organic felt	ASTM D 227
Coal-tar pitch used in roofing	ASTM D 450; Type I or II
Coal-tar primer used in roofing, dampproofing and waterproofing	ASTM D 43
Glass mat, coal tar	ASTM D 4990
Glass mat, venting type	ASTM D 4897
Mineral-surfaced inorganic cap sheet	ASTM D 3909
Thermoplastic fabrics used in roofing	ASTM D 5665, D 5726

1507.11 Modified bitumen roofing. The installation of modified bitumen roofing shall comply with the provisions of this section.

❖ Modified bitumen roofing is a membrane-type roofing made up of composite sheets consisting of polymer-modified bitumen often reinforced and sometimes surfaced with various types of mats, films, foils and mineral granules. The bitumen is modified through inclusion of one or more polymers. There are two general types of polymer-modified bitumen membranes: those with the principal modifier being atactic polypropylene (APP), and those with bitumen modified with styrene butadiene styrene (SBS). They differ in characteristics, as well as application. For more information on the application of polymer-modified bitumen roofing membranes, refer to the *NRCA Roofing Manual: Membrane Roof Systems*.

1507.11.1 Slope. Modified bitumen membrane roofs shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

❖ According to this section, all roofs must have a minimum slope of $^1/_4$:12 so that there is positive drainage of storm water to gutters, roof drains and other components of an approved storm drainage system in order to divert water away from the building or structure.

1507.11.2 Material standards. Modified bitumen roof coverings shall comply with CGSB 37-GP-56M, ASTM D 6162, ASTM D 6163, ASTM D 6164, ASTM D 6222, ASTM D 6223, ASTM D 6298 or ASTM D 6509.

❖ The materials and installation of modified bitumen roof coverings must be in accordance with the listed standards, which regulate modified bituminous roofing membranes, either prefabricated or reinforced. The standards are: CGSB 37-GP-56M, which regulates membrane, modified, bituminous, prefabricated and reinforced for roofing; ASTM D 6162, which regulates SBS modified bituminous sheet materials; ASTM D 6163, which regulates SBS using glass fiber reinforcements, ASTM D 6164, which regulates SBS using polyester reinforcements; ASTM D 6222, which regulates APP modified bituminous sheet materials; ASTM D 6223, which regulates APP using polyester and glass fiber reinforcements; ASTM D 6298, which regulates SBS with a metal surface; and ASTM D 6509, which regulates APP using glass fiber reinforcements.

1507.12 Thermoset **single-ply roofing.** The installation of thermoset single-ply roofing shall comply with the provisions of this section.

❖ Thermoset is a material that solidifies or "sets" irreversibly when heated. Thinners evaporate during the curing process. Thermoset materials are those whose polymers are chemically cross-linked, commonly referred to as being "cured." Once they are fully cured, they can only be bonded to like material with an adhesive, as new molecular links may not be formed. There are four common subcategories of thermoset roof membranes: neoprene, chlorosulfonated polyethylene (CSPE), epichlorohydrin (DCH) and ethylene-propylene-diene monomer (or terpolymer) (EPDM).

1507.12.1 Slope. Thermoset single-ply membrane roofs shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

❖ All roofs must have a minimum slope of $^1/_4$:12 so that there is positive drainage of storm water to gutters, roof drains and other components of an approved storm drainage system in order to divert water away from the building or structure.

1507.12.2 Material standards. Thermoset single-ply roof coverings shall comply with ASTM D 4637, ASTM D 5019 or CGSB 37-GP-52M.

❖ This section describes the standards to be used for materials and installation. The standards are: (1) ASTM D 4637, which regulates unreinforced and fabric-reinforced vulcanized rubber sheets made from EPDM or polychloroprene, and is intended for use in single-ply roof membranes exposed to weather; and (2) ASTM D 5019, which regulates reinforced nonvulcanized polymeric sheets made from CSPE and polyisobutylene used in single-ply roof membranes; and (3) CGSB 37-GP-52M, which regulates sheet-applied elastomeric roofing membranes.

1507.12.3 Ballasted thermoset **low-slope roofs.** Ballasted thermoset low-slope roofs (roof slope < 2:12) shall be installed in accordance with this section and Section 1504.4. Stone used as ballast shall comply with ASTM D 448.

❖ The purpose of this section is to identify that this type of roof covering is allowed and to provide installation requirements. Further, this section specifies the minimum requirements for stone ballast to be used with this type of roofing system.

1507.13 Thermoplastic single-ply roofing. The installation of thermoplastic single-ply roofing shall comply with the provisions of this section.

❖ Thermoplastics are materials that soften when heated and harden when cooled. This process can be repeated, provided the material is not heated above the point at which decomposition occurs. Thermoplastic materials are distinguished from thermosets in that there is no chemical cross linking. Because of the materials' chemical nature, some thermoplastic membranes may be seamed by either heat (hot air) or solvent welding.

1507.13.1 Slope. Thermoplastic single-ply membrane roofs shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope).

❖ All roofs must have a minimum slope of $^1/_4$:12 so that there is positive drainage of storm water to gutters, roof drains and other components of an approved storm drainage system in order to divert water away from the building or structure.

1507.13.2 Material standards. Thermoplastic single-ply roof coverings shall comply with ASTM D 4434, ASTM D 6754, ASTM D 6878 or CGSB CAN/CGSB 37-54.

❖ This section establishes standards and performance criteria for the installation of thermoplastic single-ply roof coverings. Four standards are recognized: ASTM D 4434, ASTM D 6754, ASTM D 6878 and CGSB 37-GP-54M. These specifications cover flexible sheet made from poly (vinyl chloride) resin,

ketone ethylene ester-based sheet roofing and thermoplastic polyolefin- based sheet roofing.

1507.13.3 Ballasted thermoplastic low-slope roofs. Ballasted thermoplastic low-slope roofs (roof slope < 2:12) shall be installed in accordance with this section and Section 1504.4. Stone used as ballast shall comply with ASTM D 448.

❖ The purpose of this section is to identify that this type of roof covering is allowed and to provide installation requirements. Further, this section specifies the minimum requirements for stone ballast to be used with this type of roofing system.

1507.14 Sprayed polyurethane foam roofing. The installation of sprayed polyurethane foam roofing shall comply with the provisions of this section.

❖ Sprayed polyurethane foam is a foamed plastic material constructed by mixing a two-part liquid that is spray applied to form the base of an adhered roof system. The two-part component mixture reacts chemically and immediately expands when applied through special metering equipment to form a closed-cell foam. As the foam rises, it sets into a solid and a skin forms on the surface. The foam provides a thermal insulation and the skin provides a water-resistant surface.

1507.14.1 Slope. Sprayed polyurethane foam roofs shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

❖ All roofs must have a minimum slope of $^1/_4$:12 so that there is positive drainage of storm water to gutters, roof drains and other components of an approved storm drainage system in order to divert water away from the building or structure.

1507.14.2 Material standards. Spray-applied polyurethane foam insulation shall comply with Type III or IV as defined in ASTM C 1029.

❖ ASTM C 1029 is the standard that regulates spray-applied rigid cellular polyurethane thermally insulated roof coverings. This specification covers the types and physical properties of spray-applied rigid cellular polyurethane intended for use as thermal insulation. Type III or IV foam insulation is required based on their higher compressive strengths. The operating temperatures of the surfaces to which the insulation is applied cannot be lower than -22°F (-30°C) or greater than 225°F (107°C).

1507.14.3 Application. Foamed-in-place roof insulation shall be installed in accordance with the manufacturer's instructions. A liquid-applied protective coating that complies with Table 1507.14.3 shall be applied no less than 2 hours nor more than 72 hours following the application of the foam.

❖ The roof system must be protected from ultraviolet light and degradation through the use of surfacing. Liquid-applied protected elastomeric coatings are the recommended surfacing for sprayed polyurethane foam roofing systems.

TABLE 1507.14.3
PROTECTIVE COATING MATERIAL STANDARDS

MATERIAL	STANDARD
Acrylic coating	ASTM D 6083
Silicone coating	ASTM D 6694
Moisture-cured polyurethane coating	ASTM D 6947

❖ This table identifies the applicable material standards for protective coating materials that are suitable for sprayed polyurethane foam roof systems.

1507.14.4 Foam plastics. Foam plastic materials and installation shall comply with Chapter 26.

❖ Chapter 26 addresses foam plastic materials and installation.

1507.15 Liquid-applied roofing. The installation of liquid-applied roofing shall comply with the provisions of this section.

❖ Liquid-applied coatings are nonsynthetic roofing materials that are termed "cold applied" because hot bitumen is not employed in their application.

1507.15.1 Slope. Liquid-applied roofing shall have a design slope of a minimum of one-fourth unit vertical in 12 units horizontal (2-percent slope).

❖ All roofs must have a minimum slope of $^1/_4$:12 so that there is positive drainage of storm water to gutters, roof drains and other components of an approved storm drainage system in order to divert water away from the building or structure.

1507.15.2 Material standards. Liquid-applied roofing shall comply with ASTM C 836, ASTM C 957, ASTM D 1227 or ASTM D 3468, ASTM D 6083, ASTM D 6694 or ASTM D 6947.

❖ Liquid-applied roof coatings must be installed in accordance with the manufacturer's instructions. The coatings must comply with ASTM C 836, ASTM C 957, ASTM D 1227, D 3468 or ASTM D 6694. ASTM C 836 describes the required properties and test methods for a cold liquid-applied elastomeric membrane, one or two components, for waterproofing building decks subject to hydrostatic pressure in building areas to be occupied by personnel, vehicles or equipment. This specification only applies to a membrane system above which a separate wearing or traffic course will be applied. ASTM C 957 describes the required properties and test methods for a cold liquid-applied elastomeric membrane for waterproofing building decks not subject to hydrostatic pressure. The specification applies only to a membrane system that has an integral wearing surface. It does not include specific requirements for skid resistance or fire retardance, although both may be important in specific applications. ASTM D 1227 describes emulsified asphalt suitable for use as a protective coating for built-up roofs and other exposed surfaces with inclines of not less than 4 percent. ASTM D 3468 describes liquid-applied neoprene and CSPE synthetic rubber solutions suitable for use in roofing and waterproofing. ASTM D 6694

describes liquid-applied silicone coatings used in spray on polyurethane foam roofing. ASTM D 6947 describes liquid-applied moisture cured polyurethane coatings used in spray polyurethane foam roofing systems.

1507.16 Roof gardens and landscaped roofs. Roof gardens and landscaped roofs shall comply with the requirements of this chapter and Sections 1607.12.3 and 1607.12.3.1 and the *International Fire Code*.

❖ The purpose of this section is to require roof gardens and landscaped roofs to comply with the requirements for other roof systems contained in this chapter. Further, this section requires these types of roofs to meet the requirements for special purpose roofs as contained in Chapters 15 and 16 as well as providing a reference to the *International Fire Code*® (IFC®).

1507.16.1 Structural fire resistance. The structural frame and roof construction supporting the load imposed upon the roof by the roof gardens or landscaped roofs shall comply with the requirements of Table 601.

❖ This section is a reminder to verify compliance with Table 601 for the portion of the structure that supports the additional load of a landscaped roof.

1507.17 Photovoltaic modules/shingles. The installation of photovoltaic modules/shingles shall comply with the provisions of this section.

❖ This section provides guidance for the installation of photovoltaic modules/shingles. These shingles are integrated with the building and provide both a roof covering and source of electrical power.

1507.17.1 Material standards. Photovoltaic modules/shingles shall be listed and labeled in accordance with UL 1703.

❖ This section references UL 1703 as the standard used for determining code compliance of photovoltaic modules/shingles.

1507.17.2 Attachment. Photovoltaic modules/shingles shall be attached in accordance with the manufacturer's installation instructions.

❖ Referring to the manufacturer's instructions is appropriate since the required slope and fastening of the photovoltaic modules/shingles are different for each manufacturer's product.

1507.17.3 Wind resistance. Photovoltaic modules/shingles shall be tested in accordance with procedures and acceptance criteria in ASTM D 3161. Photovoltaic modules/shingles shall comply with the classification requirements of Table 1507.2.7.1(2) for the appropriate maximum nominal design wind speed. Photovoltaic modules/shingle packaging shall bear a label to indicate compliance with the procedures in ASTM D 3161 and the required classification from Table 1507.2.7.1(2).

❖ For wind resistance, the procedures and acceptance criteria used in ASTM D 3161 for asphalt shingles are appropriate when adapted for photovoltaic modules/shingles.

SECTION 1508
ROOF INSULATION

1508.1 General. The use of above-deck thermal insulation shall be permitted provided such insulation is covered with an *approved* roof covering and passes the tests of FM 4450 or UL 1256 when tested as an assembly.

Exceptions:

1. Foam plastic roof insulation shall conform to the material and installation requirements of Chapter 26.
2. Where a concrete roof deck is used and the above-deck thermal insulation is covered with an *approved* roof covering.

❖ This section addresses two requirements for the use of above-deck thermal insulation. The first requirement is that an approved roof covering be used. The second requirement is that an under-deck flame spread test must be conducted and passed using either FM 4450 or the UL 1256 test methods. These tests were developed to evaluate the contribution of above-deck thermal insulations and their installation when exposed to a fire from below the deck. The primary construction for which these tests have been developed are roof assemblies that utilize a steel roof deck with above-deck insulation materials.

In addition to serving as thermal insulation, roof insulation may be used as a substrate to which the roof membrane is applied. In protected roof membrane systems, the insulation is applied over the membrane and is not expected to act as a substrate. The insulation should provide adequate support for the membrane and other associated rooftop materials and stand up to limited rooftop traffic, such as for regular roof inspections and maintenance.

Rigid board roof insulations currently among the most commonly used for low-slope roofs are: cellular glass, glass fiber, mineral fiber, perlite, phenolic foam, polyisocyanurate foam, polystyrene foam, polyurethane foam, wood fiberboard and composite board.

Nonrigid roof insulations are generally used in steep-slope and some metal-roof assembly construction. Commonly made from cellulose, glass fiber and mineral fiber, these nonrigid insulations may be available in batts, blankets and loose-fiber forms.

Exception 2 recognizes that if a concrete deck is employed as part of the assembly it will provide protection to the above-deck insulation materials. This exception will apply to nonfoam plastic roof insulation materials, since foam plastic roof insulations are covered under Exception 1 and Chapter 26 of the code.

1508.1.1 Cellulosic fiberboard. Cellulosic fiberboard roof insulation shall conform to the material and installation requirements of Chapter 23.

❖ Chapter 23 addresses cellulosic fiberboard roof installation.

1508.2 Material standards. Above-deck thermal insulation board shall comply with the standards in Table 1508.2.

❖ The referenced material standards provide additional guidance on the physical properties of roof insulation when utilized as above-deck components of roof assemblies.

TABLE 1508.2
MATERIAL STANDARDS FOR ROOF INSULATION

Cellular glass board	ASTM C 552
Composite boards	ASTM C 1289, Type III, IV, V or VI
Expanded polystyrene	ASTM C 578
Extruded polystyrene board	ASTM C 578
Mineral fiber insulation board	ASTM C 726
Perlite board	ASTM C 728
Polyisocyanurate board	ASTM C 1289, Type I or Type II
Wood fiberboard	ASTM C 208

❖ This table incorporates industry-recognized material standards into the code for materials commonly used in above-roof-deck insulation practices. For instance, the table references ASTM C 726, which specifies the composition and physical properties for mineral fiber insulation board.

SECTION 1509
ROOFTOP STRUCTURES

1509.1 General. The provisions of this section shall govern the construction of rooftop structures.

❖ This section identifies and establishes the criteria used in evaluating penthouse-type roof structures. Other rooftop structures, such as water tanks, cooling towers, towers, spires, domes, cupolas, etc., are not to be considered as penthouses since the code has specific provisions for these structures (see Sections 1509.3 through 1509.6).

1509.2 Penthouses. Penthouses in compliance with Sections 1509.2.1 through 1509.2.5 shall be considered as a portion of the story directly below the roof deck on which such penthouses are located. All other penthouses shall be considered as an additional story of the building.

❖ This section introduces the requirements necessary for a penthouse to be considered as a portion of the story directly below. Section 1509.2.1 contains height limitations, Section 1509.2.2 contains area limitations and Section 1509.2.3 contains use limitations.

1509.2.1 Height above roof deck. Penthouses constructed on buildings of other than Type I construction shall not exceed 18 feet (5486 mm) in height above the roof deck as measured to the average height of the roof of the penthouse.

Exceptions:

1. Where used to enclose tanks or elevators that travel to the roof level, penthouses shall be permitted to have a maximum height of 28 feet (8534 mm) above the roof deck.
2. Penthouses located on the roof of buildings of Type I construction shall not be limited in height.

❖ The height of roof structures is not limited on buildings of Type I construction (see Exception 2). For other types of construction, the roof structure is limited to 18 feet (3658 mm) in height unless it encloses tanks or elevators that extend to the roof (see Exception 1), for which the maximum height is 28 feet (8534 mm). If the height exceeds that permitted, the roof structure should be counted as, and meet all the requirements for, an additional story. This section also addresses how the height of a penthouse is measured.

1509.2.2 Area limitation. The aggregate area of penthouses and other enclosed rooftop structures shall not exceed one-third the area of the supporting roof deck. Such penthouses and other enclosed rooftop structures shall not be required to be included in determining the building area or number of stories as regulated by Section 503.1. The area of such penthouses shall not be included in determining the fire area specified in Section 901.7.

❖ The aggregate area of penthouses and any other enclosed rooftop structure is limited to one-third of the supporting roof deck. If the area of the penthouse exceeds this threshold, regardless of height, then the penthouse must be considered an additional story.

1509.2.3 Use limitations. Penthouses shall not be used for purposes other than the shelter of mechanical or electrical equipment, tanks, or vertical shaft openings in the roof assembly.

❖ The use of the penthouse is also limited. Regardless of height or area, roof structures used for anything except sheltering electrical or mechanical equipment or vertical shaft openings must be considered as an additional story.

1509.2.4 Weather protection. Provisions such as louvers, louver blades or flashing shall be made to protect the mechanical and electrical equipment and the building interior from the elements.

❖ Since the penthouse is a shelter for equipment or vertical shaft openings, it is often necessary to incorporate air intake and ventilation openings in the penthouse construction. In order to protect the equipment and the building from the detrimental effects of weather exposure, this section requires that measures be taken to minimize exposure to the elements. In so doing, this section essentially reiterates other provisions that address the integrity of the building envelope (see Sections 1503 and 1405.2).

1509.2.5 Type of construction. Penthouses shall be constructed with walls, floors and roofs as required for the type of construction of the building on which such penthouses are built.

Exceptions:

1. On buildings of Type I construction, the exterior walls and roofs of penthouses with a *fire separation distance* greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire-resistance rating. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall not be required to have a fire-resistance rating.
2. On buildings of Type I construction two stories or less in height above grade plane or of Type II construction, the exterior walls and roofs of penthouses with a fire separation distance greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire-resistance rating or a lesser fire-resistance rating as required by Table 602 and be constructed of fire-retardant-treated wood. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall be permitted to be constructed of fire-retardant-treated wood and shall not be required to have a fire-resistance rating. Interior framing and walls shall be permitted to be constructed of fire-retardant-treated wood.
3. On buildings of Type III, IV or V construction, the exterior walls of penthouses with a fire separation distance greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire-resistance rating or a lesser fire-resistance rating as required by Table 602. On buildings of Type III, IV or VA construction, the exterior walls of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall be permitted to be of Type IV or noncombustible construction or fire-retardant-treated wood and shall not be required to have a fire-resistance rating.

❖ The general premise of this section requires a penthouse to be treated no differently than any other portion of the building as it is constructed of exterior walls, a floor and a roof. Where the exterior walls of the penthouse are located within 5 feet (1524 mm) of the building's lot line, they are required to be of the same fire-resistance rating as the exterior wall of the story immediately below the penthouse. However, the exceptions recognize the reduced exposure where the exterior wall of a penthouse is set back from the exterior wall line of the building itself. Thus, the exceptions are based on two thresholds of fire separation distance: the first is greater than 5 feet (1524 mm) and up to 20 feet (6096 mm); the second is greater than 20 feet (6096 mm) (see Section 202 for the definition of "Fire separation distance").

If a penthouse is set back by a fire separation distance of 5 feet (1524 mm) or more from the lot line, the risk of exposure to adjacent property from a fire within the penthouse, as well as fire exposure to the penthouse from the adjacent lot, is reduced. Accordingly, if a penthouse is set back 5 feet (1524 mm) or more from the building's lot line, the penthouse construction may be able to take advantage of one of the exceptions, typically based on the type of construction, resulting in a reduction in rating of the exterior wall of the penthouse. It should be noted that, in many cases, penthouses located at least 20 feet (6096 mm) from the lot line are allowed further reductions.

1509.3 Tanks. Tanks having a capacity of more than 500 gallons (2 m^3) located on the roof deck of a building shall be supported on masonry, reinforced concrete, steel or Type IV construction provided that, where such supports are located in the building above the lowest *story*, the support shall be fire-resistance rated as required for Type IA construction.

❖ This section establishes the criteria used in evaluating rooftop tanks, such as water tanks.

1509.3.1 Valve and drain. In the bottom or on the side near the bottom of the tank, a pipe or outlet, fitted with a suitable quick-opening valve for discharging the contents into a drain in an emergency shall be provided.

❖ In the event of an emergency, there must be a means to drain the tank. This not only involves a quick-opening valve on the tank but also drains that are capable of handling the discharge. The drains must be sized and installed in accordance with the *International Plumbing Code*® (IPC®).

1509.3.2 Location. Tanks shall not be placed over or near a stairway or an elevator shaft, unless there is a solid roof or floor underneath the tank.

❖ Tanks are not permitted to be located above a stairway or elevator enclosure unless a solid roof or floor deck is provided underneath the tank. This is intended as ensurance that a shaft will not be affected by discharges from a leaking tank.

1509.3.3 Tank cover. Unenclosed roof tanks shall have covers sloping toward the perimeter of the tanks.

❖ Roof tanks must be covered to prevent the accumulation of rain, ice and snow, which may cause an uncovered tank to overflow.

1509.4 Cooling towers. Cooling towers located on the roof deck of a building and greater than 250 square feet (23.2 m^2) in base area or greater than 15 feet (4572 mm) in height above the roof deck, as measured to the highest point on the cooling tower, where the roof is greater than 50 feet (15 240 mm) in height above grade plane shall be constructed of noncombustible materials. The base area of cooling towers shall not exceed one-third the area of the supporting roof deck.

Exception: Drip boards and the enclosing construction shall be permitted to be of wood not less than 1 inch (25

mm) nominal thickness, provided the wood is covered on the exterior of the tower with noncombustible material.

❖ This section identifies and establishes criteria that require rooftop cooling towers to be of noncombustible construction.

1509.5 Towers, spires, domes and cupolas. Towers, spires, domes and cupolas shall be of a type of construction having fire-resistance ratings not less than required for the building on top of which such tower, spire, dome or cupola is built. Towers, spires, domes and cupolas greater than 85 feet (25 908 mm) in height above grade plane as measured to the highest point on such structures, and either greater than 200 square feet (18.6 m^2) in horizontal area or used for any purpose other than a belfry or an architectural embellishment, shall be constructed of and supported on Type I or II construction.

❖ This section identifies the criteria used in evaluating structures such as towers, spires, domes and cupolas. When any of those structures exceed either 85 feet (25 908 mm) in height above grade plane or are greater than 200 square feet (18.6 m^2) in area, the construction type is limited to Type I or II. Section 1509.5.1 further restricts construction to noncombustible when the heights become more excessive (see commentary, Section 1509.5.1). These restrictions are related to the difficultly posed in fighting fires in such structures and also the danger to surrounding people, emergency responders and other buildings if such elements should fail during a fire.

1509.5.1 Noncombustible construction required. Towers, spires, domes and cupolas greater than 60 feet (18 288 mm) in height above the highest point at which such structure contacts the roof as measured to the highest point on such structure, or that exceeds 200 square feet (18.6 m^2) in area at any horizontal section, or which is intended to be used for any purpose other than a belfry or architectural embellishment, or is located on the top of a building greater than 50 feet (1524 mm) in building height shall be constructed of and supported by noncombustible materials and shall be separated from the building below by construction having a fire-resistance rating of not less than 1.5 hours with openings protected in accordance with Section 712. Such structures located on the top of a building greater than 50 feet (15 240 mm) in building height shall be supported by noncombustible construction.

❖ These rooftop structures include communication towers, spires, cupolas and similar structures. Such structures must generally be constructed of the same type of construction as the building to which they are attached. Because of the difficulty in fighting fires on tall buildings and structures and the hazards associated with locating combustible materials on roofs of taller buildings, when the height of such structures exceeds 60 feet (18 288 mm) above the highest point at which it comes in contact with the roof or is in excess of 200 square feet (19 m^2) in area at any horizontal section, the structure and its supports must be of noncombustible construction. In addition, they must be separated from the building with construction that has a minimum 1.5-hour fire-resistance rating. Any opening in that construction must be protected in accordance with Section 712, which addresses the protection of openings in horizontal assemblies. While openings in horizontal assemblies are typically protected with shaft enclosures, there are floor fire door assemblies that could be used in this situation.

For similar reasons, most roof structures of any height or area placed on tall buildings [greater than 50 feet (15 240 mm) in height] are required to be constructed of noncombustible materials and be supported by noncombustible construction.

1509.5.2 Towers and spires. Enclosed towers and spires shall have exterior walls constructed as required for the building on top of which such towers and spires are built. The roof covering of spires shall not be less than the same class of roof covering required for the building on top of which the spire is located.

❖ As with penthouses and roof structures, the code intends to obtain construction and fire resistance for enclosed towers and spires that is consistent with that of the building on which they are supported.

1509.6 Mechanical equipment screens. Mechanical equipment screens shall be constructed of the materials specified for the exterior walls in accordance with the type of construction of the building. Where the fire separation distance is greater than 5 feet (1524 mm), mechanical equipment screens shall not be required to comply with the fire-resistance rating requirements.

❖ As the definition for "Mechanical equipment screen" makes clear, it is a rooftop structure that is not covered by a roof. This section conservatively requires that mechanical equipment screens must be constructed of the same materials as required for exterior walls, based on the type of construction of the building on which they are located. However, it does exempt them from any fire-resistance-rating requirement once the fire separation distance is greater than 5 feet (1524 mm) since, without a roof, they do not fully enclose a space and they pose a lesser exposure hazard than a penthouse.

1509.6.1 Height limitations. Mechanical equipment screens shall not exceed 18 feet (5486 mm) in height above the roof deck, as measured to the highest point on the mechanical equipment screen.

Exception: Where located on buildings of Type IA construction, the height of mechanical equipment screens shall not be limited.

❖ The height limits specified in this section are based on those required for penthouses in Section 1509.2.1. The exception for mechanical equipment screens located on buildings of Type IA construction is for consistency, since Table 503 does not limit the building height.

1509.6.2 Types I, II, III and IV construction. Regardless of the requirements in Section 1509.6, mechanical equipment screens shall be permitted to be constructed of combustible

materials where located on the roof decks of building of Type I, II, III or IV construction in accordance with any one of the following limitations:

1. The fire separation distance shall not be less than 20 feet (6096 mm) and the height of the mechanical equipment screen above the roof deck shall not exceed 4 feet (1219 mm) as measured to the highest point on the mechanical equipment screen.
2. The fire separation distance shall not be less than 20 feet (6096 mm) and the mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2303.2 for exterior installation.
3. Where exterior wall covering panels are used, the panels shall have a flame spread index of 25 or less when tested in the minimum and maximum thicknesses intended for use with each face tested independently in accordance with ASTM E 84 or UL 723. The panels shall be tested in the minimum and maximum thicknesses intended for use in accordance with, and shall comply with the acceptance criteria of, NFPA 285 and shall be installed as tested. Where the panels are tested as part of an exterior wall assembly in accordance with NFPA 285, the panels shall be installed on the face of the mechanical equipment screen supporting structure in the same manner as they were installed on the tested exterior wall assembly.

❖ This section is an exception to the requirements in Section 1509.6 for the types of construction that typically require the exterior walls to be constructed of noncombustible materials. The three itemized limitations in this section allow for combustible materials to be used for the construction of mechanical equipment screens when the stated conditions are met.

Item 1 recognizes that the hazard posed by a combustible mechanical equipment screen located on the roof of a Type I, II, III or IV building with a fire separation distance of at least 20 feet (6096 mm) and with the height of the mechanical equipment screen limited to 4 feet (1219 mm) above the roof deck is not significant.

Item 2 is based on Exceptions 2 and 3 for penthouses in Section 1509.2.5. The two-story limit in Exception 2 for Type I buildings is omitted. This is considered reasonable since the hazard doesn't justify limiting the Type I buildings to two stories in height where fire-retardant-treated wood is used to construct an unenclosed mechanical equipment screen. The main difference between this limitation and Item 1 is that it does not include the 4-foot (1219 mm) height limit on the mechanical equipment screen. This is because it must be constructed of fire-retardant-treated wood as compared to any combustible material allowed by the code. The height of the mechanical equipment screen would still be limited to 18 feet (5486 mm) by Section 1509.6.1. It is also limited to the maximum building height, based on the type of construction of the building in accordance with Section 1509.6.1.

Item 3 applies where the combustible materials used to build the mechanical equipment screen are limited to a maximum flame spread index of 25 (similar to fire-retardant-treated wood) and the materials are successfully tested in accordance with NFPA 285, *Standard Method of Test for the Evaluation of Flammability Characteristics of Exterior Nonload-Bearing Wall Assemblies Containing Combustible Components*. This is the test method that is used to validate the use of foam plastic insulations in exterior walls of Types I, II, III and IV construction, as well as for the use of metal composite materials in accordance with Section 1407.10. Although the material would be tested as the outer face of the exterior wall in the NFPA 285 test as part of an exterior wall assembly, the test assesses the surface flame spread resistance of the materials constituting the outer face, as well as to a certain degree, the inner face where it is exposed to any open cavities in the wall assembly. The NFPA 285 test is conducted for a full 30 minutes under severe fire-exposure conditions to both the inside of the wall assembly and the outside of the wall assembly with an exterior window burner replicating a fire that has gone to post-flashover and has broken out a window, exposing the outside face of the exterior wall finish. Since the materials used to construct the mechanical equipment screen do not comprise a completely enclosed wall assembly, the maximum flame spread index of 25 has been proposed as a conservative limitation for the backside face of the material, which may not have been directly exposed to the exterior window burner flame in the NFPA 285 test. Since the NFPA 285 test is used to qualify combustible materials for use where noncombustible exterior walls are required, it seems reasonable to allow panels tested as wall assemblies to be installed as equipment screen panels, utilizing the materials tested on the exterior face of the wall system in accordance with NFPA 285.

1509.6.3 Type V construction. The height of mechanical equipment screens located on the roof decks of buildings of Type V construction, as measured from grade plane to the highest point on the mechanical equipment screen, shall be permitted to exceed the maximum building height allowed for the building by other provisions of this code where complying with any one of the following limitations, provided the fire separation distance is greater than 5 feet (1524 mm):

1. Where the fire separation distance is not less than 20 feet (6096 mm), the height above grade plane of the mechanical equipment screen shall not exceed 4 feet (1219 mm) more than the maximum building height allowed;
2. The mechanical equipment screen shall be constructed of noncombustible materials;
3. The mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2303.2 for exterior installation; or
4. Where the fire separation distance is not less than 20 feet (6096 mm), the mechanical equipment screen shall be constructed of materials having a flame spread index

of 25 or less when tested in the minimum and maximum thicknesses intended for use with each face tested independently in accordance with ASTM E 84 or UL 723.

❖ This section is an exception to the height limitations in Section 1509.6.1. It is specific for Type V buildings, which are allowed to be constructed entirely of combustible materials. The one condition that must be met for all four options in this section is that the minimum fire separation distance must be greater than 5 feet (1524 mm). That restriction is based on Section 1406.

Item 1 is based on the belief that a 4-foot (1219 mm) height increase due to the presence of a mechanical equipment screen represents a relatively minor hazard on a building of Type V construction, particularly if the fire separation distance is at least 20 feet (6096 mm).

Item 2 allows these mechanical equipment screens to be taller when they are constructed of noncombustible materials where combustible materials would otherwise be permitted. Noncombustible materials pose no additional fire load or fire exposure to the building.

Item 3 allows the use of fire-retardant-treated wood which, although combustible, does not pose a significant fire hazard when constructed as a mechanical equipment screen where there is a minimum 5-foot (1524 mm) fire separation distance.

Item 4 criteria follows from Item 3 since fire-retardant-treated wood is required to have a maximum flame spread index of 25. There is an additional requirement that the fire separation distance is at least 20 feet (6096 mm). The lesser fire hazard associated with this type of installation should allow the greater heights for the mechanical equipment screens installed on these Type V buildings.

1509.7 Photovoltaic systems. Rooftop mounted photovoltaic systems shall be designed in accordance with this section.

❖ Rooftop-mounted photovoltaic systems need to comply with building code requirements similar to other rooftop structures.

1509.7.1 Wind resistance. Rooftop mounted photovoltaic systems shall be designed for wind loads for component and cladding in accordance with Chapter 16 using an effective wind area based on the dimensions of a single unit frame.

❖ This section clarifies that rooftop-mounted photovoltaic systems need to resist components and cladding wind loads and specifies that a single unit must be used to establish the effective wind area.

1509.7.2 Fire classification. Rooftop mounted photovoltaic systems shall have the same fire classification as the roof assembly required by Section 1505.

❖ The minimum requirements set forth here are intended for the rooftop-mounted photovoltaic system to comply with the same minimum requirements as the underlying roof assembly.

1509.7.3 Installation. Rooftop mounted photovoltaic systems shall be installed in accordance with the manufacturer's installation instructions.

❖ Rooftop-mounted photovoltaic systems need to be installed in accordance with the manufacturer's instructions.

1509.7.4 Photovoltaic panels and modules. Photovoltaic panels and modules mounted on top of a roof shall be listed and labeled in accordance with UL 1703 and shall be installed in accordance with the manufacturer's installation instructions.

❖ This section addresses the safety of photovoltaic panels and modules by requiring these products to comply with UL 1703 and to be installed in accordance with the manufacturer's instructions. UL 1703 is a standard used to investigate photovoltaic modules and panels and includes construction and performance requirements that address potential safety hazards.

1509.8 Other rooftop structures. Rooftop structures not regulated by Sections 1509.2 through 1509.7 shall comply with Sections 1509.8.1 through 1509.8.5 as applicable.

❖ This section addresses other rooftop structures that are not specifically regulated by Sections 1509.2 through 1509.7. These include rooftop structures such as aerial supports (Section 1509.8.1), bulkheads (Section 1509.8.2), dormers (Section 1509.8.3), fences (Section 1509.8.4) and flagpoles (Section 1509.8.5).

1509.8.1 Aerial supports. Aerial supports shall be constructed of noncombustible materials.

Exception: Aerial supports not greater than 12 feet (3658 mm) in height as measured from the roof deck to the highest point on the aerial supports shall be permitted to be constructed of combustible materials.

❖ This section addresses construction of aerial supports.

1509.8.2 Bulkheads. Bulkheads used for the shelter of mechanical or electrical equipment or vertical shaft openings in the roof assembly shall comply with Section 1509.2 as penthouses. Bulkheads used for any other purpose shall be considered as an additional story of the building.

❖ This provision treats bulkheads like penthouses. A definition of the term "bulkhead" that is closest to the context of Section 1509 is "a projecting framework with a sloping door giving access to a cellar stairway or a shaft."

1509.8.3 Dormers. Dormers shall be of the same type of construction as required for the roof in which such dormers are located or the exterior walls of the building.

❖ This section recognizes typical dormer construction and requires dormers to be the same type of construction as the roof or exterior wall in which the dormer is located.

1509.8.4 Fences. Fences and similar structures shall comply with Section 1509.6 as mechanical equipment screens.

❖ This section treats fences similar to mechanical equipment screens since they are similar structures and can be considered to have a similar fire hazard.

1509.8.5 Flagpoles. Flagpoles and similar structures shall not be required to be constructed of noncombustible materials and shall not be limited in height or number.

❖ This section exempts flagpoles from the rooftop height and construction limitations that apply to most other rooftop structures.

SECTION 1510
REROOFING

1510.1 General. Materials and methods of application used for recovering or replacing an existing roof covering shall comply with the requirements of Chapter 15.

Exception: Reroofing shall not be required to meet the minimum design slope requirement of one-quarter unit vertical in 12 units horizontal (2-percent slope) in Section 1507 for roofs that provide positive roof drainage.

❖ This section simply states that when a roof is replaced or recovered it must comply with Chapter 15 for the materials and methods used with only one exception for low-sloped roofs. This section does not mandate that the entire roof be replaced but simply that the portion being replaced comply with Chapter 15.

For low-sloped roofs, the exception indicates that reroofing (i.e., recovering or replacement) is not required to meet the $^1/_4$:12 minimum slope requirement of Section 1507, provided that the roof has positive drainage. The term "positive drainage" is defined as the drainage condition in which consideration has been made for all loading deflections of the roof deck, and additional roof slope has been provided to ensure drainage of the roof area within 48 hours of rainfall.

1510.2 Structural and construction loads. Structural roof components shall be capable of supporting the roof-covering system and the material and equipment loads that will be encountered during installation of the system.

❖ The structural integrity of the roof must be maintained during reroofing operations, which can significantly contribute to the loading of the roof due to workers and material being present during this period of time. The roof support system must be able to structurally support all additional layers of roof covering material.

1510.3 Recovering versus replacement. New roof coverings shall not be installed without first removing all existing layers of roof coverings down to the roof deck where any of the following conditions occur:

1. Where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing.
2. Where the existing roof covering is wood shake, slate, clay, cement or asbestos-cement tile.
3. Where the existing roof has two or more applications of any type of roof covering.

Exceptions:

1. Complete and separate roofing systems, such as standing-seam metal roof systems, that are designed to transmit the roof loads directly to the building's structural system and that do not rely on existing roofs and roof coverings for support, shall not require the removal of existing roof coverings.
2. Metal panel, metal shingle and concrete and clay tile roof coverings shall be permitted to be installed over existing wood shake roofs when applied in accordance with Section 1510.4.
3. The application of a new protective coating over an existing spray polyurethane foam roofing system shall be permitted without tear-off of existing roof coverings.
4. Where the existing roof assembly includes an ice barrier membrane that is adhered to the roof deck, the existing ice barrier membrane shall be permitted to remain in place and covered with an additional layer of ice barrier membrane in accordance with Section 1507.

❖ This section determines when all layers of previously installed roof covering systems must be removed prior to the installation of the new roof covering system. Note that roof coverings need to be removed down to the roof decking or sheathing.

When the existing roof or roof covering is water soaked, it must be allowed to dry completely so as not to trap moisture beneath the new layer of covering. This could cause a rapid deterioration of the new covering material, as well as the existing sheathing. The existing covering is required to be removed if it cannot adequately dry out or if its physical properties have been permanently altered.

Wood shake, slate, clay, cement or asbestos-cement tile types of existing roof coverings historically do not make an adequate base for new roof coverings and could prevent the new covering from making a weather-tight seal. They could also allow penetration of water, snow, etc. These types of existing coverings must always be removed.

When the existing roof has two or more layers of any type of covering system, all layers need to be removed to enable the inspector and contractor to verify that the existing sheathing is not water damaged and still capable of providing an adequate nailing base.

Exception 1 states that new roofing systems that are designed to transmit all roof loads directly to the structural supports of the building do not necessitate that the existing roofing system be removed. Exception 2 allows certain roof covering, including metal, concrete panel and clay, to be placed over wood shingle and shake roofs only if any concealed com-

bustible spaces are properly addressed in accordance with Section 1510.4 (see commentary, Section 1510.4). Exception 3 refers to the practice of "recoating" in which a new protective coating is placed over an existing spray polyurethane foam roofing system. Recoating can add many years to the effective life of a spray polyurethane foam roofing system without the associated downside of adding significant weight associated with other reroofing-type systems.

When removing roof coverings, it can be difficult, if not impossible, to remove an existing layer of adhered ice barrier membrane without damaging or replacing the roof deck. Exception 4 accounts for this condition by allowing an existing adhered ice barrier membrane to remain in place and be covered with a new ice barrier membrane as required in Section 1507, followed by the installation of the new primary roof-covering material.

1510.4 Roof recovering. Where the application of a new roof covering over wood shingle or shake roofs creates a combustible concealed space, the entire existing surface shall be covered with gypsum board, mineral fiber, glass fiber or other *approved* materials securely fastened in place.

❖ "Roof recovering" is defined as the process of installing an additional roof covering over a prepared existing roof covering without removing the existing roof covering. Where recovering over wood shingles or shakes creates a combustible concealed space, the code requires that the entire surface of the wood shakes and shingles be covered with a material that will reduce the possibility of such materials adding fuel to a fire in such a space.

1510.5 Reinstallation of materials. Existing slate, clay or cement tile shall be permitted for reinstallation, except that damaged, cracked or broken slate or tile shall not be reinstalled. Existing vent flashing, metal edgings, drain outlets, collars and metal counterflashings shall not be reinstalled where rusted, damaged or deteriorated. Aggregate surfacing materials shall not be reinstalled.

❖ This section places conditions on the reuse of roof-covering materials. Historically, various types of materials have been removable without substantially damaging the material. Materials such as wood shingles and shakes, roll roofing and asphalt shingles are usually torn or cracked and cannot be reused. Fastener holes also violate the integrity of the material. Before reuse is allowed, materials such as slate, clay or cement tile should be examined thoroughly for cracks and deterioration.

1510.6 Flashings. Flashings shall be reconstructed in accordance with *approved* manufacturer's installation instructions. Metal flashing to which bituminous materials are to be adhered shall be primed prior to installation.

❖ Flashings to be reused or reconstructed must be in accordance with the manufacturer's installation instructions. Metal flashings that are to be reused for bituminous materials must be primed in accordance with the manufacturer's instructions.

SECTION 1511
SOLAR PHOTOVOLTAIC PANELS/MODULES

1511.1 Solar photovoltaic panels/modules. Solar photovoltaic panels/modules installed upon a roof or as an integral part of a roof assembly shall comply with the requirements of this code and the *International Fire Code*.

❖ Roof-mounted solar photovoltaic panels/modules should comply with roofing requirements, such as supporting the load of these systems on roofs and structural framing. This section also makes a needed reference to relevant requirements in the IFC.

1511.1.1 Structural fire resistance. The structural frame and roof construction supporting the load imposed upon the roof by the photovoltaic panels/modules shall comply with the requirements of Table 601.

❖ This section is a reminder to verify compliance with Table 601 for the portion of the structure that supports the additional load of roof-mounted solar photovoltaic panels/modules.

INTERNATIONAL CODE COUNCIL®

People Helping People Build a Safer World™

When it comes to code education, ICC has you covered.

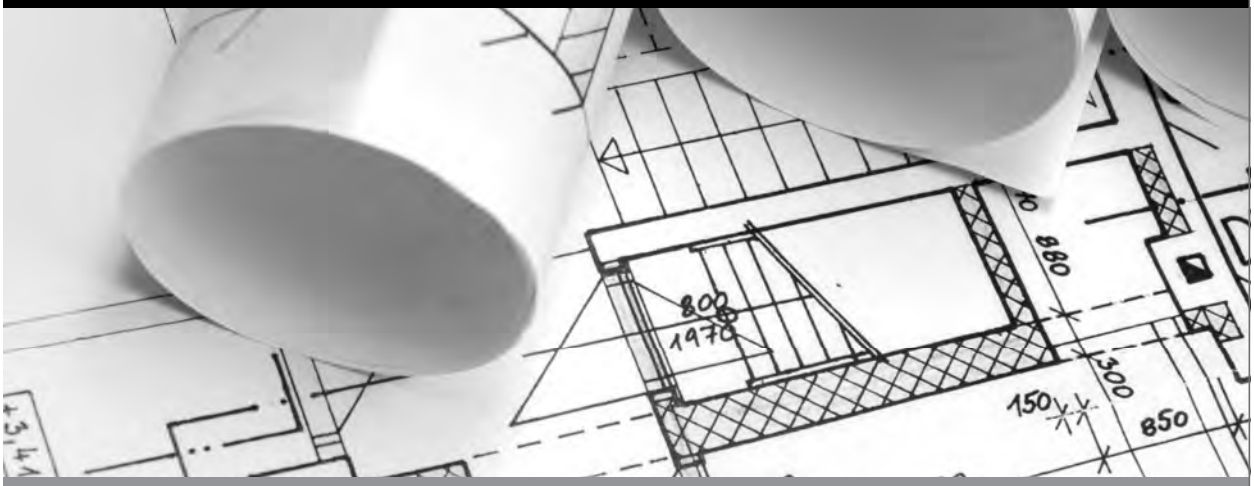
ICC publishes building safety, fire prevention and energy efficiency codes that are used in the construction of residential and commercial buildings. Most U.S. cities, counties, and states choose the I-Codes based on their outstanding quality.

ICC also offers the highest quality training resources and tools to properly apply the codes.

TRAINING RESOURCES

- **Customized Training:** Training programs tailored to your specific needs.
- **Institutes:** Explore current and emerging issues with like-minded professionals.
- **ICC Campus Online:** Online courses designed to provide convenience in the learning process.
- **Webinars:** Training delivered online by code experts.
- **ICC Training Courses:** On-site courses taught by experts in their field at select locations and times.

TRAINING TOOLS



- **Online Certification Renewal Update Courses:** Need to maintain your ICC certification? We've got you covered.
- **Training Materials:** ICC has the highest quality publications, videos and other materials.

For more information on ICC training, visit http://www.iccsafe.org/Education or call 1-888-422-7233, ext. 33818.

People Helping People Build a Safer World™

ICC Plan Review Services: Imagine what we can accomplish together

ICC helps building departments review plans for high-rises, retail facilities, schools, and residential developments. Our qualified staff delivers comprehensive and accurate code-base plan reviews—on schedule and on budget.

Choose a complete review or just one aspect of a plan, including building (structural and nonstructural), mechanical, plumbing, electrical, accessibility, energy, and fire protection systems (including sprinklers). We also offer evaluations of specific code topics or special studies of building components, characteristics, or applications. Just ask!

No job is too small or too large for the ICC Plan Review Services. ICC Plan Review fees are based on the scope of work requested.

To learn more about the ICC Plan Review Services, visit www.iccsafe.org/planreview

To speak with an expert, call (888) ICC-SAFE (422-7233) and talk to Chris Reeves at x4309 or Doug Connell at x5226.

Valuable Guides to Changes in the 2012 I-Codes®

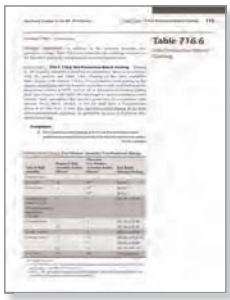
NEW!

FULL COLOR! HUNDREDS OF PHOTOS AND ILLUSTRATIONS!

SIGNIFICANT CHANGES TO THE 2012 INTERNATIONAL CODES®

Practical resources that offer a comprehensive analysis of the critical changes made between the 2009 and 2012 editions of the codes. Authored by ICC code experts, these useful tools are "must-have" guides to the many important changes in the 2012 International Codes.

SIGNIFICANT CHANGES TO THE IBC, 2012 EDITION
#7024S12



SIGNIFICANT CHANGES TO THE IRC, 2012 EDITION
#7101S12

SIGNIFICANT CHANGES TO THE IFC, 2012 EDITION
#7404S12

SIGNIFICANT CHANGES TO THE IPC/IMC/IFGC, 2012 EDITION
#7202S12

Changes are identified then followed by in-depth discussion of how the change affects real world application. Photos, tables and illustrations further clarify application.

A117.1—Improving Accessibility for 50 Years

Since 1961, the A117.1 standard has been at the forefront of creating a built environment open to everyone. Today, A117.1 developer and publisher ICC introduces its updated edition with essential new requirements and insightful resources spotlighting changes.

ICC A117.1-2009: ACCESSIBLE AND USABLE BUILDINGS AND FACILITIES

This updated edition of the ANSI-approved standard includes:

- Additional coordination and clarification of requirements for dwelling units.
- Addition of Type C dwelling unit requirements for use by jurisdictions adopting visitability ordinances for dwellings not regulated by Fair Housing.
- A series of revisions for restroom requirements.
- A new section that addresses variable message signs (VMS).
- A new chapter for recreational facilities. (120 pages)
