# PREFACE

The principal purpose of the Commentary is to provide a basic volume of knowledge and facts relating to building construction as it pertains to the regulations set forth in the 2015 *International Fire Code*. The person who is serious about effectively designing, constructing and regulating buildings and structures will find the Commentary to be a reliable data source and reference to almost all components of the built environment.

As a follow-up to the *International Fire Code*, we offer a companion document, the *International Fire Code Commentary—Volume I*. Volume I covers Chapters 1 through 19 of the 2015 *International Fire Code*. The basic appeal of the Commentary is thus: it provides in a small package and at reasonable cost thorough coverage of many issues likely to be dealt with when using the *International Fire Code* — and then supplements that coverage with historical and technical background. Reference lists, information sources and bibliographies are also included.

Throughout all of this, effort has been made to keep the vast quantity of material accessible and its method of presentation useful. With a comprehensive yet concise summary of each section, the Commentary provides a convenient reference for regulations applicable to the construction of buildings and structures. In the chapters that follow, discussions focus on the full meaning and implications of the code text. Guidelines suggest the most effective method of application, and the consequences of not adhering to the code text. Illustrations are provided to aid understanding; they do not necessarily illustrate the only methods of achieving code compliance.

The format of the Commentary includes the full text of each section, table and figure in the code, followed immediately by the commentary applicable to that text. At the time of printing, the Commentary reflects the most up-to-date text of the 2015 *International Fire Code*. Each section's narrative includes a statement of its objective and intent, and usually includes a discussion about why the requirement commands the conditions set forth. Code text and commentary text are easily distinguished from each other. All code text is shown as it appears in the *International Fire Code*, and all commentary is indented below the code text and begins with the symbol ❖.

Readers should note that the Commentary is to be used in conjunction with the *International Fire Code* and not as a substitute for the code. The Commentary is advisory only; the code official alone possesses the authority and responsibility for interpreting the code.

Comments and recommendations are encouraged, for through your input, we can improve future editions. Please direct your comments to the Codes and Standards Development Department at the Chicago District Office.

The International Code Council would like to extend its thanks to the following individuals for their contributions to the technical content of this commentary:

Jeff Hugo  
Elley Klausbruckner

## Arrangement and Format of the 2015 IFC

Before applying the requirements of the IFC it is beneficial to understand its arrangement and format. The IFC, like other codes published by the International Code Council, is arranged and organized to follow sequential steps that generally occur during a plan review or inspection. The 2015 IFC is organized into seven Parts as illustrated in the tables below. Each Part represents a broad subject matter and includes the chapters that logically fit under the subject matter of each Part. It is also foreseeable that additional chapters will need to be added in the future as regulations for new processes or operations are developed. Accordingly, the reorganization was designed to accommodate such future chapters by providing reserved (unused) chapters in several of the Parts. This will allow the subject matter parts to be conveniently and logically expanded without requiring a major renumbering of the IFC chapters.

<b>2015 ORGANIZATION OF THE IFC</b>	
<b>Parts and Chapters</b>	<b>Subject Matter</b>
Part I – Chapters 1 and 2	Administrative and definitions
Part II – Chapters 3 and 4	General safety provisions
Part III – Chapters 5 through 11	Building and equipment design features
Part III – Chapters 12 through 19	Reserved for future use
Part IV – Chapters 20 through 37	Special occupancies and operations
Part IV – Chapters 38 through 49	Reserved for future use
Part V – Chapters 50 through 67	Hazardous materials
Part V – Chapters 68 through 79	Reserved for future use
Part VI – Chapter 80	Referenced standards
Part VII – Appendices A through M	Adoptable and informational appendices

The IFC requirements for fire-resistive construction, interior finish, fire protection systems, means of egress and construction safeguards are directly correlated to the chapters containing parallel requirements in the IBC, as follows:

<b>IFC Chapter</b>	<b>Subject</b>
7	Fire and smoke protection features
8	Interior finish, decorative materials and furnishings
9	Fire protection systems
10	Means of egress
33	Fire safety during construction and demolition

# LEGISLATION

The *International Codes* are designed and promulgated to be adopted by reference by legislative action. Jurisdictions wishing to adopt the 2015 *International Fire Code Commentary* as an enforceable set of regulations for the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises should ensure that certain factual information is included in the adopting legislation at the time adoption is being considered by the appropriate governmental body. The following sample adoption legislation addresses several key elements, including the information required for insertion into the code text.

## SAMPLE LEGISLATION FOR ADOPTION OF THE *INTERNATIONAL FIRE CODE* ORDINANCE NO. \_\_\_\_\_

A[N] [ORDINANCE/STATUTE/REGULATION] of the [NAME OF JURISDICTION] adopting the 2015 edition of the *International Fire Code*, regulating and governing the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises in the [NAME OF JURISDICTION]; providing for the issuance of permits and collection of fees therefor; repealing [ORDINANCE/STATUTE/REGULATION] No. \_\_\_\_\_ of the [NAME OF JURISDICTION] and all other ordinances or parts of laws in conflict therewith.

The [GOVERNING BODY] of the [NAME OF JURISDICTION] does ordain as follows:

**Section 1.** That a certain document, three (3) copies of which are on file in the office of the [TITLE OF JURISDICTION'S KEEPER OF RECORDS] of [NAME OF JURISDICTION], being marked and designated as the *International Fire Code*, 2015 edition, including Appendix Chapters [FILL IN THE APPENDIX CHAPTERS BEING ADOPTED] (see *International Fire Code* Section 101.2.1, 2015 edition), as published by the International Code Council, be and is hereby adopted as the Fire Code of the [NAME OF JURISDICTION], in the State of [STATE NAME] regulating and governing the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises as herein provided; providing for the issuance of permits and collection of fees therefor; and each and all of the regulations, provisions, penalties, conditions and terms of said Fire Code on file in the office of the [NAME OF JURISDICTION] are hereby referred to, adopted, and made a part hereof, as if fully set out in this legislation, with the additions, insertions, deletions and changes, if any, prescribed in Section 2 of this ordinance.

**Section 2.** That the following sections are hereby revised:

Section 101.1. Insert: [NAME OF JURISDICTION]

Section 109.4. Insert: [OFFENSE, DOLLAR AMOUNT, NUMBER OF DAYS]

Section 111.4. Insert: [DOLLAR AMOUNT IN TWO LOCATIONS]

**Section 3.** That the geographic limits referred to in certain sections of the 2015 *International Fire Code* are hereby established as follows:

Section 5704.2.9.6.1 (geographic limits in which the storage of Class I and Class II liquids in above-ground tanks outside of buildings is prohibited): [JURISDICTION TO SPECIFY]

Section 5706.2.4.4 (geographic limits in which the storage of Class I and Class II liquids in above-ground tanks is prohibited): [JURISDICTION TO SPECIFY]

Section 5806.2 (geographic limits in which the storage of flammable cryogenic fluids in stationary containers is prohibited): [JURISDICTION TO SPECIFY]

Section 6104.2 (geographic limits in which the storage of liquefied petroleum gas is restricted for the protection of heavily populated or congested areas): [JURISDICTION TO SPECIFY]

**Section 4.** That [ORDINANCE/STATUTE/REGULATION] No. \_\_\_\_\_ of [NAME OF JURISDICTION] entitled [FILL IN HERE THE COMPLETE TITLE OF THE LEGISLATION OR LAWS IN EFFECT AT THE PRESENT TIME SO THAT THEY WILL BE REPEALED BY SPECIFIC REFERENCE] and all other ordinances or parts of laws in conflict herewith are hereby repealed.

**Section 5.** That if any section, subsection, sentence, clause or phrase of this legislation is, for any reason, held to be unconstitutional, such decision shall not affect the validity of the remaining portions of this ordinance. The [GOVERNING BODY] hereby declares that it would have passed this law, and each section, subsection, clause or phrase thereof, irrespective of the fact that any one or more sections, subsections, sentences, clauses and phrases be declared unconstitutional.

**Section 6.** That nothing in this legislation or in the Fire Code hereby adopted shall be construed to affect any suit or proceeding impending in any court, or any rights acquired, or liability incurred, or any cause or causes of action acquired or existing, under any act or ordinance hereby repealed as cited in Section 4 of this law; nor shall any just or legal right or remedy of any character be lost, impaired or affected by this legislation.

**Section 7.** That the [JURISDICTION'S KEEPER OF RECORDS] is hereby ordered and directed to cause this legislation to be published. (An additional provision may be required to direct the number of times the legislation is to be published and to specify that it is to be in a newspaper in general circulation. Posting may also be required.)

**Section 8.** That this law and the rules, regulations, provisions, requirements, orders and matters established and adopted hereby shall take effect and be in full force and effect [TIME PERIOD] from and after the date of its final passage and adoption.

## Part I—Administrative

# Chapter 1: Scope and Administration

### General Comments

This chapter addresses the administration and enforcement of the code. The objectives and mandate for enforcement are beyond the scope of this chapter. Before adopting the code, a state or local government must establish an agency with staff trained to administer and enforce the code. The administrative relationships, designation of the enforcement authority (fire code official), funding, training and certification of inspectors and scope of the enforcement program are determined by the adopting body.

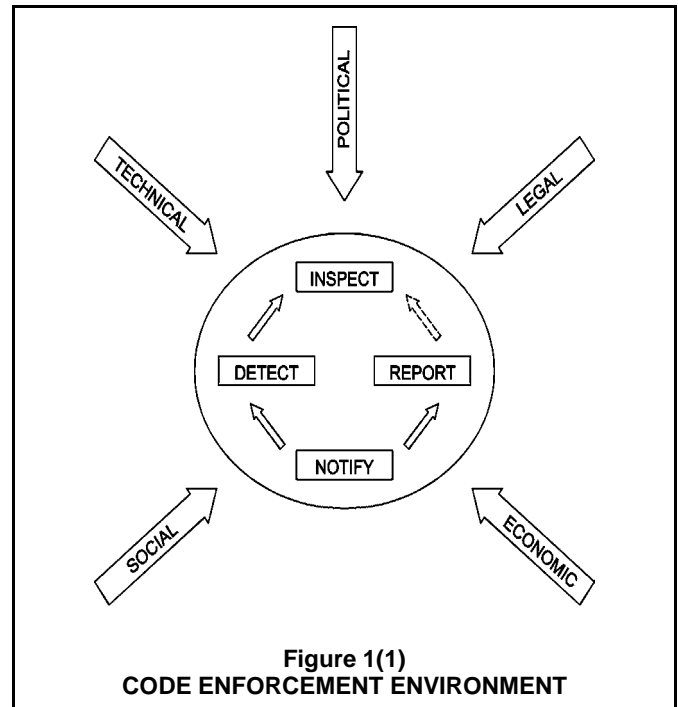

Management personnel generally perform functions, such as planning, organizing, directing, controlling, analyzing and budgeting. Though the code administrator's duties may include all of these functions, this chapter takes a much narrower view of the code administrative function, dealing mainly with technical and legal areas. Fire prevention code administration must be considered in the context of a complex environment containing political, social, economic, technical and legal dimensions. Enforcement, too, is a broad, all-inclusive term that includes a range of activities aimed at identifying and eliminating hazards; in this case, hazards causing or contributing to a fire or impairing life safety.

Four functions are commonly associated with enforcement: inspecting, detecting, notifying and reporting [see Commentary Figure 1(1)]. This chapter describes the technical and legal requirements associated with administering a code enforcement program to achieve these functions. The examination of these concepts specifically provides a better understanding of the fire code official's authority, duties and liabilities.

Two main duties of the fire code official are administration and enforcement. In administration, the following concepts are most important:

### Code Administrative Environment

Many administrative or management functions are not addressed in the code. Before the provisions of this document can be of any use, many basic questions must be answered. Jurisdictions adopting a code enforcement program are using discretionary powers to fulfill a community need. The need in the community must be clearly identified, the program mission clearly established and the most appropriate delivery system selected. To address the technical and legal demands of the code administrative environment, the code

assumes that jurisdictions adopting the document are interested in protecting the health, safety and welfare of its citizens from the effects of fires and explosions. Additionally, the code assumes that these jurisdictions are authorized to use the police power of the state to receive these benefits. Finally, the code assigns principal responsibility for enforcing this document to the department or agency (fire department or fire prevention bureau) most frequently available to perform this mission.

The particular objectives and social or political mandate of a code enforcement program are not considered in the context of this document. These items, however, are often cited as the most frustrating problems faced by code administrators. Code enforcers often complain of being overwhelmed by demands for leniency or special consideration based on the economic, social or political effects of their decisions.

As stated, this chapter establishes ground rules for enforcing the code; however, these ground rules are only the technical and legal requirements binding both fire code officials and the general public. For guidance on the political, social and economic considerations associated with code enforcement activities, adopting

authorities must turn elsewhere; however, none of this is intended to imply that these considerations are absent from the code process. To the contrary, by establishing these requirements as “minimums,” the ICC voting membership (see ICC Board of Directors Policy CP-28) has, through a democratic process of public hearings and debate, attempted to weigh these considerations carefully when deliberating, modifying and adopting the provisions appearing in this document. In the end, each jurisdiction must give careful consideration to how these requirements should be adopted; who should be responsible for enforcing them; how enforcement personnel should be trained; how the operation will be financed; and when and how to modify or change operations, if necessary. These considerations deserve careful, thorough public attention before a decision is made to adopt and enforce the code.

### Scope and Applicability of the Code

The code applies to new and existing structures and premises as prescribed in Sections 102.1 and 102.2, in matters related to occupancy and maintenance for the protection of lives and property from fire. Conditions related to fire spread, occupant hazard protection and maintenance are regulated as follows:

**Retroactivity:** Because the code applies to both new and existing structures and premises as prescribed in Sections 102.1 and 102.2, the existing building provisions may be considered retroactive. Existing structures and premises built in compliance with the codes and standards in effect at the time of their original construction or alteration are not in all cases exempt from code compliance.

**Other codes and standards:** The code relies heavily on other codes and standards to specify a means of complying with its provisions, including, among others, the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), the *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>), the *International Fuel Gas Code*<sup>®</sup> (IFGC<sup>®</sup>) and the standards referenced in the text. Additionally, other federal, state and local codes and ordinances may establish certain requirements related to fire protection and life safety. Code requirements are intended to complement other regulations. When conflicts arise between code provisions and the referenced standards, the code provisions apply. Where a standard provides additional technical detail or guidance beyond that provided in the related code text, the fire code official must use judgment when applying these provisions to prevent conflicts with the code provisions. If a conflict arises, it is the fire code official's duty to determine which provisions secure the code's intent. When a conflict between codes or other legal action causes a portion of this document to be “struck down,” such action is not intended to invalidate the remaining code provisions. The severability of code provisions, however, does not imply that these same provisions

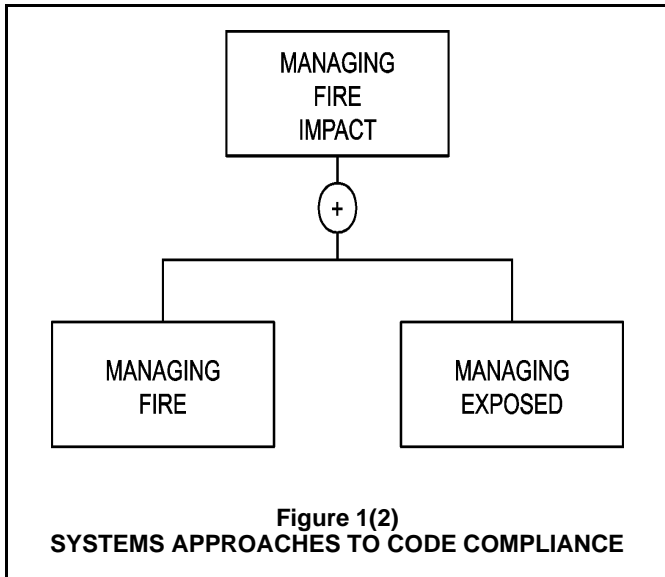

should be considered or applied outside of their context as a part of the code.

### Fire Code Official's Judgment

The code relies heavily not only on other codes and standards but also on the judgment and experience of the fire code official.

**Approval:** The code details occupancy and maintenance requirements; however, it relies heavily on performance criteria, as opposed to detailed specifications, to accomplish this task. The fire code official, therefore, must exercise judgment when approving or permitting operations, processes and procedures required by the code. Proof of compliance may include certification or labeling by independent testing laboratories; however, regardless of the conclusions of these external agencies and authorities, the fire code official remains the sole judge of what fulfills the intent of the code. This becomes particularly important when the fire code official is asked to evaluate equivalent methods and materials. Having piles of data may seem helpful, but the data may prove to be meaningless when it is considered in the context of the code's intent. Data in support of alternative methods and materials must demonstrate not only compliance with the code's intent but also relevance to the issues at hand. Evidence, such as a label or an independent laboratory test report, may sometimes be used inappropriately to support an application for recognition of equivalency. The fire code official must evaluate all submitted evidence to make sure it applies to its intended use, as well as to the code's intent. In an increasingly technical and litigious society, learning how to make such judgments may be the biggest challenge facing fire code officials. Relying on strict interpretations of intent or the “letter” of the code may be the conservative way, but conservative approaches may simply increase the social and political pressures confronting fire code officials. Decision-making aids employing contemporary computer technology permit a designer to propose more innovative and creative responses to complex problems. Fire code officials must begin to recognize, use and interpret these tools and data to maintain effective protection. These models permit designers to quickly and easily evaluate the relationships and performance of a variety of complex variables.

Another model that does not rely on a computer is NFPA 550 [see Commentary Figure 1(2)]. This model requires little training to use or understand and is an all-inclusive representation of the variables contributing to fire safety. The model may, therefore, serve as a useful tool for qualitatively evaluating the contribution of various approaches to an overall fire safety system. Once equivalent alternative methods have been identified using the Fire Safety Concepts Tree (see “General Comments” in Chapter 3), quantitative (cost/benefit) analyses may be applied.

**Fire Code Officials and Liability**

Like all professionals, fire code officials are subject to legal action. The two most common legal actions that may be pursued against fire code officials are breach of contract lawsuits and tort claims. Tort claims, by far, are the most common lawsuits. These lawsuits allege that some damage, injury or harm (a tort) resulted from the actions of the fire code official. A successful tort claim must prove that the plaintiff was injured or harmed; that the fire code official had a legal duty or obligation to perform with respect to the plaintiff and that the cause of the plaintiff's injury was the fire code official's actions or inactions while performing these duties.

The Law of Torts includes the following:

*The tort.* Damages arising from the acts of fire code officials fall into two broad categories: property and personal [see Commentary Figure 1(3)]. Property torts involve the control, use, operation or ownership of personal and real property by private individuals. Personal torts involve physical, verbal or written assaults on the character, person, psyche or privacy of individuals. Such assaults or invasions may involve actual contact or threat of harm. For example, fire code officials' acts of commission may restrain business or trade activity, while acts of omission may fail to recognize that haz-

**Figure 1(3)**  
**TYPES OF TORTS**

ards need to be corrected, thus resulting in life or property losses.

Two actions dominate lawsuits filed against enforcement authorities: Most lawsuits either allege improper acts by the fire code official (acts of commission) or failure to fulfill specified or implied legal obligations (acts of omission). In the former, plaintiffs usually seek temporary or permanent relief from a fire code official's decision. In these actions, plaintiffs usually allege improper interpretation or application of the code or its intent. Other lawsuits usually allege failure to exercise a reasonable standard of care in the performance of duties of the fire code official. In either type of lawsuit, and often in the case of omissions, plaintiffs seek compensatory and even punitive damages. Infringements on constitutional protections may be, though occurring infrequently, the basis for lawsuits against fire code officials. Common constitutional issues raised in lawsuits against fire code officials include violations of the Fourth Amendment's protection against unreasonable searches and seizures, the Sixth Amendment's due process protections and the Fourteenth Amendment's equal protection provisions. First Amendment rights guaranteed under freedom of association protections may be raised in cases involving public assembly occupancies, especially churches.

*Condition of negligence:* To prevail in a tort claim action, a plaintiff must demonstrate negligence on the part of the defendant. Negligence may be simple—a failure to exercise reasonable or adequate care when performing assigned duties (commonly known as misfeasance)—or it may be gross—represented by wanton, willful, reckless or malicious disregard for public safety. Criminal activities, including dereliction (nonfeasance) or the failure to perform required assigned duties, may be cause for claims of gross negligence. Likewise, malfeasance, the willful or malicious violation of a legal duty, may constitute grossly negligent behavior. The following three elements must be proven to sustain a claim of negligence: the defendant had a duty to act, the defendant failed to exercise the required standard of care in the performance of that duty and, as a result of that failure, damage was incurred or harm was suffered by the plaintiff.

*Duty to act.* The code establishes few duties of the fire code official; instead, it places greatest emphasis on the responsibility of structure or premises owners and operators to perform their duties with adequate regard for public health, safety and welfare. The duties owed to the the public by the fire code official fall under the following categories: approvals, enforcement, personnel, inspections, investigations, reports and record keeping. Other duties may be assumed by fire code officials through the performance of their official duties. Recently, some courts have ruled that failure to perform timely reinspections or exhaust legal remedies against violators in fire code cases creates a special relationship between the fire code official and the occupants of properties in violation of the code, especially when the

occupants do not own the property and are not responsible for code compliance. Some court rulings have even implied that conducting inspections not otherwise required by the code constitutes an *ultra vires* (beyond the authority of) liability. Fire code officials should consult their jurisdiction's legal counsel to determine how these decisions, the jurisdiction's enforcement policies and the code provisions combined affect their enforcement program and jurisdictional and personal liabilities.

**Standard of care:** Taken together, the fire code official's duties are the basis for determining his or her standard of care. When assessing whether fire code officials have met this standard, judges and juries must determine whether they performed the required duties as reasonable, comparably trained and experienced fire code officials. Failure to meet the appropriate standard of care may be classified in three ways: nonfeasance, misfeasance or malfeasance. Nonfeasance is the failure to perform a required duty. Improper performance of a required duty constitutes misfeasance, and malicious or willful violation of a required duty is malfeasance. Of the three, misfeasance or simple negligence is the most common cause of action. The code and most tort claims either hold the government immune from specific claims of misfeasance or severely limit damage awards in such cases. For all purposes, sovereign immunity—the doctrine inherited from British common law mandating that “the King can do no wrong”—is obsolete. Similarly, courts in many states have abandoned the public duty doctrine, which states that a duty to all is a duty to no one. Holding that most code provisions and governmental regulations secure benefits for select groups, some state courts recognize that specific enforcement activities secure greater benefits for some members of the public than others. Such judicial reasoning holds that the inspector's duty applies to the individual who may be injured as a result of failure to detect a hazard or diligently pursue compliance. Moreover, this duty may include acts of omission, such as failure to perform required inspections. With courts today recognizing only limited immunity for government officials, fire code officials must become more aware of their duties and liabilities. Although tort claim acts limit damage awards, they still permit lawsuits to proceed against governmental officials and agencies to determine their responsibility for negligent acts. Claims of gross negligence arising from nonfeasance or malfeasance are less common than misfeasance actions but are predictably harder to defend. The code provides no relief from liability where the fire code official either fails to perform a required duty or acts *ultra vires*; that is, beyond his or her authority. The jurisdiction is generally immune from claims when its agents perform acts beyond the scope of their authority, unless such acts were implicitly endorsed by the government (explicit endorsement may constitute a discretionary governmental act and, similarly, immunize the government). Nonfeasance is considered a criminal offense in many jurisdictions. An employee's dereliction of duty exempts the jurisdiction from immunity under most circumstances, unless the employee's failure to

perform was the direct result of explicit instructions from governmental superiors; however, the employee may be held criminally liable.

In addition to the Law of Torts, the following have an impact on fire code officials and liability:

**Awards:** Lawsuits may seek declarative judgments (injunctive relief or monetary awards) in favor of the plaintiff. Monetary awards fall into four categories: nominal, special, compensatory and punitive. The first purpose of monetary awards should be to the claimant or plaintiff for real losses. This is the purpose of compensatory and special damages. Compensatory awards reimburse the claimant or plaintiff for the direct costs resulting from the defendant's negligence or carelessness. Many times, a plaintiff will also seek additional compensation for the indirect results of the defendant's acts. Such special damage claims may result in additional compensation beyond that provided by compensatory damages. Punitive awards are intended to punish the defendant for the misdeed and discourage him or her from future unlawful activity. These awards are often held up as examples to the community as a whole and are a way to discourage unlawful activities by others. Nominal damage awards serve to assign blame in intentional tort cases when the facts of the case do not merit a substantial settlement.

**Protection:** The best protection against a lawsuit is professional conduct and preparation; that is, training, education and research. Lawsuits filed against public officials have become commonplace and are probably inevitable. In 1983, H. M. Markman suggested six rules to manage legal liability [see Commentary Figure 1(4)].

- **You cannot prevent someone from filing a lawsuit against you.**
- **Do not take the lawsuit personally.**
- **Understand your risk exposure or exposures.**
- **Be professional.**
- **You are not an insurer.**
- **Do not make stupid mistakes.**

**Figure 1(4)  
MARKMAN'S SIX RULES**

Although no single rule should be considered more important than another, the last one is perhaps the best to remember. Everyone makes mistakes, so strive to learn from the mistakes rather than repeat them. Nonetheless, every mistake may be potential exposure. Acting professionally helps minimize exposure to error, especially when training, and common sense is encouraged. Using common sense, exercising reasonable care and acting professionally are no insurance against a lawsuit, but they all may provide considerable protection in the event a lawsuit is filed. No matter how hard

someone may try to avoid a lawsuit, someone may sue. When a lawsuit is filed, the most important things to remember are not to take it personally and not to forget the other five rules.

### Enforcement

The enforcement duty of the fire code official's position is composed of four distinct functions: inspection, detection, notification and reporting. All four functions define phases in the enforcement process duties of fire code officials.

During the code enforcement process, structures or premises requiring inspections are identified. Inspectors are assigned and inspections are performed. During these inspections, any code violations found are usually noted. Then, the owner or occupant is verbally advised or notified that the deficiencies noted are code violations. To promote code compliance, the inspector may suggest remedial actions that may be taken to establish compliance. Finally, a written violation notice serving as further notice to the owner or occupant is issued. The written notice also serves as a permanent record or report of the inspection.

### Inspection

Inspections are careful examinations of plans or premises for the presence of fire and life safety hazards. Upon observing a hazardous condition, the fire code official begins a process directed at correcting the situation. This may be accomplished by removing or eliminating the hazardous condition or providing some countermeasure designed to lessen its effects on the property, occupants or neighbors. Inspections should demonstrate a systematic method that keeps the inspection process in a proper perspective and recognizes that code enforcement is limited to legal and technical means of pursuing fire safety. Achieving fire safety objectives means using a balanced approach composed of some elements seeking to prevent ignitions and others attempting to control fire effects. Fire safety objectives are not defined by the code but rather by the users. Each jurisdiction must establish what risks and costs are reasonable while pursuing fire safety.

There may be as many different methods of conducting inspections as there are inspectors. No single method is necessarily the correct one; however, each method probably has some strong and weak points. The following three approaches can form the basis for any number of different inspection techniques.

*Outside to inside:* Beginning outside is not only logical but necessary. Inspectors too often neglect hazards and clues outside the building that suggest significant danger to the occupants. An inspector must ask the following question: "Do the things I see outside match those I see inside?" For example:

- Do doors identified as exits inside actually discharge outside to acceptable refuge areas or the public way?

- Are trash receptacles or other obstructions outside located so the effectiveness of exits is not reduced, or do receptacles alone pose a fire hazard?
- Does the site permit sufficient access for fire-fighter rescue operations and fire suppression?

*Top to bottom:* Once inside a structure, deciding where to start is more than a matter of preference. One question inspectors may ask is: "If completeness is the principal criterion, why not start at the bottom and work up?" The answer to this question is that walking down stairs is easier than walking up stairs. This easier path of travel allows the inspector to concentrate more completely on the inspection itself. After performing many inspections, there will not be a need for additional exercise obtained from beginning at the bottom.

*General to specific:* Without constructing a detailed inspection framework, many fire code officials find it helpful to move from the general to the specific when evaluating occupancies and hazards. This helps keep the whole problem in focus while preserving attention to detail. The inspector can focus on a specific problem without losing sight of the "big picture."

### Detection

Systematic inspection procedures, like those described, should aid in the detection of code violations. By keeping the premises, processes or objectives in clear focus, the inspector keeps the task in context. A systematic inspection process implies not only organization but an understanding of the entire process. Achieving fire safety objectives means understanding how structures, premises, occupants and fire interact [see Commentary Figure 1(5)]. To keep the system in balance and prevent uncontrolled fires means understanding how people use structures and premises.

Figure 1(5)  
HOW BUILDINGS, PEOPLE AND FIRE INTERACT

In such a context, a fire hazard is anything that either fails to prevent an uncontrolled fire or permits a fire to spread unchecked. Similarly, hazardous conditions are

those preventing occupants from escaping or fire fighters from entering a structure and premises to control a fire.

**Notification**

Inspection programs cannot identify and abate all hazards. Code enforcement alone cannot secure absolute protection for people and property. Further, many code requirements maintain or reinforce features not intended to prevent a fire but rather to minimize a fire's effects should one occur. Every inspection program, therefore, should consider the benefits of educating building owners and occupants about the hazards endangering their lives and property. Not only do such efforts help secure compliance with code requirements, but they are likely to secure long-term commitments to fire safety as well. Another equally apt metaphor describes the fire prevention process as the "Three E's": engineering, education and enforcement. A balanced approach composed of these three elements can be an especially effective way of achieving desired fire safety objectives.

**Reporting**

The first three elements of the code enforcement process are directed at identifying and eliminating hazards at their source. Reporting is intended to help document and reinforce the lessons learned from the previous three phases. The words, "If it's not written down, it didn't happen!" reinforce the message that reporting is just as important as any of the other three elements of the code enforcement system. Few people enjoy paperwork. Without documentation, however, prosecuting an effective code enforcement program becomes nearly

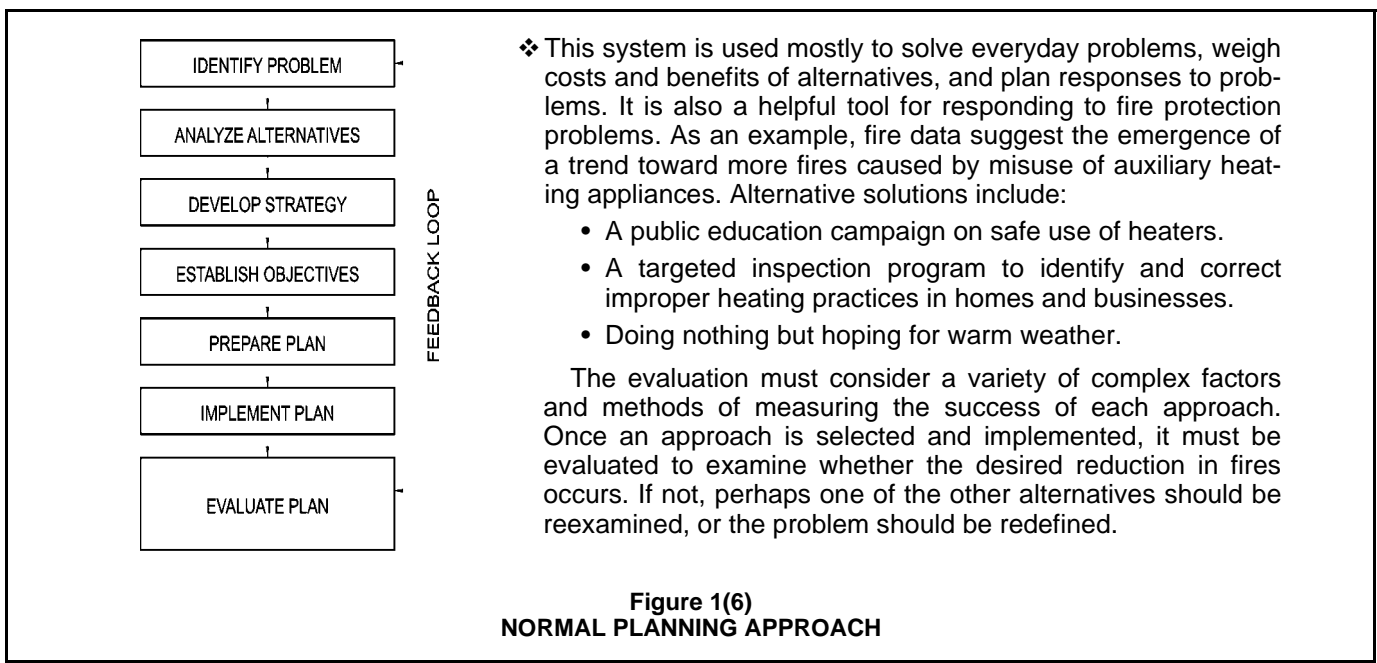

impossible. Accurate, concise and timely records are essential for both legal and historical reasons. Documenting the inspection and violation history of a particular premises or owner is essential when prosecuting criminal actions under the code provisions.

Commentary Figure 1(6) illustrates a systems approach using data generated by fire incidents and inspections to direct code enforcement, public education activities or code development. This approach is equivalent to the one typically used to make ordinary decisions about problems with many competing solutions, to plan for the future and to consider the cost and benefits of these decisions.

Understanding the code administration process and the environment influencing it allows the fire code official to be more effective. Adhering to the provisions of Chapter 1 not only minimizes the fire code official's liability, but also provides an effective code enforcement program. Just as owners and occupants have obligations under the code, so does the fire code official. Following these procedures enables him or her to identify and respond to the community's needs, thus reducing the community's fire risk.

**Purpose**

Chapter 1 establishes provisions to ensure that code administration and enforcement is reasonable, appropriate and fair. This chapter outlines the duties and powers of the fire code official; the scope of the fire code official's authority to enforce the code; the applicability of the document and proofs of compliance; the means of securing compliance with its provisions and procedures for protecting due process rights of applicants, owners, occupants and others affected by the code provisions and the enforcement activities of the fire code official.

## PART 1—GENERAL PROVISIONS

SECTION 101  
SCOPE AND GENERAL REQUIREMENTS

[A] **101.1 Title.** These regulations shall be known as the *Fire Code* of [NAME OF JURISDICTION], hereinafter referred to as “this code.”

❖ This section identifies jurisdictional applicability in legal terms. The local jurisdiction is to insert its name into this section by including a modification to the code in the adopting ordinance. This will make the code applicable to the local jurisdiction. See page xxi of the code for a sample ordinance for adoption.

[A] **101.2 Scope.** This code establishes regulations affecting or relating to structures, processes, premises and safeguards regarding all of the following:

1. The hazard of fire and explosion arising from the storage, handling or use of structures, materials or devices.
2. Conditions hazardous to life, property or public welfare in the occupancy of structures or premises.
3. Fire hazards in the structure or on the premises from occupancy or operation.
4. Matters related to the construction, extension, repair, alteration or removal of fire suppression or alarm systems.
5. Conditions affecting the safety of fire fighters and emergency responders during emergency operations.

❖ The code does not attempt to achieve perfection by requiring every conceivable or available safeguard for every structure, premises or operation within the scope of the code; rather, the code seeks to establish a minimum acceptable safety level to balance the many factors that must be considered, including loss statistics, relative hazard and the economic and social impact. The code is maintained through the use of a democratic code development process so that everyone affected by these minimum requirements has an equal opportunity to present his or her concern, both for and against any of the requirements.

The question is often asked, “Does the code apply only to buildings and facilities, or does it cover vehicles as well?” Though the scope text does not specifically mention vehicles, vehicles are intended to be covered by the terms of “... use of ... devices ...” and “... occupancy of ... structures or premises ...” in Items 1 and 2 of the section. It is clear that the code specifically intends to regulate vehicles because, in some cases, there are regulations in the code that are specific to vehicles, such as those in Sections 309 and 5706. However, in most cases, unless vehicles are specifically mentioned, provisions in the code would not apply to them (see also Section 904.12).

[A] **101.2.1 Appendices.** Provisions in the appendices shall not apply unless specifically adopted.

❖ The code has several appendices, which provide additional information regarding the provisions in the code and additional regulations that are available for adoption if desired by the adopting jurisdiction. If the jurisdiction decides to include any of the appendices as part of the code, each of the appendices to be adopted must be specifically listed in the adoption ordinance for the code. A sample adoption ordinance is on page xxi of the code.

[A] **101.3 Intent.** The purpose of this code is to establish the minimum requirements consistent with nationally recognized good practice for providing a reasonable level of life safety and property protection from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises, and to provide a reasonable level of safety to fire fighters and emergency responders during emergency operations.

❖ Code requirements regulate conditions that are likely to cause or contribute to fires or explosions, endanger life or property if a fire occurs or contribute to the spread of a fire. The intent of the code is to regulate conditions related to the health, safety and welfare of the public, the fire fighters and other emergency responders called upon to conduct emergency operations in or on any building, structure or premises. Note that the code requirements are minimum (see commentary, Section 101.2 for a discussion on minimum requirements).

While the code does serve as a maintenance code for buildings constructed in accordance with the IBC, it has provisions that go far beyond maintenance of construction regulations for buildings. Much of the code prescribes construction regulations of several sorts, which can be seen throughout the code in the general provisions for safety and in special occupancies, processes and equipment. These regulations supplement the construction regulations in the IBC for cases where special hazards exist.

A common question that arises is, “Is it the intent of the code to apply to noncommercial structures?” Yes. The code applies to all structures within a jurisdiction, including residential occupancies, unless such occupancies are specifically excluded within the text of a particular code section. For example, Sections 503.1.1 and 507.1 require that all occupancies, including residential occupancies, be provided with fire apparatus access and a water supply for fire fighting. Though it is true that there are many provisions in the code that would not normally be applicable to a residential occupancy based on the scope of the particular provision, the overall application of the code is not limited to commercial structures (see the commentary to Section 503.1.1 and Appendix D107.1 for further discussion of this topic).

## SCOPE AND ADMINISTRATION

[A] **101.4 Severability.** If a section, subsection, sentence, clause or phrase of this code is, for any reason, held to be unconstitutional, such decision shall not affect the validity of the remaining portions of this code.

- ❖ All sections of the code not invalidated by legal action remain in effect. While a dispute over a particular issue (such as hazardous materials quantity limitation) may have caused litigation that resulted in the provision being found unconstitutional, the remainder of the code is still applicable.

[A] **101.5 Validity.** In the event any part or provision of this code is held to be illegal or void, this shall not have the effect of making void or illegal any of the other parts or provisions hereof, which are determined to be legal; and it shall be presumed that this code would have been adopted without such illegal or invalid parts or provisions.

- ❖ The code provisions are intended to be construed as severable. If any part of the code is ruled invalid by a court of competent jurisdiction, the remaining sections of the code are intended to stand as though the invalid section never existed. Fire code officials and adopting bodies should carefully and promptly evaluate the impact of any such ruling on ongoing enforcement activities and the remaining code provisions. Such changes that are necessary to preserve and protect the enforcement authority of the jurisdiction and the public should be instituted through legislative action as soon as practical. Additionally, the International Code Council® (ICC®) should be advised of court actions invalidating any code provisions. For the same reason local officials must evaluate the effects of court decisions, the influence of court decisions on the remainder of the code must be evaluated for national impact.

### SECTION 102 APPLICABILITY

[A] **102.1 Construction and design provisions.** The construction and design provisions of this code shall apply to:

1. Structures, facilities and conditions arising after the adoption of this code.
  2. Existing structures, facilities and conditions not legally in existence at the time of adoption of this code.
  3. Existing structures, facilities and conditions where required in Chapter 11.
  4. Existing structures, facilities and conditions that, in the opinion of the *fire code official*, constitute a distinct hazard to life or property.
- ❖ This section establishes the scope of application of the code provisions that regulate construction and design. Construction and design requirements include, but are not limited to, the installation of fire protection systems; drainage and secondary containment facilities for hazardous materials; fire-resistive construction and the activities stated in Section 105.7 for which a construction permit is required.

Item 1 specifies that the construction and design code requirements apply to new construction that occurs following the adoption of the code.

Item 2 means that the construction and design code requirements are to apply to existing structures that did not have a certificate of occupancy at the time the code was adopted. An example would be a building that was built when there was no adopted construction code in the jurisdiction.

Item 3 refers to Chapter 11, "Construction Requirements for Existing Buildings," which was added in the 2009 edition of the code to assemble in a single location all of the construction and design code requirements that specifically target existing structures, facilities and conditions for retroactive application, which had previously been scattered throughout the code.

Item 4 generally requires the fire code official to determine that a "distinct hazard to life or property" exists prior to enforcing a construction and design code provision retroactively. Simply claiming that a violation exists because a building does not comply with the most recent edition of the code does not necessarily establish that a hazard actually exists. The fire code official should be prepared to demonstrate, based on evidence or case histories that would be defensible in a court of law, that a distinct hazard exists. This would be especially true where enforcement would result in substantial expense to the property owner or when a building has remained in compliance with the edition of the code under which it was originally constructed.

Further legal counsel should be consulted prior to the retroactive application of the code in order to establish the defensibility of the fire code official's determination in a court of law. Also, similar occupancies in the jurisdiction should be treated equally using a written policy to avoid the possibility of charges of selective enforcement.

[A] **102.2 Administrative, operational and maintenance provisions.** The administrative, operational and maintenance provisions of this code shall apply to:

1. Conditions and operations arising after the adoption of this code.
  2. Existing conditions and operations.
- ❖ This section specifies that the administrative, operational and maintenance requirements of the code apply to conditions and operations that exist when the code is adopted and new conditions and operations that begin after the code is adopted. Although Sections 102.1 and 102.2 are the controlling sections for retroactive application of the code to existing buildings, they do not provide for retroactive code application solely on the basis of a change in ownership or the occupying tenant. If a change in the occupancy group or the character of use occurs, the current edition of the code becomes enforceable. In such cases, Section 102.3 also applies.

**[A] 102.3 Change of use or occupancy.** Changes shall not be made in the use or occupancy of any structure that would place the structure in a different division of the same group or occupancy or in a different group of occupancies, unless such structure is made to comply with the requirements of this code and the *International Building Code*. Subject to the approval of the *fire code official*, the use or occupancy of an existing structure shall be allowed to be changed and the structure is allowed to be occupied for purposes in other groups without conforming to all of the requirements of this code and the *International Building Code* for those groups, provided the new or proposed use is less hazardous, based on life and fire risk, than the existing use.

❖ A change in occupancy in an existing structure may change the level of inherent hazards that the code was initially intended to address.

Regardless of whether the change is to an occupancy considered to be more or less hazardous, this section applies the provisions of the IBC for new construction to the existing structure with the new occupancy to match the specific requirements of the code to the specific hazards of the new occupancy. For example, a change from an existing Group M mercantile occupancy to a Group B business occupancy renders all Group B provisions applicable to all portions of the structure where the occupancy has changed, or that are adversely affected by the change.

**[A] 102.4 Application of building code.** The design and construction of new structures shall comply with the *International Building Code*, and any *alterations*, additions, changes in use or changes in structures required by this code, which are within the scope of the *International Building Code*, shall be made in accordance therewith.

❖ The code is the companion fire and life safety maintenance code to the IBC. Maintenance of other building features is governed by other *International Codes*<sup>®</sup> (I-Codes<sup>®</sup>). When existing buildings change occupancy group or are altered, increased in area or demolished, the IBC provisions must apply. When compliance with the code requires alterations, additions or modifications within the scope of the IBC, the IBC regulations and the building official's authority must prevail. This makes it essential that the code officials responsible for enforcing the building and fire codes establish a sound working relationship. Clear communication is essential to achieve compliance with the respective code officials' orders.

**[A] 102.5 Application of residential code.** Where structures are designed and constructed in accordance with the *International Residential Code*, the provisions of this code shall apply as follows:

1. Construction and design provisions of this code pertaining to the exterior of the structure shall apply including, but not limited to, premises identification, fire apparatus access and water supplies. Where interior or exterior systems or devices are installed, construc-

tion permits required by Section 105.7 of this code shall apply.

2. Administrative, operational and maintenance provisions of this code shall apply.

❖ This section clarifies the extent to which the *International Residential Code*<sup>®</sup> (IRC<sup>®</sup>) and the code are interrelated and how the provisions of the code apply to the development of one- and two-family dwelling projects built under the IRC.

The IRC is designed and intended for use as a stand-alone code for the construction of detached one- and two-family dwellings and townhouses not more than three stories in height. As such, the construction of detached one- and two-family dwellings and townhouses is regulated exclusively by the IRC and not subject to the provisions of any other I-Codes other than to the extent specifically referenced. Although the IRC regulates the construction of detached one- and two-family dwellings and townhouse structures, it does not regulate the design and construction of emergency access to and community fire protection for residential developments containing such dwelling structures. Accordingly, where the code is adopted, the design, construction, regulation and maintenance of fire apparatus access roads for servicing such residential developments must comply with the provisions of Section 503 and, if adopted, Appendix D. Also, the design, construction, regulation and maintenance of fire protection water supplies for servicing such residential developments must comply with the provisions of Section 507 and, if adopted, Appendices B and C. These specific requirements of the code are applicable because they include design and construction regulations that provide necessary emergency access and community fire protection for residential developments containing structures that are regulated within the scope of the IRC.

**[A] 102.6 Historic buildings.** The provisions of this code relating to the construction, *alteration*, repair, enlargement, restoration, relocation or moving of buildings or structures shall not be mandatory for existing buildings or structures identified and classified by the state or local jurisdiction as historic buildings where such buildings or structures do not constitute a distinct hazard to life or property. Fire protection in designated historic buildings shall be provided with an *approved* fire protection plan as required in Section 1103.1.1.

❖ This section provides a blanket exception from code requirements when the building in question has historic value. The most important criterion for application of this section is that the building must be recognized by a qualified party or agency as having historic significance. Usually this is done by a state or local authority after considerable scrutiny of the historical value of the building. Most, if not all, states have such authorities, as do many local jurisdictions. The agencies with such authority can be located at the state or local government level or through the

local chapter of the American Institute of Architects (AIA). This section does require an approved fire protection plan. More specifically reference is made to Section 1103.1.1, which provides some minimal requirements. Section 1103.1.1 requires a plan to be developed in accordance with NFPA 914. The reference to NFPA 914 provides specific guidance to code officials, design professionals and building owners as to the provisions that are applicable to fire protection plans for historic buildings in order to provide a reasonable level of building and life safety provisions.

**[A] 102.7 Referenced codes and standards.** The codes and standards referenced in this code shall be those that are listed in Chapter 80, and such codes and standards shall be considered to be part of the requirements of this code to the prescribed extent of each such reference and as further regulated in Sections 102.7.1 and 102.7.2.

❖ The use of referenced codes and standards to cover certain aspects of various occupancies and operations rather than write parallel or competing requirements into the code is a long-standing and successful code development principle. Often, however, questions and potential conflicts in the use of referenced codes and standards can arise, which can lead to inconsistent enforcement of the code. This section establishes the relationship between the code and the codes or standards that it references. A referenced code or standard or portion thereof is to be considered an enforceable extension of the code as if the specified content of the referenced code or standard were included in the body of the code. The extent to which the provisions of a referenced standard may be enforced is limited to those portions of the standard that are specifically identified in the code section that makes the reference. As an example of such limiting references, in regard to Chapter 57, “Flammable and Combustible Liquids,” the question has been posed as to whether the entire referenced standard, NFPA 30, is applicable since it is referenced 30 times in Chapter 57. The answer is no. The applicability of NFPA 30 content would be limited to only the specific content indicated in the code section making the reference, e.g., Section 5703.6.2 limits the applicable NFPA 30 content to only Chapter 27 of that document; Section 5704.2.7 limits the applicable NFPA 30 content to only the tank design, fabrication and construction provisions of Chapters 21 and 22 or 23 of that document, and various other code sections such as 5704.2.7.8 and 5704.2.7.9 limit the reference to specifically enumerated sections of NFPA 30.

**[A] 102.7.1 Conflicts.** Where conflicts occur between provisions of this code and referenced codes and standards, the provisions of this code shall apply.

❖ Where a code section referencing a standard contains no content limitation, any applicable provisions of the standard may be applied to the extent that they do not conflict with similar provisions in the code or other I-Codes. See the commentary to Section

102.7.2 for further discussion of conflicting provisions.

**[A] 102.7.2 Provisions in referenced codes and standards.** Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code, the provisions of this code, as applicable, shall take precedence over the provisions in the referenced code or standard.

❖ This new section expands upon the provisions of Section 102.7.1 by making it clear that, even if a referenced standard contains requirements that parallel the code (or the other referenced I-Codes) in the standards own duly referenced section(s), the provisions of the code (or the other referenced I-Codes) will always take precedence. One of the most common examples of such conflicting provisions is that many referenced standards contain building construction requirements that may differ from the requirements of the IBC whose applicability is established in Section 102.4 of the code. In such cases, the IBC would supersede the standard.

**[A] 102.8 Subjects not regulated by this code.** Where applicable standards or requirements are not set forth in this code, or are contained within other laws, codes, regulations, ordinances or bylaws adopted by the jurisdiction, compliance with applicable standards of the National Fire Protection Association or other nationally recognized fire safety standards, as *approved*, shall be deemed as prima facie evidence of compliance with the intent of this code. Nothing herein shall derogate from the authority of the *fire code official* to determine compliance with codes or standards for those activities or installations within the *fire code official's* jurisdiction or responsibility.

❖ This section provides guidance for situations in which no specific standard is designated in the code or otherwise adopted by the jurisdiction. In this instance, compliance with the requirements of a standard of the NFPA or other nationally recognized standards can be approved by the fire code official.

**[A] 102.9 Matters not provided for.** Requirements that are essential for the public safety of an existing or proposed activity, building or structure, or for the safety of the occupants thereof, that are not specifically provided for by this code, shall be determined by the *fire code official*.

❖ Evolving technology in our society will sometimes result in a situation or circumstance that the code does not cover. The reasonable application of the code to such hazardous, unforeseen conditions is provided in this section. Clearly, such a section is needed and the fire code official's experience and judgment must be used. The section, however, does not override requirements that may be preferred when the code provides alternative methods. Additionally, the section can be used to implement the general performance-oriented language of the code in specific enforcement situations.

**[A] 102.10 Conflicting provisions.** Where there is a conflict between a general requirement and a specific requirement,

the specific requirement shall be applicable. Where, in a specific case, different sections of this code specify different materials, methods of construction or other requirements, the most restrictive shall govern.

- ❖ The provisions of this section provide guidance to both fire code officials and other code users on the application of the code when different sections specify different materials, methods of construction or other requirements.

The importance of this section should not be understated. It resolves the question of how to handle conflicts between the general and specific provisions found in the code or those instances where different sections specify different requirements. This section provides a necessary hierarchy for application of code provisions and clarifies code applications that would otherwise leave persistent questions and lead to debate. The code requires that where different sections of the code apply but contain different requirements, the most restrictive provisions shall govern. The code also resolves conflicts between the general requirements of any particular issue with any specific requirements of the same issue by indicating that the specific requirements take precedence over the general requirements.

**[A] 102.11 Other laws.** The provisions of this code shall not be deemed to nullify any provisions of local, state or federal law.

- ❖ Compliance with the requirements of the code does not entail authorization, approval or permission to violate the regulations of other local, state or federal laws. Other laws, ordinances and regulations not regulated or enforced by the fire code official could be in existence and enforced by another authority having jurisdiction over those provisions. Although the requirements may have similar provisions to those of the code, the work must be in conformance with the other regulations.

**[A] 102.12 Application of references.** References to chapter or section numbers, or to provisions not specifically identified by number, shall be construed to refer to such chapter, section or provision of this code.

- ❖ There are many instances in the code where a reference is merely a chapter number, section number or, in some cases, a provision not specified by number. In all such situations, these references are to the content of the code and not some other code or publication.

## PART 2—ADMINISTRATIVE PROVISIONS

### SECTION 103 DEPARTMENT OF FIRE PREVENTION

**[A] 103.1 General.** The department of fire prevention is established within the jurisdiction under the direction of the *fire code official*. The function of the department shall be the

implementation, administration and enforcement of the provisions of this code.

- ❖ The traditional enforcement agency for the code is the fire department or fire prevention bureau of a state, county or municipal government. Such agencies usually perform administrative functions and provide public safety services related to fire protection; however, a variety of less-traditional arrangements have also been used to enforce the code, including private corporations, such as fire districts and fire companies employed by a local government to act as its agent; police and other law enforcement agencies; building, housing or zoning authorities; and community and economic development departments. Regardless of who is designated by the legislative or administrative authority to adopt and enforce the code, this section establishes the legal duty of the fire code official to enforce the code.

**[A] 103.2 Appointment.** The *fire code official* shall be appointed by the chief appointing authority of the jurisdiction; and the *fire code official* shall not be removed from office except for cause and after full opportunity to be heard on specific and relevant charges by and before the appointing authority.

- ❖ A fire code official's independence is essential so that public safety decisions are not based on political, economic or social expediency. This is not to say that social, political and economic considerations should not matter when deciding some code questions, but the interests of public health, safety and welfare must not be compromised to achieve such objectives. Protection of officials from removal from office without cause helps ensure that reasonable and competent professionals will be willing to serve.

**[A] 103.3 Deputies.** In accordance with the prescribed procedures of this jurisdiction and with the concurrence of the appointing authority, the *fire code official* shall have the authority to appoint a deputy *fire code official*, other related technical officers, inspectors and other employees.

- ❖ Most jurisdictions require more than one official to enforce the code. With the technical and legal demands on code enforcers increasing, additional personnel will certainly be required in this area to serve adequately the public interest. Though the professional qualifications of fire code officials are not detailed in the code, individuals appointed to code enforcement positions should be technically competent, motivated, well-adapted and possess good written and oral communication skills.

Many jurisdictions find it helpful, if not essential, to appoint an individual who is second-in-command and who would assume leadership of the organization in the absence of the chief code enforcement official.

**[A] 103.4 Liability.** The *fire code official*, member of the board of appeals, officer or employee charged with the enforcement of this code, while acting for the jurisdiction, in good faith and without malice in the discharge of the duties required by this code or other pertinent law or ordinance,

## SCOPE AND ADMINISTRATION

shall not thereby be rendered civilly or criminally liable personally, and is hereby relieved from all personal liability for any damage accruing to persons or property as a result of an act or by reason of an act or omission in the discharge of official duties.

❖ The fire code official, other department employees and members of the appeals board are not intended to be held liable, both civilly or criminally, for those actions performed in accordance with the code in a reasonable and lawful manner. However, the responsibility of the fire code official in this regard is subject to local, state and federal laws that may supersede this provision. This section further establishes that fire code officials (or subordinates) must not be liable for costs in any legal action instituted in response to the performance of lawful duties. Section 103.4.1 states that those costs are to be borne by the state, county or municipality, as applicable. The best way to be certain that the fire code official's action is a "lawful duty" is always to cite the applicable code section on which the enforcement action is based.

**[A] 103.4.1 Legal defense.** Any suit or criminal complaint instituted against any officer or employee because of an act performed by that officer or employee in the lawful discharge of duties and under the provisions of this code shall be defended by the legal representatives of the jurisdiction until the final termination of the proceedings. The *fire code official* or any subordinate shall not be liable for costs in an action, suit or proceeding that is instituted in pursuance of the provisions of this code; and any officer of the department of fire prevention, acting in good faith and without malice, shall be free from liability for acts performed under any of its provisions or by reason of any act or omission in the performance of official duties in connection therewith.

❖ Section 103.4 establishes that fire code officials or subordinates must not be liable for costs in any legal action, whether criminal or civil in nature, in response to the performance of lawful duties. This section states that these costs must be borne by the state or municipality. The best way to be certain that the fire code official's action is a lawful duty is to always cite the applicable code section substantiating the action.

## SECTION 104

### GENERAL AUTHORITY AND RESPONSIBILITIES

**[A] 104.1 General.** The *fire code official* is hereby authorized to enforce the provisions of this code and shall have the authority to render interpretations of this code, and to adopt policies, procedures, rules and regulations in order to clarify the application of its provisions. Such interpretations, policies, procedures, rules and regulations shall be in compliance with the intent and purpose of this code and shall not have the effect of waiving requirements specifically provided for in this code.

❖ The duty of the fire code official is to enforce the code. Because the fire code official must also act on all questions related to this responsibility, except as

specifically exempted by statutory requirements or elsewhere in the code, the fire code official is the "authority having jurisdiction" for all matters relating to the code and its enforcement.

This section also gives the fire code official interpretation authority. Note, however, that the interpretations are to be consistent with the intent and purpose of the code and are not allowed to set aside any specific requirement in the code.

**[A] 104.2 Applications and permits.** The *fire code official* is authorized to receive applications, review *construction documents* and issue permits for construction regulated by this code, issue permits for operations regulated by this code, inspect the premises for which such permits have been issued and enforce compliance with the provisions of this code.

❖ The fire code official is obligated to receive, review and act on permit applications required by the code as detailed in Section 105. All permitted premises must be inspected either before or after the permit is issued to determine compliance with the code provisions and terms of the permit.

**[A] 104.3 Right of entry.** Where it is necessary to make an inspection to enforce the provisions of this code, or where the *fire code official* has reasonable cause to believe that there exists in a building or upon any premises any conditions or violations of this code that make the building or premises unsafe, dangerous or hazardous, the *fire code official* shall have the authority to enter the building or premises at all reasonable times to inspect or to perform the duties imposed upon the *fire code official* by this code. If such building or premises is occupied, the *fire code official* shall present credentials to the occupant and request entry. If such building or premises is unoccupied, the *fire code official* shall first make a reasonable effort to locate the *owner*, the *owner's* authorized agent or other person having charge or control of the building or premises and request entry. If entry is refused, the *fire code official* has recourse to every remedy provided by law to secure entry.

❖ This section establishes the right of the fire code official to enter the premises to make the permit inspections required by Section 105.2.2. Permit application forms typically include a statement in the certification signed by the applicant (who is the owner or owner's authorized agent) granting the fire code official the authority to enter areas covered by the permit to enforce related code provisions.

The right to enter other structures or premises is more limited. First, to protect the right of privacy, the owner or occupant must grant the building official permission before an interior inspection of the property can be conducted. Permission is not required for inspections that can be accomplished from within the public right-of-way. Second, such access may be denied by the owner or occupant. Unless the inspector has reasonable cause to believe that a violation of the code exists, access may be unattainable. Third, fire code officials must present proper identification (see Section 104.4) and request admittance during

reasonable hours—usually the normal business hours of the establishment—to be admitted. Fourth, inspections must be aimed at securing or determining compliance with the provisions and intent of the regulations that are specifically within the established scope of the fire code official's authority.

Searches to gather information for the purpose of enforcing other codes, ordinances or regulations are considered unreasonable and are prohibited by the Fourth Amendment to the U.S. Constitution. "Reasonable cause" in the context of this section must be distinguished from "probable cause," which is required to gain access to property in criminal cases. The burden of proof establishing reasonable cause may vary among jurisdictions. Usually, an inspector must show that the property is subject to inspection under the provisions of the code; that the interests of the public health, safety and welfare outweigh the individual's right to maintain privacy and that such an inspection is required solely to determine compliance with the provisions of the code.

Many jurisdictions do not recognize the concept of an administrative warrant and may require the fire code official to prove probable cause in order to gain access upon refusal. This burden of proof is usually more substantial, often requiring the fire code official to stipulate in advance why access is needed (usually access is restricted to gathering evidence for seeking an indictment or making an arrest); what specific item or information is sought; its relevance to the case against the individual subject; how knowledge of the relevance of the information or items sought was obtained; and how the evidence sought will be used. In all such cases, the right to privacy must always be weighed against the right of the fire code official to conduct an inspection to verify that public health, safety and welfare are not in jeopardy. Such important and complex constitutional issues should be discussed with the jurisdiction's legal counsel. Jurisdictions should establish procedures for securing the necessary court orders when an inspection is deemed necessary following a refusal.

**[A] 104.3.1 Warrant.** Where the *fire code official* has first obtained a proper inspection warrant or other remedy provided by law to secure entry, an *owner*, the *owner's* authorized agent or occupant or person having charge, care or control of the building or premises shall not fail or neglect, after proper request is made as herein provided, to permit entry therein by the *fire code official* for the purpose of inspection and examination pursuant to this code.

❖ Very simply, the requirements in this section specify that when the fire code official has obtained a warrant to inspect the property, the owner, owner's authorized agent or occupant is to allow the fire code official entry to do the inspection (see commentary, Section 104.3).

**[A] 104.4 Identification.** The *fire code official* shall carry proper identification when inspecting structures or premises in the performance of duties under this code.

❖ This section requires the fire code official (including, by definition, all authorized designees) to carry appropriate official identification in the course of conducting the duties of the position. Such official identification may take the form of a badge, an identification card or both and removes any question as to the purpose and authority of the inspector.

**[A] 104.5 Notices and orders.** The *fire code official* is authorized to issue such notices or orders as are required to affect compliance with this code in accordance with Sections 109.1 and 109.2.

❖ The fire code official is required to issue orders to abate illegal or hazardous conditions and to pursue correction or abatement of hazardous conditions by issuing legal notices and orders as described by the code. Courts are increasingly ruling that failure to follow up and pursue appropriate legal remedies promptly exposes both the fire code official and the jurisdiction to a liability in tort.

**[A] 104.6 Official records.** The *fire code official* shall keep official records as required by Sections 104.6.1 through 104.6.4. Such official records shall be retained for not less than 5 years or for as long as the structure or activity to which such records relate remains in existence, unless otherwise provided by other regulations.

❖ In keeping with the need for an efficiently conducted business practice, the fire code official must keep official records. Such documentation provides a valuable resource of information if questions arise throughout the life of the building and its occupants. The code requires that the construction documents be kept until the project is complete or for at least 5 years, whichever is longer.

**[A] 104.6.1 Approvals.** A record of approvals shall be maintained by the *fire code official* and shall be available for public inspection during business hours in accordance with applicable laws.

❖ Records of prior approvals may be needed to determine the status of an existing operation or for future validation of a specific condition.

**[A] 104.6.2 Inspections.** The *fire code official* shall keep a record of each inspection made, including notices and orders issued, showing the findings and disposition of each.

❖ Records of inspections are needed to support the issuance of a certificate of occupancy. The inspection records should document any code violations that were subsequently corrected.

**104.6.3 Fire records.** The fire department shall keep a record of fires occurring within its jurisdiction and of facts concerning the same, including statistics as to the extent of such fires

and the damage caused thereby, together with other information as required by the *fire code official*.

- ❖ Fire records provide a history of the fire experience of a facility and a cumulative record for all of the facilities of a jurisdiction. Fire records support consideration for construction code requirements based on the need to prevent additional fire occurrences.

**[A] 104.6.4 Administrative.** Application for modification, alternative methods or materials and the final decision of the *fire code official* shall be in writing and shall be officially recorded in the permanent records of the *fire code official*.

- ❖ The written approval of modifications or alternative materials and methods of construction or operation are needed to support the approval of these items in the future. This file could be used to verify that an existing condition had been previously approved.

**[A] 104.7 Approved materials and equipment.** Materials, equipment and devices *approved* by the *fire code official* shall be constructed and installed in accordance with such approval.

- ❖ The code is a compilation of criteria with which materials, equipment, devices and systems must comply to be acceptable for a particular application. The fire code official has a duty to evaluate such materials, equipment, devices and systems for code compliance and, when compliance is determined, approve them for use. As a result of this approval, the material, equipment, device or system must be constructed and installed in compliance with that approval, and with all the conditions and limitations considered as a basis for that approval. For example, the manufacturer's instructions and recommendations are to be followed if the approval of the material was based, even in part, on those instructions and recommendations.

The approval authority given to the fire code official is a significant responsibility and is a key to code compliance. The approval process is first technical and then administrative and must be approached that way. For example, if data to determine code compliance are required, such data should be in the form of test reports or engineering analysis—not simply taken from a sales brochure.

**[A] 104.7.1 Material and equipment reuse.** Materials, equipment and devices shall not be reused or reinstalled unless such elements have been reconditioned, tested and placed in good and proper working condition and *approved*.

- ❖ Used materials, equipment and devices are considered to have completed their life span; however, adequate substitutes are occasionally not available for existing items that still serve a useful and practical purpose. In such cases, existing used equipment should be approved, provided the application is consistent with the purpose for which the equipment was designed, the function is the same as the “new” item, if one were available, and the intended use can be demonstrated as not compromising the public's safety.

**[A] 104.7.2 Technical assistance.** To determine the acceptability of technologies, processes, products, facilities, materials and uses attending the design, operation or use of a building or premises subject to inspection by the *fire code official*, the *fire code official* is authorized to require the *owner* or owner's authorized agent to provide, without charge to the jurisdiction, a technical opinion and report. The opinion and report shall be prepared by a qualified engineer, specialist, laboratory or fire safety specialty organization acceptable to the *fire code official* and shall analyze the fire safety properties of the design, operation or use of the building or premises and the facilities and appurtenances situated thereon, to recommend necessary changes. The *fire code official* is authorized to require design submittals to be prepared by, and bear the stamp of, a registered design professional.

- ❖ No one person has the technical knowledge to evaluate all of the various operations and uses from a safety standpoint. This section provides the fire code official the authority to require the owner or owner's authorized agent to provide a technical opinion safety report. The report is to be prepared by parties that have the technical ability to evaluate the design of the facility or the operational process in question. A registered design professional is commonly used for these services. It is critical that the preparer of the report have the proper background and experience for the project since the credibility of the report depends on these qualifications.

**[A] 104.8 Modifications.** Where there are practical difficulties involved in carrying out the provisions of this code, the *fire code official* shall have the authority to grant modifications for individual cases, provided the *fire code official* shall first find that special individual reason makes the strict letter of this code impractical and the modification is in compliance with the intent and purpose of this code and that such modification does not lessen health, life and fire safety requirements. The details of action granting modifications shall be recorded and entered in the files of the department of fire prevention.

- ❖ The fire code official may amend or make exceptions to the code as needed to respond to “practical difficulties” in work on new or existing buildings. Consideration of a particular difficulty is to be based on the application of the owner and a demonstration that the intent of the code is satisfied. This section is not intended to allow a code provision to be set aside or ignored; rather, it is intended to provide for the acceptance of equivalent protection. Such modifications do not, however, extend to actions that are necessary to correct violations of the code. In other words, a code violation or the expense of correcting a code violation cannot constitute a practical difficulty.

Comprehensive written records are an essential part of an effective administrative system. Unless clearly written records of the considerations and documentation used in the modification process are created and maintained, subsequent enforcement action cannot be supported.

**[A] 104.9 Alternative materials and methods.** The provisions of this code are not intended to prevent the installation of any material or to prohibit any method of construction not specifically prescribed by this code, provided that any such alternative has been *approved*. The *fire code official* is authorized to approve an alternative material or method of construction where the *fire code official* finds that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, at least the equivalent of that prescribed in this code in quality, strength, effectiveness, *fire resistance*, durability and safety. Where the alternative material, design or method of construction is not approved, the *fire code official* shall respond in writing, stating the reasons why the alternative was not approved.

- ❖ Performance requirements have replaced detailed specifications to permit ready substitution and integration of new technologies in the marketplace. The code is not intended to restrict or prevent the development or application of new technologies or applications of existing technologies, provided they meet the intent of the code to protect public health, safety and welfare. When new methods or materials are developed, they should be evaluated.

The fire code official has the authority to recognize alternative and equivalent methods and materials, provided they maintain the level of protection required by the code. One of the most frequent criticisms of codes is that their provisions apply too broadly to classes of occupancies and, therefore, are incapable of recognizing the inherent dissimilarities within occupancy groups. While some criticism may be justified, it is the fire code official's duty to evaluate scrupulously the conditions in each case, as well as judge whether the intent of the code (to provide the minimum acceptable level of protection to life and property) is met. Fire code officials should, therefore, be prepared to use decision aids, the appeal process and outside experts as needed to show that code requirements are met.

The last sentence is similar to that included in Section 105.2.1 when a permit application is rejected. The reason for this additional level of communication is that the nonapproval of an alternative method is not the same as the nonapproval of a permit. In other words, the permit application may have been approved but an alternative method might not be approved until a later date. However, the reasons for responding to the applicant in writing are the same. In order to ensure effective communication and due process of law, the reasons for denial are required to be in writing. Similar language is found in all of the I-Codes.

**[A] 104.9.1 Research reports.** Supporting data, where necessary to assist in the approval of materials or assemblies not specifically provided for in this code, shall consist of valid research reports from *approved* sources.

- ❖ When an alternative material or method is proposed for construction, it is incumbent upon the fire code

official to determine whether the alternative is, in fact, equivalent to the methods prescribed by the code. Reports providing evidence of this equivalency are required to be supplied by an approved source, meaning a source that the fire code official finds to be reliable and accurate. The ICC Evaluation Service (ICC-ES) is an example of an agency that provides research reports for alternative materials and methods.

**[A] 104.9.2 Tests.** Where there is insufficient evidence of compliance with the provisions of this code, or evidence that a material or method does not conform to the requirements of this code, or in order to substantiate claims for alternative materials or methods, the *fire code official* shall have the authority to require tests as evidence of compliance to be made at no expense to the jurisdiction. Test methods shall be as specified in this code or by other recognized test standards. In the absence of recognized and accepted test methods, the *fire code official* shall approve the testing procedures. Tests shall be performed by an *approved* agency. Reports of such tests shall be retained by the *fire code official* for the period required for retention of public records.

- ❖ To provide the basis on which the fire code official can make a decision regarding an alternative material or method, sufficient technical data, test reports and documentation must be provided for evaluation. If evidence satisfactory to the fire code official indicates that the alternative material or construction method is equivalent to that required by the code, he or she may approve it. Any such approval cannot have the effect of waiving any requirements of the code. The burden of proof of equivalence lies with the applicant who proposes the use of alternative materials or methods.

The fire code official must require the submission of any appropriate information and data to assist in the determination of equivalency. This information must be submitted before a permit can be issued. The type of information required includes test data in accordance with referenced standards, evidence of compliance with the referenced standard specifications and design calculations. A research report issued by an authoritative agency is particularly useful in providing the fire code official with the technical basis for evaluation and approval of new and innovative materials and methods of construction. The use of authoritative research reports can greatly assist the fire code official by reducing the time-consuming engineering analysis necessary to review these materials and methods. Failure to substantiate adequately a request for the use of an alternative is a valid reason for the building official to deny a request. Any tests submitted in support of an application must have been performed by an agency approved by the fire code official based on evidence that the agency has the technical expertise, equipment and quality assurance to properly conduct and report the necessary testing. The test reports submitted to the fire code official must be retained in accordance with the requirements of Section 104.6.

**104.10 Fire investigations.** The *fire code official*, the fire department or other responsible authority shall have the authority to investigate the cause, origin and circumstances of any fire, explosion or other hazardous condition. Information that could be related to trade secrets or processes shall not be made part of the public record, except as directed by a court of law.

❖ The prompt and thorough investigation of fires is important for many reasons, not the least of which is the identification of incendiary fires and prosecution of arsonists. In such cases, the duty of the fire code official is clear—evidence must be preserved and leads pursued through criminal prosecution, if possible. However, a more important and frequently overlooked aspect of fire investigation is loss analysis. Whether or not the fire code official has jurisdiction to investigate incendiary fires and prosecute arsonists, it is extremely important that the enforcement agency be involved in the process of determining why fires occur; what can be done to prevent fires; how their effects can be lessened and how people behave once fires occur. Such lessons gleaned from past tragedies have influenced the code-development efforts of various organizations across the country

**104.10.1 Assistance from other agencies.** Police and other enforcement agencies shall have authority to render necessary assistance in the investigation of fires when requested to do so.

❖ When needed, the fire code official has the authority to ask for assistance from the police department or other enforcement agencies, such as fire code officials in nearby jurisdictions, to investigate fires.

**104.11 Authority at fires and other emergencies.** The fire chief or officer of the fire department in charge at the scene of a fire or other emergency involving the protection of life or property, or any part thereof, shall have the authority to direct such operation as necessary to extinguish or control any fire, perform any rescue operation, investigate the existence of suspected or reported fires, gas leaks or other hazardous conditions or situations, or take any other action necessary in the reasonable performance of duty. In the exercise of such power, the fire chief is authorized to prohibit any person, vehicle, vessel or thing from approaching the scene, and is authorized to remove, or cause to be removed or kept away from the scene, any vehicle, vessel or thing that could impede or interfere with the operations of the fire department and, in the judgment of the fire chief, any person not actually and usefully employed in the extinguishing of such fire or in the preservation of property in the vicinity thereof.

❖ This section describes the specific conditions of authority that are granted to the fire code official at a fire or other emergencies. The first half of the paragraph simply describes the fire code official's authority to carry out the fire operation at the site. The fire code official also needs to be able to control who and what is allowed to be at the site so that emergency operations are not hampered.

**104.11.1 Barricades.** The fire chief or officer of the fire department in charge at the scene of an emergency is authorized to place ropes, guards, barricades or other obstructions across any street, alley, place or private property in the vicinity of such operation so as to prevent accidents or interference with the lawful efforts of the fire department to manage and control the situation and to handle fire apparatus.

❖ This section gives the fire code official the authority to control access to the emergency site so that fire-fighting operations can occur without interference. This authority is also addressed in Section 104.11.

**104.11.2 Obstructing operations.** Persons shall not obstruct the operations of the fire department in connection with extinguishment or control of any fire, or actions relative to other emergencies, or disobey any lawful command of the fire chief or officer of the fire department in charge of the emergency, or any part thereof, or any lawful order of a police officer assisting the fire department.

❖ This section requires that fire department operations not be obstructed and that directions from the fire department official in command at the emergency site be carried out. This is necessary for efficient emergency operations.

**104.11.3 Systems and devices.** Persons shall not render a system or device inoperative during an emergency unless by direction of the fire chief or fire department official in charge of the incident.

❖ This section is an extension of the requirements in Section 104.11. The fire department official is in complete charge of the fire-fighting operation at the site. No person is to tamper with the equipment needed for the emergency.

## SECTION 105 PERMITS

**[A] 105.1 General.** Permits shall be in accordance with Sections 105.1.1 through 105.7.18.

❖ This section includes the regulations covering permits, including a comprehensive list of the kinds of activities that require permits.

**[A] 105.1.1 Permits required.** A property owner or owner's authorized agent who intends to conduct an operation or business, or install or modify systems and equipment that are regulated by this code, or to cause any such work to be performed, shall first make application to the *fire code official* and obtain the required permit.

❖ This section identifies that the property owner or an owner's authorized agent is required to make application and obtain a permit. It is important that the owner or an owner's authorized agent performs this function to confirm that they are aware of and give consent for permitted operations that may include hazardous materials that could pollute or contaminate the property. See the commentary for permit fees (Section 113.1) and keeping permits on the premises and available for inspection (Section 105.3.5).

**105.1.2 Types of permits.** There shall be two types of permits as follows:

1. Operational permit. An operational permit allows the applicant to conduct an operation or a business for which a permit is required by Section 105.6 for either:
  - 1.1. A prescribed period.
  - 1.2. Until renewed or revoked.
2. Construction permit. A construction permit allows the applicant to install or modify systems and equipment for which a permit is required by Section 105.7.

❖ The types of activities that require an operational permit are listed in Section 105.6. Construction activities that require a permit are listed in Section 105.7.

**105.1.3 Multiple permits for the same location.** Where more than one permit is required for the same location, the *fire code official* is authorized to consolidate such permits into a single permit provided that each provision is listed in the permit.

❖ The code allows for a number of activities to be included on a single permit in order to decrease the paperwork for all concerned. In this instance, the permit must list in detail the activities that are covered by the combined permit.

**[A] 105.1.4 Emergency repairs.** Where equipment replacement and repairs must be performed in an emergency situation, the permit application shall be submitted within the next working business day to the *fire code official*.

❖ This section recognizes that, in some cases, emergency replacement and repair work must be done as quickly as possible, so it is not practical to take the necessary time to apply for and obtain approval. A permit for the work must be obtained the next day that the building department is open for business. Any work performed before the permit is issued must be done in accordance with the code and corrected if not approved by the fire code official. For example, if a concealed trap failed on a Sunday, the plumber could replace the trap at that time, but he would have to apply for a permit on Monday and have the repair pass an inspection.

**[A] 105.1.5 Repairs.** Application or notice to the *fire code official* is not required for ordinary repairs to structures, equipment or systems. Such repairs shall not include the cutting away of any wall, partition or portion thereof, the removal or change of any required *means of egress*, or rearrangement of parts of a structure affecting the egress requirements; nor shall any repairs include addition to, alteration of, replacement or relocation of any standpipe, fire protection water supply, *automatic sprinkler system*, fire alarm system or other work affecting fire protection or life safety.

❖ This section distinguishes between alterations, wherein the code is to be applicable, and ordinary repairs, which are maintenance activities that do not require a permit.

**[A] 105.1.6 Annual permit.** Instead of an individual construction permit for each alteration to an already *approved* system or equipment installation, the *fire code official* is authorized to issue an annual permit upon application therefor to any person, firm or corporation regularly employing one or more qualified tradespersons in the building, structure or on the premises owned or operated by the applicant for the permit.

❖ Some large buildings or industrial facilities require repair, replacement or alteration of systems and equipment on a frequent basis. This section allows the fire code official to issue an annual permit for such work. This relieves both the fire department and the owners of such facilities from the burden of filing and processing individual applications for this activity; however, there are restrictions on who is entitled to these permits. They can be issued only for work on a previously approved installation and only to an individual or corporation that employs persons specifically qualified in the trade for which the permit is issued. If tradespeople who perform the work involved are required to be licensed in the jurisdiction, only those persons would be permitted to perform the work. If trade licensing is not required, the fire code official must review and approve the qualifications of the persons who will perform the work. The annual permit can apply only to the individual property that is owned or operated by the applicant.

**[A] 105.1.6.1 Annual permit records.** The person to whom an annual permit is issued shall keep a detailed record of alterations made under such annual permit. The *fire code official* shall have access to such records at all times or such records shall be filed with the *fire code official* as designated.

❖ The work performed in accordance with an annual permit must be inspected by the fire code official, so it is necessary to know when and where such work was performed. This can be accomplished by having records of the work available to the building official either at the premises or in the official's office, as determined by the official.

**[A] 105.2 Application.** Application for a permit required by this code shall be made to the *fire code official* in such form and detail as prescribed by the *fire code official*. Applications for permits shall be accompanied by such plans as prescribed by the *fire code official*.

❖ Applications provided by the jurisdiction should be complete, concise and relevant. Though the burden of proof is on the applicant to supply all necessary information to determine compliance with the code provisions, it is the fire code official's duty to request sufficient information to make a reasonable and informed judgment prior to approving a permit.

**[A] 105.2.1 Refusal to issue permit.** If the application for a permit describes a use that does not conform to the requirements of this code and other pertinent laws and ordinances, the *fire code official* shall not issue a permit, but shall return

the application to the applicant with the refusal to issue such permit. Such refusal shall, where requested, be in writing and shall contain the reasons for refusal.

- ❖ This section directs the fire code official not to issue a permit if the application describes a use that does not conform to the requirements of the code. Note that this direction is not advisory. The fire code official would be in violation of the code if a permit were issued in such circumstances.

**[A] 105.2.2 Inspection authorized.** Before a new operational permit is *approved*, the *fire code official* is authorized to inspect the receptacles, vehicles, buildings, devices, premises, storage spaces or areas to be used to determine compliance with this code or any operational constraints required.

- ❖ The inspections described in this section are necessary for the fire code official to determine that the application for an operational permit complies with the code prior to issuing that permit. Operations may not proceed without an operational permit.

**[A] 105.2.3 Time limitation of application.** An application for a permit for any proposed work or operation shall be deemed to have been abandoned 180 days after the date of filing, unless such application has been diligently prosecuted or a permit shall have been issued; except that the *fire code official* is authorized to grant one or more extensions of time for additional periods not exceeding 90 days each. The extension shall be requested in writing and justifiable cause demonstrated.

- ❖ Permit applications lingering indefinitely in an incomplete condition can be an administrative nuisance to the fire code official, while also overburdening the filing system. This section establishes 180 days as the time limit for the permit applicant to provide the fire code official with sufficient information to evaluate the application and take appropriate action. 180 days should normally be more than enough time for an applicant to satisfy code requirements for submittal of construction documents and all other required information.

There may be circumstances, however, that could cause an application to age beyond 180 days prior to permit issuance, such as awaiting issuance of a report by a quality assurance agency. If the fire code official is satisfied that every effort is being made by the applicant to pursue the application, an extension of time would be acceptable.

**[A] 105.2.4 Action on application.** The *fire code official* shall examine or cause to be examined applications for permits and amendments thereto within a reasonable time after filing. If the application or the *construction documents* do not conform to the requirements of pertinent laws, the *fire code official* shall reject such application in writing, stating the reasons therefor. If the *fire code official* is satisfied that the proposed work or operation conforms to the requirements of this code and laws and ordinances applicable thereto, the *fire code official* shall issue a permit therefor as soon as practicable.

- ❖ While the fire code official has the duty to take all necessary and prudent actions to determine the

applicant's compliance with the code, the evaluation must be completed promptly. Once the fire code official's review of the application is complete, either a permit will be issued or a written disapproval notice will be given. The disapproval notice must outline the reasons for rejection and should include a list of applicable code sections with which the applicant must comply to obtain approval.

**[A] 105.3 Conditions of a permit.** A permit shall constitute permission to maintain, store or handle materials; or to conduct processes that produce conditions hazardous to life or property; or to install equipment utilized in connection with such activities; or to install or modify any *fire protection system* or equipment or any other construction, equipment installation or modification in accordance with the provisions of this code where a permit is required by Section 105.6 or 105.7. Such permission shall not be construed as authority to violate, cancel or set aside any of the provisions of this code or other applicable regulations or laws of the jurisdiction.

- ❖ In effect, a permit is a contract or covenant between the jurisdiction and the applicant, allowing the applicant to operate, perform, conduct or direct a hazardous operation, process or occupancy. As with all contracts, the terms remain binding for a finite period. This process allows continual review of the applicant's compliance with the contract's terms. Failure to meet the terms of the contract may result in the applicant's forfeiture of the right to conduct or operate the process, operation or occupancy, and subsequently the fire code official may revoke the permit without further notice.

This section also states the fundamental premise that the permit is only a license to proceed with the work. It is not a license to violate, cancel or set aside any provisions of the code. This is significant because, even if there are errors or oversights in the permit approval process, the permit applicant, not the fire code official, is responsible for code compliance.

**[A] 105.3.1 Expiration.** An operational permit shall remain in effect until reissued, renewed or revoked, or for such a period of time as specified in the permit. Construction permits shall automatically become invalid unless the work authorized by such permit is commenced within 180 days after its issuance, or if the work authorized by such permit is suspended or abandoned for a period of 180 days after the time the work is commenced. Before such work recommences, a new permit shall be first obtained and the fee to recommence work, if any, shall be one-half the amount required for a new permit for such work, provided that changes have not been made and will not be made in the original construction documents for such work, and provided further that such suspension or abandonment has not exceeded one year. Permits are not transferable and any change in occupancy, operation, tenancy or ownership shall require that a new permit be issued.

- ❖ A construction permit is invalid when 180 days go by without any of the authorized work being done. The permit holder should be notified in writing that the permit is invalid, including the reasons why.

Permits are neither transferable nor assignable because they are agreements between two specific parties: the fire code official, who is acting for the jurisdiction, and the applicant. Any changes amending the application or terms of the original agreement will require a new application and permit approval.

**[A] 105.3.2 Extensions.** A permittee holding an unexpired permit shall have the right to apply for an extension of the time within which the permittee will commence work under that permit where work is unable to be commenced within the time required by this section for good and satisfactory reasons. The *fire code official* is authorized to grant, in writing, one or more extensions of the time period of a permit for periods of not more than 180 days each. Such extensions shall be requested by the permit holder in writing and justifiable cause demonstrated.

- ❖ The significant issue in this section is that an extension of time is to be granted when justifiable cause is demonstrated by the permit applicant. For example, a construction permit might be granted for certain equipment installation, but the equipment might not be received at the site until after the installation permit expires. To get a time extension, the applicant is to submit a request in writing to the fire code official, including a written explanation of why the work did not proceed within the permit time frame.

**[A] 105.3.3 Occupancy prohibited before approval.** The building or structure shall not be occupied prior to the *fire code official* issuing a permit and conducting associated inspections indicating the applicable provisions of this code have been met.

- ❖ The owner of an existing structure may request that the fire code official issue a certificate of occupancy for the structure, provided that there are no pending violations. A final inspection is usually done to verify that the work covered by the permit has been completed in accordance with the code.

**[A] 105.3.4 Conditional permits.** Where permits are required and upon the request of a permit applicant, the *fire code official* is authorized to issue a conditional permit to occupy the premises or portion thereof before the entire work or operations on the premises is completed, provided that such portion or portions will be occupied safely prior to full completion or installation of equipment and operations without endangering life or public welfare. The *fire code official* shall notify the permit applicant in writing of any limitations or restrictions necessary to keep the permit area safe. The holder of a conditional permit shall proceed only to the point for which approval has been given, at the permit holder's own risk and without assurance that approval for the occupancy or the utilization of the entire premises, equipment or operations will be granted.

- ❖ The fire code official is allowed to issue a conditional permit prior to the completion of all work. Such a permit is to be issued only when the building or structure is available for safe occupancy prior to full completion. The permit is intended to acknowledge that

some building features may not be completed even though the building is safe for occupancy.

**[A] 105.3.5 Posting the permit.** Issued permits shall be kept on the premises designated therein at all times and shall be readily available for inspection by the *fire code official*.

- ❖ Note that this section does not require the permit to be posted, but it is to be kept on site at all times for inspection by the fire code official.

**[A] 105.3.6 Compliance with code.** The issuance or granting of a permit shall not be construed to be a permit for, or an approval of, any violation of any of the provisions of this code or of any other ordinance of the jurisdiction. Permits presuming to give authority to violate or cancel the provisions of this code or other ordinances of the jurisdiction shall not be valid. The issuance of a permit based on *construction documents* and other data shall not prevent the *fire code official* from requiring the correction of errors in the *construction documents* and other data. Any addition to or alteration of *approved construction documents* shall be *approved* in advance by the *fire code official*, as evidenced by the issuance of a new or amended permit.

- ❖ This section includes an important principle regarding construction documents. The fire code official has the authority to require that errors in construction be corrected, even if the construction is based on documents that were part of the applicant's submittal for a construction permit. Thus, the code requirements are not set aside by approved drawings that may include noncomplying items of construction. Any changes amending the application or construction of the original agreement will require a new application and permit approval.

**[A] 105.3.7 Information on the permit.** The *fire code official* shall issue all permits required by this code on an *approved* form furnished for that purpose. The permit shall contain a general description of the operation or occupancy and its location and any other information required by the *fire code official*. Issued permits shall bear the signature of the *fire code official* or other *approved* legal authorization.

- ❖ This section describes the form of the permit and requires that it be either signed by the fire code official or otherwise reflect the legal authorization of the jurisdiction. In many jurisdictions, permits are electronically generated and do not require a traditional signature.

**[A] 105.3.8 Validity of permit.** The issuance or granting of a permit shall not be construed to be a permit for, or an approval of, any violation of any of the provisions of this code or of any other ordinances of the jurisdiction. Permits presuming to give authority to violate or cancel the provisions of this code or other ordinances of the jurisdiction shall not be valid. The issuance of a permit based on *construction documents*, operational documents and other data shall not prevent the *fire code official* from requiring correction of errors in the documents or other data.

- ❖ This section states the fundamental premise that the permit is only a license to proceed with the work. It is

not a license to violate, cancel or set aside any provisions of the code. This is significant because it means that despite any errors or oversights in the approval process, the permit applicant, not the fire code official, is responsible for code compliance. Also, the permit can be revoked in accordance with Section 105.5.

**[A] 105.4 Construction documents.** *Construction documents* shall be in accordance with Sections 105.4.1 through 105.4.6.

❖ This section states the scope of the sections covering construction documents.

**[A] 105.4.1 Submittals.** *Construction documents* and supporting data shall be submitted in two or more sets with each application for a permit and in such form and detail as required by the *fire code official*. The *construction documents* shall be prepared by a registered design professional where required by the statutes of the jurisdiction in which the project is to be constructed.

**Exception:** The *fire code official* is authorized to waive the submission of *construction documents* and supporting data not required to be prepared by a registered design professional if it is found that the nature of the work applied for is such that review of *construction documents* is not necessary to obtain compliance with this code.

❖ A detailed description of the work for which an application is made must be submitted in the form and detail required by the fire code official. Construction documents are to be prepared by a registered design professional when required by state laws in effect in the jurisdiction. States have professional registration laws that specify the type of construction documents to be prepared by a registered design professional. The code relies on these state laws to determine when a registered design professional is required.

The requirement for the preparation of construction documents and the submittal of calculations is specified by the code in several chapters. For example, Section 901.2 specifies that construction documents and calculations are to be submitted for fire protection systems when required by the fire code official.

**[A] 105.4.1.1 Examination of documents.** The *fire code official* shall examine or cause to be examined the accompanying *construction documents* and shall ascertain by such examinations whether the work indicated and described is in accordance with the requirements of this code.

❖ The requirements of this section are related to those found in Section 105.2.4 regarding the action of the fire code official in response to a permit application. The fire code official can delegate review of the construction documents to subordinates as provided for in Section 103.3.

**[A] 105.4.2 Information on construction documents.** *Construction documents* shall be drawn to scale upon suitable material. Electronic media documents are allowed to be submitted where *approved* by the *fire code official*. *Construction documents* shall be of sufficient clarity to indicate the loca-

tion, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code and relevant laws, ordinances, rules and regulations as determined by the *fire code official*.

❖ Construction documents are not sketches. They are comprehensive drawings, drawn to scale, that provide the details to verify the work will comply with the code. The permit applicant must be familiar with the code requirements to prepare code-compliant construction documents. If the applicant is not familiar with the code, the construction documents will most likely not have sufficient detail to determine compliance and, thus, not be satisfactory as the basis for a permit.

**[A] 105.4.2.1 Fire protection system shop drawings.** Shop drawings for the fire protection system(s) shall be submitted to indicate compliance with this code and the *construction documents*, and shall be *approved* prior to the start of installation. Shop drawings shall contain all information as required by the referenced installation standards in Chapter 9.

❖ It is common for the fire protection contractor(s) for a project not to have been selected at the time a permit is issued; thus, detailed shop drawings for fire protection systems would not be available. Because they provide the information necessary to determine code compliance, as specified in the appropriate referenced standard in Chapter 9, detailed shop drawings for fire protection systems must be submitted and approved by the fire code official before the contractor can begin installing the system. For example, the professional responsible for the design of an automatic sprinkler system should determine that the water supply is adequate, but will not be able to prepare a final set of hydraulic calculations if the specific materials and pipe sizes, lengths and arrangements have not been identified. Once the installing contractor is selected, specific hydraulic calculations can be prepared. Factors such as classification of the hazard, amount of water supply available and the density or concentration to be achieved by the system are to be included with the submission of the shop drawings. Specific data sheets identifying sprinklers, pipe dimensions, power requirements for smoke detectors, etc., should also be included with the submission.

**[A] 105.4.3 Applicant responsibility.** It shall be the responsibility of the applicant to ensure that the *construction documents* include all of the fire protection requirements and the shop drawings are complete and in compliance with the applicable codes and standards.

❖ This requirement is similar to the one in Section 901.2 regarding construction documents for fire protection systems.

The requirement in this section regarding shop drawings applies to all types of shop drawings, not just those for fire protection systems. The permit applicant is responsible for the review of the shop drawings, not the fire code official. The permit appli-

cant is also responsible for seeing that the work on the job site complies with the code. Since a lot of the construction work is done in accordance with shop drawings, the applicant should review those drawings for code compliance to make sure field construction complies with the code.

**[A] 105.4.4 Approved documents.** *Construction documents approved by the fire code official are approved with the intent that such construction documents comply in all respects with this code. Review and approval by the fire code official shall not relieve the applicant of the responsibility of compliance with this code.*

❖ The applicant is responsible for making sure that construction complies with the code. If approved drawings include errors that do not comply with the code, the fire code official still has the authority to require that the errors be corrected. Thus, it is important that the permit applicant is familiar with code requirements to prevent preparation of construction documents that do not meet the code.

**[A] 105.4.4.1 Phased approval.** *The fire code official is authorized to issue a permit for the construction of part of a structure, system or operation before the construction documents for the whole structure, system or operation have been submitted, provided that adequate information and detailed statements have been filed complying with pertinent requirements of this code. The holder of such permit for parts of a structure, system or operation shall proceed at the holder's own risk with the building operation and without assurance that a permit for the entire structure, system or operation will be granted.*

❖ The fire code official has the authority to issue a partial permit to allow for the practice of "fast tracking" a job. Any construction under a partial permit is, as stated in the code, "at the holder's own risk" and "without assurance that a permit for the entire structure, system or operation will be granted." The fire code official is under no obligation to accept work or issue a complete permit in violation of the code, ordinances or statutes simply because a partial permit has been issued. "Fast tracking" puts an unusual administrative and technical burden on the fire code official. The purpose is to proceed with construction while the design continues for other aspects of the work. Coordinating and correlating the code aspects into the project in phases requires attention to detail and project tracking so that all code issues are addressed.

**[A] 105.4.5 Amended construction documents.** *Work shall be installed in accordance with the approved construction documents, and any changes made during construction that are not in compliance with the approved construction documents shall be resubmitted for approval as an amended set of construction documents.*

❖ Any amendments to the approved construction documents must be filed before constructing the amended item. In the broadest sense, amendments include all addenda, change orders, revised drawings and

marked-up shop drawings. Fire code officials should maintain a policy that all amendments be submitted for review. Otherwise, a significant amendment may not be submitted, resulting in an activity that is not approved and that causes a needless delay in obtaining approval of the finished work.

**[A] 105.4.6 Retention of construction documents.** *One set of construction documents shall be retained by the fire code official for a period of not less than 180 days from date of completion of the permitted work, or as required by state or local laws. One set of approved construction documents shall be returned to the applicant, and said set shall be kept on the site of the building or work at all times during which the work authorized thereby is in progress.*

❖ It is important that a complete, current set of construction documents be kept on the job site at all times. Another set of construction documents is to be kept by the fire code official until final approval of the completed work. It is not unusual for state laws to establish records-retention criteria, and the intent of this section is to not only make the code consistent with such laws but also to provide a minimum post-construction retention period since the months immediately following construction completion are typically when most disputes arise that depend on the construction documents for resolution. The construction documents are part of the official records of the department and should be kept in accordance with Section 104.6.

**[A] 105.5 Revocation.** *The fire code official is authorized to revoke a permit issued under the provisions of this code where it is found by inspection or otherwise that there has been a false statement or misrepresentation as to the material facts in the application or construction documents on which the permit or approval was based including, but not limited to, any one of the following:*

1. The permit is used for a location or establishment other than that for which it was issued.
2. The permit is used for a condition or activity other than that listed in the permit.
3. Conditions and limitations set forth in the permit have been violated.
4. There have been any false statements or misrepresentations as to the material fact in the application for permit or plans submitted or a condition of the permit.
5. The permit is used by a different person or firm than the name for which it was issued.
6. The permittee failed, refused or neglected to comply with orders or notices duly served in accordance with the provisions of this code within the time provided therein.
7. The permit was issued in error or in violation of an ordinance, regulation or this code.

❖ The fire code official must revoke all permits shown to be based, all or in part, on any false statement or misinterpretation of fact. An applicant may subsequently

reapply for a permit. The code specifies seven specific conditions that allow the fire code official to revoke a permit.

**105.6 Required operational permits.** The *fire code official* is authorized to issue operational permits for the operations set forth in Sections 105.6.1 through 105.6.48.

- ❖ Sections 105.6.1 through 105.6.48 list the conditions requiring operational permits. Many of the items are stated in general terms, in which case the fire code official is to determine whether a specific operation is a significant hazard that requires a permit.

**105.6.1 Aerosol products.** An operational permit is required to manufacture, store or handle an aggregate quantity of Level 2 or Level 3 aerosol products in excess of 500 pounds (227 kg) net weight.

- ❖ See Chapter 51 for code requirements covering aerosol products (see commentary, Section 105.6).

**105.6.2 Amusement buildings.** An operational permit is required to operate a special amusement building.

- ❖ For requirements that apply to special amusement buildings, see Sections 202, 907.2.12 and 914.7.1, and Section 411 of the IBC (see commentary, Section 105.6).

**105.6.3 Aviation facilities.** An operational permit is required to use a Group H or Group S occupancy for aircraft servicing or repair and aircraft fuel-servicing vehicles. Additional permits required by other sections of this code include, but are not limited to, hot work, hazardous materials and flammable or combustible finishes.

- ❖ See Chapter 20 for aviation facility requirements (see commentary, Section 105.6).

**105.6.4 Carbon dioxide systems used in beverage dispensing applications.** An operational permit is required for carbon dioxide systems used in beverage dispensing applications having more than 100 pounds of carbon dioxide.

- ❖ A permit is required only for larger systems, having more than 100 pounds of carbon dioxide, where the hazard of release and possible asphyxiation is more likely. The amount correlates with the applicability of Section 5307. See commentaries for Sections 908.7 and 5307 for more detailed requirements.

**105.6.5 Carnivals and fairs.** An operational permit is required to conduct a carnival or fair.

- ❖ See Section 3103.3 for carnival requirements (see commentary, Section 105.6).

**105.6.6 Cellulose nitrate film.** An operational permit is required to store, handle or use cellulose nitrate film in a Group A occupancy.

- ❖ Although cellulose nitrate film is no longer in general use, there are a small number of locations in which this type of film is archived or restored for historical purposes. This section applies to those few locations

(see Section 306 for cellulose nitrate film requirements).

**105.6.7 Combustible dust-producing operations.** An operational permit is required to operate a grain elevator, flour starch mill, feed mill, or a plant pulverizing aluminum, coal, cocoa, magnesium, spices or sugar, or other operations producing *combustible dusts* as defined in Chapter 2.

- ❖ See Chapter 22 for combustible dust-producing operations (see commentary, Section 105.6).

**105.6.8 Combustible fibers.** An operational permit is required for the storage and handling of *combustible fibers* in quantities greater than 100 cubic feet (2.8 m<sup>3</sup>).

**Exception:** A permit is not required for agricultural storage.

- ❖ See Chapter 37 for combustible fiber requirements. The exception is for agricultural storage facilities where the hazard to persons is minimal (see Section 105.6).

**105.6.9 Compressed gases.** An operational permit is required for the storage, use or handling at *normal temperature and pressure* (NTP) of *compressed gases* in excess of the amounts listed in Table 105.6.9.

**Exception:** Vehicles equipped for and using *compressed gas* as a fuel for propelling the vehicle.

- ❖ See Chapter 53 for compressed gas requirements. The exception exempts vehicles equipped for compressed gas, since the code requirements for compressed gases do not apply to them.

**TABLE 105.6.9  
PERMIT AMOUNTS FOR COMPRESSED GASES**

TYPE OF GAS	AMOUNT (cubic feet at NTP)
Corrosive	200
Flammable (except cryogenic fluids and liquefied petroleum gases)	200
Highly toxic	Any Amount
Inert and simple asphyxiant <sup>a</sup>	6,000
Oxidizing (including oxygen)	504
Pyrophoric	Any Amount
Toxic	Any Amount

For SI: 1 cubic foot = 0.02832 m<sup>3</sup>.

a. For carbon dioxide used in beverage dispensing applications, see Section 105.6.4.

- ❖ When the use of compressed gases exceeds the amounts indicated in Table 105.6.9, an operational permit is required. The quantities in the table are at normal temperature and pressure (NTP) (see Chapter 53 for compressed gas requirements). A reference is provided to Section 105.6.4 addressing a specific requirement for systems having more than 100 pounds of carbon dioxide used for beverage dispensing.

**105.6.10 Covered and open mall buildings.** An operational permit is required for:

1. The placement of retail fixtures and displays, concession equipment, displays of highly combustible goods and similar items in the mall.
2. The display of liquid- or gas-fired equipment in the mall.
3. The use of open-flame or flame-producing equipment in the mall.

❖ The listed operations in a covered or open mall building require an operational permit, since they involve a significant hazard to the occupants. See Section 308 for open-flame regulations (see Section 105.6).

**105.6.11 Cryogenic fluids.** An operational permit is required to produce, store, transport on site, use, handle or dispense *cryogenic fluids* in excess of the amounts listed in Table 105.6.11.

**Exception:** Permits are not required for vehicles equipped for and using *cryogenic fluids* as a fuel for propelling the vehicle or for refrigerating the lading.

❖ See Chapter 55 for requirements regarding cryogenic fluids. The exception exempts vehicles using cryogenic fluids, since the code requirements do not apply to them.

**TABLE 105.6.11  
PERMIT AMOUNTS FOR CRYOGENIC FLUIDS**

TYPE OF CRYOGENIC FLUID	INSIDE BUILDING (gallons)	OUTSIDE BUILDING (gallons)
Flammable	More than 1	60
Inert	60	500
Oxidizing (includes oxygen)	10	50
Physical or health hazard not indicated above	Any Amount	Any Amount

For SI: 1 gallon = 3.785 L.

❖ Where cryogenic fluids are used in excess of the amounts shown in Table 105.6.10, an operational permit is required. The listed amounts are significantly different inside or outside of a building, since the hazard is greatly reduced if a leak occurs outdoors.

**105.6.12 Cutting and welding.** An operational permit is required to conduct cutting or welding operations within the jurisdiction.

❖ See Chapter 35 for welding requirements (see commentary, Section 105.6).

**105.6.13 Dry cleaning.** An operational permit is required to engage in the business of dry cleaning or to change to a more hazardous cleaning solvent used in existing dry cleaning equipment.

❖ See Chapter 21 for dry cleaning regulations (see commentary, Section 105.6).

**105.6.14 Exhibits and trade shows.** An operational permit is required to operate exhibits and trade shows.

❖ The primary concern is to identify hazardous and highly flammable materials that could be involved in an exhibit or booth (see commentary, Section 105.6).

**105.6.15 Explosives.** An operational permit is required for the manufacture, storage, handling, sale or use of any quantity of *explosives, explosive materials*, fireworks or pyrotechnic special effects within the scope of Chapter 56.

**Exception:** Storage in Group R-3 occupancies of smokeless propellant, black powder and small arms primers for personal use, not for resale and in accordance with Section 5606.

❖ See Chapter 56 for requirements for explosives and fireworks (see commentary, Section 105.6 and Chapter 56).

The exception correlates the permit requirements for the possession, storage or use of smokeless propellant, black powder and small arms primers for personal use in Group R-3 residential occupancies with the scope of Chapter 56, as stated in Section 5601.1, Exception 4, and Section 5606.4. The exception is also consistent with NFPA 495, referenced in Chapter 56, which limits quantities allowed in residences, but allows for quantities in residences outside the scope of Chapter 56 to be regulated without a permit.

**105.6.16 Fire hydrants and valves.** An operational permit is required to use or operate fire hydrants or valves intended for fire suppression purposes that are installed on water systems and accessible to a fire apparatus access road that is open to or generally used by the public.

**Exception:** A permit is not required for authorized employees of the water company that supplies the system or the fire department to use or operate fire hydrants or valves.

❖ An operational permit is required for persons other than authorized employees of the water company or the fire department to operate fire hydrants or valves. This restriction is intended to make sure that the use will not result in a lack of water supply and pressure that may be needed for fire-fighting purposes. The exception allows water company employees or the fire department to use fire hydrants or valves without a permit. Such use is common in order to flush out the piping periodically. When fire departments or fire districts interact with water districts, they should communicate the need for the fire department to use the hydrants and valves for nonemergency situations, such as training. A notification procedure is needed to let the water district know of this planned use.

**105.6.17 Flammable and combustible liquids.** An operational permit is required:

1. To use or operate a pipeline for the transportation within facilities of flammable or *combustible liquids*.

This requirement shall not apply to the off-site transportation in pipelines regulated by the Department of Transportation (DOTn) nor does it apply to piping systems.

2. To store, handle or use Class I liquids in excess of 5 gallons (19 L) in a building or in excess of 10 gallons (37.9 L) outside of a building, except that a permit is not required for the following:
  - 2.1. The storage or use of Class I liquids in the fuel tank of a motor vehicle, aircraft, motorboat, mobile power plant or mobile heating plant, unless such storage, in the opinion of the *fire code official*, would cause an unsafe condition.
  - 2.2. The storage or use of paints, oils, varnishes or similar flammable mixtures where such liquids are stored for maintenance, painting or similar purposes for a period of not more than 30 days.
3. To store, handle or use Class II or Class IIIA liquids in excess of 25 gallons (95 L) in a building or in excess of 60 gallons (227 L) outside a building, except for fuel oil used in connection with oil-burning equipment.
4. To store, handle or use Class IIIB liquids in tanks or portable tanks for fueling motor vehicles at motor fuel-dispensing facilities or where connected to fuel-burning equipment.
 

**Exception:** Fuel oil and used motor oil used for space heating or water heating.
5. To remove Class I or II liquids from an underground storage tank used for fueling motor vehicles by any means other than the *approved*, stationary on-site pumps normally used for dispensing purposes.
6. To operate tank vehicles, equipment, tanks, plants, terminals, wells, fuel-dispensing stations, refineries, distilleries and similar facilities where flammable and *combustible liquids* are produced, processed, transported, stored, dispensed or used.
7. To place temporarily out of service (for more than 90 days) an underground, protected above-ground or above-ground flammable or *combustible liquid* tank.
8. To change the type of contents stored in a flammable or *combustible liquid* tank to a material that poses a greater hazard than that for which the tank was designed and constructed.
9. To manufacture, process, blend or refine flammable or *combustible liquids*.
10. To engage in the dispensing of liquid fuels into the fuel tanks of motor vehicles at commercial, industrial, governmental or manufacturing establishments.
11. To utilize a site for the dispensing of liquid fuels from tank vehicles into the fuel tanks of motor vehicles, marine craft and other special equipment at commer-

cial, industrial, governmental or manufacturing establishments.

- ❖ See Chapter 57 for regulations regarding flammable and combustible liquids (see commentary, Section 105.6).

**105.6.18 Floor finishing.** An operational permit is required for floor finishing or surfacing operations exceeding 350 square feet (33 m<sup>2</sup>) using Class I or Class II liquids.

- ❖ The concern of this section is the proper use and handling of Class I or II liquids that are used in the floor-finishing process. If such liquids are not used, an operational permit is not required for floor finishing.

**105.6.19 Fruit and crop ripening.** An operational permit is required to operate a fruit- or crop-ripening facility or conduct a fruit-ripening process using ethylene gas.

- ❖ See Chapter 25 for regulations for fruit- and crop-ripening processes where ethylene gas is used (see commentary, Section 105.6).

**105.6.20 Fumigation and insecticidal fogging.** An operational permit is required to operate a business of fumigation or insecticidal fogging, and to maintain a room, vault or chamber in which a toxic or flammable fumigant is used.

- ❖ See Chapter 26 for fumigation and insecticidal fogging regulations within structures (see commentary, Section 105.6).

**105.6.21 Hazardous materials.** An operational permit is required to store, transport on site, dispense, use or handle hazardous materials in excess of the amounts listed in Table 105.6.21.

- ❖ See Chapter 50 for the general provisions regarding hazardous materials. Also see Chapters 51 through 67 for regulations regarding a specific hazardous material (see commentary, Section 105.6).

**TABLE 105.6.21.** See page 3-25.

- ❖ Where the amounts of hazardous materials in the table are exceeded, an operational permit is required. This applies to the storage, transportation on site, dispensing, use or handling of the hazardous materials that are listed in the table.

Table Notes a and b create parity for Class 3 oxidizer permit amounts with the adjustments to the maximum allowable quantity per control area (MAQ) specified in Table 5003.1.1(1), Note k. This eliminates the need for small apartment complexes and similar occupancies with swimming pools to obtain permits for normal pool maintenance using relatively small amounts of material.

**105.6.22 HPM facilities.** An operational permit is required to store, handle or use hazardous production materials.

- ❖ See Chapter 27 for regulations regarding semiconductor fabrication facilities (see commentary, Section 105.6).

**TABLE 105.6.21  
PERMIT AMOUNTS FOR HAZARDOUS MATERIALS**

TYPE OF MATERIAL	AMOUNT
Combustible liquids	See Section 105.6.17
Corrosive materials	
Gases	See Section 105.6.9
Liquids	55 gallons
Solids	1000 pounds
Explosive materials	See Section 105.6.15
Flammable materials	
Gases	See Section 105.6.9
Liquids	See Section 105.6.17
Solids	100 pounds
Highly toxic materials	
Gases	See Section 105.6.9
Liquids	Any Amount
Solids	Any Amount
Oxidizing materials	
Gases	See Section 105.6.9
Liquids	
Class 4	Any Amount
Class 3	1 gallon <sup>a</sup>
Class 2	10 gallons
Class 1	55 gallons
Solids	
Class 4	Any Amount
Class 3	10 pounds <sup>b</sup>
Class 2	100 pounds
Class 1	500 pounds
Organic peroxides	
Liquids	
Class I	Any Amount
Class II	Any Amount
Class III	1 gallon
Class IV	2 gallons
Class V	No Permit Required
Solids	
Class I	Any Amount
Class II	Any Amount
Class III	10 pounds
Class IV	20 pounds
Class V	No Permit Required
Pyrophoric materials	
Gases	Any Amount
Liquids	Any Amount
Solids	Any Amount
Toxic materials	
Gases	See Section 105.6.9
Liquids	10 gallons
Solids	100 pounds
Unstable (reactive) materials	
Liquids	
Class 4	Any Amount
Class 3	Any Amount
Class 2	5 gallons
Class 1	10 gallons
Solids	
Class 4	Any Amount
Class 3	Any Amount
Class 2	50 pounds
Class 1	100 pounds

(continued)

**TABLE 105.6.21—continued  
PERMIT AMOUNTS FOR HAZARDOUS MATERIALS**

TYPE OF MATERIAL	AMOUNT
Water-reactive materials	
Liquids	
Class 3	Any Amount
Class 2	5 gallons
Class 1	55 gallons
Solids	
Class 3	Any Amount
Class 2	50 pounds
Class 1	500 pounds

For SI: 1 gallon = 3.785 L, 1 pound = 0.454 kg.

- a. 20 gallons where Table 5003.1.1(1) Note k applies and hazard identification signs in accordance with Section 5003.5 are provided for quantities of 20 gallons or less.
- b. 200 pounds where Table 5003.1.1(1) Note k applies and hazard identification signs in accordance with Section 5003.5 are provided for quantities of 200 pounds or less.

**105.6.23 High-piled storage.** An operational permit is required to use a building or portion thereof as a *high-piled storage area* exceeding 500 square feet (46 m<sup>2</sup>).

❖ See Chapter 32 for high-piled storage provisions (see commentary, Section 105.6).

**105.6.24 Hot work operations.** An operational permit is required for hot work including, but not limited to:

1. Public exhibitions and demonstrations where hot work is conducted.
2. Use of portable hot work equipment inside a structure.

**Exception:** Work that is conducted under a construction permit.

3. Fixed-site hot work equipment, such as welding booths.
4. Hot work conducted within a wildfire risk area.
5. Application of roof coverings with the use of an open-flame device.
6. Where *approved*, the *fire code official* shall issue a permit to carry out a hot work program. This program allows *approved* personnel to regulate their facility's hot work operations. The *approved* personnel shall be trained in the fire safety aspects denoted in this chapter and shall be responsible for issuing permits requiring compliance with the requirements found in Chapter 35. These permits shall be issued only to their employees or hot work operations under their supervision.

❖ See Chapter 35 for hot work regulations. The exception to Item 2 in this section recognizes that work done under a construction permit is already covered by that permit so an operational permit is not required (see commentary, Section 105.6).

**105.6.25 Industrial ovens.** An operational permit is required for operation of industrial ovens regulated by Chapter 30.

❖ See Chapter 30 for regulations regarding industrial ovens (see commentary, Section 105.6).

**105.6.26 Lumber yards and woodworking plants.** An operational permit is required for the storage or processing of lumber exceeding 100,000 board feet (8,333 ft<sup>3</sup>) (236 m<sup>3</sup>).

❖ See Chapter 28 for provisions for lumber yards and woodworking plants (see commentary, Section 105.6).

**105.6.27 Liquid- or gas-fueled vehicles or equipment in assembly buildings.** An operational permit is required to display, operate or demonstrate liquid- or gas-fueled vehicles or equipment in assembly buildings.

❖ See Section 314.4 for requirements regarding liquid- or gas-fueled vehicles inside buildings (see commentary, Section 105.6).

**105.6.28 LP-gas.** An operational permit is required for:

1. Storage and use of LP-gas.

**Exception:** A permit is not required for individual containers with a 500-gallon (1893 L) water capacity or less or multiple container systems having an aggregate quantity not exceeding 500 gallons (1893 L), serving occupancies in Group R-3.

2. Operation of cargo tankers that transport LP-gas.

❖ See Chapter 61 for liquefied petroleum gas (LP-gas) regulations. The exception to Item 1 in this section exempts small tanks with an individual capacity of 500 gallons (1893 L) or multiple small tanks with an aggregate capacity of 500 gallons (1893 L) commonly found in residential service. A permit is required where the aggregate quantity of multiple small LP-gas containers exceeds 500 gallons (1893 L). It has become commonplace for LP-gas distributors to install LP-gas systems exceeding 500 gallons (1893 L) that consist of multiple containers in series with individual containers that do not exceed 500 gallons (1893 L), thereby avoiding the permit requirement. It is appropriate to require a permit at these locations given the significant hazard associated with these quantities. Item 2 covers cargo tankers, since they transport LP-gas onto premises covered by the code and, therefore, represent a potential hazard.

**105.6.29 Magnesium.** An operational permit is required to melt, cast, heat treat or grind more than 10 pounds (4.54 kg) of magnesium.

❖ See Section 5906 for the code requirements for magnesium (see commentary, Section 105.6).

**105.6.30 Miscellaneous combustible storage.** An operational permit is required to store in any building or upon any premises in excess of 2,500 cubic feet (71 m<sup>3</sup>) gross volume of combustible empty packing cases, boxes, barrels or similar containers, rubber tires, rubber, cork or similar combustible material.

❖ See Section 315 for requirements for miscellaneous combustible material storage (see commentary, Section 105.6).

**105.6.31 Motor fuel-dispensing facilities.** An operational permit is required for the operation of automotive, marine and fleet motor fuel-dispensing facilities.

❖ See Chapter 23 for requirements for motor fuel-dispensing facilities (see commentary, Section 105.6).

**105.6.32 Open burning.** An operational permit is required for the kindling or maintaining of an open fire or a fire on any public street, alley, road, or other public or private ground. Instructions and stipulations of the permit shall be adhered to.

**Exception:** *Recreational fires.*

❖ See Section 307 for open burning provisions. Section 202 includes the definition of "Open burning." The exception exempts recreational fires, which are also defined in Section 202.

**105.6.33 Open flames and torches.** An operational permit is required to remove paint with a torch; or to use a torch or open-flame device in a wildfire risk area.

❖ See Section 308 for regulations regarding open flames (see commentary, Section 105.6).

**105.6.34 Open flames and candles.** An operational permit is required to use open flames or candles in connection with assembly areas, dining areas of restaurants or drinking establishments.

❖ See Section 308 for regulations regarding open flames (see commentary, Section 105.6).

**105.6.35 Organic coatings.** An operational permit is required for any organic-coating manufacturing operation producing more than 1 gallon (4 L) of an organic coating in one day.

❖ The manufacture of organic coatings is addressed in Chapter 29 (see commentary, Section 105.6).

**105.6.36 Places of assembly.** An operational permit is required to operate a place of assembly.

❖ Because of the higher occupant loads found in Group A occupancies, such occupancies justify an increased level of scrutiny, such as is provided through the permit process.

**105.6.37 Private fire hydrants.** An operational permit is required for the removal from service, use or operation of private fire hydrants.

**Exception:** A permit is not required for private industry with trained maintenance personnel, private fire brigade or fire departments to maintain, test and use private hydrants.

❖ The purpose of an operational permit for the removal of private fire hydrants is to see that adequate fire hydrants are maintained for use during a fire. The exception allows testing and use of private fire hydrants by trained private industry personnel without an operational permit.

**105.6.38 Pyrotechnic special effects material.** An operational permit is required for use and handling of pyrotechnic special effects material.

❖ See Chapter 56 for fireworks regulations. The definition of “Pyrotechnic special effects material” is listed in Section 56 (see commentary, Section 105.6).

**105.6.39 Pyroxylin plastics.** An operational permit is required for storage or handling of more than 25 pounds (11 kg) of cellulose nitrate (pyroxylin) plastics, and for the assembly or manufacture of articles involving pyroxylin plastics.

❖ See Chapter 65 for requirements regarding pyroxylin (cellulose nitrate) plastics (see commentary, Section 105.6).

**105.6.40 Refrigeration equipment.** An operational permit is required to operate a mechanical refrigeration unit or system regulated by Chapter 6.

❖ See Section 606 for mechanical refrigeration regulations (see commentary, Section 105.6).

**105.6.41 Repair garages and motor fuel-dispensing facilities.** An operational permit is required for operation of repair garages.

❖ See Chapter 23 for requirements for repair garages (see commentary, Section 105.6).

**105.6.42 Rooftop heliports.** An operational permit is required for the operation of a rooftop heliport.

❖ See Chapter 20 for aviation facility requirements. Section 2007 contains helistop and heliport requirements (see commentary, Section 105.6).

**105.6.43 Spraying or dipping.** An operational permit is required to conduct a spraying or dipping operation utilizing flammable or *combustible liquids*, or the application of combustible powders regulated by Chapter 24.

❖ See Chapter 24 for flammable finish requirements. Section 2404 contains the spray finishing provisions, Section 2405 addresses dipping operations and Section 2406 includes powder coating regulations (see commentary, Section 105.6).

**105.6.44 Storage of scrap tires and tire byproducts.** An operational permit is required to establish, conduct or maintain storage of scrap tires and tire byproducts that exceeds 2,500 cubic feet (71 m<sup>3</sup>) of total volume of scrap tires, and for indoor storage of tires and tire byproducts.

❖ See Chapter 34 for regulations regarding tire rebuilding and tire storage (see Section 105.6).

**105.6.45 Temporary membrane structures and tents.** An operational permit is required to operate an air-supported temporary membrane structure, a temporary stage canopy or a tent having an area in excess of 400 square feet (37 m<sup>2</sup>).

**Exceptions:**

1. Tents used exclusively for recreational camping purposes.

2. Tents open on all sides, which comply with all of the following:
  - 2.1. Individual tents having a maximum size of 700 square feet (65 m<sup>2</sup>).
  - 2.2. The aggregate area of multiple tents placed side by side without a fire break clearance of not less than 12 feet (3658 mm) shall not exceed 700 square feet (65 m<sup>2</sup>) total.
  - 2.3. A minimum clearance of 12 feet (3658 mm) to structures and other tents shall be provided.

❖ See Chapter 31 for requirements for tents and other membrane structures. The first exception in this section exempts recreational camping tents, since they are small, temporary and have few occupants. The second exception exempts relatively small tents that are very low hazard, since they are spaced at least 12 feet (3658 mm) apart (see also commentary, Section 3103.20).

**105.6.46 Tire-rebuilding plants.** An operational permit is required for the operation and maintenance of a tire-rebuilding plant.

❖ See Chapter 34 for regulations regarding tire rebuilding operations (see commentary, Section 105.6).

**105.6.47 Waste handling.** An operational permit is required for the operation of wrecking yards, junk yards and waste material-handling facilities.

❖ See Section 315 for miscellaneous combustible materials storage requirements, Section 5004 for provisions regarding the storage of hazardous materials and Section 2808 for provisions regarding yard waste and recycling facilities (see commentary, Section 105.6).

**105.6.48 Wood products.** An operational permit is required to store chips, hogged material, lumber or plywood in excess of 200 cubic feet (6 m<sup>3</sup>).

❖ See Section 2808 for requirements regarding the storage and handling of wood chips, hogged material, fines, compost and raw product in association with yard waste and recycling facilities (see commentary, Section 105.6).

**[A] 105.7 Required construction permits.** The *fire code official* is authorized to issue construction permits for work as set forth in Sections 105.7.1 through 105.7.18.

❖ This section addresses conditions requiring a construction permit (see Section 105.6). Generally, a construction permit is required when a safety related system or hazardous material storage is installed or an existing system or facility is modified. Other sections of the code may also apply.

In some cases, the requirements in Sections 105.7.1 through 105.7.18 are stated in only general terms. In these instances, the fire code official is to

evaluate the scope of work involved for the modification or installation and determine whether a construction permit is required for the specific project.

**[A] 105.7.1 Automatic fire-extinguishing systems.** A construction permit is required for installation of or modification to an automatic fire-extinguishing system. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

❖ See Chapter 9 for fire protection system requirements. A construction permit is required for the installation or modification of an automatic fire-extinguishing system so that the work can be verified to meet the code requirements, since the system is obviously safety related (see commentary, Section 105.7).

**[A] 105.7.2 Battery systems.** A permit is required to install stationary storage battery systems having a liquid capacity of more than 50 gallons (189 L).

❖ See Sections 602.1 and 608 for battery system requirements (see commentary, Section 105.7).

**[A] 105.7.3 Compressed gases.** Where the compressed gases in use or storage exceed the amounts listed in Table 105.6.9, a construction permit is required to install, repair damage to, abandon, remove, place temporarily out of service, or close or substantially modify a *compressed gas* system.

**Exceptions:**

1. Routine maintenance.
  2. For emergency repair work performed on an emergency basis, application for permit shall be made within two working days of commencement of work.
- ❖ See Chapter 53 for the requirements for compressed gas systems. Where the volume of the compressed gas presents a significant health hazard and the quantity exceeds the allowed amounts in Table 105.6.9, a permit is needed to trigger construction document submittal, document review and inspections of the work on the system. The exceptions exempt maintenance work and allow emergency work to proceed immediately.

**[A] 105.7.4 Cryogenic fluids.** A construction permit is required for installation of or *alteration* to outdoor stationary *cryogenic fluid* storage systems where the system capacity exceeds the amounts listed in Table 105.6.11. Maintenance performed in accordance with this code is not considered to be an *alteration* and does not require a construction permit.

❖ See Chapter 55 for the requirements for cryogenic fluids and Chapter 58 for the requirements for flammable cryogenic fluids. The application for a construction permit for cryogenic fluids is intended to trigger a plan review that will examine constraints on location and the requirements of Chapters 55 and 58.

**[A] 105.7.5 Emergency responder radio coverage system.** A construction permit is required for installation of or modification to emergency responder radio coverage systems and

related equipment. Maintenance performed in accordance with this code is not considered to be a modification and does not require a construction permit.

❖ This section establishes that a permit must be obtained for the installation or modification of the emergency responder radio coverage system (ERRCS) to ensure that the work is done correctly and that any parts replacement will be compatible with the existing system components. Since the normal maintenance of a system typically would not involve alteration of the system, it would not require a permit.

**[A] 105.7.6 Fire alarm and detection systems and related equipment.** A construction permit is required for installation of or modification to fire alarm and detection systems and related equipment. Maintenance performed in accordance with this code is not considered to be a modification and does not require a construction permit.

❖ See Section 907 for fire alarm and detection requirements. A construction permit is required for installation or modification of these systems since they are obviously safety related. A permit is not required for maintenance when no modifications are made to the systems (see commentary, Section 105.7).

**[A] 105.7.7 Fire pumps and related equipment.** A construction permit is required for installation of or modification to fire pumps and related fuel tanks, jockey pumps, controllers and generators. Maintenance performed in accordance with this code is not considered to be a modification and does not require a construction permit.

❖ See Section 913 for requirements regarding fire pumps. A construction permit is required for modification or installation of equipment that is necessary to serve the sprinkler or standpipe system. This construction work must be monitored since these are safety-related systems (see commentary, Section 105.7).

**[A] 105.7.8 Flammable and combustible liquids.** A construction permit is required:

1. To install, repair or modify a pipeline for the transportation of flammable or *combustible liquids*.
2. To install, construct or alter tank vehicles, equipment, tanks, plants, terminals, wells, fuel-dispensing stations, refineries, distilleries and similar facilities where flammable and *combustible liquids* are produced, processed, transported, stored, dispensed or used.
3. To install, alter, remove, abandon or otherwise dispose of a flammable or *combustible liquid* tank.

❖ See Chapter 57 for provisions for flammable and combustible liquids. The intent of this section is to require a construction permit for any of the three activities listed, since flammable and combustible liquids are a significant hazard (see commentary, Section 105.7).

**[A] 105.7.9 Gates and barricades across fire apparatus access roads.** A construction permit is required for the instal-

lation of or modification to a gate or barricade across a fire apparatus access road.

- ❖ The permit gives the fire code official the ability to ensure that access requirements are met.

Current code requirements for gates and barricades include an approved method of locking/securing, proper dimensions and opening width, and proper devices for operation. See the commentary to Sections 503.5 and 503.6.

**[A] 105.7.10 Hazardous materials.** A construction permit is required to install, repair damage to, abandon, remove, place temporarily out of service, or close or substantially modify a storage facility or other area regulated by Chapter 50 where the hazardous materials in use or storage exceed the amounts listed in Table 105.6.21.

**Exceptions:**

1. Routine maintenance.
  2. For repair work performed on an emergency basis, application for permit shall be made within two working days of commencement of work.
- ❖ A construction permit is needed for hazardous-material-related construction to ensure submittal of construction documents, document review and inspection of the work for code compliance. The exceptions provide exemptions for maintenance work and allow emergency work to proceed immediately, provided the permit application is submitted within two working days of starting the job.

**[A] 105.7.11 Industrial ovens.** A construction permit is required for installation of industrial ovens covered by Chapter 30.

**Exceptions:**

1. Routine maintenance.
  2. For repair work performed on an emergency basis, application for permit shall be made within two working days of commencement of work.
- ❖ A construction permit is required for industrial oven installation so that the requirements in Chapter 30 for industrial ovens can be verified. The exceptions provide exemptions for maintenance work and allow emergency work to proceed immediately, provided the permit is applied for within two working days after work begins.

**[A] 105.7.12 LP-gas.** A construction permit is required for installation of or modification to an LP-gas system. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

- ❖ See Chapter 61 for the requirements for LP-gas storage, handling and transportation (see commentary, Section 105.7). Ordinary maintenance that does not involve modifications to the system does not require a construction permit.

**[A] 105.7.13 Private fire hydrants.** A construction permit is required for the installation or modification of private fire hydrants. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

- ❖ A construction permit is needed for the installation or modification of private fire hydrants so that they remain in service for fire protection purposes. The water flow rate and pressure capability need to be maintained. Ordinary maintenance that does not involve modifications does not require a construction permit.

**[A] 105.7.14 Smoke control or smoke exhaust systems.** Construction permits are required for installation of or alteration to smoke control or smoke exhaust systems. Maintenance performed in accordance with this code is not considered to be an alteration and does not require a permit.

- ❖ Smoke control and smoke exhaust systems are required fire protection systems by Chapter 9. A permit is necessary to ensure proper design and installation. Ordinary maintenance that does not involve modifications to the system does not require a construction permit.

**[A] 105.7.15 Solar photovoltaic power systems.** A construction permit is required to install or modify solar photovoltaic power systems. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

- ❖ Section 605.11 regulates solar photovoltaic power system installations on buildings. Because of the unique electrical and physical hazards they present to fire fighters and the impact such systems have on fire suppression operations, a permit is required. Ordinary maintenance that does not involve modifications to the system does not require a construction permit.

**[A] 105.7.16 Spraying or dipping.** A construction permit is required to install or modify a spray room, dip tank or booth. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

- ❖ See Chapter 24 for flammable finish requirements. The spray finishing requirements are in Section 2404, while dipping operations regulations are in Section 2405 (see commentary, Section 105.7). Ordinary maintenance that does not involve modifications does not require a construction permit.

**[A] 105.7.17 Standpipe systems.** A construction permit is required for the installation, modification or removal from service of a standpipe system. Maintenance performed in accordance with this code is not considered to be a modification and does not require a permit.

- ❖ See Section 905 for standpipe system requirements. Construction permits are required for standpipe systems because they are safety-related fire protection

systems. Ordinary maintenance that does not involve modifications to the system does not require a construction permit.

**[A] 105.7.18 Temporary membrane structures and tents.** A construction permit is required to erect an air-supported temporary membrane structure, a temporary stage canopy or a tent having an area in excess of 400 square feet (37 m<sup>2</sup>).

**Exceptions:**

1. Tents used exclusively for recreational camping purposes.
  2. Funeral tents and curtains, or extensions attached thereto, when used for funeral services.
  3. Tents and awnings open on all sides, which comply with all of the following:
    - 3.1. Individual tents shall have a maximum size of 700 square feet (65 m<sup>2</sup>).
    - 3.2. The aggregate area of multiple tents placed side by side without a fire break clearance of not less than 12 feet (3658 mm) shall not exceed 700 square feet (65 m<sup>2</sup>) total.
    - 3.3. A minimum clearance of 12 feet (3658 mm) to structures and other tents shall be maintained.
- ❖ See Chapter 31 for requirements regarding tents and other membrane structures. The exceptions are for tents where the hazard is very low. They provide needed exemptions for tents used for recreational camping and funerals. Relatively small tents and awnings that are open on all sides and are located a minimum of 12 feet (3658 mm) apart are also exempt (see commentary, Section 3103.2).

**SECTION 106  
INSPECTIONS**

**[A] 106.1 Inspection authority.** The *fire code official* is authorized to enter and examine any building, structure, marine vessel, vehicle or premises in accordance with Section 104.3 for the purpose of enforcing this code.

❖ The first part of this section establishes the right of the fire code official to enter the premises to make the permit inspections required by Section 104. Permit application forms typically include a statement in the certification signed by the applicant (who is the owner or owner’s agent) granting the fire code official the authority to enter areas covered by the permit to enforce code provisions related to the permit.

The right to enter other structures or premises is more limited. First, to protect the right of privacy, the owner or occupant must grant the fire code official permission before the interior of the property can be inspected. Permission is not required for inspections that can be accomplished from within the public right-of-way. Second, such access may be denied by the owner or occupant. Unless the inspector has “reasonable cause” to believe that a violation of the code

exists, access may be unattainable. Third, fire code officials must present proper identification (see Section 104.4) and request admittance during reasonable hours—usually the normal business hours of the establishment—to be admitted. Fourth, inspections must be aimed at securing or determining compliance with the provisions and intent of the regulations that are specifically within the established scope of the fire code official’s authority. Searches to gather information for the purpose of enforcing other codes, ordinances or regulations are considered unreasonable and are prohibited by the Fourth Amendment to the U.S. Constitution.

Reasonable cause in the context of this section must be distinguished from probable cause, which is required to gain access to property in criminal cases. The burden of proof for establishing reasonable cause may vary among jurisdictions. Usually, an inspector must show that the property is subject to inspection under the provisions of the code (see Section 104), that the interests of the public health, safety and welfare outweigh the individual’s right to maintain privacy and that such an inspection is required solely to determine compliance with the provisions of the code. Many jurisdictions do not recognize the concept of an administrative warrant, and may require the fire code official to prove probable cause in order to gain access upon refusal. This burden of proof is usually more substantial, often requiring the fire code official to stipulate in advance why access is needed (usually access is restricted to gathering evidence for seeking an indictment or making an arrest); what specific item or information is sought; its relevance to the case against the individual subject; how knowledge of the relevance of the information or items sought was obtained; and how the evidence sought will be used. In all such cases, the right to privacy must always be weighed against the right of the fire code official to conduct an inspection to determine whether the health, safety or welfare of the public is in jeopardy. Such important and complex constitutional issues should be discussed with the jurisdiction’s legal counsel. Jurisdictions should establish procedures for securing the necessary court orders when an inspection is considered necessary following a refusal.

**[A] 106.2 Inspections.** The *fire code official* is authorized to conduct such inspections as are deemed necessary to determine the extent of compliance with the provisions of this code and to approve reports of inspection by *approved* agencies or individuals. Reports of such inspections shall be prepared and submitted in writing for review and approval. Inspection reports shall be certified by a responsible officer of such *approved* agency or by the responsible individual. The *fire code official* is authorized to engage such expert opinion as deemed necessary to report upon unusual, detailed or complex technical issues subject to the approval of the governing body.

❖ This section establishes the fire code official’s authority to inspect buildings, structures or premises to ver-

ify that the requirements of the code are met or to accept written reports of inspections by an approved agency. The code does not, however, establish the frequency of inspections or even require that inspections be conducted, since the code does not presume to interpret or influence the adopting jurisdiction's political, social and economic priorities. Jurisdictions may establish their inspection priorities and frequencies based on a variety of factors, including the availability of inspection resources; the level of available fire suppression services; the value of premises to the community; or the potential disruption to community services or stability if a fire occurs. In summary, each community determines and assumes its own acceptable risk level.

In order to expand the available resources for inspection purposes, the fire code official is also authorized to approve a third-party agency that is regularly engaged in conducting relevant tests or furnishing inspection services. Approval of such an agency may be acquired through review of the résumés and references of the agency and its personnel, and analyzing the capacity and capability of the agency to perform the work. Additional guidance can be obtained by reviewing the provisions of Sections 1703 and 1704 of the IBC.

When unusual, extraordinary or complex technical issues arise relative to building safety, the fire code official has the authority to seek the opinion and advice of experts. Since this usually involves the expenditure of funds, the approval of the jurisdiction's chief administrative authority must be obtained.

**[A] 106.2.1 Inspection requests.** It shall be the duty of the holder of the permit or their duly authorized agent to notify the *fire code official* when work is ready for inspection. It shall be the duty of the permit holder to provide access to and means for inspections of such work that are required by this code.

❖ It is the responsibility of the permit holder or other authorized person, such as the contractor performing the work, to arrange for the required inspections when completed work is ready and to allow for sufficient time for the fire code official to schedule a visit to the site to prevent work from being concealed prior to being inspected. Access to the work to be inspected must be provided, including any special means such as a ladder to gain access.

**[A] 106.2.2 Approval required.** Work shall not be done beyond the point indicated in each successive inspection without first obtaining the approval of the *fire code official*. The *fire code official*, upon notification, shall make the requested inspections and shall either indicate the portion of the construction that is satisfactory as completed, or notify the permit holder or his or her agent wherein the same fails to comply with this code. Any portions that do not comply shall be corrected, and such portion shall not be covered or concealed until authorized by the *fire code official*.

❖ This section establishes that work cannot progress beyond the point of a required inspection without the

fire code official's approval. Upon making the inspection, the fire code official must either approve the completed work or notify the permit holder or other responsible party of that which does not comply with the code. Approvals and notices of noncompliance must be in writing, as required by Section 109.3, to avoid any misunderstanding as to what is required. Any item not approved cannot be covered or concealed until it has been corrected and approved by the fire code official.

**[A] 106.3 Concealed work.** It shall be the duty of the permit applicant to cause the work to remain accessible and exposed for inspection purposes. Where any installation subject to inspection prior to use is covered or concealed without having first been inspected, the *fire code official* shall have the authority to require that such work be exposed for inspection. Neither the *fire code official* nor the jurisdiction shall be liable for expense entailed in the removal or replacement of any material required to allow inspection.

❖ This section addresses the procedure that is available to the fire code official for inspection of concealed work. In many jurisdictions, the contractor or permit holder of an operation or a construction project is to contact the local fire inspection authority when work is completed but still exposed to allow inspection. The section requires that any work to be concealed upon completion must remain exposed until an inspection is made. If the work requiring inspection is covered up before the inspection takes place, the fire code official has the authority to require removal of the concealing construction. The section also makes it clear that any expense incurred in removing or replacing material that conceals an item to be inspected is not the responsibility of either the fire code official or the jurisdiction. Obviously, this can be a time-consuming and expensive procedure that can be eliminated by good communication and cooperation between the contractor or permit holder and the fire code official.

**[A] 106.4 Approvals.** Approval as the result of an inspection shall not be construed to be an approval of a violation of the provisions of this code or of other ordinances of the jurisdiction. Inspections presuming to give authority to violate or cancel provisions of this code or of other ordinances of the jurisdiction shall not be valid.

❖ As with the issuance of permits (see commentary, Section 105.3), approval as a result of an inspection is not a license to violate the code. Further, approval in violation of the code does not relieve the applicant from complying with the code and is not valid. This is significant because even if there are errors or oversights in the approval process, the permit applicant or other recipient of the inspection, not the fire code official, is still responsible for code compliance.

## SECTION 107 MAINTENANCE

**[A] 107.1 Maintenance of safeguards.** Where any device, equipment, system, condition, arrangement, level of protection, or any other feature is required for compliance with the provisions of this code, or otherwise installed, such device, equipment, system, condition, arrangement, level of protection, or other feature shall thereafter be continuously maintained in accordance with this code and applicable referenced standards.

❖ This section does not identify who is responsible for maintenance because that determination should be made in accordance with the legal documents created between owners and occupants, such as a lease. The owner of a structure or premises, however, is usually primarily responsible for its maintenance, since the owner stands to gain the most from a well-maintained property. One of the underlying assumptions is that maintaining a commercial property in good condition allows the owner to recoup a substantial portion of his or her investment in maintenance. There are three factors that may influence owners to comply with code requirements:

- Code compliance requires only a small additional investment in the property.
- The owner has a long-term interest in the property.
- The owner expects profitability after incurring the additional expense of complying with the code.

While all these factors represent economic incentives, fire code officials should be equally aware of potential disincentives to compliance, such as assessable value, expiring tax credits or historic, architectural or aesthetic criteria. The fire code official need not belabor the justifications for compliance, but should be prepared to acknowledge the owner's rationalizations for failure to comply.

This section also emphasizes that any "otherwise installed" system that currently exists must be maintained. For example, an existing fire protection system cannot be removed from a building just because it is not required in new or existing buildings by current codes.

**[A] 107.2 Testing and operation.** Equipment requiring periodic testing or operation to ensure maintenance shall be tested or operated as specified in this code.

❖ This section addresses periodic testing or operation to verify that the equipment can be expected to operate when needed. For example, see Section 901.6 for inspection and testing requirements for fire protection systems.

Test and inspection records must be available to the fire code official for verification that the tests and inspections required by the code and the referenced standards are in compliance.

If the fire code official requests, such records must be filed with the jurisdictional office.

**[A] 107.2.1 Reinspection and testing.** Where any work or installation does not pass an initial test or inspection, the necessary corrections shall be made so as to achieve compliance with this code. The work or installation shall then be resubmitted to the *fire code official* for inspection and testing.

❖ This section simply requires an installation to be of such quality that it will pass any tests or inspections required by the code. For example, if a fire alarm system did not pass the installation test upon completion of the system, the system is to be reworked until it passes the test.

**[A] 107.3 Recordkeeping.** A record of periodic inspections, tests, servicing and other operations and maintenance shall be maintained on the premises or other *approved* location for not less than 3 years, or a different period of time where specified in this code or referenced standards. Records shall be made available for inspection by the *fire code official*, and a copy of the records shall be provided to the *fire code official* upon request.

The *fire code official* is authorized to prescribe the form and format of such recordkeeping. The *fire code official* is authorized to require that certain required records be filed with the *fire code official*.

❖ Recordkeeping of testing, inspections, servicing and other operations and maintenance are critical to the successful application of this code. Proper and consistent recordkeeping will increase the safety to both building occupants and fire fighters. This section also makes it clear that records must be provided to the fire code official upon request and maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard. Also, the fire code official is authorized to prescribe the form and format of such records. The recordkeeping requirements throughout the code have been specifically coordinated with this section.

**[A] 107.4 Supervision.** Maintenance and testing shall be under the supervision of a responsible person who shall ensure that such maintenance and testing are conducted at specified intervals in accordance with this code.

❖ Maintenance supervision is needed to verify that testing and general supervision is done regularly. Section 901.6 states code requirements regarding testing and maintenance of the fire protection systems.

**107.5 Rendering equipment inoperable.** Portable or fixed fire-extinguishing systems or devices, and fire-warning systems, shall not be rendered inoperative or inaccessible, except as necessary during emergencies, maintenance, repairs, *alterations*, drills or prescribed testing.

❖ If fire protection systems are going to be effective when needed, they must be in good operating condition. This section specifies those circumstances when they are allowed to be temporarily out of service. See Section 901.6 for code requirements regarding testing and maintenance of the fire protection systems.

**[A] 107.6 Overcrowding.** Overcrowding or admittance of any person beyond the *approved* capacity of a building or a

portion thereof shall not be allowed. The *fire code official*, upon finding any overcrowding conditions or obstructions in *aisles*, passageways or other *means of egress*, or upon finding any condition that constitutes a life safety hazard, shall be authorized to cause the event to be stopped until such condition or obstruction is corrected.

❖ The key to enforcing this provision successfully is good judgment. Rarely is it possible to count accurately the number of people in any given place of public assembly. Usually, the proprietors or operators of such events have no accurate estimate of the crowd size or they are unwilling to provide an estimate. Despite these difficulties, when the number of people is too large to permit aisles and required egress elements to remain clear or at least flow smoothly, remedies must be sought. In many instances, overcrowding can be remedied by simply preventing any more occupants from entering, thus limiting the potential hazard to those occupants already inside. If the fire code official determines that preventing further access will be insufficient in itself, he or she is authorized to order the owner or operator to stop the event until the hazardous condition is abated, the approved occupant load is reestablished and resumption of the event is authorized by the fire code official.

## SECTION 108 BOARD OF APPEALS

**[A] 108.1 Board of appeals established.** In order to hear and decide appeals of orders, decisions or determinations made by the *fire code official* relative to the application and interpretation of this code, there shall be and is hereby created a board of appeals. The board of appeals shall be appointed by the governing body and shall hold office at its pleasure. The *fire code official* shall be an ex officio member of said board but shall not have a vote on any matter before the board. The board shall adopt rules of procedure for conducting its business, and shall render all decisions and findings in writing to the appellant with a duplicate copy to the *fire code official*.

❖ This section provides an objective forum for settling disputes regarding the application or interpretation of the code requirements. The board is required to issue a written decision to the appellant who brought the matter before the board and to the fire code official. Note that the fire code official is a nonvoting member of the board. The board of appeals is an effective decision-making body that is commonly used when the owner or owner's agent and the fire code official do not agree on a matter relating to the application of the code.

**[A] 108.2 Limitations on authority.** An application for appeal shall be based on a claim that the intent of this code or the rules legally adopted hereunder have been incorrectly interpreted, the provisions of this code do not fully apply, or an equivalent method of protection or safety is proposed. The

board shall not have authority to waive requirements of this code.

❖ This section states the scope of the issues that are to be addressed by the board of appeals and limits its authority to ruling on these issues. Commonly, the issues relate to the applicability of the code or the interpretation of the code to a given situation. The board listens to both the person who filed the appeal and to the fire code official before ruling on the matter.

This section specifically states that the board does not have the authority to waive code requirements; however, the board has the authority to accept an alternative method of protection or safety if, in its view, it is equivalent to the specific requirement in the code.

**[A] 108.3 Qualifications.** The board of appeals shall consist of members who are qualified by experience and training to pass on matters pertaining to hazards of fire, explosions, hazardous conditions or *fire protection systems*, and are not employees of the jurisdiction.

❖ It is important that the decisions of the board of appeals are based purely on the technical merits involved in an appeal; it is not the place for policy or political deliberations. The members of the board of appeals are, therefore, expected to have experience in matters within the scope of the code and must be of the highest character, competence and status in their professions and the community at large. Appendix A of the code provides more detailed qualifications for board of appeals members and can be adopted by jurisdictions desiring that level of expertise (see commentary, Appendix A).

## SECTION 109 VIOLATIONS

**[A] 109.1 Unlawful acts.** It shall be unlawful for a person, firm or corporation to erect, construct, alter, repair, remove, demolish or utilize a building, occupancy, premises or system regulated by this code, or cause same to be done, in conflict with or in violation of any of the provisions of this code.

❖ Section 109 establishes that compliance with the code is required, and what measures are to be taken for noncompliance.

**[A] 109.2 Owner/occupant responsibility.** Correction and abatement of violations of this code shall be the responsibility of the *owner* or the owner's authorized agent. Where an occupant creates, or allows to be created, hazardous conditions in violation of this code, the occupant shall be held responsible for the abatement of such hazardous conditions.

❖ Hazards related to use and occupancy, and not those related to fixed equipment or installations, fall within the scope of the occupants' responsibility. Owners or the owner's authorized agent, however, may become liable if they allow the unlawful operation or continua-

tion of a public nuisance on a property under their control, especially if they knowingly or willfully lease the property in violation of fire, zoning or building regulations.

The simple rule for determining what is the responsibility of the owner or owner's authorized agents, and what is the occupants' responsibility is whether the issue involves fixed equipment installations or if the structure is separate from those items related to occupancy. The owner or owner's authorized agent is usually responsible for the physical maintenance of the building or structure and its utilities and appurtenances (that is, building services and systems).

**[A] 109.3 Notice of violation.** Where the *fire code official* finds a building, premises, vehicle, storage facility or outdoor area that is in violation of this code, the *fire code official* is authorized to prepare a written notice of violation describing the conditions deemed unsafe and, where compliance is not immediate, specifying a time for reinspection.

❖ The fire code official has a duty to supply owners, agents or occupants with a written notice of code violations on the premises under their control. When possible, both the owner and the occupants should be made aware of hazardous conditions. Such notices constitute the first of several steps in the due process procedure. Violation notices must clearly indicate the defect and its location (including citation of the code section being violated), what must be done to correct the violation and the date of the reinspection. Owners, agents or occupants should also be supplied with information regarding penalties, permit applications and appeal procedures. The notice or order must be signed by the fire code official who issued it and he or she should provide a space for the owner, agent or occupants' signature to acknowledge receipt of the document. If possible, duplicate or triplicate copies should be prepared, with the original notice issued to the responsible party. Other copies should be maintained by the inspector and the departmental record keeper.

**[A] 109.3.1 Service.** A notice of violation issued pursuant to this code shall be served upon the *owner*, the owner's authorized agent, operator, occupant or other person responsible for the condition or violation, either by personal service, mail or by delivering the same to, and leaving it with, some person of responsibility upon the premises. For unattended or abandoned locations, a copy of such notice of violation shall be posted on the premises in a conspicuous place at or near the entrance to such premises and the notice of violation shall be mailed by certified mail with return receipt requested or a certificate of mailing, to the last known address of the *owner*, the owner's authorized agent, or occupant.

❖ Service methods are listed by order or preference. The first and best method is to personally serve the owners, owner's authorized agent or the occupant, in that order, at the premises cited, with a signature acknowledging receipt. The next-most desirable method is service to these same parties in the order

indicated at their place of business when it is not the premises cited.

While post office delivery by ordinary first-class mail is acceptable, most jurisdictions prefer certified mail with return receipt, followed by a certificate of mailing; however, owners or owner's authorized agents familiar with the legal process will often refuse to accept certified mail. As a result, many jurisdictions follow up returned certified mail with a request for a certificate of mailing. A certificate of mailing includes certification by the mail carrier or post office that the item was physically delivered to the address indicated, but does not verify that the addressee actually took possession of the item. The least-desirable method of service is physically posting the premises with the violation notice. When service proves difficult, many jurisdictions pursue the mailing and posting service options simultaneously to exhaust all service methods. Jurisdictions should consult legal counsel about case law regarding legal service in their communities. The following methods are most common:

- Personal to violator.
- Personal to party at premises.
- Certified mail with return receipt.
- First-class mail with certificate of mailing.
- Posting at the premises.

**[A] 109.3.2 Compliance with orders and notices.** A notice of violation issued or served as provided by this code shall be complied with by the *owner*, the owner's authorized agent, operator, occupant or other person responsible for the condition or violation to which the notice of violation pertains.

❖ The party responsible for the condition that is in non-compliance is required by this section to bring the property into code compliance. See the remainder of Section 109 for what is to be done if this does not occur.

**[A] 109.3.3 Prosecution of violations.** If the notice of violation is not complied with promptly, the *fire code official* is authorized to request the legal counsel of the jurisdiction to institute the appropriate legal proceedings at law or in equity to restrain, correct or abate such violation or to require removal or termination of the unlawful occupancy of the structure in violation of the provisions of this code or of the order or direction made pursuant hereto.

❖ The duty to pursue legal remedies through judicial due process is established by this section. Local prosecutors and fire code officials should establish policies covering the following issues regarding judicial due process proceedings:

- Length of compliance period for representative violations.
- Quality or quantity of progress toward compliance warranting an extension or representing reasonable intent to comply.

- Whether court filings should be sought during the appeal application period.
- Rules for obtaining arrest warrants for code violations.
- Rules for obtaining administrative and criminal search warrants.

The cooperation of the police department and other law enforcement agencies should be coordinated in advance. When necessary to enforce code provisions, arrangements should be made to have police or other law enforcement personnel make arrests for code violations or ignoring lawful orders of the fire code official.

**[A] 109.3.4 Unauthorized tampering.** Signs, tags or seals posted or affixed by the *fire code official* shall not be mutilated, destroyed or tampered with, or removed, without authorization from the *fire code official*.

- ❖ This section states that tampering with signs, seals or tags posted at the property is a violation of the code. The safety of occupants may depend on warning signs posted by the fire code official remaining in place.

**[A] 109.4 Violation penalties.** Persons who shall violate a provision of this code or shall fail to comply with any of the requirements thereof or who shall erect, install, alter, repair or do work in violation of the *approved construction documents* or directive of the *fire code official*, or of a permit or certificate used under provisions of this code, shall be guilty of a **[SPECIFY OFFENSE]**, punishable by a fine of not more than **[AMOUNT]** dollars or by imprisonment not exceeding **[NUMBER OF DAYS]**, or both such fine and imprisonment. Each day that a violation continues after due notice has been served shall be deemed a separate offense.

- ❖ Penalties for code violations must be established in adopting legislation. The offense, dollar amount for the fine and maximum number of days of imprisonment are to be specific in the adopting ordinance of the jurisdiction. A sample adoption ordinance is on page xxi of the code.

The code does not establish penalties for violations. The jurisdiction's judicial and legislative bodies should work with the fire code official to establish reasonable and equitable penalties for violators. The penalties set for individual violations should be representative of the severity of the act committed and the culpability of the violator. Once served with a violation notice, the violator becomes guilty of a separate offense for each day the violation continues to exist; however, most prosecutors and courts are reluctant to impose this penalty for days during the compliance period. Many violators wrongly assume that the Seventh Amendment of the U.S. Constitution, which offers protection against double jeopardy, exempts them from compliance once they have paid or served their sentence for a previous fire code violation. This is certainly not the case. Most courts reinforce the compliance requirement in such cases by making compliance a condition for completing the sentence.

Failure to comply with the judge's order mandating compliance may result in a contempt of court charge.

**[A] 109.4.1 Abatement of violation.** In addition to the imposition of the penalties herein described, the *fire code official* is authorized to institute appropriate action to prevent unlawful construction or to restrain, correct or abate a violation; or to prevent illegal occupancy of a structure or premises; or to stop an illegal act, conduct of business or occupancy of a structure on or about any premises.

- ❖ Even though the person who violated the code has paid any fine and served any sentence that may be imposed for the jurisdiction under Section 109.4, the fire code official has the right to require that the code violation be removed. If the violation is not abated, the fire code official has the right to prevent occupancy until the violation is addressed. Usually, the court will require that the violation be corrected as part of the sentence of noncompliance prior to the occupancy of the building.

## SECTION 110 UNSAFE BUILDINGS

**[A] 110.1 General.** If during the inspection of a premises, a building or structure, or any building system, in whole or in part, constitutes a clear and inimical threat to human life, safety or health, the *fire code official* shall issue such notice or orders to remove or remedy the conditions as shall be deemed necessary in accordance with this section, and shall refer the building to the building department for any repairs, *alterations*, remodeling, removing or demolition required.

- ❖ The fire code official is required to order the correction or abatement of hazardous conditions within the scope of the code and to refer the building to the building department for those operations that are within the scope of that department. The conditions listed in Section 110.1.1 represent many of the most common hazardous conditions encountered. Specific requirements supporting each of these objectives are found throughout the code.

**[A] 110.1.1 Unsafe conditions.** Structures or existing equipment that are or hereafter become unsafe or deficient because of inadequate *means of egress* or which constitute a fire hazard, or are otherwise dangerous to human life or the public welfare, or which involve illegal or improper occupancy or inadequate maintenance, shall be deemed an unsafe condition. A vacant structure that is not secured against unauthorized entry as required by Section 311 shall be deemed unsafe.

- ❖ Courts have continually upheld the right of states and their authorized subdivisions to abate public nuisances, even by demolition, and bill or assess the property owner through a tax lien for their expenses. However, care must be exercised to maintain compliance with the due process and equal protection doctrines of the Fourth and Fourteenth Amendments of the U.S. Constitution. Jurisdictions should consult legal counsel and adopt appropriate guidelines

before engaging in a nuisance abatement program.

Uninhabited or abandoned buildings that are not secured against unauthorized entry as required by Section 311 have a very high probability of intentionally set fires. When fires occur in these buildings, they present a host of unusual hazards to fire fighters. Since the buildings are uninhabited, fires may develop for significant periods of time before they are detected and reported. Accordingly, such unsecured buildings are declared by this section to be unsafe and therefore subject to remediation as provided in Section 110 (see commentary, Section 311).

**[A] 110.1.2 Structural hazards.** Where an apparent structural hazard is caused by the faulty installation, operation or malfunction of any of the items or devices governed by this code, the *fire code official* shall immediately notify the building code official in accordance with Section 110.1.

❖ The fire code official is required to report structurally unsafe buildings to the building official to secure abatement of unsafe conditions. Courts have continually upheld the right of states and their authorized subdivisions to abate public nuisances, even by demolition, and bill or assess the property owner through a tax lien for their expenses. However, care must be exercised to maintain compliance with the due process and equal protection doctrines of the Fourth and Fourteenth Amendments of the U.S. Constitution.

**[A] 110.2 Evacuation.** The *fire code official* or the fire department official in charge of an incident shall be authorized to order the immediate evacuation of any occupied building deemed unsafe where such building has hazardous conditions that present imminent danger to building occupants. Persons so notified shall immediately leave the structure or premises and shall not enter or re-enter until authorized to do so by the *fire code official* or the fire department official in charge of the incident.

❖ The fire code official must immediately order the evacuation of any premises posing a clear and imminent threat to life or property. Building occupants who are warned must comply with the evacuation order without delay. Upon leaving the building, occupants may not reenter until authorization is given by the fire code official. Severe and immediate danger anticipated in this section dictates such extreme measures to protect public health, safety and welfare.

**[A] 110.3 Summary abatement.** Where conditions exist that are deemed hazardous to life and property, the *fire code official* or fire department official in charge of the incident is authorized to abate summarily such hazardous conditions that are in violation of this code.

❖ As indicated in the commentary to Section 110.1.1, the fire code official is authorized to seek abatement action by the building department and bill the owner for abatement costs. Obviously, this is an extreme measure and should be done only when the owner, operator or occupant does not take such measures under the requirements of Section 110.4.

**[A] 110.4 Abatement.** The *owner*, the owner's authorized agent, operator or occupant of a building or premises deemed unsafe by the *fire code official* shall abate or cause to be abated or corrected such unsafe conditions either by repair, rehabilitation, demolition or other *approved* corrective action.

❖ This section describes the usual circumstance in which a building has such critical violations that it is declared unsafe by the fire code official. The owner, owner's authorized agent, operator or occupant should take abatement measures to correct the unsafe condition. If this is not done promptly, the fire code official has the authority to directly abate the unsafe conditions and bill the owner for the abatement work in accordance with Sections 110.1.1 and 110.3.

## SECTION 111 STOP WORK ORDER

**[A] 111.1 Order.** Where the *fire code official* finds any work regulated by this code being performed in a manner contrary to the provisions of this code, or in a dangerous or unsafe manner, the *fire code official* is authorized to issue a stop work order.

❖ The fire code official is authorized to issue a stop work order when the work does not comply with the code. Obviously, this is an extreme and costly measure that should be reserved for situations in which the violation is a serious safety hazard.

**[A] 111.2 Issuance.** A stop work order shall be in writing and shall be given to the *owner* of the property, or to the *owner's* authorized agent, or to the person doing the work. Upon issuance of a stop work order, the cited work shall immediately cease. The stop work order shall state the reason for the order, and the conditions under which the cited work is authorized to resume.

❖ The stop work order is to be in writing and must cite the reason for issuing the order.

Upon receipt of a violation notice from the fire code official, all construction activities identified in the notice must immediately cease, except as expressly permitted to correct the violation.

Construction activities that are outside of the scope of the issue involved with the stop work order are not affected and need not stop; thus, the scope of the order must be clearly stated.

**[A] 111.3 Emergencies.** Where an emergency exists, the *fire code official* shall not be required to give a written notice prior to stopping the work.

❖ This section gives the fire code official the authority to stop the work in dispute immediately when, in his or her opinion, there is an unsafe emergency condition that has been created by the work. The need for the written notice is suspended for this situation so that the work can be stopped immediately. After the work is stopped, immediate measures should be taken to correct the work at issue.

[A] **111.4 Failure to comply.** Any person who shall continue any work after having been served with a stop work order, except such work as that person is directed to perform to remove a violation or unsafe condition, shall be liable to a fine of not less than [AMOUNT] dollars or more than [AMOUNT] dollars.

- ❖ The local jurisdiction is to designate the fine that is to apply to any person who continues work that is at issue, other than abatement work. The dollar amounts for the minimum and maximum fines are to be specified in the adopting ordinance. A sample adoption ordinance is on page xxi of the code.

## SECTION 112 SERVICE UTILITIES

[A] **112.1 Authority to disconnect service utilities.** The *fire code official* shall have the authority to authorize disconnection of utility service to the building, structure or system in order to safely execute emergency operations or to eliminate an immediate hazard. The *fire code official* shall notify the serving utility and, where possible, the *owner* or the owner's authorized agent and the occupant of the building, structure or service system of the decision to disconnect prior to taking such action. If not notified prior to disconnection, then the *owner*, the owner's authorized agent or occupant of the building, structure or service system shall be notified in writing as soon as practical thereafter.

- ❖ This section authorizes the fire code official to order the disconnection of building utilities that interfere with emergency operations or contribute to a public safety hazard. This section also provides that such an action must be preceded by written notice to the utility and the owner or owner's authorized agent and occupants of the building. When the hazard to the public health, safety or welfare is so imminent as to mandate immediate disconnection, this section makes it clear that the fire code official has the authority and even the obligation to cause disconnection without notice.

## SECTION 113 FEES

[A] **113.1 Fees.** A permit shall not be issued until the fees have been paid, nor shall an amendment to a permit be released until the additional fee, if any, has been paid.

- ❖ The code anticipates that jurisdictions will establish their own fee schedules. It is the intent that the fees collected by the department for permit issuance, plan review and inspection be adequate to cover the costs to the department in these areas. If the department has additional duties, then its budget will need to be supplemented from the general fund. This section requires that all fees be paid prior to permit issuance or release of an amendment to a permit. Since department operations are intended to be supported by fees paid by the user of department activities, it is

important that these fees are received before incurring any expense. This philosophy has resulted in some departments having fees paid prior to the performance of two areas of work: plan review and inspection.

[A] **113.2 Schedule of permit fees.** A fee for each permit shall be paid as required, in accordance with the schedule as established by the applicable governing authority.

- ❖ The jurisdiction is responsible for promulgating a schedule of fees to be charged for operational or construction permits. Permit fees should be established by law, such as in an ordinance adopting the code, a separate ordinance or a legally promulgated regulation, as required by state or local law. Fee schedules for operational permits should be based on an analysis of the amount of time and resources to be expended by the jurisdiction in administering the permit. Fee schedules for construction permits are often based on a valuation of the work to be performed. This concept is based on the proposition that the valuation of a project is related to the amount of work to be expended in plan review, inspections and administering the permit, plus an excess to cover the department overhead.

[A] **113.3 Work commencing before permit issuance.** A person who commences any work, activity or operation regulated by this code before obtaining the necessary permits shall be subject to an additional fee established by the applicable governing authority, which shall be in addition to the required permit fees.

- ❖ The fire code official will incur certain costs (i.e., inspection time and administrative) when investigating and citing a person who has commenced work, activity or operation without having obtained a permit. The fire code official is, therefore, entitled to recover these costs by establishing a fee, in addition to that collected when the required permit is issued, to be imposed on the responsible party. Note that this is not a penalty, as described in Section 109.4, for which the person can also be liable.

[A] **113.4 Related fees.** The payment of the fee for the construction, *alteration*, removal or demolition of work done in connection to or concurrently with the work or activity authorized by a permit shall not relieve the applicant or holder of the permit from the payment of other fees that are prescribed by law.

- ❖ The fees for a permit may be in addition to other fees required by the jurisdiction or others for related items, such as sewer connections, water service taps, driveways and signs and others. It cannot be construed that the fire code permit fee includes these other items.

[A] **113.5 Refunds.** The applicable governing authority is authorized to establish a refund policy.

- ❖ This section allows for a refund of fees, which may be full or partial, typically resulting from the revocation, abandonment or discontinuance of a project or oper-

## SCOPE AND ADMINISTRATION

ation for which a permit has been issued and fees have been collected. The refund of fees should be related to the cost of enforcement services not provided because of the termination of the project or operation. The fire code official, when authorizing a fee refund, is authorizing the disbursement of public funds; therefore, the request for a refund should be in writing and for good cause.

# Chapter 2: Definitions

## General Comments

All terms used in the code and their definitions are listed alphabetically in Chapter 2. While a defined term may be used in one chapter or another, the meaning provided in Chapter 2 is applicable throughout the code.

Where understanding of a term's definition is especially key to or necessary for understanding of a particular code provision, the term is shown in italics wherever it appears in the code. This is true only for those terms that have a meaning that is unique to the code. In other words, the generally understood meaning of a term or phrase might not be sufficient or consistent with the meaning prescribed by the code; therefore, it is essential that the code-defined meaning be known.

Guidance regarding tense, gender and plurality of defined terms as well as terms not defined in the code is also provided.

## Purpose

Codes by their very nature are technical documents. Every word, term and punctuation mark can alter a sentence's meaning and, if misused, muddy its intent.

Further, the code, with its broad scope of applicability, includes terms that have a different meaning than the generally accepted meaning of the term. Additionally, these terms can have multiple meanings depending on the context or discipline in which they are being used.

For these reasons, maintaining a consensus on the specific meaning of terms contained in the code is essential. Chapter 2 performs this function by stating clearly what specific terms mean for the purpose of the code.

---

## SECTION 201 GENERAL

**201.1 Scope.** Unless otherwise expressly stated, the following words and terms shall, for the purposes of this code, have the meanings shown in this chapter.

❖ This section contains the definitions for application of the code and the use of the words and terms is governed by the provisions of this section. This includes code-defined terms as well as those terms that are not.

**201.2 Interchangeability.** Words used in the present tense include the future; words stated in the masculine gender include the feminine and neuter; the singular number includes the plural and the plural, the singular.

❖ While the definitions are to be taken literally, gender and tense are to be considered interchangeable.

**201.3 Terms defined in other codes.** Where terms are not defined in this code and are defined in the *International Building Code*, *International Fuel Gas Code*, *International Mechanical Code* or *International Plumbing Code*, such terms shall have the meanings ascribed to them as in those codes.

❖ This section states that when a term is not defined in the code but is defined in another volume of the *International Code*<sup>®</sup> family, the meaning found in those

codes can be used. This adds consistency to the application of the codes.

**201.4 Terms not defined.** Where terms are not defined through the methods authorized by this section, such terms shall have ordinarily accepted meanings such as the context implies. *Merriam Webster's Collegiate Dictionary, 11th Edition*, shall be considered as providing ordinarily accepted meanings.

❖ Another resource for defining words or terms not defined within the code or other *International Codes*<sup>®</sup> (I-Codes<sup>®</sup>) is simply their "ordinarily accepted meaning." With some words, a dictionary definition may be sufficient, if the definition is applied within an appropriate context. Not all dictionaries, however, define words the same and not all parts of this country apply the same meanings to all words. The dictionary referenced in this section provides a standardized resource for defining terms and establishing "ordinarily accepted" meanings of words, thus reducing the likelihood of inconsistent enforcement of the code.

Some terms used throughout the code may not be defined in Chapter 2 or in a dictionary. In those cases, the user should first turn to the definitions contained in the referenced standards (see Chapter 80) and then refer to published textbooks on the subject in question.

## SECTION 202 GENERAL DEFINITIONS

**[BG] 24-HOUR BASIS.** The actual time that a person is an occupant within a facility for the purpose of receiving care. It shall not include a facility that is open for 24 hours and is capable of providing care to someone visiting the facility during any segment of the 24 hours.

❖ Care offered over a 24-hour basis is used to differentiate groups and levels of protection between institutional facilities that typically house patients for more than a day, such as hospitals, detoxification facilities, foster care and nursing homes, from other care facilities that keep patients for only part of a day, such as day cares, clinics, day surgery centers and outpatient facilities. To better understand how these concepts work together, see the definitions for “Ambulatory care facility,” “Custodial care,” “Medical care,” “Personal care service” and “Incapable of self-preservation.” Facilities that have patients/residents/customers that typically stay for 24 hours or more are considered to be providing care on a 24-hour care basis. However, a facility such as a day care or an urgent care facility, that operates 24 hours a day, would not be considered as providing care on a 24-hour basis if the clients did not stay 24 hours, but instead were in and out of the facility similar to one that closed for the night.

**[BE] ACCESSIBLE MEANS OF EGRESS.** A continuous and unobstructed way of egress travel from any *accessible* point in a building or facility to a *public way*.

❖ Accessible means of egress requirements are needed to provide those persons with physical disabilities or mobility impairments a means of egress to exit the building. Because of physical limitations, some occupants may need assistance to exit a building. See Section 1009 for requirements establishing areas where people can safely wait for assisted rescue. Chapter 4 also includes requirements in the fire safety and evacuation plans for specific planning to address occupants who may need assistance in evacuation during emergencies. In addition, Chapter 9 of the code includes requirements for emergency evacuation notification for persons with hearing and vision disabilities.

The accessible means of egress requirements may not be the same route as that required for ingress into the building [see Sections 1104 and 1105 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>)]. For example, a two-story building requires one accessible route to connect all accessible spaces within the building. The accessible route to the second level is typically by an elevator. During a fire emergency, persons with mobility impairments on the second level would be moving to the exit stairways for assisted rescue, not back the way they came in, via the elevator.

**[BE] ACCESSIBLE ROUTE.** A continuous, unobstructed path that complies with Chapter 11 of the *International Building Code*.

❖ There are typically more physical barriers in the built environment to people with a mobility impairment than in any other category of disability. An accessible route enables a person with a mobility impairment to approach and utilize a facility’s accessible fixtures and features. While there are a variety of mobility devices, the design and construction of an accessible route is based predominantly on provisions necessary for accessibility to a person using a wheelchair. Accessible routes are required for both ingress and egress (see Sections 1009 and 1104).

An accessible route must also be safe and usable by people with other disabilities and those without disabilities; therefore, requirements are set forth in consideration of those needs. For example, there are restrictions on objects that protrude into a circulation path in consideration not only of a person with a visual impairment but also the possibility of smoke limiting visibility during an emergency.

**AEROSOL.** A product that is dispensed from an aerosol container by a propellant.

Aerosol products shall be classified by means of the calculation of their chemical heats of combustion and shall be designated Level 1, Level 2 or Level 3.

**Level 1 aerosol products.** Those with a total chemical heat of combustion that is less than or equal to 8,600 British thermal units per pound (Btu/lb) (20 kJ/g).

**Level 2 aerosol products.** Those with a total chemical heat of combustion that is greater than 8,600 Btu/lb (20 kJ/g), but less than or equal to 13,000 Btu/lb (30 kJ/g).

**Level 3 aerosol products.** Those with a total chemical heat of combustion that is greater than 13,000 Btu/lb (30 kJ/g).

❖ The intent of the code is to regulate those aerosols that contain a flammable propellant, such as butane, isobutane or propane and cannot be protected easily. An aerosol product such as whipped cream is a water-based material with a nonflammable propellant (nitrous oxide) and would, therefore, not be regulated as a hazardous material. Many aerosols are water based and, while containing some flammable material, do not produce a threat to standard commodity protection scenarios. The contents of the aerosol container may be dispensed in the form of a mist, spray, foam, gel or aerated powder.

Because of the wide range of flammability of aerosol products, a classification system was established to determine the required level of fire protection. Categories are defined according to the aerosol’s chemical heat of combustion expressed in Btus per pound (Btu/lb). Aerosol category classifications of Levels 1,

2 and 3 are used to avoid confusion with flammable liquid classifications.

Examples of Level 1 aerosol products are air fresheners, shaving gel and whipped cream. Level 1 aerosols are not regulated as a hazardous material and are essentially exempt from the requirements of Sections 307 and 414 of the IBC. Examples of Level 2 aerosols include some hair sprays and insect repellents. Level 3 aerosols include carburetor cleaner and other petroleum-based aerosols.

While aerosols are defined as hazardous materials, note that they are not listed in Table 5003.1.1(1) or 5003.1.1(2) [IBC Table 307.1(1) or 307.1(2)] as having a maximum allowable quantity per control area. As stated in Section 307.1, Exception 11 of the IBC, a building or structure used for aerosol storage is classified as Group S-1, provided the requirements of Chapter 51 of the code are satisfied; therefore, the Group H classification is not utilized since the design must satisfy Chapter 51 of the code in order to be in compliance.

It is important to note that, in dealing with aerosols, the designation of “flammable” on an aerosol can is strictly a consumer warning labeling and must not be confused with the aerosol level printed on the carton. This is important because there are instances where a Level 3 aerosol product requiring the highest level of sprinkler protection will not be flammable for consumer use, and conversely there are instances where a flammable aerosol may be a Level 1 aerosol product and could require only Class III commodity protection in accordance with NFPA 13.

**AEROSOL CONTAINER.** A metal can, or a glass or plastic bottle designed to dispense an aerosol.

- ❖ All design criteria for the aerosol container, including the maximum size and minimum strength, are set by the U.S. Department of Transportation (DOTn 49 CFR) and addressed in Section 5104. These container regulations are necessary for the safe transportation of aerosol products.

**AEROSOL WAREHOUSE.** A building used for warehousing aerosol products.

- ❖ Any building used primarily for storing large quantities of aerosol products would be considered an aerosol warehouse and would be subject to fire safety requirements that are consistent with the types of aerosol products stored and their known hazards. Commodities other than aerosol products are allowed to be stored in an aerosol warehouse in accordance with Chapter 51 (see Section 5104.4).

**AGENCY.** Any emergency responder department within the jurisdiction that utilizes radio frequencies for communication. This could include, but not be limited to, various public safety agencies such as fire departments, emergency medical services and law enforcement.

- ❖ This definition provides clarification as to the primary emergency responders that are intended to be included in the term, but does not rule out other

responders who might also need the use of the emergency responders radio coverage system (ERRCS), based on the needs and policies of the adopting jurisdiction.

**AGENT.** A person who shall have charge, care or control of any structure as *owner*, or agent of the *owner*, or as executor, executrix, administrator, administratrix, trustee or guardian of the estate of the *owner*. Any such person representing the actual *owner* shall be bound to comply with the provisions of this code to the same extent as if that person was the *owner*.

- ❖ An agent, for purposes of the code, is a person who has full authority under the law to act for or represent the owner of a building subject to the provisions of the code. An agent acts by the authority of the person he or she represents and generally has the same powers as the person represented. It is commonplace for building owners to retain the services of management agents to conduct all affairs pertinent to their building, including code compliance.

**[BG] AGRICULTURAL BUILDING.** A structure designed and constructed to house farm implements, hay, grain, poultry, livestock or other horticultural products. This structure shall not be a place of human habitation or a place of employment where agricultural products are processed, treated or packaged, nor shall it be a place used by the public.

- ❖ This definition is needed for the proper application of the utility and miscellaneous occupancy group provisions. The use of the building is quite restricted such that buildings that include habitable or public spaces are not agricultural buildings by definition.

**AGRO-INDUSTRIAL.** A facility, or portion thereof, housing operations involving the transforming of raw agricultural products into intermediate or consumable products.

- ❖ This definition coordinates with the requirements in Chapter 28 that have been scoped to address facilities addressing the creation of these products. Providing this definition helps to understand what types of facilities are regulated by Sections 2808 and 2809.

**[BG] AIR-INFLATED STRUCTURE.** A structure that uses air-pressurized membrane beams, arches or other elements to enclose space. Occupants of such a structure do not occupy the pressurized areas used to support the structure.

- ❖ This type of membrane structure is characterized by multiple layers arranged such that air-pressurized membrane beams, arches or similar elements are formed. These elements are pressurized with air and form the membrane structure. Note that the occupants of the structure are not subjected to the pressurized areas, because the pressurization is in the structural elements, not within the space used by the occupants. This type of structure is generally much smaller than an air-supported structure and differs in that it depends for support on the inflation of balloon-like sections over, under or around the occupants. The occupants normally are found within a surrounding structure consisting of these inflated sections. Possibly the most common example of this kind of

## DEFINITIONS

structure is the “Moonwalk” children’s entertainment structure, which has an inflated floor structure for children to play on and also inflated columns that support an overhead canopy and plastic mesh walls. Commentary Figure 202-A1 illustrates an air-inflated structure.

**[BG] AIR-SUPPORTED STRUCTURE.** A structure wherein the shape of the structure is attained by air pressure, and occupants of the structure are within the elevated pressure area. Air supported structures are of two basic types:

❖ An air-supported structure identifies those membrane structures that are completely pressurized for the purposes of supporting the membrane covering. Most “domed” sports arenas use air pressure within the structure to support the membrane covering. The membrane covering can consist of one layer or multi-

ple layers; thus, air-supported structures are classified as either “single skin” or “double skin.” Commentary Figure 202-A2 illustrates an air-supported structure.

**Double skin.** Similar to a single skin, but with an attached liner that is separated from the outer skin and provides an airspace which serves for insulation, acoustic, aesthetic or similar purposes.

❖ A double-skin, air-supported structure contains multiple layers of membrane sheathing. The membranes are usually separated by enough distance to allow for pressurized air or other materials to be inserted between the plies. The pressurized air or other materials usually serve to increase the insulating and acoustical properties.

**Figure 202-A1**  
**EXAMPLE OF AIR-INFLATED MEMBRANE STRUCTURE**

**Figure 202-A2**  
**AIR-SUPPORTED MEMBRANE STRUCTURE—SWIMMING POOL COVER**

**Single skin.** Where there is only the single outer skin and the air pressure is directly against that skin.

- ❖ A single-skin, air-supported structure consists of just one membrane covering that is directly supported by the interior pressurized air. No other membranes are provided for insulating or acoustical purposes. If the membrane covering consists of several laminated plies, such an arrangement is still considered a single-skin, air-supported structure.

**AIRCRAFT MOTOR-VEHICLE FUEL-DISPENSING FACILITY.** That portion of property where flammable or *combustible liquids* or gases used as motor fuels are stored and dispensed from fixed automotive-type equipment into the fuel tanks of aircraft.

- ❖ Since the first edition of the code, Sections 2003.5 and 2006.1 have required that aircraft motor-vehicle fuel-dispensing facilities comply with Chapter 23. This definition, in addition to the scope statement in Section 2301.1, provides correlation with Chapter 20, making it clear that Chapter 23 does, in fact, apply to aircraft motor-vehicle fuel-dispensing facilities. While the text does not specify limitations on the types of aircraft involved, the typical aircraft that might be brought to a fixed fueling station that uses equipment similar to that used at automotive service stations, rather than fueling from hydrants or fuel tanker trucks that are used on larger aircraft, would likely be small general aviation-type aircraft.

**AIRCRAFT OPERATION AREA (AOA).** Any area used or intended for use for the parking, taxiing, takeoff, landing or other ground-based aircraft activity.

- ❖ Any area involving aircraft, whether moving or stationary, is known as the aircraft operating area. This area has special operating procedures and hazards.

**AIRPORT.** An area of land or structural surface that is used, or intended for use, for the landing and taking off of aircraft with an overall length greater than 39 feet (11 887 mm) and an overall exterior fuselage width greater than 6.6 feet (2012 mm), and any appurtenant areas that are used or intended for use for airport buildings and other airport facilities.

- ❖ Those structures and operations included in an airport are terminal buildings; maintenance hangars; runways; taxiways; loading and unloading of passengers, luggage and freight; and control towers with all the land involved in performing these functions.

**[BE] AISLE.** An unenclosed *exit access* component that defines and provides a path of egress travel.

- ❖ Aisles and aisle accessways are both utilized as part of the means of egress in facilities where tables, seats, displays or other furniture may limit the path of travel. The aisle accessways lead to the main aisles that lead to the exits from the space and building (see Commentary Figure 202-A3). While both may result in a confined path of travel, an aisle is an unenclosed component, while a corridor would be an enclosed component of the means of egress. See Sections 1018 and 1029 for requirements for aisles.

**[BE] AISLE ACCESSWAY.** That portion of an *exit access* that leads to an *aisle*.

- ❖ As illustrated in Commentary Figure 202-A3, an aisle accessway is intended for one-way travel or limited two-way travel. The space between tables, seats, displays or other furniture (i.e., aisle accessway) utilized for means of egress will lead to a main aisle. See Sections 1018 and 1029 for requirements for aisle accessways.

**Figure 202-A3  
AISLES AND AISLE ACCESSWAYS**

**ALARM, NUISANCE.** See “Nuisance alarm.”

**ALARM DEVICE, MULTIPLE STATION.** See “Multiple-station alarm device.”

**ALARM NOTIFICATION APPLIANCE.** A fire alarm system component such as a bell, horn, speaker, light or text display that provides audible, tactile or visible outputs, or any combination thereof. See also “Audible alarm notification appliance” or “Visible alarm notification appliance.”

- ❖ The code requires that fire alarm systems be equipped with approved alarm notification appliances so that in an emergency, the fire alarm system will notify the occupants of the need for evacuation or implementation of the fire emergency plan. Alarm notification devices required by the code are of two general types: visible and audible. Except for emergency voice/alarm communication systems, once the fire alarm system has been activated, all visible and audible communication alarms are required to activate. Emergency voice/alarm communication systems are special signaling systems that are activated selectively in response to specific emergency conditions but have the capability to be activated throughout the building if necessary.

## DEFINITIONS

**ALARM SIGNAL.** A signal indicating an emergency requiring immediate action, such as a signal indicative of fire.

❖ This is a general term for all types of supervisory and trouble signals. An example would be a supervisory (tamper) switch on a sprinkler control valve. It could also be the response to a specific device that is not part of the alarm notification system but causes a specific function, such as a smoke detector for elevator recall. The activation of the device does not necessarily indicate that there is a fire; however, the level of protection may have been compromised (see also the definitions of “Fire alarm signal” and “Supervisory signal”).

**ALARM VERIFICATION FEATURE.** A feature of automatic fire detection and alarm systems to reduce unwanted alarms wherein smoke detectors report alarm conditions for a minimum period of time, or confirm alarm conditions within a given time period, after being automatically reset, in order to be accepted as a valid alarm-initiation signal.

❖ False fire (evacuation) alarms are a nuisance. For this reason the code specifies that alarms activated by smoke detectors are not to be sounded until the alarm signal is verified by cross-zoned detectors in a single protected area or by system features that will retard the alarm until the signal is determined to be valid. Valid alarm initiation signals can be determined by detectors that report alarm conditions for a minimum period of time or that, after being reset, continue to report an alarm condition. The alarm verification feature may not retard signal activation for a period of more than 60 seconds and must not apply to alarm-initiating devices other than smoke detectors (which may be connected to the same circuit). Alarm verification is not the same as presignal features that delay an alarm signal for more than 1 minute and that are allowed only where specifically permitted by the authority having jurisdiction.

**ALCOHOL-BASED HAND RUB.** An alcohol-containing preparation designed for application to the hands for reducing the number of viable microorganisms on the hands and containing ethanol or isopropanol in an amount not exceeding 95-percent by volume.

❖ Alcohol-based hand rub solutions are typically packaged in pump bottles or nonrefillable soft bladders for insertion into a wall-mounted pump dispenser. They are typically closed to the atmosphere with no mixing or refilling of containers, which makes the ignition of fugitive vapors very unlikely. See the commentary to Sections 5705.5 and 5705.5.1 for further information.

As part of ongoing research to control the outbreak of multiple-drug resistant bacteria, such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant *Enterococcus* (VRE) and similar “super bugs,” which are highly resistant to antibiotics, the U.S. Centers for Disease Control (CDC) and Food and Drug Administration (FDA) have continued to study the performance of alcohol-based hand rubs. As a result of their research, both agencies now rec-

ommend that the concentration of ethanol or isopropanol in alcohol-based hand rubs be increased to 95 percent by volume. The research found that a higher alcohol concentration offers much more virucidal activity when compared to alcohol-based hand rubs formulated with 70-percent alcohol by volume. To help protect health care workers, hospital patients and long-term care residents against health care-acquired infections, the definition of 11 alcohol-based hand rubs has been revised in the 2012 edition of the code to increase the permissible volume of ethyl or isopropyl alcohol from 70 to 95 percent. It should be noted that alcohol-based hand rubs formulated at this concentration are classified as Class IB flammable liquids.

Because of the increased volume of alcohol in alcohol-based hand rubs and to supplement the original fire test and modeling findings, the heat release rate and burning time of 95-percent ethanol were calculated using formulae found in the *SFPE Handbook of Fire Protection Engineering* and compared to weaker solutions found in older alcohol-based hand rubs. The calculations confirmed that 95-percent ethanol will exhibit the highest heat release (282 kW) when compared to more dilute ethanol/water solutions (146-240 kW) but exhibited the shortest duration pool fire (83 seconds versus 95 to 119 seconds) because the lack of water allowed quicker volatilization of the fuel.

**ALCOHOL-BLENDED FUELS.** Flammable liquids consisting of 10-percent or greater, by volume, ethanol or other alcohols blended with gasoline.

❖ Alcohols are polar compounds that exhibit increased moisture absorption, water solubility, polar solvency and solution conductivity relative to gasoline. Alcohol-gasoline blended fuels have unique properties that may affect dispensing equipment and hardware material compatibility and fire response. The most common alcohol blended fuel is E85, which consists of nominally 85-percent ethanol and 15-percent unleaded gasoline. The blending is usually done at the processing plant, or may be accomplished filling the delivery tanker with the designated percentage of each fuel required to achieve the desired percentage. In cold climates, the fuel blend may include more gasoline to improve vehicle performance. The properties of E85 are listed in Commentary Figure 202-A4. Ethanol is a flammable, colorless liquid with a faint alcohol odor. The color of ethanol fuel blends depends on the color of the gasoline in the blend. Blends may also have a gasoline-like odor. See the commentary to Section 2306.8 for a more detailed discussion of the hazards presented by these alternative fuels.

**[A] ALTERATION.** Any construction or renovation to an existing structure other than a repair or addition.

❖ The code utilizes this term to reflect construction operations intended for an existing building but not within the scope of an addition or repair [see the defi-

nitions of “Addition” and “Repair” in the IEBC). (see IBC Section 101.4.7 for a reference to the *International Existing Building Code*® (IEBC®))

**[BE] ALTERNATING TREAD DEVICE.** A device that has a series of steps between 50 and 70 degrees (0.87 and 1.22 rad) from horizontal, usually attached to a center support rail in an alternating manner so that the user does not have both feet on the same level at the same time.

❖ An alternating tread device is commonly used in areas that would otherwise be provided with a ladder where there is not adequate space for a full stairway. Where these devices are permitted is specifically listed (e.g., Section 1006.2.2.1). The device is used extensively in industrial facilities for worker access to platforms or equipment. Requirements are found in Section 1011.

**[BG] AMBULATORY CARE FACILITY.** Buildings or portions thereof used to provide medical, surgical, psychiatric, nursing or similar care on a less-than-24-hour basis to persons who are rendered incapable of self-preservation by the services provided.

❖ The code provides different requirements for outpatient clinics, ambulatory care facilities and hospitals. Ambulatory care facilities, while still classified as a Group B occupancy, have additional standards above those of an outpatient clinic primarily due to the fact that patients are temporarily unable to respond to emergencies because of the treatment processes (see commentary, Section 422 of the IBC). Ambulatory care facilities include day surgery centers and

similar facilities where patients may receive fairly intensive treatment, but do not stay at the facility more than a few hours. If patients are receiving care on a 24-hour basis, such facilities would be defined as hospitals. (See definition of “24-hour basis.”)

**AMMONIUM NITRATE.** A chemical compound represented by the formula NH<sub>4</sub>NO<sub>3</sub>.

❖ Ammonium nitrate is a fairly simple compound (NH<sub>4</sub>NO<sub>3</sub>) but one that has an extremely complex set of reactions in a fire. The history of ammonium nitrate has been marked by major fires and explosions. Certain characteristics have caused or contributed to these fires and explosions. The following properties of ammonium nitrate are similar to those of other nitrates: (1) it is an oxidizing agent—it contains available oxygen that can make ignition easier and cause a fire to burn with surprising intensity; (2) it is hygroscopic—absorbing moisture from the air or from substances it touches and (3) it is deliquescent—as it absorbs moisture, a portion will liquefy and nearby combustibles can become impregnated with an oxidizing salt.

**ANNUNCIATOR.** A unit containing one or more indicator lamps, alphanumeric displays or other equivalent means in which each indication provides status information about a circuit, condition or location.

❖ This refers to the panel that displays the status of the monitored fire protection systems and devices. It is not the fire alarm control unit; however, the control panel may function as an annunciator.

Vapor density	Ethanol vapor, like gasoline vapor, is denser than air and tends to settle in low areas. However, ethanol vapor disperses rapidly.
Solubility in water	Fuel ethanol will mix with water, but at high enough concentrations of water, the ethanol will separate from the water.
Energy content	For identical volumes, ethanol contains less energy than gasoline. On an energy basis, 1.0 gallon of E85 is equivalent to 0.72 gallons of gasoline.
Flame visibility	A fuel ethanol flame is less bright than a gasoline flame but is easily visible in daylight.
Specific gravity	Pure ethanol and ethanol blends are heavier than gasoline.
Conductivity	Ethanol and ethanol blends conduct electricity. Gasoline, by contrast, is an electrical insulator.
Toxicity	Ethanol is less toxic than gasoline or methanol. Carcinogenic compounds are not present in pure ethanol; however, because gasoline is used in the blend, E85 is considered to be potentially carcinogenic.
Flammability	At low temperatures, the vapor concentration in an E85 tank can fall into the flammable range. The temperature for flammable E85 vapors depends on the E85 volatility. Although less likely than with E85, gasoline tanks can also contain flammable vapors at extremely low temperature.
Fire fighting	Fuel ethanol fires, like all fires, should be taken seriously. An E85 fire should be handled like a gasoline fire. Use a CO <sub>2</sub> or dry chemical extinguisher that is marked B, BC or ABC. An alcohol-type or alcohol-resistant (ARF) foam may be used to effectively combat fuel ethanol fires. Never use water to control a fire involving high-concentration fuel ethanol such as E85.

For SI: 1 gallon = 3.785 L.

**Figure 202-A4  
PROPERTIES OF FUEL ETHANOL**

## DEFINITIONS

[A] **APPROVED.** Acceptable to the *fire code official*.

❖ As related to the process of acceptance of building installations, including materials, equipment and construction systems, this definition identifies where the ultimate authority rests. Whenever this term is used, it intends that only the enforcing authority can accept a specific installation or component as complying with the code. For the IBC and *International Residential Code*® (IRC®), the “building official” is identified as the person responsible for administering its provisions. For the *International Fire Code*® (IFC®), the “fire code official” is identified as the person responsible for administering IFC provisions. For the *International Energy Conservation Code*® (IECC®), *International Fuel Gas Code*® (IFGC®), *International Green Construction Code*® (IgCC®), *International Mechanical Code*® (IMC®), *International Plumbing Code*® (IPC®), *International Property Maintenance Code*® (IPMC®), *International Swimming Pool and Spa Code*® (ISPSA®) and *International Wildfire-Urban Interface Code*® (IWUIC®), the “code official” is identified as the person responsible.

[BG] **AREA, BUILDING.** The area included within surrounding *exterior walls* (or *exterior walls* and *fire walls*) exclusive of vent shafts and *courts*. Areas of the building not provided with surrounding walls shall be included in the building area if such areas are included within the horizontal projection of the roof or floor above.

❖ Allowable building areas (as established by the provisions of Chapter 5 and Table 506.2 of the IBC) are a function of the potential fire hazard and the level of fire endurance of the building's structural elements, as defined by the types of construction in Chapter 6 of the IBC. A building area is the “footprint” of the building; that is, the area measured within the perimeter formed by the inside surface of the exterior walls. This excludes spaces that are inside this perimeter and open to the outside atmosphere at the top, such as open shafts and courts (see Section 1206 of the IBC). When a portion of the building has no exterior walls, the area regulated by Chapter 5 of the IBC is defined by the projection of the roof or floor above [see IBC Commentary Figure 202(5)]. The roof overhang on portions of a building where there are exterior enclosure walls does not add to the building area because the area is defined by exterior walls.

[BE] **AREA OF REFUGE.** An area where persons unable to use *stairways* can remain temporarily to await instructions or assistance during emergency evacuation.

❖ The area of refuge is a temporary waiting area used during emergency evacuations for persons who are unable to exit the building using the stairways. The fire safety plans (in accordance with Section 404) include the locations of areas of refuge so that the fire department will know where people may be waiting for rescue assistance. See Section 1009 for where

areas of refuge are required at stairways and elevators. Areas of refuge have requirements for separation, size, signage, instructional information and two-way communication systems.

**ARRAY.** The configuration of storage. Characteristics considered in defining an array include the type of packaging, flue spaces, height of storage and compactness of storage.

❖ This term defines the configuration of storage, with its essential components being the manner in which the commodity is packaged (stored either in piled formation or on a rack storage system); the amount of flue space between formations of the commodity; height, width and length of any one array and compactness.

**ARRAY, CLOSED.** A storage configuration having a 6-inch (152 mm) or smaller width vertical flue space that restricts air movement through the stored commodity.

❖ The term “closed array” was effectively defined as the result of a number of fire tests. These tests were conducted with the sample test assembly array employing 6-inch-wide (152 mm) longitudinal flues and no transverse flues.

[BG] **ATRIUM.** An opening connecting two or more stories other than enclosed *stairways*, elevators, hoistways, escalators, plumbing, electrical, air-conditioning or other equipment, which is closed at the top and not defined as a mall. Stories, as used in this definition, do not include balconies within assembly groups or mezzanines that comply with Section 505 of the *International Building Code*.

❖ The definition identifies that an atrium is a floor opening or a series of floor openings that connect the environments of adjacent stories. The definition of “Atrium” excludes enclosed stairways, elevators, hoistways and other similar openings in order to clarify that those elements would not fall under the purview as to what is considered an atrium and, therefore, the associated requirements found in Section 404 of the IBC would not apply. What this does not preclude is the inclusion of elevators and open stairways within atriums. Such elements would need to be entirely within the atrium to meet the separation requirements found in Section 404.6 of the IBC. Building features, such as stairways, elevators, hoistways, escalators, plumbing, electrical, air conditioning or other equipment openings, are required to be enclosed in fire-resistance-rated shafts in accordance with Sections 712 and 713 of the IBC. Atriums are specified in Section 712.1.7 of the IBC to address openings in horizontal assemblies. An atrium is not defined by size or use. A series of floor openings that are enclosed with exterior walls, yet open at the roof, would be considered a court and would be exempt from the requirements of Section 404 of the IBC. Balconies associated with assembly occupancies and mezzanines are not considered individual stories that would contribute to the classification of a space as an atrium.

**[BG] ATTIC.** The space between the ceiling beams of the top story and the roof rafters.

❖ The definition of “Attic” identifies the specific portion of a building or structure for the purposes of determining the applicability of requirements that are specific to attics, such as ventilation (see Section 1203 of the IBC) and draftstopping (see Section 718 of the IBC). Additionally, the IBC has access requirements (see Section 1209 of the IBC) and uniformly distributed live load requirements (see Table 1607.1 of the IBC) for attics. An attic is considered the space or area located immediately below the roof sheathing within the roof framing system of a building. Pitched roof systems, such as gabled, hip, sawtoothed or curved roofs, all create spaces between the roof sheathing and ceiling membrane, which are considered attics.

**AUDIBLE ALARM NOTIFICATION APPLIANCE.** A notification appliance that alerts by the sense of hearing.

❖ Audible alarms that are part of a fire alarm system must be loud enough to be heard in every occupied space of a building. Section 907.5.2.1.1 prescribes the minimum sound pressure level for all audible alarm notification appliances depending on the occupancy of the building and the function of the space.

**AUTOMATED RACK STORAGE.** Automated rack storage is a stocking method whereby the movement of pallets, products, apparatus or systems are automatically controlled by mechanical or electronic devices.

❖ This definition for automated rack storage systems applies to storage and retrieval systems designed for movement of palletized loads commonly used in warehouses containing extra-high-rack storage of Class I-IV commodities over 40 feet (12 192 mm) in height or high-hazard commodities over 30 feet (9144 mm) in height. Conventional material handling equipment such as forklifts generally cannot be used above this height to safely retrieve or store palletized loads. It is not uncommon for these systems to be used in buildings with roof heights over 100 feet (30 480 mm). NFPA 13 has no limit on the height of storage racks. See also the commentary to Section 3209.4.

**AUTOMATIC.** As applied to fire protection devices, a device or system providing an emergency function without the necessity for human intervention and activated as a result of a predetermined temperature rise, rate of temperature rise or combustion products.

❖ This term, when used in conjunction with fire protection systems or devices, means that the system or device will perform its intended function without a person being present or performing any task in its control or operation. The device or system has the inherent capability to detect a developing fire condition and perform some predetermined function. Automatic devices and systems operate completely without human presence or intervention.

**AUTOMATIC FIRE-EXTINGUISHING SYSTEM.** An *approved* system of devices and equipment which automatically detects a fire and discharges an *approved* fire-extinguishing agent onto or in the area of a fire.

❖ This term is the generic name for all types of automatic fire-extinguishing systems, including the most common type—the automatic sprinkler system. See Section 904 for requirements for particular alternative automatic fire-extinguishing systems, such as wet-chemical, dry-chemical, foam, carbon dioxide, Halon, clean-agent systems and automatic water mist.

**AUTOMATIC SMOKE DETECTION SYSTEM.** A fire alarm system that has initiation devices that utilize smoke detectors for protection of an area such as a room or space with detectors to provide early warning of fire.

❖ Chapter 9 provides requirements for various automatic fire protection systems including automatic fire detection system, automatic sprinkler system, automatic fire alarm system, and automatic smoke detection system. Automatic smoke detection systems are required for various occupancies as specified in Section 907. They are required to increase the likelihood that fire is detected and occupants of the building are given an early warning of danger.

**AUTOMATIC SPRINKLER SYSTEM.** An *automatic sprinkler system*, for fire protection purposes, is an integrated system of underground and overhead piping designed in accordance with fire protection engineering standards. The system includes a suitable water supply. The portion of the system above the ground is a network of specially sized or hydraulically designed piping installed in a structure or area, generally overhead, and to which automatic sprinklers are connected in a systematic pattern. The system is usually activated by heat from a fire and discharges water over the fire area.

❖ An automatic sprinkler system is one type of automatic fire-extinguishing system. Automatic sprinkler systems are the most common, and their life safety attributes are widely recognized. The code specifies three types of automatic sprinkler systems: one installed in accordance with NFPA 13, one in accordance with NFPA 13R and the other in accordance with NFPA 13D. To be considered for most code design alternatives, a building automatic sprinkler system must be installed throughout in accordance with NFPA 13 (see Section 903.3.1.1).

In a fire, sprinklers automatically open and discharge water onto the fire in a spray pattern that is designed to contain or extinguish the fire. Originally, automatic sprinkler systems were developed just for the protection of buildings and their contents. Because of the development and improvements in sprinkler head response time and water distribution, however, automatic sprinkler systems are now also considered a life safety system. Proper operation of an automatic sprinkler system requires careful selection of the sprinkler heads so that water in sufficient quantity at adequate pressure and properly distrib-

## DEFINITIONS

uted will be available to suppress the fire. Note that the context of the use of the term “fire area” in the last sentence of the definition is to refer to the area in which the fire is occurring, not in the context of the defined term “fire area.”

There are many different types of automatic sprinkler systems—wet pipe, dry pipe, preaction, anti-freeze and various combinations. Sprinklers can be pendant, upright or sidewall and can be designed for standard or extended coverage. Additional information can be found in NFPA 13.

**AUTOMATIC WATER MIST SYSTEM.** A system consisting of a water supply, a pressure source and a distribution piping system with attached nozzles which, at or above a minimum operating pressure, defined by its listing, discharges water in fine droplets meeting the requirements of NFPA 750 for the purpose of the control, suppression or extinguishment of a fire. Such systems include wet-pipe, dry-pipe and pre-action types. The systems are designed as engineered, preengineered, local-application or total flooding systems.

❖ The code recognizes water mist systems as an alternative extinguishing system to automatic sprinkler systems. However, no exceptions, reductions or tradeoffs for water mist systems are granted or permitted by the code because such systems are not considered to be equivalent to automatic sprinkler systems. Automatic water mist systems have been approved by FM Global for occupancies similar to a Light Hazard Group (as defined by NFPA 13) and listed by UL for occupancies similar to Ordinary Hazard Group I (as defined by NFPA 13). These listings permit automatic water mist systems to be installed as the primary suppression systems in a variety of occupancy classifications.

Water mist systems are used for special applications where creating a heat absorbent vapor consisting of water droplets with a size of less than 1,000 microns at the discharge nozzle is the primary extinguishing method. These systems are typically used where water damage may be an issue or where water supplies are limited. The droplet size can be controlled by adjusting the discharge pressure through the nozzle. Creating a mist and an equal volume of water will create a larger total service area exposed to the fire and thus better facilitate the absorption of heat, allowing more water droplets to turn to steam more quickly and thus more effectively cool the room.

**AUTOMOTIVE MOTOR FUEL-DISPENSING FACILITY.** That portion of property where flammable or *combustible liquids* or gases used as motor fuels are stored and dispensed from fixed equipment into the fuel tanks of motor vehicles.

❖ Automotive motor fuel-dispensing facilities may be attended or unattended and they may take the form of the conventional motor fuel-dispensing facility,

convenience store or other location that transfers fuel from a storage tank to the fuel tank of some type of motorized equipment. Motor fuel-dispensing facilities are classified in occupancy Group M by the IBC.

**AVERAGE AMBIENT SOUND LEVEL.** The root mean square, A-weighted sound pressure level measured over a 24-hour period, or the time any person is present, whichever time period is less.

❖ The ambient noise that can be expected depends on the occupancy of the building. To attract the attention of the occupants, the audible alarm devices must be heard above the ambient noise in the space. For this reason, the alarm devices must have minimum sound pressure levels above the average ambient sound level. Section 907.5.2.1.1 prescribes the minimum sound pressure levels for the audible alarm notification appliances for all occupancy conditions.

Although it is possible to measure the ambient sound within an occupied space, the alarm notification devices are usually designed and installed before buildings are occupied, thus it is typically a careful analysis of the types of uses within a space that will determine the average ambient sound level. If, after the building is occupied, the alarm notification devices are below expected audibility, a field measurement may be necessary to determine whether or not the design assumptions are correct.

**[BG] AWNING.** An architectural projection that provides weather protection, identity or decoration and is partially or wholly supported by the building to which it is attached. An awning is comprised of a lightweight frame structure over which a covering is attached.

❖ Similar to a canopy, an awning typically provides weather protection, signage or decoration. Its distinguishing characteristic is the lightweight frame structure. It is also supported, at least in part, by the building from which it projects. See Section 3105 of the IBC for general requirements and Section 3202 of the IBC for encroachment requirements. This definition helps to clarify the applicability of roof loads in Section 1607.12.4 of the IBC. Also see the definitions of “Retractable awning,” “Canopy” and “Marquee” in the IBC.

**[BE] BALANCED DOOR.** A door equipped with double-pivoted hardware so designed as to cause a semicounter balanced swing action when opening.

❖ Balanced doors are commonly used to decrease the force necessary to open the door or to reduce the length of the door swing. Balanced doors typically reduce the clear opening width more than normally hinged doors (see Commentary Figure 202-B1 and Section 1010.1.10.2).

**BALED COTTON.** See “Cotton.”

**BALED COTTON, DENSELY PACKED.** See “Cotton.”

**Figure 202-B1  
BALANCED DOOR**

**BARRICADE.** A structure that consists of a combination of walls, floor and roof, which is designed to withstand the rapid release of energy in an explosion and which is fully confined, partially vented or fully vented; or other effective method of shielding from *explosive materials* by a natural or artificial barrier.

❖ Barricade means effectively screening a building containing explosives by means of a natural or artificial barrier from a magazine, another building, a railway or a highway.

**Artificial barricade.** An artificial mound or revetment with a minimum thickness of 3 feet (914 mm).

❖ Barricade means effectively screening a building containing explosives by means of a natural or artificial barrier from a magazine, another building, a railway or a highway.

**Natural barricade.** Natural features of the ground, such as hills, or timber of sufficient density that the surrounding exposures that require protection cannot be seen from the magazine or building containing *explosives* when the trees are bare of leaves.

❖ Native land features capable of protecting adjacent buildings, people and property from blast effects if an explosion in a magazine occurs may qualify as reduced separation distances permitted by Table 5604.5.2(2). Trees and other ground cover must be thick enough for effective visual screening for the magazine when the branches are bare of leaves or other seasonal foliage.

**BARRICADED.** The effective screening of a building containing *explosive materials* from the magazine or other building, railway or highway by a natural or an artificial barrier. A straight line from the top of any sidewall of the building containing *explosive materials* to the eave line of any magazine or other building or to a point 12 feet (3658 mm) above the center of a railway or highway shall pass through such barrier.

❖ Natural or artificial barriers must exist or be constructed to qualify for the separation distance reductions allowed in Table 5604.5.2(2). These barriers are intended to provide protection for people and property equivalent to the larger separation distances by absorbing or deflecting blast effects and debris from explosions involving magazines. Commentary Figure 202-B2 illustrates the arrangement of natural and artificial barricades for protection from two 2,000-pound (908 kg) Type 1 magazines.

**Figure 202-B2  
ARRANGEMENT OF BARRICADE**

## DEFINITIONS

**[BG] BASEMENT.** A story that is not a story above grade plane.

❖ Unlike previous editions of the I-Codes where a story would be defined as a basement if any portion of the story was below grade, a basement is now defined as a story that has its floor surface below the adjoining ground level and that does not qualify as a story above grade plane (see the commentary to the definition of “Story above grade plane”). IBC Commentary Figure 202.2(7) illustrates the application of the definition of “Story above grade plane.” Since a basement is not a story above grade, it does not contribute to the height of the building for the purpose of applying the allowable building height in stories from Table 504.4 of the IBC.

**BATTERY SYSTEM, STATIONARY LEAD ACID.** A system which consists of three interconnected subsystems:

1. A lead-acid battery.
2. A battery charger.
3. A collection of rectifiers, inverters, converters and associated electrical equipment as required for a particular application.

❖ The definition describes the completed battery system, consisting of all the components needed to make a functioning battery power system (see commentary, Section 608).

### BATTERY TYPES.

**Lithium-ion battery.** A storage battery that consists of lithium ions embedded in a carbon graphite or nickel metal-oxide substrate. The electrolyte is a carbonate mixture or a gelled polymer. The lithium ions are the charge carriers of the battery.

❖ This definition describes a specific type of sealed, nonventing, recombinant storage batteries similar to nickel-metal hydride batteries, although they are not as durable. Lithium-ion batteries, also commonly known as “Li-ion” batteries, are typically lighter than other comparably sized types of rechargeable batteries which makes them a popular choice for portable devices and automotive applications. They hold their charge well, are generally durable and may be recharged many times. Like other types of sealed batteries with a high-viscosity, immobilized electrolyte, Li-ion batteries have the advantage of not requiring spill control safeguards and also pose a reduced fugitive gas hazard. Lithium-ion batteries, when exposed to prolonged hot conditions with inadequate ventilation, can rupture, ignite, or explode. In recent history, Li-ion batteries were the subject of a massive battery recall initiative by several computer and cell phone manufacturers due to the Li-ion batteries used in their products overheating from internal contamination defects and causing fires or burn injuries.

**Lithium metal polymer battery.** A storage battery that is comprised of nonaqueous liquid or polymerized electrolytes, which provide ionic conductivity between lithiated

positive active material electrically separated from metallic lithium or lithiated negative active material.

❖ This definition describes lithium metal polymer (LMP) batteries, a specific type of sealed, nonventing storage battery similar to lithium-ion batteries and which are undergoing evaluation for use as stationary battery back-up systems to replace the currently used lead-acid and valve-regulated lead acid (VRLA) batteries. The LMP battery is similar to the Lithium-ion type in its characteristics (light, energy-dense, no liquid electrolyte, etc.). This technology is becoming more popular for deployment in outdoor cabinets and in buildings as well. Like lithium-ion batteries, LMP batteries use Lithium ions as the charge carrier. However, LMP batteries have more lithium because their anode is a solid thin foil of pure lithium encased in a plastic-like polymer that serves as the electrolyte. A significant advantage of LMP batteries is that they store more energy per unit of weight when compared to other batteries using nickel or lead anodes. Lithium is also an extremely lightweight metal when compared to other cathode or anode materials which results in a rechargeable battery with a high-energy density.

Even though LMP batteries should be recycled, they don't pose as much of an environmental hazard as lead-acid or Ni-Cad technologies if they are simply disposed. LMP batteries do not produce or liberate hydrogen or oxygen during their charging cycles and are, therefore, not classified as being recombinant or nonrecombinant. Since gases are not liberated from LMP batteries, the requirement in Section 608.2 for either vented caps or self-resealing flame arresting caps are not applicable. Because LMP batteries do not off-gas flammable or oxidizing gases while being charged, Section 608.6.1 does not require a mechanical ventilation system.

LMP batteries are constructed with an internal means of thermal runaway management which is required by Section 608.3. Each battery is equipped with an internal heating system that is located within the electrochemical stack of anodes and cathodes. This heating element ensures that the battery temperature limits are not exceeded when the battery is being charged or discharged.

These batteries contain no liquid electrolytes or electrolytes suspended in a gel or similar liquids. The electrolyte is a solid lithium-ion that is normally mixed with a rubber polymer that is located between the cathode and anode. Since these batteries do not contain any liquid, the code does not require spill control or a means of neutralization.

While LMP batteries do not have the potential for spills or discharging of hydrogen or oxygen, they still present a potential fire threat if they are somehow overheated and can be a threat to fire fighters because they will be connected to an energized circuit. Accordingly, Table 608.1 requires that the area housing these batteries be provided with signs com-

plying with Section 608.7 and a means of smoke detection complying with Section 608.9. Section 606.8 also requires batteries installed inside of buildings within seismically active areas be appropriately braced and anchored in accordance with the IBC.

**Nickel cadmium (Ni-Cd) battery.** An alkaline storage battery in which the positive active material is nickel oxide, the negative contains cadmium and the electrolyte is potassium hydroxide.

- ❖ This definition describes a specific type of nonrecombinant storage battery. Nickel-cadmium (Ni-Cd) batteries are durable and may be recharged many times. One of the hazards of storage batteries is overcharging and, in the case of Ni-Cd batteries, overcharging can produce either hydrogen gas or oxygen that could result in a rupture of the cell casing. Ni-Cd cells are, therefore, provided with safety venting caps to allow the generated gas to escape from inside the cell. See the commentary to Section 608.2 for further discussion of vents.

**Nonrecombinant battery.** A storage battery in which, under conditions of normal use, hydrogen and oxygen gases created by electrolysis are vented into the air outside of the battery.

- ❖ Nonrecombinant batteries, also called flooded cell batteries, are those where the electrodes/plates are immersed in electrolyte, and the gases (hydrogen and oxygen) created during charging are vented to the atmosphere. These batteries require maintenance in the form of distilled water occasionally being added to the cells to bring the electrolyte back to its required level. The most familiar example of a flooded lead-acid cell is the 12-V automobile battery (see also the commentary to the definition of “Recombinant battery”).

**Recombinant battery.** A storage battery in which, under conditions of normal use, hydrogen and oxygen gases created by electrolysis are converted back into water inside the battery instead of venting into the air outside of the battery.

- ❖ Recombinant batteries are designed so that the oxygen generated during charging is captured and recombined in the battery. This is called an oxygen recombination cycle and works well as long as the charge rate is not too high. An overly high charge rate could result in cell case rupture, thermal runaway or internal mechanical damage.

The VRLA battery is the most common type of recombinant battery. It was developed for stationary and telecommunication battery applications. These types of sealed batteries have a spring-controlled valve that vents gases at a predetermined pressure. Typical pressure thresholds are from 2 to 5 pounds per square inch gauge (psig) (14 to 34 kPa), depending on the battery design. Although the term “valve-regulated” is often used synonymously with describing sealed lead-acid batteries, not all sealed batteries are valve-regulated. Some battery designs employ

replaceable vent plugs or other mechanisms to relieve excess pressure. Sealed batteries were developed to reduce the maintenance required for batteries in active service. Since electrolyte levels are preserved by trapping and recombining off-gases, there should not be any need to add distilled water over the life of the battery. These batteries are often misnamed “maintenance free.” In fact, all maintenance practices applicable to unsealed-type batteries are applicable to sealed-type batteries. The only exception is that electrolyte levels cannot, and should not, need to be maintained.

**Stationary storage battery.** A group of electrochemical cells interconnected to supply a nominal voltage of DC power to a suitably connected electrical load, designed for service in a permanent location. The number of cells connected in a series determines the nominal voltage rating of the battery. The size of the cells determines the discharge capacity of the entire battery. After discharge, it may be restored to a fully charged condition by an electric current flowing in a direction opposite to the flow of current when the battery is discharged.

- ❖ The term “stationary storage battery” applies to all battery types made up of multiple electrochemical cells interconnected to supply a nominal voltage of direct current (DC) power. The batteries consist of a positive and a negative lead plate immersed in an electrolyte solution, which is considered a corrosive liquid. The definition includes both the vented type, in which hydrogen and oxygen are produced and vented, and the valve-regulated type, which is sealed to prevent the venting of the generated gases.

Stationary storage batteries come in a wide variety of designs for different applications. They are used for applications where power is necessary only on a standby or emergency basis. Stationary batteries are infrequently discharged. Stationary batteries remain on a continuous float charge so that they can be used on demand. The largest types of stationary batteries are those used for electrical load leveling. Load-leveling batteries store electrical energy for times of peak power demand and are taken off-line during times of low power demand. Such batteries are typically used for uninterrupted power supply (UPS) systems, emergency power or standby power applications and are manufactured in a variety of plate designs.

**Valve-regulated lead-acid (VRLA) battery.** A lead-acid battery consisting of sealed cells furnished with a valve that opens to vent the battery whenever the internal pressure of the battery exceeds the ambient pressure by a set amount. In VRLA batteries, the liquid electrolyte in the cells is immobilized in an absorptive glass mat (AGM cells or batteries) or by the addition of a gelling agent (gel cells or gelled batteries).

- ❖ Valve-regulated lead-acid (VRLA) batteries (sometimes referred to as “gel cells”) differ substantially from flooded batteries in design, operation and potential hazard. VRLA-type batteries are uniquely different from the traditional liquid electrolyte lead-acid batter-

## DEFINITIONS

ies in that they have no liquid electrolyte to flow from the container if it were to break. Also, the VRLA batteries do not vent their off-gases to the atmosphere but rather implement an oxygen recombination cycle that minimizes the emissions of gas from the batteries during overcharging. Though these batteries are considered sealed, their design includes spring-controlled valves that vent gases at a pressure threshold of 2 to 5 psig (14 to 34 kPa). These batteries are sometimes mistakenly called “maintenance free”; however, they should be maintained in accordance with the manufacturer's instructions as with any other building system.

**Vented (flooded) lead-acid battery.** A lead-acid battery consisting of cells that have electrodes immersed in liquid electrolyte. Flooded lead-acid batteries have a provision for the user to add water to the cell and are equipped with a flame-arresting vent which permits the escape of hydrogen and oxygen gas from the cell in a diffused manner such that a spark, or other ignition source, outside the cell will not ignite the gases inside the cell.

- ❖ There are basically two types of lead-acid storage batteries, which are based on how they are constructed and vented: they are either vented (flooded) or sealed. Vented (flooded) and sealed batteries differ in how they dispose of the hydrogen (explosive in air at 4 percent by volume) and oxygen produced by electrolysis during their recharging (off-gassing). In a vented (flooded) battery, these gases are allowed to escape to the atmosphere. In a sealed battery, the gases are contained within the battery cell(s) and recombined with the electrolyte. Because the gases created during battery charging are vented to the atmosphere, distilled water must be added by the owner periodically to bring the electrolyte level back to that required by the battery specifications. One of the most common types of vented (flooded) lead-acid batteries is the automobile battery.

**BIN BOX.** A five-sided container with the open side facing an aisle. Bin boxes are self-supporting or supported by a structure designed so that little or no horizontal or vertical space exists around the boxes.

- ❖ Proprietary storage systems, such as bin box storage, are common in warehousing and manufacturing industries, such as automotive assembly plants and mail-order mercantile operations. Many bin box systems rely on the rigidity of adjacent bins and interlocking design for stability. Provisions for fastening the self-supporting units together to permit higher stacking are typical in most designs. Other bin box systems are designed in conjunction with a supporting rack system to minimize unusable space between bins. Bin boxes can be constructed of combustible materials, such as wood or cardboard, or of noncombustible materials such as metal.

**BIOMASS.** Plant- or animal-based material of biological origin excluding material embedded in geologic formations or transformed into fossils.

- ❖ This term is provided to coordinate with the requirements in Chapter 28 and the inclusion of these materials in the commodity classifications for high-piled combustible storage found in Chapter 32. These materials are becoming more prevalent and guidance is needed in terms of the hazards they pose and how they should be regulated.

**BLAST AREA.** The area including the blast site and the immediate adjacent area within the influence of flying rock, missiles and concussion.

- ❖ The area of a blast is affected by flying rock missiles, gases and concussion and also includes the blast site and the immediately adjacent area that is owned, leased or controlled by the blast operator.

**BLAST SITE.** The area in which *explosive materials* are being or have been loaded and which includes all holes loaded or to be loaded for the same blast and a distance of 50 feet (15 240 mm) in all directions.

- ❖ The area where explosive material is handled during loading, which includes 50 feet (15 240 mm) in all directions from loaded blast holes or holes to be loaded.

**BLASTER.** A person qualified in accordance with Section 3301.4 to be in charge of and responsible for the loading and firing of a blast.

- ❖ In general, the blaster should be qualified, experienced and of sound judgment when performing the duties of blasting. This person is authorized to use explosives for blasting purposes. The blaster is trained and experienced in the use of explosives and licensed by the department.

**BLASTING AGENT.** A material or mixture consisting of fuel and oxidizer, intended for blasting provided that the finished product, as mixed for use or shipment, cannot be detonated by means of a No. 8 test detonator when unconfined. Blasting agents are labeled and placarded as Class 1.5 material by US DOTn.

- ❖ This definition is derived from federal explosive regulations and is intended to distinguish blasting agents from more dangerous explosive materials on the basis of their propensity to mass detonate by initiation using a standard device.

**[BE] BLEACHERS.** Tiered seating supported on a dedicated structural system and two or more rows high and is not a building element (see “*Grandstand*”).

- ❖ Bleachers, folding and telescopic seating and grandstands are essentially unique forms of tiered seating that are supported on a dedicated structural system. All types are addressed in ICC 300, *Standard on*

*Bleachers, Folding and Telescopic Seating and Grandstands*, the safety standard for these types of seating arrangements (see Section 1029.1.1). Bleachers can have backrests or just seatboards. The term “building element” used in Section 1029.1.1 is a defined term in the IBC, which is primarily used in conjunction with the structural elements regulated in Table 601 of the IBC. Bleachers have a separate structural system and are not considered a building element of the building or structure in which they are located. An individual bench seat directly attached to a floor system is not a bleacher. The terms “bleacher” and “grandstand” are basically interchangeable. There is no cut-off in size or number of seats that separates bleachers and grandstands.

**[BG] BOARDING HOUSE.** A building arranged or used for lodging for compensation, with or without meals, and not occupied as a single-family unit.

- ❖ A boarding house is a structure where the occupants are provided sleeping accommodations or meals and accommodations for a fee. The individual rooms used usually do not contain all of the permanent living provisions of a dwelling unit (e.g., permanent cooking facilities). Most often, the term “boarding house” describes a facility that is primarily for transient occupants; however, these facilities might also be used for nontransient purposes. Depending on the extent of transiency, a boarding house could be classified as Group R-1 when an occupant typically stays for not more than 30 days or Group R-2 when the length of stay is greater than 30 days. Boarding houses are distinct from lodging houses. Lodging houses allow transient guests within a residence that is also occupied by the owner or primary residents of the dwelling unit. Lodging houses are classified as Group R-3 occupancies.

**BOILING POINT.** The temperature at which the vapor pressure of a liquid equals the atmospheric pressure of 14.7 pounds per square inch absolute (psia) (101 kPa) or 760 mm of mercury. Where an accurate boiling point is unavailable for the material in question, or for mixtures which do not have a constant boiling point, for the purposes of this classification, the 20-percent evaporated point of a distillation performed in accordance with ASTM D 86 shall be used as the boiling point of the liquid.

- ❖ The purpose of the boiling point is to assist in classifying flammable liquids. The classification of flammable liquids is based on the flash point and the boiling point. When one compares a Class IA liquid and a Class IB liquid, the only difference in their definitions is the boiling point. The lower the boiling point of a flammable liquid, the greater the hazard due to increased vapor pressure at NTP. This information will be found in the material safety data sheet (MSDS) and must be evaluated by the fire code official.

**BONFIRE.** An outdoor fire utilized for ceremonial purposes.

- ❖ Bonfires are usually very large and are associated with a crowd activity. Failure to follow good safety

practices with these fires can lead to serious injuries and property damage.

**[BE] BREAKOUT.** For revolving doors, a process whereby wings or door panels can be pushed open manually for *means of egress* travel.

- ❖ In addition to the swinging doors in the immediate area, revolving doors have a breakout feature as an additional safety requirement. The panels in the door can be operated manually to collapse or fold in the direction of egress during an emergency. This should increase the number of people that could exit per minute when not using the revolving door in the standard manner.

**BRITISH THERMAL UNIT (BTU).** The heat necessary to raise the temperature of 1 pound (0.454 kg) of water by 1°F (0.5565°C).

- ❖ This definition describes the English unit of heat used throughout the document. A British thermal unit (Btu) is used as a way to describe the heat content of combustibles. The metric equivalent of a Btu is a joule. This term should not be confused with heat release rate. Heat release rate would be described as Btu per second (joule per second = watt).

**[A] BUILDING.** Any structure used or intended for supporting or sheltering any use or occupancy.

- ❖ The code uses this term to identify those structures that provide shelter for a function or activity. See the definition for “Area, building” for situations when a single structure may be two or more “Buildings” created by fire walls.

**BUILDING AREA.** See “Area, building.”

**BUILDING HEIGHT.** See “Height, building.”

**[A] BUILDING OFFICIAL.** The officer or other designated authority charged with the administration and enforcement of the *International Building Code*, or a duly authorized representative.

- ❖ The statutory power to enforce the building code is normally vested in a building department of a state, county or municipality that has a designated enforcement officer termed the “building official” (see Section 103.1 of the IBC).

**BULK OXYGEN SYSTEM.** An assembly of equipment, such as oxygen storage containers, pressure regulators, safety devices, vaporizers, manifolds and interconnecting piping, that has a storage capacity of more than 20,000 cubic feet (566 m<sup>3</sup>) of oxygen at *normal temperature and pressure (NTP)* including unconnected reserves on hand at the site. The bulk oxygen system terminates at the point where oxygen at service pressure first enters the supply line. The oxygen containers can be stationary or movable, and the oxygen can be stored as a gas or liquid.

- ❖ As indicated in Section 6301.1, NFPA 55 contains installation and maintenance requirements for bulk oxygen systems. NFPA 55 also has the requirements for the protection of bulk oxygen systems from potential fire exposures. Oxygen storage systems with less

## DEFINITIONS

than the capacities indicated in the definition are not required to comply with NFPA 55, but are regulated by this chapter.

**BULK PLANT OR TERMINAL.** That portion of a property where flammable or *combustible liquids* are received by tank vessel, pipelines, tank car or tank vehicle and are stored or blended in bulk for the purpose of distributing such liquids by tank vessel, pipeline, tank car, tank vehicle, portable tank or container.

❖ All of us have seen the large storage tanks surrounded by containment berms that constitute what is commonly called a “tank farm.” A facility of this kind may consist of one tank or several tanks and typically receives, stores and dispenses anywhere from thousands of gallons to hundreds of thousands of gallons of flammable or combustible liquids daily.

**BULK TRANSFER.** The loading or unloading of flammable or *combustible liquids* from or between tank vehicles, tank cars or storage tanks.

❖ This term refers to the loading or unloading of a flammable or combustible liquid from or between storage tanks, tank vehicles or tank cars or any combination thereof. See also the definition of “Process transfer” and Section 5706.5. This transfer is for the storage or transportation of flammable or combustible liquids.

**BULLET RESISTANT.** Constructed so as to resist penetration of a bullet of 150-grain M2 ball ammunition having a nominal muzzle velocity of 2,700 feet per second (fps) (824 mps) when fired from a 30-caliber rifle at a distance of 100 feet (30 480 mm), measured perpendicular to the target.

❖ Tests to determine bullet resistance are to be conducted on test panels or empty magazines. The panels or magazines are to resist a penetration of five out of five shots placed independently of each other in an area at least 3 feet by 3 feet (0.9 m by 0.9 m). If hardwood or softwood is used, its water content is not to exceed 15 percent.

Where a magazine roof or ceiling is required to be bullet resistant, it must be constructed of materials comparable to the sidewalls or of other materials that can withstand the penetration of bullets fired at an angle of 45 degrees (0.79 rad) from perpendicular.

**CANOPY.** A structure or architectural projection of rigid construction over which a covering is attached that provides weather protection, identity or decoration, and may be structurally independent or supported by attachment to a building on one end and by not less than one stanchion on the outer end.

❖ A canopy can be either an architectural projection from a building, or it can be an independent structure. An example of the former is typically found covering an entrance walkway in front of a hotel or apartment

building or perhaps a restaurant. An example of the latter is a canopy built over fuel pumps at a motor fuel-dispensing facility. This definition distinguishes a canopy from an awning which consists of a light-weight frame that is supported by the building from which it projects. In doing so, the definition clarifies the applicability of roof loads in Section 1607.12.4 of the IBC. See Section 3105 of the IBC for general requirements and Section 3202 of the IBC for encroachment requirements. Commentary Figures 202-C1, 202-C2 and 202-C3 illustrate types of canopies.

**Figure 202-C1**  
**EXAMPLE OF A FREE-STANDING**  
**MEMBRANE-COVERED CANOPY**

**Figure 202-C2**  
**EXAMPLE OF A CANOPY SUPPORTED**  
**BY A BUILDING AND STANCHION**

**Figure 202-C3**  
**EXAMPLE OF A FREE-STANDING**  
**MOTOR FUEL-DISPENSING FACILITY CANOPY**

**CARBON DIOXIDE EXTINGUISHING SYSTEM.** A system supplying carbon dioxide (CO<sub>2</sub>) from a pressurized vessel through fixed pipes and nozzles. The system includes a manual- or automatic-actuating mechanism.

❖ Carbon dioxide (CO<sub>2</sub>) extinguishing systems are useful in extinguishing fires in specific hazards or equipment in occupancies where an inert electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents, such as dry-chemical residue, presents a problem. The system works by displacing the oxygen in an enclosed area by flooding the space with carbon dioxide. To effectively flood the enclosure, automatic door and window closers and control dampers for the mechanical ventilation system must be installed.

These types of gaseous extinguishing systems have some inherent disadvantages that should be considered before selection. Because the oxygen is being displaced, occupants should not be in the space for a period after discharge, depending on the concentration of CO<sub>2</sub> to be achieved. Additionally, the discharge rate can result in a rapid increase in pressure within the space where the system is discharged. However, where water is not a desired means of suppression carbon dioxide and other gaseous suppression systems can be very effective. NFPA 12 contains minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of carbon dioxide extinguishing systems.

**[BG] CARE SUITE.** In Group I-2 occupancies, a group of treatment rooms, care recipient sleeping rooms and the support rooms or spaces and circulation space within the suite where staff are in attendance for supervision of all care recipients within the suite, and the suite is in compliance with the requirements of Section 407.4.4 of the *International Building Code*.

❖ Care suites are designed to allow for a group of rooms to function as a unit in the treatment and care of patients. Suites are recognized to be an effective tool to provide flexibility in reaching an exit access due to functional considerations. Suites are particu-

larly useful in intensive care units and emergency department in-patient treatment areas. Suites allow staff to have clear and unobstructed supervision of patients/care recipients in specific treatment and sleeping rooms through the elimination of corridor width or rating requirements. The term is not intended to apply to day rooms or business sections of the hospital. This term is only applicable to suites of patient rooms in Group I-2 occupancies, and should not be confused with similar layouts in other parts of the hospital or within other occupancies that may be referred to as a "suite." Care suites are to meet the requirements of Section 407 of the IBC.

**CARTON.** A cardboard or fiberboard box enclosing a product.

❖ This term is commonly used when applying the high-piled storage requirements of Chapter 32 and also for packaging of aerosols in Chapter 51. This definition provides a consistent understanding of a word often used to describe packaging.

**CEILING LIMIT.** The maximum concentration of an airborne contaminant to which one may be exposed. The ceiling limits utilized are those published in DOL 29 CFR Part 1910.1000. The ceiling Recommended Exposure Limit (REL-C) concentrations published by the U.S. National Institute for Occupational Safety and Health (NIOSH), Threshold Limit Value-Ceiling (TLV-C) concentrations published by the American Conference of Governmental Industrial Hygienists (ACGIH), Ceiling Workplace Environmental Exposure Level (WEEL-Ceiling) Guides published by the American Industrial Hygiene Association (AIHA), and other *approved*, consistent measures are allowed as surrogates for hazardous substances not listed in DOL 29 CFR Part 1910.1000.

❖ This limit is the concentration at which immediate irritation to skin, respiratory system or both will occur. This is an important level for emergency personnel and workers to be aware of. Mechanical ventilation may be used to assist in keeping the working environment below these levels.

**[A] CHANGE OF OCCUPANCY.** A change in the use of a building or a portion of a building. A change of occupancy shall include any change of occupancy classification, any change from one group to another group within an occupancy classification or any change in use within a group for a specific occupancy classification.

❖ This term describes the condition when an existing building or structure is used for a different use or the same use with an increase in the level of activity (see Section 101.4.7 for a reference to the IEBC). This term is only applicable to existing buildings, never new ones. For example, Group B includes both beauty parlors and post offices. If a beauty shop moved into an old post office, while remaining a Group B building, there would be a change in the level of activity; therefore, this would be considered a change of occupancy.

## DEFINITIONS

**CHEMICAL.** An element, chemical compound or mixture of elements or compounds or both.

- ❖ Chemicals may be hazardous, in which case the buildings, processes and storage that use them are regulated, or they may be nonhazardous, in which case their storage is regulated. These regulations are typically found in the IBC, IMC, IPC, IFGC and the code.

**CHEMICAL NAME.** The scientific designation of a chemical in accordance with the nomenclature system developed by the International Union of Pure and Applied Chemistry, the Chemical Abstracts Service rules of nomenclature, or a name which will clearly identify a chemical for the purpose of conducting an evaluation.

- ❖ This name can be used to research the product in resource manuals to determine the hazard characteristics of the product. Some examples of resources are: National Toxicology Program (NTP), Chemical Hazards Response Information System (CHRIS) manual, Emergency Response Guidebook (ERG), MSDS, etc.

**[M] CHIMNEY.** A primarily vertical structure containing one or more flues for the purpose of carrying gaseous products of combustion and air from a fuel-burning appliance to the outdoor atmosphere.

- ❖ The IFGC and the IMC address the installation of chimneys and venting systems that are required to convey products of combustion from fuel-burning appliances to the atmosphere. The code regulates the maintenance of masonry chimneys in Section 603.6.1. Chimneys differ from metal vents in the materials from which they are constructed and the type of appliance they are designed to serve. Chimneys can vent much hotter flue gases than metal vents.

**Factory-built chimney.** A listed and labeled chimney composed of factory-made components, assembled in the field in accordance with manufacturer's instructions and the conditions of the listing.

- ❖ A factory-built chimney is a manufactured listed and labeled chimney that has been tested by an approved agency to determine its performance characteristics. Factory-built chimneys are manufactured in two basic designs: either a double-wall insulated design or a triple-wall air-cooled design. Both designs use stainless steel inner liners to resist the corrosive effects of combustion products.

**Masonry chimney.** A field-constructed chimney composed of solid masonry units, bricks, stones, or concrete.

- ❖ Masonry chimneys can have one or more flues within them, and are field constructed of brick, stone, concrete or fire-clay materials. Masonry chimneys can stand alone or be part of a masonry fireplace.

**Metal chimney.** A field-constructed chimney of metal.

- ❖ A metal chimney is an unlisted chimney constructed and installed in accordance with NFPA 211 and is sometimes referred to as a "smokestack." Metal chimneys are typically field constructed and installed in industrial structures.

**CLEAN AGENT.** Electrically nonconducting, volatile or gaseous fire extinguishant that does not leave a residue upon evaporation.

- ❖ The two categories of clean agents are halocarbon compounds and inert gas agents. Halocarbon compounds include bromine, carbon, chloride, fluorine, hydrogen and iodine. Halocarbon compounds suppress the fire through a combination of breaking the chemical chain reaction of the fire, reducing the ambient oxygen supporting the fire and reducing the ambient temperature of the fire origin to reduce the propagation of fire. The clean agents that are inert gas agents contain primary components consisting of helium, neon or argon, or a combination of all three. Inert gases work by reducing the oxygen concentration around the fire origin to a level that does not support combustion (see commentary, Section 904.10).

**[BG] CLINIC, OUTPATIENT.** Buildings or portions thereof used to provide medical care on a less-than-24-hour basis to persons who are not rendered incapable of self-preservation by the services provided.

- ❖ Outpatient clinics generally consist of doctors' offices where various medical services can be provided. These clinics typically function during normal business hours (i.e., less than 24 hours) and, unlike ambulatory care facilities, the patients are generally ambulatory and capable of self-preservation. This definition clarifies the difference between ambulatory surgery centers (ambulatory care facilities) and the typical doctor's office. In many cities, outpatient clinics are open at all hours to be available to people who work a variety of shifts. The term "urgent care" is often used to describe such facilities. An outpatient facility that is open 24/7 may still be classified as a Group B occupancy, provided all patients are outpatients and individual patients are not treated for periods in excess of 24 hours. The latter would describe a Group I-2 hospital. See the commentaries for Sections 407 and 422 of the IBC.

**CLOSED CONTAINER.** A container sealed by means of a lid or other device such that liquid, vapor or dusts will not escape from it under ordinary conditions of use or handling.

- ❖ A closed container is one that is sealed so that no vapors or dust can escape. The important difference in dealing with an open container and a closed container is that the open container is more dangerous and calls for more safety requirements. The fire tetrahedron is made up of fuel, heat, oxygen and a chain

reaction. In a closed container there is only the fuel part of the tetrahedron; in an open container, there is the fuel and oxygen sides of the tetrahedron. In this case, a closed container is less hazardous than an open container unless there is a leak.

**CLOSED SYSTEM.** The use of a solid or liquid hazardous material involving a closed vessel or system that remains closed during normal operations where vapors emitted by the product are not liberated outside of the vessel or system and the product is not exposed to the atmosphere during normal operations; and all uses of *compressed gases*. Examples of closed systems for solids and liquids include product conveyed through a piping system into a closed vessel, system or piece of equipment.

❖ This definition is used primarily with regard to hazardous materials. The difference between a closed system and an open system is whether the hazardous material involved in the process is exposed to the atmosphere. A closed system is inherently less hazardous than an open system due to the fact that vapors, dusts or similar materials are not normally released from closed systems. Because closed systems are less hazardous than open systems, credit is typically given to increase the maximum allowable quantities (MAQ) when systems are considered closed. Materials in closed or open systems are assumed to be “in use” as opposed to “in storage.” Gases are always assumed to be in closed systems since they would be immediately dispersed in an open system if exposed to the atmosphere without some means of containment (see the definition of “Open system”).

**COLD DECK.** A pile of unfinished cut logs.

❖ A cold deck is a pile of ranked logs that have different lengths. The lengths are usually greater than 8 feet (2438 mm) and up to 50 feet (15 240 mm) long.

**COMBUSTIBLE DUST.** Finely divided solid material which is 420 microns or less in diameter and which, when dispersed in air in the proper proportions, could be ignited by a flame, spark or other source of ignition. Combustible dust will pass through a U.S. No. 40 standard sieve.

❖ Combustible dusts are combustible solids in a finely divided state that are suspended in the air. An explosion hazard exists when the concentration of the combustible dust is within the explosive limits and exposed to an ignition source of sufficient energy and duration to initiate self-sustained combustion. A review of the occupancy classification for Group H-2 in Chapter 2 (based on IBC Section 307.4) indicates that combustible dusts are classified in that occupancy group. The intent of that section is that when combustible dust is determined by an engineering analysis to meet the definition parameter that, in a given occupancy, it is dispersed in air in the proper proportions so as to be ignitable by an ignition source, then the deflagration hazard is sufficient to classify the occupancy in Group H-2. Combustible dust, as a material, that does not rise to that defined

level of hazard in a particular building would not cause the building or portion thereof housing the hazard to be classified in Group H-2, but rather in the group that is most appropriate for the particular operation.

The original tabular MAQ per control area for combustible dust, included in the legacy building and fire codes, was deleted because of its questionable value, given the complexities of dust explosion hazards. In the 2012 edition of the code, a row for combustible dust was added to Table 5003.1.1(1) along with a new Note q. The note reinforces the fact that determining a theoretical MAQ of combustible dust and the potential for a dust explosion requires a thorough evaluation and technical report based on the provisions of Section 104.7.2 of the code. Such determination is complex and requires evaluation far beyond the simple 1 pound per 1,000 cubic feet (16 g/m<sup>3</sup>) MAQ previously used by the legacy codes. Critical factors, such as particle size, material density, humidity and oxygen concentration, play a major role in the evaluation of the dust hazard and are much too complex to be simply addressed.

**COMBUSTIBLE FIBERS.** Readily ignitable and free-burning materials in a fibrous or shredded form, such as cocoa fiber, cloth, cotton, excelsior, hay, hemp, henequen, istle, jute, kapok, oakum, rags, sisal, Spanish moss, straw, tow, wastepaper, certain synthetic fibers or other like materials. This definition does not include densely packed baled cotton.

❖ The basic component of all textiles is fibers. Fibers may be either natural or man-made. Cellulosic, protein and mineral fibers are considered natural fibers. Fibers produced by chemical processes (nylon, rayon, Orlon, etc.) are considered man-made. The definition clarifies that densely packed baled cotton is not to be considered a hazardous material. The density and packaging arrangements of cotton fibers meeting the definition of “Baled cotton, densely packed” in this section reduce the hazard of the material such that the hazardous materials provisions of the code need no longer apply.

**COMBUSTIBLE GAS DETECTOR.** An instrument that samples the local atmosphere and indicates the presence of ignitable vapors or gases within the flammable or explosive range expressed as a volume percent in air.

❖ This definition coordinates with the requirements in Section 3510 that provide procedures for undertaking hot work on tanks that have contained flammable or combustible liquids. One of the procedures required is the use of a combustible gas detector to evaluate the conditions of the space while hot work is occurring.

**COMBUSTIBLE LIQUID.** A liquid having a closed cup flash point at or above 100°F (38°C). Combustible liquids shall be subdivided as follows:

**Class II.** Liquids having a closed cup flash point at or above 100°F (38°C) and below 140°F (60°C).

## DEFINITIONS

**Class IIIA.** Liquids having a closed cup flash point at or above 140°F (60°C) and below 200°F (93°C).

**Class IIIB.** Liquids having closed cup *flash points* at or above 200°F (93°C).

The category of combustible liquids does not include *compressed gases* or *cryogenic fluids*.

❖ Combustible liquids differ from flammable liquids in that the closed-cup flash point of all combustible liquids is at or above 100°F (38°C) (see the definition of “Flash point”). There are three categories of combustible liquids. The range of their closed-cup flash point dictates the class of combustible liquid. The flash point range of 100°F (38°C) to 140°F (60°C) for Class II liquids was based on a possible indoor ambient temperature exceeding 100°F (38°C). Only a moderate degree of heating would be required to bring the liquid to its flash point at this temperature. Class III liquids, which have flash points higher than 140°F (60°C), would require a significant heat source above ambient temperature to reach their flash point (see the definition of “Flammable liquid”). Class IIIA has a closed-cup flash point range of 140°F (60°C) to 200°F (93°C). Class IIIB has a closed-cup flash point at or above 200°F (93°C). The term “combustible liquid” does not include liquefied compressed gases or cryogenic fluids. Compressed gases are regulated in Chapter 53 and cryogenic fluids are regulated in Chapter 55.

**[M] COMMERCIAL COOKING APPLIANCES.** Appliances used in a commercial food service establishment for heating or cooking food and which produce grease vapors, steam, fumes, smoke or odors that are required to be removed through a local exhaust ventilation system. Such appliances include deep fat fryers, upright broilers, griddles, broilers, steam-jacketed kettles, hot-top ranges, under-fired broilers (charbroilers), ovens, barbecues, rotisseries, and similar appliances. For the purpose of this definition, a food service establishment shall include any building or a portion thereof used for the preparation and serving of food.

❖ This definition is important in the application of Section 609, which requires a commercial kitchen hood above commercial cooking appliances. A definition of “Food service establishment” is included within this definition. “Food service” includes operations, such as preparing, handling, cleaning, cooking and packaging food items of any kind.

**COMMERCIAL MOTOR VEHICLE.** A motor vehicle used to transport passengers or property where the motor vehicle:

1. Has a gross vehicle weight rating of 10,000 pounds (454 kg) or more; or
2. Is designed to transport 16 or more passengers, including the driver.

❖ This definition clarifies what constitutes a “commercial vehicle.” This term has often been misinterpreted in previous editions. These criteria are from the DOT

49 CFR; Part 390.5, and correlate with IBC Section 1607.7. Where vehicles of this size are present in buildings greater than 5,000 square feet (464 m<sup>2</sup>) in area, the code requires an automatic sprinkler system be provided in repair garages, commercial parking garages and in Group S-1 storage occupancies (see Section 903.2).

**COMMODITY.** A combination of products, packing materials and containers.

❖ Commodity is a term used to identify the product being stored, its container or housing and the type of stackable mechanism (with or without pallet). Commodities and their containers are generally identified as classes, with each classification identifying the combustibility (potential fire hazard). The quantity and locations of each type of commodity will define the type of general and special fire protection and life safety requirements necessary for the building or structure. See the commentary for the various commodities in Section 3203.

**[BE] COMMON PATH OF EGRESS TRAVEL.** That portion of the *exit access* travel distance measured from the most remote point within a story to that point where the occupants have separate and distinct access to two *exits* or *exit access* doorways.

❖ The common path of egress travel is a concept used to refine travel distance criteria. A common path of travel is the route an occupant will travel where the one way in is also the one way out, similar to a dead-end corridor or single exit suite. Once occupants reach a point where two different routes are available, and the two different routes continue to two separate exits, then common path of travel is finished. The length of a common path of egress travel is limited so that the means of egress path of travel provides a choice before the occupant has traveled an excessive distance (see Section 1006). This reduces the possibility that, although the exits are remote from one another, a single fire condition will render both paths unavailable. The common path of egress travel is part of the overall exit access travel distance. To be compliant, the path of egress must meet criteria for both common path of egress travel and exit access travel distance.

**[BE] COMMON USE.** Interior or exterior circulation paths, rooms, spaces or elements that are not for public use and are made available for the shared use of two or more people.

❖ Some buildings include areas that are restricted to employees only or where public access is limited. Common-use spaces may be part of employee work areas but do not include public-use spaces. Any space that is shared by two or more persons, such as copy areas, break rooms, toilet rooms or circulation paths, are common use areas. A grade school classroom would be another example of a common-use space (see also the commentary for the definition of “Public-use areas” and “Employee work area”).

**COMPRESSED GAS.** A material, or mixture of materials that:

1. Is a gas at 68°F (20°C) or less at 14.7 psia (101 kPa) of pressure; and
2. Has a *boiling point* of 68°F (20°C) or less at 14.7 psia (101 kPa) which is either liquefied, nonliquefied or in solution, except those gases which have no other health- or physical-hazard properties are not considered to be compressed until the pressure in the packaging exceeds 41 psia (282 kPa) at 68°F (20°C).

The states of a compressed gas are categorized as follows:

1. Nonliquefied compressed gases are gases, other than those in solution, which are in a packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).
  2. Liquefied compressed gases are gases that, in a packaging under the charged pressure, are partially liquid at a temperature of 68°F (20°C).
  3. Compressed gases in solution are nonliquefied gases that are dissolved in a solvent.
  4. Compressed gas mixtures consist of a mixture of two or more compressed gases contained in a packaging, the hazard properties of which are represented by the properties of the mixture as a whole.
- ❖ This term refers to all types of gases that are under pressure at normal room or outdoor temperatures inside their containers, including, but not limited to, flammable, nonflammable, highly toxic, toxic, cryogenic and liquefied gases. The vapor pressure limitations provide the distinction between a liquid and a gas.

**COMPRESSED GAS CONTAINER.** A pressure vessel designed to hold *compressed gases* at pressures greater than one atmosphere at 68°F (20°C) and includes cylinders, containers and tanks.

- ❖ Containers covered by this definition range from the small compressed air tanks carried by some road service trucks to the very large storage tanks mounted on permanent bases at industrial plants. Designs vary considerably depending on the gases they are intended to hold, whether they are designed for upright or horizontal mounting and the environment they will be used in.

**COMPRESSED GAS SYSTEM.** An assembly of equipment designed to contain, distribute or transport *compressed gases*. It can consist of a *compressed gas* container or containers, reactors and appurtenances, including pumps, compressors and connecting piping and tubing.

- ❖ This definition is intended to include every component used to convey the gas to or from manufacturing, storage and use facilities. System designs will vary widely depending on their intended use.

**[BG] CONGREGATE LIVING FACILITIES.** A building or part thereof that contains sleeping units where residents share bathroom and/or kitchen facilities.

- ❖ Congregate living facilities are those pertaining to group housing (i.e., dormitories, fraternities, convents) that combine individual sleeping quarters with communal facilities for food, care, sanitation and recreation. The number of occupants in the facility determines the appropriate occupancy classification. There are two thresholds: 10 and 16. A congregate living facility with 16 or fewer nontransient residents falls in the R-3 classification—for above 16 nontransient residents the classification is R-2. For transient residents, if there are 10 or fewer in the facility, it is also in the R-3 classification. If over 10 transient residents, it is an R-1 occupancy.

**CONSTANTLY ATTENDED LOCATION.** A designated location at a facility staffed by trained personnel on a continuous basis where alarm or supervisory signals are monitored and facilities are provided for notification of the fire department or other emergency services.

- ❖ These locations are intended to receive trouble, supervisory and fire alarm signals transmitted by the fire protection equipment installed within a protected facility. It is the intent of the code to have both an approved location and personnel who are acceptable to the fire code official responsible for actions taken when the fire protection system requires attention. The term “constantly attended” implies 24-hour surveillance of the system, at the designated location.

**[A] CONSTRUCTION DOCUMENTS.** The written, graphic and pictorial documents prepared or assembled for describing the design, location and physical characteristics of the elements of the project necessary for obtaining a permit.

- ❖ To determine whether proposed construction is in compliance with code requirements, sufficient information must be submitted to the fire code official for review. This definition describes in general which items are to be included in that documentation. This typically will include drawings (floor plans, elevations, sections, details, etc.), specifications and product information describing the proposed work. In the past, these documents were referred to as “plans and specifications.” Those terms are not broad enough to include all information, such as calculations or graphs.

**CONTAINER.** A vessel of 60 gallons (227 L) or less in capacity used for transporting or storing hazardous materials. Pipes, piping systems, engines and engine fuel tanks are not considered to be containers.

- ❖ This definition establishes the intended capacity of the container to avoid confusion with portable or stationary tanks. A container could include typical 55-gallon (208 L) drums or 2-ounce (59 ml) cans. It is

## DEFINITIONS

important to note the size difference between a drum and a barrel. A drum has a capacity of 55 U.S. gallons (208 L) and a barrel has a capacity of 42 U.S. gallons (158 L). These terms are sometimes reported incorrectly when determining the amount of storage in a facility.

**CONTAINMENT SYSTEM.** A gas-tight recovery system comprised of equipment or devices which can be placed over a leak in a *compressed gas* container, thereby stopping or controlling the escape of gas from the leaking container.

❖ A containment system consists of various components that will capture gases from a leaking container by being placed at the source of the leak.

**CONTAINMENT VESSEL.** A gas-tight recovery vessel designed so that a leaking *compressed gas* container can be placed within its confines thereby encapsulating the leaking container.

❖ A containment vessel is a closed unit that a leaking container can be placed in that will fully contain any unwanted release.

**CONTINUOUS GAS DETECTION SYSTEM.** A gas detection system where the analytical instrument is maintained in continuous operation and sampling is performed without interruption. Analysis is allowed to be performed on a cyclical basis at intervals not to exceed 30 minutes.

❖ This term refers to a system that is capable of constantly monitoring the presence of highly toxic or toxic compressed gases at or below the permissible exposure limit (PEL) for the gas. A continuous gas detection system will provide notification of a leak or rupture in a compressed gas cylinder or tank in a storage or use condition.

Numerous techniques exist for detecting and measuring gases. Two of the most common types of detection methods are briefly described below:

*Colorimetric Detection (Chemcassette Detection):* Colorimetric detection involves a circuit that is usually completed by the presence of an electrolyte within the cell itself. A carefully prepared reel of porous paper tape is impregnated with a chemical that will change color in the presence of the target gas—this reaction can be very specific to particular gases of interest. This tape is then positioned so that the sample of air or gas passes through a section of the tape. Color changes are measured optically and converted to a direct concentration value of the target gas.

*Electrochemical Detection:* Electrochemical cells work on the fuel-cell principle. As the target gas enters the cell, it reacts at the active electrode and generates a very small current, which flows through an external measuring circuit back to the counter electrode.

**CONTROL AREA.** Spaces within a building where quantities of hazardous materials not exceeding the *maximum allowable quantities per control area* are stored, dispensed,

used or handled. See also the definition of “Outdoor control area.”

❖ The use of control areas allows for the use and storage of hazardous materials without classifying the building or structure as a high-hazard Group H occupancy when the total quantity of hazardous materials in the entire building might exceed the MAQ. This concept is based on regulating the allowable quantities of hazardous materials in each control area by giving credit for further compartmentation through the use of fire barriers having a minimum fire-resistance rating of 1 hour. Maximum quantities of hazardous materials within each control area cannot exceed the MAQ for a given material. Thus, the quantities in each control area will be less than the MAQ, while the overall quantity in the entire building could exceed the MAQ (see commentary, Section 5003.8.3).

**[BE] CORRIDOR.** An enclosed *exit access* component that defines and provides a path of egress travel.

❖ Corridors are regulated in the code because they serve as principal elements of travel in many means of egress systems within buildings. Typically, corridors have walls that extend from the floor to the ceiling. They need not extend above the ceiling or have doors in their openings unless a fire-resistance rating is required (see Section 1020).

While both aisles and corridors may result in a confined path of travel, an aisle is an unenclosed component, while a corridor would be an enclosed component of the means of egress. The enclosed character of the corridor restricts the sensory perception of the user. A fire located on the other side of the corridor wall, for example, may not be as readily seen, heard or smelled by the occupants traveling through the egress corridor. The code does not specifically state what is considered “enclosed” when corridors are not fire-resistance rated. When an egress path is bounded by partial-height walls, such as work-station partitions in an office, issues would be if the walls provided a confined path of travel and limited fire recognition in adjacent spaces by restricting line of sight, hearing and smell.

**CORRIDOR, OPEN-ENDED.** See “Open-ended corridor.”

**CORROSIVE.** A chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the point of contact. A chemical shall be considered corrosive if, when tested on the intact skin of albino rabbits by the method described in DOTn 49 CFR 173.137, such chemical destroys or changes irreversibly the structure of the tissue at the point of contact following an exposure period of 4 hours. This term does not refer to action on inanimate surfaces.

❖ This definition is derived from DOT 49 CFR; Part 173. While corrosive materials may not pose a fire, explosion or reactivity hazard, they do pose a handling and storage problem. Corrosive materials, therefore, are

primarily considered a health hazard, and an occupancy containing such materials in excess of the maximum allowable quantity per control area (MAQ) is classified in Group H-4. It should be noted that many corrosive chemicals are also strong oxidizing agents that would require review as a multiple-hazard material in accordance with Section 5001.1.

## COTTON.

**Baled cotton.** A natural seed fiber wrapped in and secured with industry-accepted materials, usually consisting of burlap, woven polypropylene, polyethylene or cotton or sheet polyethylene, and secured with steel, synthetic or wire bands, or wire; also includes linters (lint removed from the cottonseed) and motes (residual materials from the ginning process).

- ❖ Since Section 3705 deals with baled fibers, this definition of standard “Baled cotton” is being included only to distinguish it from “Baled cotton, densely packed” (see commentary to the definition of “Baled cotton, densely packed”). The Joint Cotton Industry Bale Packaging Committee (JCIBPC) is a committee that represents all parts of the cotton industry and sets standards and specifications for packaging of cotton bales that include bale density. The JCIBPC specifications for baling of cotton require that all cotton bales be secured with fixed length wire bands, polyester plastic strapping or cold-rolled high tensile steel strapping and then covered in fully coated woven polyolefin, polyethylene film or burlap.

**Baled cotton, densely packed.** Cotton, made into banded bales, with a packing density of not less than 22 pounds per cubic foot (360 kg/m<sup>3</sup>), and dimensions complying with the following: a length of 55 inches (1397 mm), a width of 21 inches (533.4 mm) and a height of 27.6 to 35.4 inches (701 to 899 mm).

- ❖ Currently, over 99 percent of all U.S. cotton is pressed and stored as densely packed baled cotton, with bales meeting the weight and dimension requirements of ISO 8115. One reason that the cotton industry has chosen to use mostly such bales is because the bales are very difficult to ignite, which allows the industry to transport them without being labeled as “flammable solids” or “dangerous goods” by the national or international transport authorities. This definition should be used to distinguish such bales from other combustible fibers.

In order to counteract some erroneous information regarding the combustibility characteristics of densely packed cotton bales, flammability research was conducted on baled cotton. The research demonstrated that densely packed baled cotton meeting the size and weight requirements of ISO 8115 is not a hazardous material. In view of that data, the U.S. Department of Transportation (DOT) (U.S. Coast Guard), the United Nations (U.N.) and the International Maritime Organization (IMO) have all removed baled cotton from the list of hazardous materials and

flammable solids, provided the cotton bales are the densely packed type that meet the standard noted above. The research conclusions were:

1. Standard cotton fiber “passed” the DOT spontaneous combustion test: the cotton did not exceed the oven temperature and was not classified as self-heating.
2. Cotton, as densely packed baled cotton, did not cause sustained smoldering propagation: an electric heater placed within the bale was unable to cause sustained smoldering propagation, due to the lack of oxygen inside the densely packed bale.
3. Cotton, as densely packed baled cotton, was exposed to ignition from a cigarette and a match and performed very well: no propagating combustion with either.
4. Cotton, as densely packed baled cotton, was exposed to ignition from the gas burner source in ASTM E1590 (also known as California Technical Bulletin 129) of 12 L/min of propane gas for 180 seconds and passed all the criteria, including mass loss of less than 1.36 kg (3 pounds), heat release rate less than 100 kW and total heat release of less than 25 MJ in the first 10 minutes of the test.

**Seed cotton.** Perishable raw agricultural commodity consisting of cotton fiber (lint) attached to the seed of the cotton plant, which requires ginning to become a commercial product.

- ❖ Before cotton can be spun into yarn or thread and woven into cloth, the fibers must be separated from their seeds by a cotton gin (short for “cotton engine”) in a process called “cotton ginning,” which takes seed cotton and converts it into cotton fibers that are then stored in bales. Thus, seed cotton is a perishable raw material without commercial value that is not stored, but exists simply as a step on the way from the cotton field to the gin plant. Seed cotton is held in modules on the way from the harvest to the ginning factory, and is neither a loose cotton fiber (it has not been converted into fibers yet) nor densely packed baled cotton. As such, it is still a perishable agricultural product.

In the typical harvesting process (for example, grain harvesting), threshing machines are used to separate the raw agricultural product into a product that can then be stored and marketed, such as use as food or animal feed, and a byproduct that is usually left in the field. The cotton ginning process is essentially the same as the grain harvesting process in that a raw agricultural product (seed cotton) is converted by specially designed equipment into products with commercial value. These products are: cotton fiber (that exits the ginning process packaged as densely packed cotton bales and is either stored in a cotton warehouse or shipped to a textile mill) and cotton-

## DEFINITIONS

seeds (that go either to cottonseed oil mills or are fed directly to dairy cattle).

**[BG] COURT.** An open, uncovered space, unobstructed to the sky, bounded on three or more sides by exterior building walls or other enclosing devices.

❖ Though not specifically identified in the definition, the provisions in the code for courts (Section 1206 of the IBC) are only applicable to those areas created by the arrangement of exterior walls and used to provide natural light or ventilation (see Section 1206.1 of the IBC and the definition of “Yard.” See also the definition of “Egress court” for courts that are utilized for exit discharge.)

**[BG] COVERED MALL BUILDING.** A single building enclosing a number of tenants and occupants such as retail stores, drinking and dining establishments, entertainment and amusement facilities, passenger transportation terminals, offices, and other similar uses wherein two or more tenants have a main entrance into one or more malls. Anchor buildings shall not be considered as a part of the covered mall building. The term “covered mall building” shall include open mall buildings as defined below.

❖ The covered mall building is the entire area of the building (area of mall plus gross leasable area), excluding the anchor buildings. Passenger transportation terminals frequently are developed as wide concourses with small shops along the sides. For this reason, passenger transportation facilities are included. Transportation facilities used for freight or other purposes are not to be considered a covered mall building.

**Mall.** A roofed or covered common pedestrian area within a covered mall building that serves as access for two or more tenants and not to exceed three levels that are open to each other. The term “mall” shall include open malls as defined below.

❖ A mall is an interior, climate-controlled pedestrian way that is open to the tenant spaces within the mall building and typically connects to the anchor buildings. The term “mall” also includes open mall. Unless noted otherwise, an open mall must comply with all the provisions for a mall.

**Open mall.** An unroofed common pedestrian way serving a number of tenants not exceeding three levels. Circulation at levels above grade shall be permitted to include open exterior balconies leading to *exits* discharging at grade.

❖ A mall is an interior, climate-controlled pedestrian way that is open to the tenant spaces within the mall building and typically connects to the anchor buildings. The term “mall” also includes open mall. Unless noted otherwise, an open mall must comply with all the provisions for a mall.

**Open mall building.** Several structures housing a number of tenants such as retail stores, drinking and dining establishments, entertainment and amusement facilities, offices, and other similar uses wherein two or more tenants have a

main entrance into one or more open malls. Anchor buildings are not considered as a part of the open mall building.

❖ An open mall building includes all of the buildings housing a number of tenants wherein two or more tenants have a main entrance into one or more open malls. Because the open mall is characterized by there not being a roof connecting one side of the pedestrian mall to the other, the covered mall “building” may actually be a collection of separate buildings which all rely on a shared pedestrian concourse for egress. Similar to the covered mall building, the open mall “building” does not include the anchor buildings. Unless noted otherwise, open mall buildings must comply with all the provisions for covered mall buildings.

**CRITICAL CIRCUIT.** A circuit that requires continuous operation to ensure safety of the structure and occupants.

❖ The purpose of this definition is to clarify the applicability of the provisions of Section 604.3 of the code. Critical circuits are those electrical circuits supplying power to systems and equipment that are vital to the safety of building occupants and to the operational continuity of safety systems such as fire alarm systems, security systems, emergency communication systems and similar systems identified throughout the code, most notably in sections pertaining to emergency power. Although the term “critical circuit” is used widely throughout many industry standards, there is no specific definition for the term. As such, this definition was created based on definitions found in NFPA 70 and is similar to the definition of “Critical Operations Power Systems (COPS)” in that standard (see the commentary to Section 604.3).

**CRYOGENIC CONTAINER.** A cryogenic vessel of any size used for the transportation, handling or storage of *cryogenic fluids*.

❖ This definition is necessary to differentiate containers that hold cryogenic fluids from those that are used for ordinary compressed gases as addressed in Chapter 53, flammable and combustible liquids as addressed in Chapter 57 or other liquid or gaseous hazardous materials. Because of the extreme pressures and temperatures, these containers are unique in construction (see also commentary for the definition of “Container”).

**CRYOGENIC FLUID.** A fluid having a *boiling point* lower than -130°F (-89.9°C) at 14.7 pounds per square inch atmosphere (psia) (an absolute pressure of 101.3 kPa).

❖ This definition contains the criteria for determining whether Chapter 55 is applicable. If a fluid falls outside of these criteria, it would likely be treated as a compressed gas and addressed within Chapter 53 (see also the definition for “Compressed gas”).

**CRYOGENIC VESSEL.** A pressure vessel, low-pressure tank or atmospheric tank designed to contain a *cryogenic fluid* on which venting, insulation, refrigeration or a combina-

tion of these is used in order to maintain the operating pressure within the design pressure and the contents in a liquid phase.

- ❖ Cryogenic vessels differ from basic containers in that they are designed for use as either a pressure vessel, a low-pressure tank or an atmospheric tank that regulates the operating pressure to maintain the fluid as a liquid. Such vessels not only contain the fluids but also play an active role in regulating the state of the fluids.

**[BG] CUSTODIAL CARE.** Assistance with day-to-day living tasks; such as assistance with cooking, taking medication, bathing, using toilet facilities and other tasks of daily living. Custodial care includes persons receiving care who have the ability to respond to emergency situations and evacuate at a slower rate and/or who have mental and psychiatric complications.

- ❖ Care facilities encompass a full spectrum of occupant acuity and support services and span a wide range of occupancy types, including Groups E, I, and R. There are three types of care defined in the IBC and IFC: personal, custodial, and medical.

- Personal care is on one end of the care spectrum. It occurs in Group E occupancies for child day care services for persons over 2<sup>1</sup>/<sub>2</sub> years of age. Occupants are supervised but do not need custodial or medical care.
- Custodial care occurs in Groups I-1, I-4 and R4, where occupants may be elderly or impaired, or require adult or child day care of any age. Care recipients may need daily living assistance such as cooking, cleaning, bathing or help with taking medications. Persons who receive custodial care may or may not require assistance with evacuation depending on the occupancy and the “condition” in the occupancy. See also the commentary to the definitions of Groups I-1, I-4 and R4.
- Medical care occurs in Group I-2 occupancies on the opposite end of the spectrum, where care recipients are incapable of self-preservation. They may be completely bedridden, meaning bed movement may be required during emergencies, and may be dependent on life support systems such as medical gases and emergency power to maintain life. This level of acuity is not allowed in custodial care or personal care.

There are two other key defining aspects of custodial care that also differentiate it from medical care. The first is the evacuation capability of custodial care recipients. Custodial care recipients’ evacuation capabilities are limited by the occupancy classification criteria or the occupancy condition in which care occurs. Group I-1 Condition 1 and Group R-4 Condition 1 only includes occupants with the ability to self-evacuate. Group I-1 Condition 2 and Group R-4 Condition 2 includes limited assistance

with evacuation. Group I-4 also assumes that the occupants may not be able to respond on their own during emergencies. The second differentiating aspect is that Group I-1 and R-4 custodial care recipients also participate in fire drills in accordance with the code, versus Group I-2 medical care that implements defend-in-place strategies during emergencies.

The level of care provided describes the condition and capabilities of an occupant which then indicates the appropriate standards for protection systems, both active and passive. See also the definitions of “24-hour basis,” “Ambulatory care facility,” “Detoxification facilities,” “Foster care facilities,” “Group home,” “Hospitals and psychiatric hospitals,” “Incapable of self-preservation,” “Medical care,” “Nursing homes” and “Personal care service.”

**CYLINDER.** A pressure vessel designed for pressures higher than 40 psia (275.6 kPa) and having a circular cross section. It does not include a portable tank, multiunit tank car tank, cargo tank or tank car.

- ❖ As referenced in the code, cylinders are vessels containing flammable or nonflammable compressed gases. Gas cylinders are fabricated to comply with regulations specified by DOTn and are generally limited to a capacity equivalent to the volume of 1,000 pounds (454 kg) of water.

**DAMPER.** See “Fire damper” and “Smoke damper.”

**DAY BOX.** A portable magazine designed to hold *explosive* materials and constructed in accordance with the requirements for a Type 3 magazine as defined and classified in Chapter 56.

- ❖ Day boxes are basically Type 3 magazines used to isolate in-process material from a workstation as a means to minimize the potential for involvement should an event occur within the immediate vicinity of the work area. See the commentary to Section 5604.5.1.3 for a more complete discussion of the use of day boxes.

**DECORATIVE MATERIALS.** All materials applied over the building interior finish for decorative, acoustical or other effect including, but not limited to, curtains, draperies, fabrics, streamers and all other materials utilized for decorative effect including, but not limited to, bulletin boards, artwork, posters, photographs, paintings, batting, cloth, cotton, hay, stalks, straw, vines, leaves, trees, moss and similar items, foam plastics and materials containing foam plastics. Decorative materials do not include wall coverings, ceiling coverings, floor coverings, ordinary window shades, interior finish and materials 0.025 inch (0.64 mm) or less in thickness applied directly to and adhering tightly to a substrate.

- ❖ Decorative materials have historically been characterized by easily ignitable materials that burn very rapidly and contribute to fire spread. In order to properly classify decorative materials, it is important to define the term and this definition captures the essential elements. The significance of this definition is to provide information as to what is not regulated as

## DEFINITIONS

decorative materials in the application of code requirements. While any dictionary would define floor coverings, window shades and wallpaper as being “decorative” in a building interior, they are not considered decorative materials for the flame-resistance testing to which the code requirements are intended to apply (see Section 807).

**DEFLAGRATION.** An exothermic reaction, such as the extremely rapid oxidation of a flammable dust or vapor in air, in which the reaction progresses through the unburned material at a rate less than the velocity of sound. A deflagration can have an explosive effect.

❖ Materials posing a deflagration hazard usually burn very quickly with an energy release from a chemical reaction in the form of intense heat. Confined deflagration hazards under pressure can result in an explosion. Most hazardous materials posing a severe deflagration hazard are classified as Group H-2.

**DELUGE SYSTEM.** A sprinkler system employing open sprinklers attached to a piping system connected to a water supply through a valve that is opened by the operation of a detection system installed in the same area as the sprinklers. When this valve opens, water flows into the piping system and discharges from all sprinklers attached thereto.

❖ A deluge system applies large quantities of water or foam throughout the protected area by means of a system of open sprinklers. In a fire, the system is activated by a fire detection system that makes it possible to apply water to a fire more quickly and to cover a larger area than with a conventional automatic sprinkler system, which depends on sprinklers being activated individually as the fire spreads. As the definition indicates, the sprinklers are open. There is no fusible link so when water is admitted into the system by the fire detection system, it flows through the piping and is immediately discharged through the sprinkler heads.

Deluge systems are particularly beneficial in hazardous areas where the fuel loads (combustible contents) are of such a nature that fire may grow with exceptional rapidity and possibly flash ahead of the operations of conventional automatic sprinklers.

**DESIGN PRESSURE.** The maximum gauge pressure that a pressure vessel, device, component or system is designed to withstand safely under the temperature and conditions of use expected.

❖ A container that is subjected to an internal pressure higher than its design pressure faces a high failure rate. If the container is used to store flammable liquids or gases, a boiling liquid expanding vapor explosion (BLEVE), which is a form of pressure-releasing explosion, may occur.

**DETACHED BUILDING.** A separate single-story building, without a *basement* or crawl space, used for the storage or use

of hazardous materials and located an *approved* distance from all structures.

❖ This term refers to the type of structure that the code recognizes for using and storing Group H materials exceeding MAQ. A detached storage building is required only for Group H, as indicated in Table 5003.8.2 of the code or Table 415.6.2 of the IBC, and as may be required in Chapters 50 through 67 of the code.

**DETEARING.** A process for rapidly removing excess wet coating material from a dipped or coated object or material by passing it through an electrostatic field.

❖ Detearing applies to dip tank operations. It is the process of rapidly removing excess wet coating materials from an object.

**DETECTOR, HEAT.** A fire detector that senses heat, either abnormally high temperature or rate of rise, or both.

❖ In a fire, heat is released that causes the temperature in a room or space to increase. Automatic fire detectors that sense abnormally high temperature or rate of temperature rise are known as heat detectors. These include fixed temperature detectors, rate compensation detectors and rate-of-rise detectors. The code requires all automatic fire detectors to be smoke detectors, except that heat detectors tested and approved in accordance with NFPA 72 may be used as an alternative to smoke detectors in rooms and spaces where, during normal operation, products of combustion are present in sufficient quantity to actuate a smoke detector.

**DETONATING CORD.** A flexible cord containing a center core of high *explosive* used to initiate other *explosives*.

❖ Outwardly, detonating cord, or primacord, is somewhat similar to a safety fuse in size and appearance. But instead of being filled with black powder, detonating cord generally contains pentaerythritol tetranitrate (PETN). Like other explosives, primacord is generally set off by a blasting cap. It propagates a detonation at a rate of 9,000 yards per second (8.23 km/s), a little over 5 miles per hour (8.05 km/h). A length of detonating cord stretching from San Francisco to New York will explode over its entire length of 3,000 miles (4828.03 km) in about 10 minutes.

**DETONATION.** An exothermic reaction characterized by the presence of a shock wave in the material which establishes and maintains the reaction. The reaction zone progresses through the material at a rate greater than the velocity of sound. The principal heating mechanism is one of shock compression. *Detonations* have an *explosive* effect.

❖ Detonations are distinguished from deflagrations, which are produced by explosive gases, dusts, vapors and mists, by the speed with which they propagate a blast effect. Both detonations and deflagra-

tions may produce explosive results when they occur in a confined space.

**DETONATOR.** A device containing any initiating or primary *explosive* that is used for initiating *detonation*. A detonator shall not contain more than 154.32 grains (10 grams) of total *explosives* by weight, excluding ignition or delay charges. The term includes, but is not limited to, electric blasting caps of instantaneous and delay types, blasting caps for use with safety fuses, detonating cord delay connectors, and noninstantaneous and delay blasting caps which use detonating cord, shock tube or any other replacement for electric leg wires. All types of detonators in strengths through No. 8 cap should be rated at 1½ pounds (0.68 kg) of explosives per 1,000 caps. For strengths higher than No. 8 cap, consult the manufacturer.

❖ These devices contain a primary explosive charge and are used to initiate other explosives. Detonators include, but are not limited to:

1. Electric detonators of instantaneous and delay types.
2. Detonators for use with safety fuses, detonating cord delay connectors and nonelectric instantaneous delay detonators that use detonating cord, shock tube or any other replacement for electric leg wires.

**[BG] DETOXIFICATION FACILITIES.** Facilities that provide treatment for substance abuse serving care recipients who are incapable of self-preservation or who are harmful to themselves or others.

❖ Persons in detoxification facilities may be physically incapable of self-preservation, or they may be confined within an area of a building for care or security

purposes. See the commentary for the definition of “Occupancy Group I-2” and Section 407 of the IBC.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant which, in turn, indicates appropriate standards for protection systems, both passive and active. See also the definitions for “24-hour basis,” “Ambulatory care facility,” “Group home,” “Hospitals and psychiatric hospitals,” “Incapable of self-preservation,” “Medical care,” “Nursing homes” and “Personal care service.”

**DIP TANK.** A tank, vat or container of flammable or combustible liquid in which articles or materials are immersed for the purpose of coating, finishing, treating and similar processes.

❖ Dip tanks can be almost any size, depending on the size of the work pieces to be immersed. They may be equipped with a fire suppression system, as well as overflow and drain pipes, all of which are based on the tank size. Regardless of size, dip tanks must be constructed of noncombustible materials, equipped with an approved self-closing cover and properly ventilated (see Commentary Figure 202-D1).

**DISCHARGE SITE.** The immediate area surrounding the fireworks mortars used for an outdoor fireworks display.

❖ The area selected for the discharge of aerial shells must be located so that the trajectory of the shells does not come within 25 feet (7620 mm) of any overhead object. Ground display pieces must be located a minimum distance of 75 feet (22 860 mm) from spectator viewing areas and parking areas.

## DEFINITIONS

**DISPENSING.** The pouring or transferring of any material from a container, tank or similar vessel, whereby vapors, dusts, fumes, mists or gases are liberated to the atmosphere.

- ❖ This term refers to any transfer of a hazardous material from one container to another that is open to the atmosphere where liberation of the material in the forms listed in the definition occurs. See also the definitions for “Closed system” and “Handling.”

**DISPENSING DEVICE, OVERHEAD TYPE.** A dispensing device that consists of one or more individual units intended for installation in conjunction with each other, mounted above a dispensing area typically within the motor fuel-dispensing facility canopy structure, and characterized by the use of an overhead hose reel.

- ❖ Dispensing devices are approved pieces of fixed equipment that control the dispensing of fuel through the dispensing hose connected to them. An overhead-type dispensing device is not to be confused with the conventional dispenser, often referred to as a “high-hose” dispenser, that is equipped with a dispensing hose connected at the top of the dispenser frame. The intent of this provision is to identify the overhead hose reel that has special requirements for the classification of electrical equipment in the vicinity of the reel in accordance with Chapter 8 of NFPA 30A.

**DISPLAY SITE.** The immediate area where a fireworks display is conducted. The display area includes the discharge site, the fallout area and the required separation distance from the mortars to spectator viewing areas. The display area does not include spectator viewing areas or vehicle parking areas.

- ❖ Where added safety precautions have been taken, or particularly favorable conditions exist, the fire code official can decrease the required separation distances upon demonstration that the hazard has been reduced or the risk has been properly protected. Where unusual or safety-threatening conditions exist, he or she can also increase the required separation distances as he or she deems necessary.

**DOOR, BALANCED.** See “Balanced door.”

- ❖ See the commentary to definition of “Balanced door.”

**DOOR, DUTCH.** See “Dutch door.”

- ❖ See the commentary to definition of “Dutch door.”

**DOOR, LOW ENERGY POWER-OPERATED.** See “Low energy power-operated door.”

- ❖ See the commentary to definition of “Low energy power-operated door.”

**DOOR, POWER-ASSISTED.** See “Power-assisted door.”

- ❖ See the commentary to definition of “Power-assisted door.”

**DOOR, POWER-OPERATED.** See “Power-operated door.”

- ❖ See the commentary to definition of “Power-operated door.”

**DOORWAY, EXIT ACCESS.** See “Exit access doorway.”

- ❖ See the commentary to definition of “Exit access doorway.”

**[BG] DORMITORY.** A space in a building where group sleeping accommodations are provided in one room, or in a series of closely associated rooms, for persons not members of the same family group, under joint occupancy and single management, as in college dormitories or fraternity houses.

- ❖ Dormitories typically consist of a large room serving as a community sleeping room or many smaller rooms grouped together and serving as private or semiprivate sleeping rooms (sleeping units). A typical setting for dormitories is on college campuses; however, sleeping areas of a fire station and similar lodging facilities for occupants not of the same family group are also considered dormitories. Dormitories most often are not the permanent residence of the occupants. They are typically occupied only for a designated period of time, such as a school year. Though limited, the period of occupancy is usually more than 30 days, which provides the occupant with a familiarity of the structure such that the occupancy is not considered transient. A dormitory is classified as Group R-2 (see the commentary to the definition of “Occupancy Group R-2”).

Structures containing a dormitory often have a cafeteria or central eating area and common recreational areas. When such conditions exist, the structure must comply with the mixed occupancy provisions of Section 508 of the IBC.

**DRAFT CURTAIN.** A structure arranged to limit the spread of smoke and heat along the underside of the ceiling or roof.

- ❖ A draft curtain restricts the passage of smoke at roof or ceiling level. Located at the roof or ceiling, draft curtains are designed to compartmentalize the roof or ceiling area in order to limit the passage of smoke to a defined area and hinder its spread throughout the entire storage area. It has also been argued that such curtains help the activation of smoke and heat vents. They are not intended to have a fire-resistance rating. Draft curtains are often termed “curtain boards.”

**[BF] DRAFTSTOP.** A material, device or construction installed to restrict the movement of air within open spaces of concealed areas of building components such as crawl spaces, floor/ceiling assemblies, roof/ceiling assemblies and attics.

- ❖ Draftstopping is required in concealed combustible spaces to limit the movement of air, smoke and other products of combustion. Draftstopping materials are permitted to be combustible based on the rationale that a large and thick enough combustible material will act as a hindrance against the free movement of air, flame/fire and products of combustion [see Commentary Figures 202-D2 and 202-D3 for typical draftstopping applications (also see Section 718 of the IBC)].

Although the term “draftstopping” would seem to imply that its primary purpose is to hinder the circula-

tion of air within the space, its intended purpose is to stop the movement of fire and products of combustion, as evidenced by the fact that draftstopping can be omitted in some cases when appropriate automatic sprinkler protection is installed (see Sections 718.3.2, 718.3.3, 718.4.2 and 718.4.3 of the IBC).

**DRY-CHEMICAL EXTINGUISHING AGENT.** A powder composed of small particles, usually of sodium bicarbonate, potassium bicarbonate, urea-potassium-based bicarbonate, potassium chloride or monoammonium phosphate, with added particulate material supplemented by special treatment

## DEFINITIONS

to provide resistance to packing, resistance to moisture absorption (caking) and the proper flow capabilities.

- ❖ A dry-chemical system extinguishes a fire by placing a chemical barrier between the fire and oxygen, which acts to smother a fire. This system is best known for protection for commercial ranges, commercial fryers and exhaust hoods. Wet-chemical extinguishing systems, however, are more commonly used for new installations in commercial cooking equipment.

The type of dry chemical to be used in the extinguishing system is a function of the hazard expected. The type of dry chemical used in a system must not be changed, unless it has been proven changeable by a testing laboratory; is recommended by the manufacturer of the equipment and is acceptable to the fire code official for the hazard expected. Additional guidance on the use of various dry-chemical agents can be found in NFPA 17, which gives minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of dry-chemical extinguishing systems.

**DRY CLEANING.** The process of removing dirt, grease, paints and other stains from such items as wearing apparel, textiles, fabrics and rugs by use of nonaqueous liquids (solvents).

- ❖ Dry cleaning is the process of cleaning textile-based items in a closed machine using solvents that are not water based; hence, the term “dry.” This process generally consists of a “wash cycle” in which the item or items to be cleaned are placed in the machine with the dry cleaning solvent and tumbled for a predetermined length of time, followed by an “extraction cycle” in which the solvent is centrifugally removed from the clean items, not unlike the “spin” cycle of a washing machine. Recovery of remaining solvent and solvent vapors in the cleaned articles is accomplished in a “reclamation cycle,” which involves heating the cleaned articles to vaporize the remaining solvent, which is then collected and condensed. Finally, an “aeration” or drying cycle occurs where warm air dries and deodorizes the cleaned articles. The dry cleaning process can also include the manual application of solvent and spotting compounds prior to the main cleaning process. See also the definitions of “Dry cleaning plant” and “Solvent or liquid classifications.”

**DRY CLEANING PLANT.** A facility in which dry cleaning and associated operations are conducted, including the office, receiving area and storage rooms.

- ❖ The type of construction, occupancy group classification and other building requirements are determined by the type of solvent and machinery used in the cleaning process. The main hazards in a dry cleaning plant are the fire hazards of the flammable and combustible solvents and the health hazards of the chlorinated hydrocarbon solvents. See also the definitions

of “Dry cleaning” and “Solvent or liquid classifications.”

**DRY CLEANING ROOM.** An occupiable space within a building used for performing dry cleaning operations, the installation of solvent-handling equipment or the storage of dry cleaning solvents.

- ❖ The IBC defines an occupiable space as “a room or enclosed space designed for human occupancy....in which occupants are engaged at labor....” Within the context of Chapter 21, a dry cleaning room is primarily the room or space in which the actual dry cleaning process is conducted. Depending on the scope of the dry cleaning establishment, it could be a room or space within a large plant or could encompass the entire plant in smaller operations. Note that the focus of the term is on the presence of the dry cleaning solvent, whether it is in the cleaning process, being stored for future use within the room or space, or being transferred from storage containers to the dry cleaning machines. See also the definitions of “Dry cleaning,” “Dry cleaning plant” and “Solvent or liquid classifications.”

**DRY CLEANING SYSTEM.** Machinery or equipment in which textiles are immersed or agitated in solvent or in which dry cleaning solvent is extracted from textiles.

- ❖ This term focuses on the actual dry cleaning machines and solvent extractors that use or recover dry cleaning solvent. Systems are classified according to the hazards of the solvent they use. See the commentary to Sections 2103.2 and 2105 for additional discussion of dry cleaning system classification and operation, respectively. See also the definition of “Solvent or liquid classifications.”

**DUTCH DOOR.** A door divided horizontally so that the top can be operated independently from the bottom.

- ❖ This definition is associated with the requirements in Section 1105.4.4.2.3 for existing Group I-2 occupancies. Dutch doors have been used in health care facilities for many years for various necessary operational reasons. Existing language in the IBC does not specifically address dutch doors. Their use is not prohibited, but if used, they must meet the requirements contained in IBC Section 407.3, including positive latching and limiting the transfer of smoke. The definition is provided for additional clarity as to what is considered a “dutch door.”

**[BG] DWELLING.** A building that contains one or two *dwelling units* used, intended or designed to be used, rented, leased, let or hired out to be occupied for living purposes.

- ❖ Dwellings are buildings intended to serve as residences for one or two families. Dwellings can be owner-occupied or rented. The term “dwelling,” which refers to the building itself, is defined to distinguish it from the term “dwelling unit,” which is a single living

unit within a building. See also the definition for “Townhouse.”

**[BG] DWELLING UNIT.** A single unit providing complete, independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

❖ A dwelling unit, as stated, is a residential unit that contains all of the necessary facilities for independent living. This provides a single, independent unit that serves a single family or single group of individuals. This terminology is used throughout the code for the determination of the application of various provisions. A dwelling unit is also distinguished from a sleeping unit which does not have all of the features of a dwelling unit and must comply with a different set of requirements (see the definition for “Sleeping unit”). A building containing one or more dwelling units is a “dwelling” (see the definitions for “Dwelling” and “Townhouse”). A building containing three or more dwelling units is regulated as a Group R-2 occupancy. The most common term used for such a building is an apartment house or condominium. To be considered a Group R-3, the structure must have one or two dwelling units, or be subdivided by fire walls between every unit or every two units.

**EARLY SUPPRESSION FAST-RESPONSE (ESFR) SPRINKLER.** A sprinkler *listed* for early suppression fast-response performance.

❖ The early suppression fast-response (ESFR) sprinkler head was originally designed to provide fire suppression for heat and fire situations that required a lower thermal response to activate the sprinkler head earlier than the standard sprinkler head. The ESFR sprinkler heads have a response time index (RTI) of 50 (meters-seconds)  $\frac{1}{2}$  or less, compared to a standard sprinkler head, which has an RTI of 80 (meters-seconds)  $\frac{1}{2}$  or more. ESFR sprinkler design requires the same concepts of sprinkler system design for it to react and suppress a fire when needed. The important difference is that ESFR systems are specifically designed to suppress a high-challenge fire versus simply controlling its growth.

**[BE] EGRESS COURT.** A court or *yard* which provides access to a *public way* for one or more *exits*.

❖ The egress court requirements address situations where the exit discharge portion of the means of egress passes through confined areas near the building and therefore faces a hazard not normally found in the exit discharge (see Section 1028.4).

**ELECTROSTATIC FLUIDIZED BED.** A container holding powder coating material that is aerated from below so as to form an air-supported expanded cloud of such material that is electrically charged with a charge opposite to that of the object to be coated. Such object is transported through the

container immediately above the charged and aerated materials in order to be coated.

❖ Because the powder used in the electrostatic fluidized bed is not as finely divided as that used in electrostatic spray methods, it is not likely to create a dust explosion potential. Electrostatic fluidized beds allow for the coating of materials that then must be cured in a baking oven (see also Chapter 30). This method of coating is typically used for small pieces [dimensions less than 4 inches (102 mm)].

**ELEVATOR GROUP.** A grouping of elevators in a building located adjacent or directly across from one another that respond to a common hall call button(s).

❖ This definition clarifies the application of the emergency voice/alarm communication system requirements in Section 907.5.2.2 as to the locations, called “paging zones,” where system speakers are required (see commentary, Section 907.5.2.2).

**EMERGENCY ALARM SYSTEM.** A system to provide indication and warning of emergency situations involving hazardous materials.

❖ Because of the potentially volatile nature of hazardous materials, an emergency alarm system is required outside of interior building rooms or areas containing hazardous materials in excess of the maximum allowable quantities permitted in Tables 5003.1.1(1) and 5003.1.1(2). The intent of the emergency alarm, upon actuation by an alarm-initiating device, is to alert the occupants to an emergency condition involving hazardous materials. The initiation of the emergency alarm can be by manual or automatic means depending on the hazard and the specific requirements for the type of hazard (see commentary, Sections 908, 5004.9 and 5005.4.4).

**EMERGENCY CONTROL STATION.** An *approved* location on the premises where signals from emergency equipment are received and which is staffed by trained personnel.

❖ This definition identifies the room or area located in the HPM facility that is used to receive various alarms and signals. The smoke detectors located in the building’s recirculation ventilation ducts, the gas-monitoring/detection system and the telephone/fire protective signaling systems located outside of HPM storage rooms must all be connected to the emergency control station. The location of this station must be approved by the fire code official. An approved location should be based on personnel being able to adequately monitor the necessary alarms and signals and on the fire department being able to gain access quickly when responding to emergency situations. Additionally, the room must be occupied by persons who are trained to respond to the various alarms and signals.

**[BE] EMERGENCY ESCAPE AND RESCUE OPENING.** An operable window, door or other similar device that

## DEFINITIONS

provides for a means of escape and access for rescue in the event of an emergency.

❖ These are commonly windows that are sized and located such that they can be used to exit a building directly from a basement or bedroom during an emergency condition. The openings are also used by emergency personnel to rescue the occupants in a building (see Section 1030). Windows are never considered to be exit or exit access components for purposes of meeting minimum number of exit requirements. An emergency escape and rescue opening could be a type of door, such as a basement door with direct access to an exterior stairway or a door to a balcony. Bulkhead-style cellar doors could also be evaluated as possible emergency escape and rescue openings.

**EMERGENCY EVACUATION DRILL.** An exercise performed to train staff and occupants and to evaluate their efficiency and effectiveness in carrying out emergency evacuation procedures.

❖ This definition provides a consistent explanation of the purpose and extent of such activities. Without drilling the staff and occupants in the emergency procedures for which they have been trained, neither management nor the staff or occupants can adequately gauge their readiness to perform in a crisis mode.

**EMERGENCY POWER SYSTEM.** A source of automatic electric power of a required capacity and duration to operate required life safety, fire alarm, detection and ventilation systems in the event of a failure of the primary power. Emergency power systems are required for electrical loads where interruption of the primary power could result in loss of human life or serious injuries.

❖ This definition is intended to provide clarity for the fire code official as to exactly what systems are considered to be emergency power systems and is consistent with the definitions in NFPA 110 and NFPA 111. However, since the list of systems in the definition is not exhaustive, reference must be made to Section 604 of the code which provides the “where required” provisions. When the normal power supply to any of the indicated systems, or other systems designated by the code, fails, the emergency power system is to provide a specified degree and duration of illumination or power for systems and equipment that are essential for life safety. See the commentary to Section 604 for more detailed discussion on the difference between standby and emergency power.

**EMERGENCY SHUTOFF VALVE.** A valve designed to shut off the flow of gases or liquids.

❖ See the commentary following the definition of “Emergency shutoff valve, manual.”

**EMERGENCY SHUTOFF VALVE, AUTOMATIC.** A fail-safe automatic-closing valve designed to shut off the

flow of gases or liquids initiated by a control system that is activated by automatic means.

❖ See the commentary following the definition of “Emergency shutoff valve, manual.”

**EMERGENCY SHUTOFF VALVE, MANUAL.** A manually operated valve designed to shut off the flow of gases or liquids.

❖ The term “emergency shutoff valve” has historically been used inconsistently throughout various sections in the code. There are fundamentally two types of shutoff valves commonly employed: manually operated or automatically operated. Those that are automatic can either fail open or fail closed. A valve that fails in the closed position is said to be “fail-safe.” Automatic valves are actuated by a control system that may activate the valves either automatically or manually. The code requires the manual activation of controls that are used to operate automatic valves.

Three definitions are now provided for emergency valves to include the function of the valve itself and the two subsets that describe the two types encountered (e.g., manual or automatic). See also the commentary to the definitions of “Fail-safe” and “Remotely located, manually activated shutdown control.”

**EMERGENCY VOICE/ALARM COMMUNICATIONS.** Dedicated manual or automatic facilities for originating and distributing voice instructions, as well as alert and evacuation signals pertaining to a fire emergency, to the occupants of a building.

❖ An emergency voice/alarm communication system is a special feature of fire alarm systems in buildings with special evacuation considerations, such as a high-rise building or a large assembly space. Emergency voice/alarm communication systems automatically communicate a fire emergency message to all occupants of a building on a general or selective basis. Such systems also enable the fire service to manually transmit voice instructions to the building occupants about a fire emergency condition and the action to be taken for evacuation or movement to another area of the building. Although most systems use prerecorded messages, some now use computer synthesized voices to communicate customized messages that are unique to the facility.

**[BG] EMPLOYEE WORK AREA.** All or any portion of a space used only by employees and only for work. *Corridors, toilet rooms, kitchenettes and break rooms are not employee work areas.*

❖ An employee work area is different in an office versus on a factory line. An employee work area will most likely expand past the station or desk where an employee performs his or her job. An employee work area could include common use spaces, but not public use spaces. Depending on the duties of the

employee, it may also include copy areas, stock rooms, filing areas, an assembly line, etc. (see also the commentary for the definitions of “Common use” and “Public-use areas”).

Note that not all employee-only areas are considered part of employee work areas (i.e., bathrooms, corridors, breakrooms).

**[BG] EQUIPMENT PLATFORM.** An unoccupied, elevated platform used exclusively for mechanical systems or industrial process equipment, including the associated elevated walkways, *stairways*, *alternating tread devices* and ladders necessary to access the platform (see Section 505.3 of the *International Building Code*).

❖ A distinction is made between equipment platforms and mezzanines by way of this definition. Equipment platforms, covered in Section 505.3 of the IBC, are unoccupied and used exclusively for housing equipment and providing access thereto, and are not subject to the requirements for mezzanines. Their purpose could also be to allow access for maintenance, repair or modification of elevated or very large equipment. Equipment platforms allow efficient use of high bay areas by locating infrequently accessed equipment or processes overhead without the occupant load or increasing the hazard to occupants in the room. Elevated floor areas that do not meet this definition would be subject to the requirements for mezzanines.

**EXCESS FLOW CONTROL.** A fail-safe system or other *approved* means designed to shut off flow caused by a rupture in pressurized piping systems.

❖ This refers to a fail-safe valve or other approved device that is required on pressurized piping systems to prevent the uncontrolled release of excess quantities of hazardous liquids and gases if piping or valve failure occurs. To safeguard as much piping as practical, the device must be installed as close to the supply container as possible.

**EXCESS FLOW VALVE.** A valve inserted into a *compressed gas* cylinder, portable tank or stationary tank that is designed to positively shut off the flow of gas in the event that its predetermined flow is exceeded.

❖ Such a valve has the ability to shut down flow when the intended flow rate has been exceeded. Quite often, when the predetermined flow has been exceeded, a failure will occur.

**EXHAUSTED ENCLOSURE.** An appliance or piece of equipment which consists of a top, a back and two sides providing a means of local exhaust for capturing gases, fumes, vapors and mists. Such enclosures include laboratory hoods, exhaust fume hoods and similar appliances and equipment used to retain and exhaust locally the gases, fumes, vapors and mists that could be released. Rooms or areas provided with general ventilation, in themselves, are not exhausted enclosures.

❖ When a hazardous chemical is being dispensed or used, an exhausted enclosure can be used to reduce

the exposure of personnel to a toxic or hazardous atmosphere. These enclosures have special requirements for protection (see Section 5003.8.5).

**EXISTING.** Buildings, facilities or conditions that are already in existence, constructed or officially authorized prior to the adoption of this code.

❖ This term is specifically defined to reduce any confusion regarding the application of the code to existing buildings, facilities and conditions. This definition would include anything that has already been in use, is already constructed or has been approved by the jurisdiction prior to the adoption of the code. If an occupancy changes use significantly, it may be considered new in some cases.

**[BE] EXIT.** That portion of a *means of egress* system between the *exit access* and the *exit discharge* or *public way*. Exit components include exterior exit doors at the *level of exit discharge*, *interior exit stairways* and *ramps*, *exit passageways*, *exterior exit stairways* and *ramps* and *horizontal exits*.

❖ Exits are the critical element of the means of egress system that the building occupants travel through to reach the exterior at the level of exit discharge. Exit stairways and ramps from upper and lower stories must be separated from adjacent areas with fire-resistance-rated construction. The fire-resistance-rated construction serves as a barrier between the fire and the means of egress and protects the occupants while they travel through the exit. Separation by fire-resistance-rated construction is not required, however, where the exit leads directly to the exterior at the level of exit discharge (e.g., exterior door at grade). Commentary Figure 202-E1 illustrates three different types of exits: interior exit stairway, exterior exit stairway and exterior exit door.

A horizontal exit, while not discharging to the outside, does discharge to another building or refuge area. The door to the refuge area is through a fire wall or fire barrier (see the definition for “Horizontal exit” and Section 1026).

**[BE] EXIT ACCESS.** That portion of a *means of egress* system that leads from any occupied portion of a building or structure to an *exit*.

❖ The exit access portion of the means of egress consists of all floor areas that lead from usable spaces within the building to the exit or exits serving that floor area. Crawl spaces and concealed attic and roof spaces are not considered to be part of the exit access. As shown in Commentary Figure 202-E2, the exit access begins at the furthest points within each room or space and ends at the entrance to the exit.

**[BE] EXIT ACCESS DOORWAY.** A door or access point along the path of egress travel from an occupied room, area or space where the path of egress enters an intervening room, *corridor*, *exit access stairway* or *ramp*.

❖ Exit access doorways are used to design many critical aspects of the means of egress including arrangement, number, separation, opening protection and

**DEFINITIONS**

exit sign placement. The term “doorway” has traditionally been limited to those situations where an actual opening, either with or without a door, is present. With “access point,” the term “exit access doorway” is inclusive of specific points in the means of egress which may not include a “door” such as when an unenclosed exit access stairway is used in the egress path.

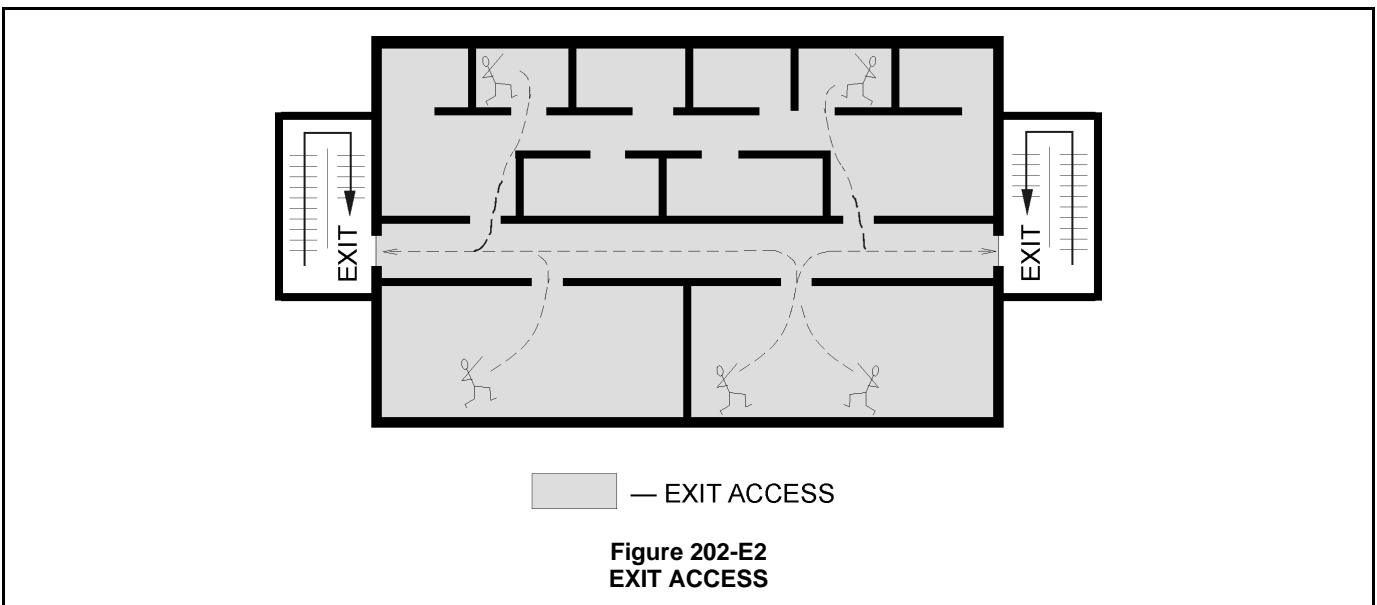

**[BE] EXIT ACCESS RAMP.** A ramp within the exit access portion of the means of egress system.

- ❖ Unenclosed ramps may serve as part of the route for exit access when floor levels have changes in elevation.

tion. For the limited situations where exit access ramps can be used between stories, see Sections 1006.3 and 1019. Exit access elements are included in the travel distance requirements unless specifically exempted (i.e., open parking garages, outdoor facilities) (see Section 1017.3.1).

**[BE] EXIT ACCESS STAIRWAY.** A stairway within the exit access portion of the means of egress system.

- ❖ Unenclosed steps and stairways may serve as part of the route for exit access when floor levels have changes in elevation. For the limited situations where exit access stairways can be used between stories,

see Sections 1006.3 and 1019. Exit access elements are included in the travel distance requirements unless specifically exempted (i.e., open parking garages, outdoor facilities) (see Section 1017.3.1).

**[BE] EXIT DISCHARGE.** That portion of a *means of egress* system between the termination of an *exit* and a *public way*.

❖ The exit discharge will typically begin when the building occupants reach the exterior at or very near grade level. It provides occupants with a path of travel away from the building. All components between the building and the public way are considered to be the exit discharge, regardless of the distance. In areas of sloping terrain, it is possible to have steps or stairs in the exit discharge leading to the public way. The exit discharge is part of the means of egress and, therefore, its components are subject to the requirements of the code (see Commentary Figures 202-E1 and 202-E3 and Section 1028).

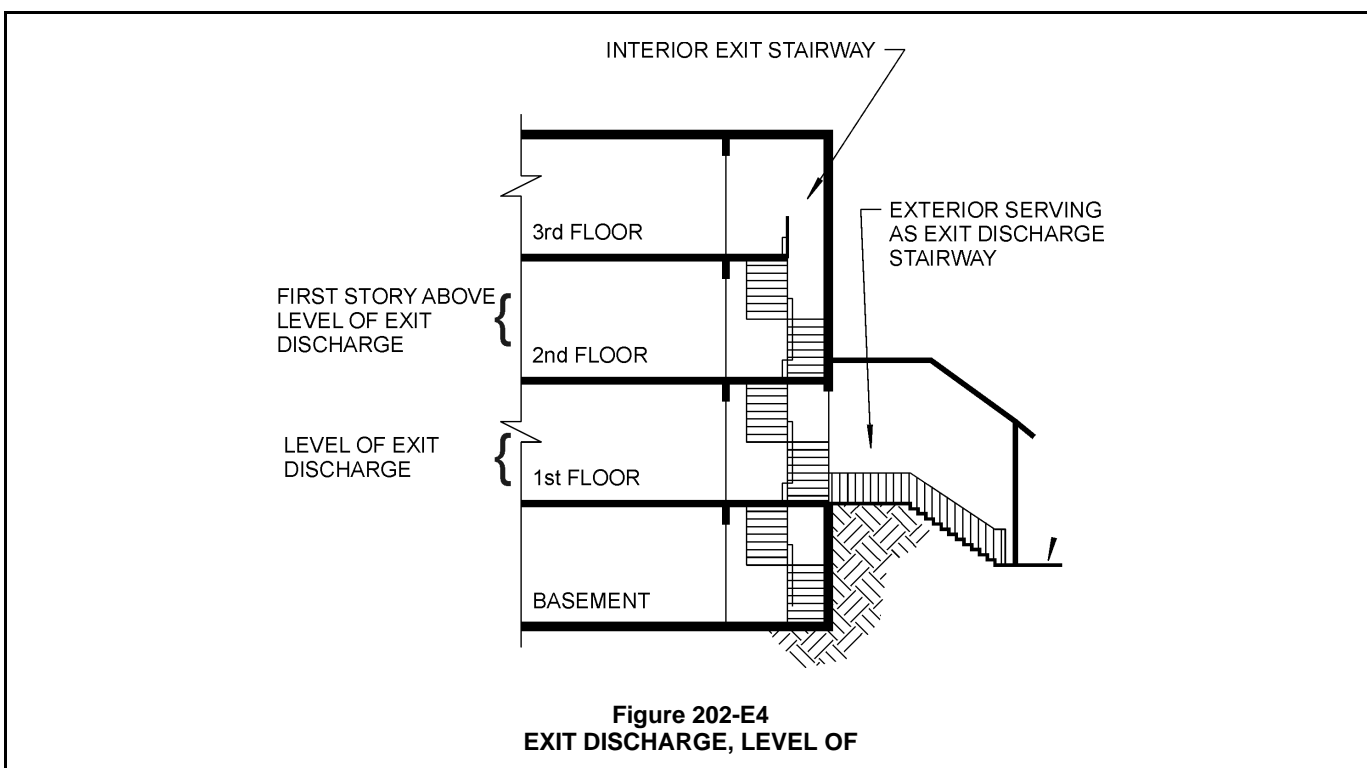

**[BE] EXIT DISCHARGE, LEVEL OF.** The *story* at the point at which an *exit* terminates and an *exit discharge* begins.

❖ The term is intended to describe the story where the transition from exit to exit discharge occurs. At this level, the occupant needs only to move in a substantially horizontal path to move along exit discharge (see Commentary Figure 202-E4). Since the level is a volume rather than a horizontal plane, exterior exit steps may be part of the exit discharge when they provide access to the level that is closest to grade.

**[BE] EXIT PASSAGEWAY.** An *exit* component that is separated from other interior spaces of a building or structure by

fire-resistance-rated construction and opening protectives, and provides for a protected path of egress travel in a horizontal direction to the *exit discharge*.

❖ This term refers to a horizontal portion of the means of egress that serves as an exit element. Since an exit passageway is considered an exit element, it must be protected and separated as required by the code for exits (see Section 1024). Exit passageways between a vertical exit enclosure and an exterior exit door are typically found on the level of exit discharge to provide a protected path from a centrally located exit stairway to the exit discharge. In taller buildings that reduce floor sizes as they move up (sometimes

## DEFINITIONS

called a wedding cake building), exit passageways are sometimes utilized at “transfer floors” where stairway shaft locations shift outward as the floor size increases. Exit passageways that lead to an exterior exit door are commonly used in malls to satisfy the travel distance in buildings having a large floor area.

**EXPANDED PLASTIC.** A foam or cellular plastic material having a reduced density based on the presence of numerous small cavities or cells dispersed throughout the material.

❖ Expanded plastic is a synthetic or natural organic material that, under high temperatures or pressures, can be shaped, formed and molded into any shape and maintain that shape at ambient temperatures. Plastics are combustible materials, some of which will give off toxic gases when exposed to fire. The most commonly recognized expanded plastic product is a disposable coffee cup. When plastic is expanded, it becomes much more susceptible to combustion due to the larger surface area of the material per unit weight.

**EXPLOSION.** An effect produced by the sudden violent expansion of gases, which may be accompanied by a shock wave or disruption, or both, of enclosing materials or structures. An explosion could result from any of the following:

1. Chemical changes such as rapid oxidation, *deflagration* or *detonation*, decomposition of molecules and runaway polymerization (usually *detonations*).
2. Physical changes such as pressure tank ruptures.
3. Atomic changes (nuclear fission or fusion).

❖ Buildings containing materials that pose a threat of explosion are classified as Group H-1 when such materials are present in quantities exceeding the MAQ in Table 5003.1.1(1). Such buildings are required to be a detached storage building meeting the requirements of Section 415.6 of the IBC and Chapter 56 of the code.

**EXPLOSIVE.** A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G.

The term “Explosive” includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G by the hazardous materials regulations of DOTn 49 CFR Parts 100-185.

❖ Explosives either detonate or deflagrate, rather than burn, when initiated by either heat, shock or electric current. Although these materials are normally designed and intended to be initiated by detonators under controlled conditions, heat, shock and electric current from uncontrolled sources may initiate these materials to produce an explosion.

**High explosive.** *Explosive material*, such as dynamite, which can be caused to detonate by means of a No. 8 test blasting cap where unconfined.

❖ High explosives can also deflagrate, but they are capable of even more. Before any appreciable amount of gas can escape and reduce the pressure, the body of the explosive is completely vaporized. The strength of a particular explosive depends on the amount of gas and heat it produces. At the very instant of their formation, the gases in a high-explosive state occupy only the original volume of the explosive material. Gas pressures can soar above 1 million pounds per square inch (psi); temperatures of 6,000°F (3316°C) and higher are common. Rapid expansion must occur and pressure waves move out at enormous velocities, often supersonic, doing tremendous damage.

**Low explosive.** *Explosive material* that will burn or deflagrate when ignited. It is characterized by a rate of reaction that is less than the speed of sound. Examples of low *explosives* include, but are not limited to, black powder, safety fuse, igniters, igniter cord, fuse lighters, fireworks, 1.3G and propellants, 1.3C.

❖ In low-explosive materials the burning rate is rapid but the created gases still have time to escape as the explosive is consumed. Gunpowder, for example, burns extremely rapidly and the gases are put to work, projecting an object out of a gun barrel. Pressures remain relatively low when the explosive is unconfined. Low explosive, like black powder, will deflagrate (burn intensely), producing a visible flame, such as a muzzle flash, but they do not ordinarily detonate.

**Mass-detonating explosives.** Division 1.1, 1.2 and 1.5 *explosives* alone or in combination, or loaded into various types of ammunition or containers, most of which can be expected to explode virtually instantaneously when a small portion is subjected to fire, severe concussion, impact, the impulse of an initiating agent or the effect of a considerable discharge of energy from without. Materials that react in this manner represent a mass explosion hazard. Such an *explosive* will normally cause severe structural damage to adjacent objects. Explosive propagation could occur immediately to other items of ammunition and *explosives* stored sufficiently close to and not adequately protected from the initially exploding pile with a time interval short enough so that two or more quantities must be considered as one for quantity-distance purposes.

❖ Mass-detonating explosives (typically stored in occupancies classified as Group H-1 by the IBC) present a detonation hazard, as do high explosives, and present a greater threat to adjacent objects and structures. The code, therefore, contains provisions in Table 5605.3 to deal with the separation distances for mass-explosion hazards.

**UN/DOtn Class 1 explosives.** The former classification system used by DOTn included the terms “high” and “low” *explosives* as defined herein. The following terms further define *explosives* under the current system applied by DOTn for all *explosive materials* defined as hazard Class 1 materials. Compatibility group letters are used in concert with the division to specify further limitations on each division noted (for example, the letter G identifies the material as a pyrotechnic substance or article containing a pyrotechnic substance and similar materials).

❖ The Department of Transportation (DOT) issued new regulations in 1991 based on the United Nations Recommendations on the Transportation of Dangerous Goods for the transportation of hazardous materials. DOT’s hazardous materials requirements with respect to hazard communications, classifications and packaging of explosives were revised by the new regulations.

**Division 1.1.** *Explosives* that have a mass explosion hazard. A mass explosion is one which affects almost the entire load instantaneously.

**Division 1.2.** *Explosives* that have a projection hazard but not a mass explosion hazard.

**Division 1.3.** *Explosives* that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard.

**Division 1.4.** *Explosives* that pose a minor explosion hazard. The explosive effects are largely confined to the package and no projection of fragments of appreciable size or range is to be expected. An external fire must not cause virtually instantaneous explosion of almost the entire contents of the package.

**Division 1.5.** Very insensitive *explosives*. This division is comprised of substances that have a mass explosion hazard but which are so insensitive that there is very little probability of initiation or of transition from burning to *detonation* under normal conditions of transport.

**Division 1.6.** Extremely insensitive articles which do not have a mass explosion hazard. This division is comprised of articles that contain only extremely insensitive detonating substances and which demonstrate a

negligible probability of accidental initiation or propagation.

❖ The DOT puts explosives in six classes according to the degree of hazard posed by the material (see Commentary Figure 202-E5). The most dangerous of these materials is capable of almost simultaneous detonation of all of the material in a single load or store. The least sensitive explosives produce blasts limited to the packages in which they are transported. This definition of “Explosive” includes materials such as: detonators, blasting agents and water gels. Examples of these materials are listed in DOTy 27, CFR 55.23.

**EXPLOSIVE MATERIAL.** The term “explosive” material means *explosives*, blasting agents and detonators.

❖ A list of explosive materials is maintained by the ATF pursuant to 18 USC, Chapter 40. This list (ATF Publication 5400.8) is available at no cost from the ATF Distribution Center, 7943 Angus Court, Springfield, VA 22153.

**[BE] EXTERIOR EXIT RAMP.** An *exit* component that serves to meet one or more *means of egress* design requirements, such as required number of *exits* or *exit access* travel distance, and is open to yards, courts or *public ways*.

❖ Requirements for an exterior exit ramp are different from those for an interior exit ramp. Exterior exit ramps are typically outside of the building, provide exits from levels above or below the level of exit discharge, and are exposed to at least some elements of weather. The protection requirements therefore are for the exterior walls between the building and the ramp, rather than interior walls. For the ramp requirements, see Section 1012. For specifics for exterior exit ramps, see Section 1027

**[BE] EXTERIOR EXIT STAIRWAY.** An *exit* component that serves to meet one or more *means of egress* design requirements, such as required number of *exits* or *exit access* travel distance, and is open to yards, courts or *public ways*.

❖ Requirements for an exterior exit stairway are different from those for an interior exit stairway. Exterior exit stairways are typically outside of the building,

BATF	OLD DOTn <sup>a</sup>	NEW DOTn <sup>b, c</sup>	Description
High Explosives	Class A Explosives	Division 1.1	Mass Explosion Potential
		Division 1.2	Projectile Hazard
Low Explosives	Class B Explosives	Division 1.3	Predominantly a Fire Hazard
	Class C Explosives	Division 1.4	No Significant Blast Hazard
Blasting Agents	Blasting Agents	Division 1.5	Very Sensitive Explosives
	Dangerous	Division 1.6	Extremely Insensitive Detonating Substances

a. Prior to September 30, 1991.

b. Effective October 1, 1991.

c. *International Fire Code* and new DOT classifications correlate.

**Figure 202-E5  
COMPARISON OF CLASSIFICATION SYSTEMS FOR EXPLOSIVE MATERIALS**

## DEFINITIONS

provide exits from above or below the level of exit discharge, and are exposed to at least some elements of weather. The protection requirements therefore are for the exterior walls between the building and the stairway, rather than interior walls. For the stairway requirements, see Section 1011. For specifics for exterior exit stairways, see Section 1027.

**[BF] EXTERIOR WALL.** A wall, bearing or nonbearing, that is used as an enclosing wall for a building, other than a *fire wall*, and that has a slope of 60 degrees (1.05 rad) or greater with the horizontal plane.

❖ A wall is defined as an exterior element that encloses a structure and that has a slope equal to or greater than 60 degrees (1.05 rad) from the horizontal plane. Exterior enclosing elements with slopes less than this are generally subjected to more severe weather exposure than vertical surfaces and thus may experience a greater amount of water intrusion. These sloped surfaces, which may include elements, such as inset windowsills, sloped parapets and other architectural elements, should be designed to resist water penetration in a manner similar to a roof.

**EXTRA-HIGH-RACK COMBUSTIBLE STORAGE.** Storage on racks of Class I, II, III or IV commodities that exceed 40 feet (12 192 mm) in height and storage on racks of high-hazard commodities that exceed 30 feet (9144 mm) in height.

❖ This term was generated to address those storage areas that were of unusual height, and where that height would have an influence on the building or structure, the contents and the safeguards from the hazards of a fire or explosion. Extra-high-rack combustible storage is common to building occupancies that require a substantial amount of storage of commodities (supply) necessary to ensure that the process remains operational. An example of this type of storage is an automotive assembly plant where the rack storage contains a sufficient amount of material to service the assembly plant operation for several days or weeks.

**FABRICATION AREA.** An area within a semiconductor fabrication facility and related research and development areas in which there are processes using hazardous production materials. Such areas are allowed to include ancillary rooms or areas such as dressing rooms and offices that are directly related to the fabrication area processes.

❖ This definition describes the basic component of an HPM facility. The code uses this definition to set certain material limitations based on both quantity and density, and to require enclosure of the fabrication areas with fire-barrier assemblies in accordance with Section 707 of the IBC, or horizontal assemblies in accordance with Section 711 of the IBC. The fabrication area of an HPM facility is the area where the hazardous materials are actively handled and processed. The fabrication area includes accessory rooms and spaces, such as workstations and employee dressing rooms.

**[A] FACILITY.** A building or use in a fixed location including exterior storage areas for flammable and combustible substances and hazardous materials, piers, wharves, tank farms and similar uses. This term includes recreational vehicles, mobile home and manufactured housing parks, sales and storage lots.

❖ The scope of a fire code is broader than the scope of a building code, in that it addresses outdoor storage, tank farms, fire department access and similar activities. The term “facility” helps to more clearly define this scope to clarify the application of this code. As noted in the definition, a building would be included in the definition for “Facility.” This definition differs from that used in Chapter 11 of the IBC, which addresses the topic of accessibility for those with disabilities.

**FAIL-SAFE.** A design condition incorporating a feature for automatically counteracting the effect of an anticipated possible source of failure; also, a design condition eliminating or mitigating a hazardous condition by compensating automatically for a failure or malfunction.

❖ This definition provides consistency of terminology among the 11 sections of the code that use the term. A fail-safe design can include an automatic emergency shutoff valve that is designed to close upon loss of power or a process upset condition. It may include an excess flow control valve or feature which is designed to stop the flow of a gas or liquid when a preset flow rate is exceeded. In most cases, the fail-safe condition would stop the movement or processing of hazardous materials. The definition is based on a combination of a definition from *Webster’s Third New International Dictionary of the English Language, Unabridged* and NFPA 70E definitions of the term.

**FALLOUT AREA.** The area over which aerial shells are fired. The shells burst over the area, and unsafe debris and malfunctioning aerial shells fall into this area. The fallout area is the location where a typical aerial shell dud falls to the ground depending on the wind and the angle of mortar placement.

❖ The area described by this definition is a large, unoccupied open space that functions as a “safety zone” between the fireworks display launch area and the spectator areas and is included in the display site definition in this section. The layout of the fallout area is usually centered around the location of, and takes into account the launch angle of, the mortars used to launch the aerial displays. Local weather wind direction and speed forecasts may also affect the layout of the area. The fallout area provides a relatively safe area in which display debris and dud or malfunctioned shells may fall and is the starting point for the post-display inspection required by Section 5608.9. Within the fallout area, no spectators or vehicles should be allowed, and the area should be free of combustible materials that could be ignited by falling debris. In reviewing the fallout area site plan, the presence and location of trees, brush and other vege-

tation that could “hide” undetonated shells or be a fire ignition hazard should be considered. In some cases, it may be necessary to wet down the fallout area to further reduce the ignition hazard to vegetation by falling hot debris.

**FALSE ALARM.** The willful and knowing initiation or transmission of a signal, message or other notification of an event of fire when no such danger exists.

- ❖ The term “false alarm” can have several meanings beyond what this particular definition provides. This definition states that for the purposes of the code a false alarm is an unnecessary, intentional activation of a fire alarm system, signal or message. It would not include alarm activation as a result of a malfunctioning detector.

**FINES.** Small pieces or splinters of wood byproducts that will pass through a 0.25-inch (6.4 mm) screen.

- ❖ Fines range in size from sawdust to chips and are usually accumulated in piles.

**FIRE ALARM.** The giving, signaling or transmission to any public fire station, or company or to any officer or employee thereof, whether by telephone, spoken word or otherwise, of information to the effect that there is a fire at or near the place indicated by the person giving, signaling or transmitting such information.

- ❖ This is a general definition intended to clarify that a fire alarm is not simply a fire alarm system. This definition would allow a person’s actions to be considered part of the fire alarm. The key is that a fire alarm notifies the correct persons or group of persons, such as the fire department or a central station, of a fire.

**FIRE ALARM BOX, MANUAL.** See “Manual fire alarm box.”

**FIRE ALARM CONTROL UNIT.** A system component that receives inputs from automatic and manual fire alarm devices and may be capable of supplying power to detection devices and transponder(s) or off-premises transmitter(s). The control unit may be capable of providing a transfer of power to the notification appliances and transfer of condition to relays or devices.

- ❖ The fire alarm control unit (panel) acts as a point where all signals initiated within the protected building are received before the signal is transmitted to a constantly attended location. As the name implies, it also contains controls to test and manually activate or silence systems.

**FIRE ALARM SIGNAL.** A signal initiated by a fire alarm-initiating device such as a manual fire alarm box, automatic fire detector, waterflow switch or other device whose activation is indicative of the presence of a fire or fire signature.

- ❖ This signal is transmitted to a fire alarm control unit as a warning that requires immediate action. The personnel at the constantly attended location are trained to immediately respond to a fire alarm signal, which indicates the presence of a fire. A fire alarm signal assumes an actual fire has been detected (see the

definition of “Alarm signal”). The fire alarm signal is not the signal used to notify the occupants of an emergency condition. Such an action would involve the audible alarm, visual alarm or emergency voice/alarm notification appliances.

**FIRE ALARM SYSTEM.** A system or portion of a combination system consisting of components and circuits arranged to monitor and annunciate the status of fire alarm or supervisory signal-initiating devices and to initiate the appropriate response to those signals.

- ❖ Fire alarm systems are installed in buildings to limit fire casualties and property losses by notifying the occupants of the building, the local fire department or both of an emergency condition. The alarm notification appliances associated with fire alarm systems are intended to be evacuation alarms. All fire alarm systems must be designed and installed to comply with NFPA 72. The term is among the most generic terms used in the code. It does not necessarily imply an automatic or manual system, nor does it identify what type of notification, if any, should be provided. The definition only indicates that an appropriate response must be provided but does not indicate what that response must be. The appropriate responses are identified within the respective sections of Section 907.

**FIRE APPARATUS ACCESS ROAD.** A road that provides fire apparatus access from a fire station to a facility, building or portion thereof. This is a general term inclusive of all other terms such as *fire lane*, public street, private street, parking lot lane and access roadway.

- ❖ Fire apparatus access roads are required to be all-weather surfaced roadways that are designed for the weight and type of emergency vehicle that may use the road. No specific surface material is required for a fire apparatus access roadway. It is up to the fire code official to decide whether the surface will support the load of the anticipated emergency vehicles in accordance with Section 503.2.3.

It should be noted that this is a general term intended to include any private roadway providing the required access to a building. As such, private driveways could be included and subject to the provisions of Section 503.

**[BF] FIRE AREA.** The aggregate floor area enclosed and bounded by *fire walls*, *fire barriers*, *exterior walls* or *horizontal assemblies* of a building. Areas of the building not provided with surrounding walls shall be included in the fire area if such areas are included within the horizontal projection of the roof or floor next above.

- ❖ This term is used to describe a specific and controlled area within a building that may consist of a portion of the floor area within a single story, one entire story or the combined floor area of several stories, depending on how these areas are enclosed and separated from other floor areas. Where a fire barrier with a fire-resistance rating in accordance with Section 707.3.10 of the IBC divides the floor area of a one-story building,

## DEFINITIONS

the floor area on each side of the wall would constitute a separate fire area. If a horizontal assembly separating the two stories in a two-story building is fire-resistance rated in accordance with Section 711.2.4 of the IBC, each story would be a separate fire area. In cases where mezzanines are present, the floor area of the mezzanine is included in the fire area calculations, even though the area of the mezzanine does not contribute to the building area calculations. See the commentary to Sections 707.3.10 and 711.2.4 of the IBC for further information. Note that, while fire walls are one way of creating fire areas, they are typically used to create separate buildings.

**[BF] FIRE BARRIER.** A fire-resistance-rated wall assembly of materials designed to restrict the spread of fire in which continuity is maintained.

- ❖ The term represents wall assemblies with a fire-resistance rating that are constructed in accordance with Section 707 of the IBC. Even though the definition applies to walls, horizontal assemblies can be fire barriers, also. See the definition of “Horizontal assembly” and the requirements in Section 711 of the IBC that apply to floor and roof assemblies designed to restrict the spread of fire.

**FIRE CHIEF.** The chief officer of the fire department serving the jurisdiction, or a duly authorized representative.

- ❖ This definition is necessary to note that when the term “fire chief” is used within the text of the code it is specifically referring to the chief officer of a fire department. This position can be delegated as necessary but must be appropriately authorized.

**FIRE CODE OFFICIAL.** The fire chief or other designated authority charged with the administration and enforcement of the code, or a duly authorized representative.

- ❖ Whoever holds the statutory power to enforce the fire code is termed the “fire code official.” Normally, responsibility for this enforcement is assigned to a fire prevention bureau or related code enforcement department of the state, county or municipality. In the case of a fire department, the role of fire code official is most often given to the fire chief, the fire marshal or the fire inspector. Often with regard to the fire code, the fire code official will be the fire marshal or fire chief. In some cases, direct reference will be made to the fire chief within the code because some situations are specific to the actions of the fire department, such as authority at fire scenes.

**FIRE COMMAND CENTER.** The principal attended or unattended location where the status of detection, alarm communications and control systems is displayed, and from which the system(s) can be manually controlled.

- ❖ Fire command centers are communication centers, typically in high-rise buildings, where dedicated manual and automatic facilities are located for the origination, control and transmission of information and instructions pertaining to a fire emergency to the

occupants (including fire department personnel) of the building. Fire command centers must provide facilities for the control and display of the status of all fire protection (detection, signaling, etc.) systems as well as critical building systems. These fire command centers must be located in secure areas as approved by the fire code official. Often, this is a location near the primary building entrance. Fire command centers may also be combined with other building operations and security facilities, when allowed by the fire code official; however, operating controls for use by the fire department must be clearly marked and not subject to tampering by unauthorized persons (see the commentary to Section 508.1 for further discussion).

**[BF] FIRE DAMPER.** A *listed* device installed in ducts and air transfer openings designed to close automatically upon detection of heat and resist the passage of flame. Fire dampers are classified for use in either static systems that will automatically shut down in the event of a fire, or in dynamic systems that continue to operate during a fire. A dynamic fire damper is tested and rated for closure under elevated temperature airflow.

- ❖ Fire dampers are used primarily in heating, ventilating and air-conditioning (HVAC) duct systems that pass through fire-resistance-rated walls or floors. Dampers may also be installed in rated walls independent of HVAC duct systems. Dampers are provided to maintain the fire-resistance rating of the penetrated assembly. Fire dampers are regulated by UL 555. See also the commentary to the definitions of “Damper” and “Smoke damper.”

**FIRE DEPARTMENT MASTER KEY.** A limited issue key of special or controlled design to be carried by fire department officials in command which will open key boxes on specified properties.

- ❖ Several companies market emergency rapid entry systems and other accessories that use fire department master keys. These keys are used to open key boxes and entry gates, and turn on/off special switches that control electric gates and certain building functions, such as smoke control systems, fans and special processes. These keys are highly secure in their design and very difficult, if not impossible, to duplicate other than by the manufacturer.

**FIRE DETECTOR, AUTOMATIC.** A device designed to detect the presence of a fire signature and to initiate action.

- ❖ Automatic fire detectors include all approved devices designed to detect the presence of a fire and automatically initiate emergency action. These include smoke-sensing fire detectors, heat-sensing fire detectors, flame-sensing fire detectors, gas-sensing fire detectors and other fire detectors that operate on other principles as approved by the fire code official. Automatic fire detectors must be selected based on the type and size of fire to be detected and the response required. The automatic fire detector sends a signal to a processing unit to initiate some predetermined action. The processing unit may be internal to

the device as is the case with single-station smoke detectors or it may be an external unit as in the case of a fire alarm control unit. Automatic fire detectors must be approved, installed and tested to comply with the code and NFPA 72.

**[BF] FIRE DOOR.** The door component of a fire door assembly.

❖ A fire door is the primary component of a fire door assembly. The fire protection rating assigned to a tested fire door is only valid if the door is installed in a labeled frame with appropriate hardware. Installation requirements within the code reference NFPA 80, *Standard for Fire Doors and Other Opening Protectives*. Door ratings are expressed in minutes or hours. Field modification of doors are primarily limited to the mounting of listed hardware.

**[BF] FIRE DOOR ASSEMBLY.** Any combination of a fire door, frame, hardware and other accessories that together provide a specific degree of fire protection to the opening.

❖ Fire door assemblies, (door, frame and hardware) are required to be tested using the appropriate standard and then installed in accordance with NFPA 80. Side-hinged doors, hardware and frames are often manufactured separately with manufacturers' and listing agencies defining acceptable combinations of assembly components that have been tested together.

**[BF] FIRE EXIT HARDWARE.** Panic hardware that is listed for use on fire door assemblies.

❖ Where a door that is required to be of fire-resistance-rated construction also has panic hardware, the hardware is required to be listed for use on the fire door. Thus, fire door hardware has been tested to function properly when exposed to the effects of a fire (see the definition for "Panic hardware" and Section 1010.1.10).

**FIRE LANE.** A road or other passageway developed to allow the passage of fire apparatus. A fire lane is not necessarily intended for vehicular traffic other than fire apparatus.

❖ The term "fire lane" is synonymous with "fire apparatus access road"; however, the driving surface may not be the same as for a public road.

**[BF] FIRE PARTITION.** A vertical assembly of materials designed to restrict the spread of fire in which openings are protected.

❖ Fire partitions are used as wall assemblies to separate adjacent tenant spaces in covered mall buildings, dwelling units, and sleeping rooms, and to enclose corridors and elevator lobbies. Section 708 of the IBC establishes the construction requirements for fire partitions. The fire-resistance ratings, continuity requirements and opening protective requirements for fire partitions are usually less restrictive than those for fire barriers.

**FIRE POINT.** The lowest temperature at which a liquid will ignite and achieve sustained burning when exposed to a test flame in accordance with ASTM D92.

❖ The fire point is the lowest temperature at which a liquid will ignite and sustain burning for a minimum of 5 seconds (fire point) when exposed to the test flame under a specific barometric pressure according to ASTM D92.

**[BF] FIRE PROTECTION RATING.** The period of time that an opening protective assembly will maintain the ability to confine a fire as determined by tests prescribed in Section 716 of the *International Building Code*. Ratings are stated in hours or minutes.

❖ The term "fire protection rating" applies to the fire performance of an opening protective, such as a fire door, which is determined through tests performed in accordance with NFPA 252 or UL 10C.

**FIRE PROTECTION SYSTEM.** Approved devices, equipment and systems or combinations of systems used to detect a fire, activate an alarm, extinguish or control a fire, control or manage smoke and products of a fire or any combination thereof.

❖ A fire protection system is any approved device or equipment used singly or in combination, either manually or automatically, and that is intended to detect a fire, notify the building occupants of a fire or suppress the fire. Fire protection systems include fire suppression systems, standpipe systems, fire alarm systems, fire detection systems, smoke control systems and smoke vents. All fire protection systems must be approved by the fire code official and tested in accordance with the referenced standards and Section 901.6.

**[BF] FIRE RESISTANCE.** That property of materials or their assemblies that prevents or retards the passage of excessive heat, hot gases or flames under conditions of use.

❖ All materials offer some degree of fire resistance. A sheet of plywood has a low level of fire resistance as compared to a concrete block, which has a higher level of fire resistance. The fire resistance of a material or an assembly is evaluated by testing performed in accordance with ASTM E119. Tested materials will be assigned a fire-resistance rating consistent with the demonstrated performance.

**[BF] FIRE-RESISTANCE RATING.** The period of time a building element, component or assembly maintains the ability to confine a fire, continues to perform a given structural function, or both, as determined by the tests, or the methods based on tests, prescribed in Section 703 of the *International Building Code*.

❖ This refers to the period of time a building element, component or assembly maintains the ability to confine a fire, continues to perform a given structural

## DEFINITIONS

function, or both, as determined by tests or the methods based on tests, prescribed in Section 703 of the IBC.

The fire-resistance rating is developed using standardized test methods (i.e., ASTM E119, etc.). Assemblies rated under these tests are deemed to be able to perform their function for a specified period of time under specific fire conditions (standard time-temperature curve).

The fire-resistance rating is not intended to be a prediction of the actual length of time that an assembly will perform its intended function under actual fire conditions. Although the time-temperature curves of standardized fire test methods are usually selected to approximate at least some real-life fire conditions, the very wide range of actual fire conditions makes the listed fire-resistance rating more of a nominal, comparative index than a predictor of fire-resistance time in any given fire incident.

**[BF] FIRE-RESISTANT JOINT SYSTEM.** An assemblage of specific materials or products that are designed, tested and fire-resistance rated in accordance with either ASTM E 1966 or UL 2079 to resist for a prescribed period of time the passage of fire through joints made in or between fire-resistance-rated assemblies.

❖ In order to maintain the fire-resistant integrity of fire-resistance-rated assemblies, joints that occur within an assembly or between adjacent assemblies must

be protected through an installation that has been tested in accordance with ASTM E1966 or UL 2079. Some common examples of applications where a fire-resistant joint system would be required are expansion joints in fire-resistance-rated floors or walls and the junction between fire-resistance-rated floors and walls (see Commentary Figure 202-F1 for examples). The regular joints that occur within a uniform assembly are most often tested as part of fire testing (e.g., in accordance with ASTM E119) for that entire assembly. The required details for these joints are specified in the listings for the underlying assembly. These joints do not need additional testing in accordance with ASTM E1966 or UL 2079. An example of such joints is the joints between individual sheets of gypsum board in a gypsum-sheathed stud wall. Consequently, other than the joints covering or filling the gaps within an assembly, the need for ASTM E1966 or UL 2079 tested joint systems is usually for the joints between dissimilar or adjacent assemblies.

**FIRE SAFETY FUNCTIONS.** Building and fire control functions that are intended to increase the level of life safety for occupants or to control the spread of the harmful effects of fire.

❖ In many cases, automatic fire detectors are installed even in buildings not required to have a fire alarm system. These fire detectors perform specific func-

**Figure 202-F1**  
**EXAMPLES OF FIRE-RESISTANT JOINT SYSTEMS**

tions, such as releasing door hold-open devices, activating elevator recall, smoke damper activation or air distribution system shutdown (see Section 907.3).

**[BF] FIRE SEPARATION DISTANCE.** The distance measured from the building face to one of the following:

1. The closest interior *lot line*.
2. To the centerline of a street, an alley or *public way*.
3. To an imaginary line between two buildings on the lot.

The distance shall be measured at right angles from the face of the wall.

❖ Fire separation distance is the distance from the exterior wall of the building to one of the three following locations, measured perpendicular to the exterior wall face: an interior lot line; the centerline of a street or public way; or an imaginary line between two buildings on the same property. The imaginary line can be located anywhere between the two buildings; it is the designer's choice, but once established, the location of the line applies to both buildings and cannot be revised.

The distance can vary with irregular-shaped lots and buildings. When applying the exterior wall requirements of Table 602 of the IBC, the required exterior wall fire-resistance rating might vary along a building side; for example, where the lot line is not parallel to the exterior wall. For further information, see Chapter 7 of the *IBC Commentary*.

**[BF] FIRE WALL.** A fire-resistance-rated wall having protected openings, which restricts the spread of fire and extends continuously from the foundation to or through the roof, with sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall.

❖ Fire walls must meet the construction requirements in Section 706 of the IBC. The requirements for fire walls are much more restrictive than for fire barriers or fire partitions. The material constituting the fire wall must be noncombustible in all construction types except Type V. The vertical and horizontal continuity requirements are much more restrictive as are the opening protectives. A fire wall also has stringent requirements for continuity and for protection of any openings through it. A fire wall, unlike the fire barrier and fire partition, must be built so it will remain in place if the construction on either side of it collapses. However, the fire wall is not required to remain in place if construction on both sides of it collapses (i.e., the fire wall is not required to be a free-standing or cantilevered wall). Fire walls are used to divide a structure into separate buildings (see the definition of "Area, building"). To be considered separate buildings, the division must be vertical. The term "fire wall" applies to vertically constructed assemblies only and not to horizontal assemblies.

**FIRE WATCH.** A temporary measure intended to ensure continuous and systematic surveillance of a building or portion thereof by one or more qualified individuals for the pur-

poses of identifying and controlling fire hazards, detecting early signs of unwanted fire, raising an alarm of fire and notifying the fire department.

❖ This term is used in several places throughout the code. A fire watch, sometimes referred to as standby personnel, provides temporary fire safety where there are potential hazards, such as during hot work operations or when fire protection systems are out of service. A fire watch is not simply to watch for a fire but also to prevent fire by identifying and controlling fire hazards, such as the separation of combustibles from areas where welding is to occur. A fire watch also provides a method of notifying the fire department if a fire should occur.

**[BF] FIREBLOCKING.** Building materials, or materials *approved* for use as fireblocking, installed to resist the free passage of flame to other areas of the building through concealed spaces.

❖ Fireblocking is required to hinder the concealed spread of flame, heat and other products of combustion within hollow spaces inside of walls or floor/ceiling assemblies. This is done by periodically subdividing that space, as indicated in Section 718.2 of the IBC, using construction materials that have some resistance to fire and by sealing the openings around penetrations through those materials.

Some fireblocking materials are permitted to be combustible based on the rationale that a substantial combustible material will provide a barrier adequate to perform the intended function (also see Section 718 of the IBC).

**FIREWORKS.** Any composition or device for the purpose of producing a visible or an audible effect for entertainment purposes by combustion, *deflagration* or *detonation* that meets the definition of 1.4G fireworks or 1.3G fireworks.

❖ This term refers to any device, other than a novelty or theatrical pyrotechnic article, intended to produce visible or audible effects by combustion, deflagration or detonation and any chemical compound or mechanically mixed preparation of an explosive or inflammable nature that is used for the purpose of making any manufactured fireworks and is not included in any other class of explosives.

**Fireworks, 1.4G.** Small fireworks devices containing restricted amounts of pyrotechnic composition designed primarily to produce visible or audible effects by combustion. Such 1.4G fireworks which comply with the construction, chemical composition and labeling regulations of the DOTn for Fireworks, UN 0336, and the U.S. Consumer Product Safety Commission as set forth in CPSC 16 CFR Parts 1500 and 1507, are not *explosive materials* for the purpose of this code.

❖ The requirements for storage, display and labeling depend on the correct application of this definition. This definition reflects the construction, chemical composition and labeling requirements of the U.S. Consumer Product Safety Commission (CPSC), found in Title 16, Code of Federal Regulations, Parts

## DEFINITIONS

1500 and 1507. Consumer 1.4G fireworks are not considered to be explosives subject to the provisions of Chapter 56. They are, however, subject to the fireworks regulations of the chapter.

**Fireworks, 1.3G.** Large fireworks devices, which are *explosive materials*, intended for use in fireworks displays and designed to produce audible or visible effects by combustion, *deflagration* or *detonation*. Such 1.3G fireworks include, but are not limited to, firecrackers containing more than 130 milligrams (2 grains) of explosive composition, aerial shells containing more than 40 grams of pyrotechnic composition and other display pieces which exceed the limits for classification as 1.4G fireworks. Such 1.3G fireworks are also described as Fireworks, UN 0335 by the DOTn.

- ❖ This category of fireworks represents a considerable life safety hazard in comparison to the consumer 1.4G fireworks. This definition reflects the construction, chemical composition and labeling requirements of the CPSC, found in Title 16, Code of Federal Regulations, Parts 1500 and 1507.

**FIREWORKS DISPLAY.** A presentation of fireworks for a public or private gathering.

- ❖ The areas selected for the discharge site, spectator viewing area, parking areas and the fallout area must be inspected and approved by the authority having jurisdiction.

**[BG] FIXED BASE OPERATOR (FBO).** A commercial business granted the right by the airport sponsor to operate on an airport and provide aeronautical services such as fueling, hangaring, tie-down and parking, aircraft rental, aircraft maintenance and flight instruction.

- ❖ Fixed base operator is a term of the aviation industry used to describe a firm that is permanently based at an airport and providing a variety of aircraft services. It is used in conjunction with Section 914.8.3 in the context of determining the appropriate level of fire suppression required in various aircraft hangars that will be found at an airport (see the commentary, Section 914.8.3).

**[BE] FIXED SEATING.** Furniture or fixtures designed and installed for the use of sitting and secured in place including bench-type seats and seats with or without back or arm rests.

- ❖ Fixed seating is secured to the floor or is a part of a seating system. Some of the varieties are bench seating, such as in bleachers, which can come with or without back rests; theater seating with arms for each viewer and seats that flip up; lecture halls with individual seats with tablet arms that are fixed or retractable; pew-type seating in courtrooms or churches; or booths in a restaurant. To allow appropriate egress from these spaces the occupant load tables allow for the individual seats to be counted to determine occupant load for the space. Space between the seats (i.e., aisle accessways) and aisles leading to the exits for these types of seating are addressed in Section 1029. Given their unique

issues, bleachers, folding and telescopic seating and grandstands are referenced to ICC 300 in Section 1029.1.1.

**[BF] FLAME SPREAD.** The propagation of flame over a surface.

- ❖ The rate at which flames travel along the surface of a combustible finish material directly impacts the speed with which a fire spreads within a room or space, and is, therefore, regulated by Chapter 8.

**[BF] FLAME SPREAD INDEX.** A comparative measure, expressed as a dimensionless number, derived from visual measurements of the spread of flame versus time for a material tested in accordance with ASTM E84 or UL 723.

- ❖ The ASTM E84 (or UL 723) test method renders measurements of surface flame spread (and smoke density) in comparison with test results obtained by using select red oak as a control material. Red oak is used as a control material for furnace calibration because it is a fairly uniform grade of lumber that is readily available nationally, is uniform in thickness and moisture content, and generally gives consistent and reproducible results. The results of this test simply provide a relative understanding of flame spread potential. The flame spread index is sometimes abbreviated as FSI.

**FLAMMABLE CRYOGENIC FLUID.** A *cryogenic fluid* that is flammable in its vapor state.

- ❖ These fluids are flammable in a vapor stage or are to be considered as flammable. It may be possible for a fluid to be nonflammable in the liquid phase but flammable in the vapor stage. The vapor phase would be the more hazardous form of the material. Again, similar to the definition of “Cryogenic fluid,” this describes the applicability of the code requirements. Flammability is dealt with in Chapter 58.

**FLAMMABLE FINISHES.** Coatings to articles or materials in which the material being applied is a flammable liquid, combustible liquid, combustible powder, fiberglass resin or flammable or combustible gel coating.

- ❖ This general definition is used to describe all the operations regulated in this chapter including spray applications, dip tank operations and powder-coating operations.

Refer to the definitions of “Combustible dust,” “Combustible liquid” and “Flammable liquid.” Note that although “combustible powder” is not defined in the code, the terms “combustible dust” and “combustible powder” have been used interchangeably. Also, the terms “gel” and “combustible gel” are not defined by the code. Gels or pastes and liquids are classified as liquids when classifying hazardous materials. For example, the flash point of a gel, paste or liquid determines the flammable or combustible classification of the product.

**FLAMMABLE GAS.** A material which is a gas at 68°F (20°C) or less at 14.7 pounds per square inch atmosphere

(psia) (101 kPa) of pressure [a material that has a *boiling point* of 68°F (20°C) or less at 14.7 psia (101 kPa)] which:

1. Is ignitable at 14.7 psia (101 kPa) when in a mixture of 13 percent or less by volume with air; or
2. Has a flammable range at 14.7 psia (101 kPa) with air of not less than 12 percent, regardless of the lower limit.

The limits specified shall be determined at 14.7 psi (101 kPa) of pressure and a temperature of 68°F (20°C) in accordance with ASTM E 681.

❖ The ASTM E681 test method covers the determination of the lower and upper concentration limits of chemicals having sufficient vapor pressure to form flammable mixtures in air at atmospheric pressure at the test temperature. The flammability limits depend on the test temperature and pressure. This test method is limited to an initial pressure of the local ambient or less, with a practical lower pressure limit of approximately 13 kPa (100 mm Hg). The maximum practical operating temperature of this equipment is approximately 302°F (150°C).

**FLAMMABLE LIQUEFIED GAS.** A liquefied *compressed gas* which, under a charged pressure, is partially liquid at a temperature of 68°F (20°C) and which is flammable.

❖ Flammable liquefied gases are widely useful because of their properties, including high heat output in combustion for most gases, high reactivity in chemical processing with other gases, extremely low temperatures available from some gases and the economy of handling them all in a compact form at high pressure or low temperature.

**FLAMMABLE LIQUID.** A liquid having a closed cup flash point below 100°F (38°C). Flammable liquids are further categorized into a group known as Class I liquids. The Class I category is subdivided as follows:

**Class IA.** Liquids having a flash point below 73°F (23°C) and having a *boiling point* below 100°F (38°C).

**Class IB.** Liquids having a *flash point* below 73°F (23°C) and having a *boiling point* at or above 100°F (38°C).

**Class IC.** Liquids having a *flash point* at or above 73°F (23°C) and below 100°F (38°C).

The category of flammable liquids does not include *compressed gases* or *cryogenic fluids*.

❖ Flammable liquids have a closed-cup flash point less than 100°F (38°C); the classification of Class I liquid into three classes is dependent on their flash point. The 100°F (38°C) flash point limitation for flammable liquids assumes possible indoor ambient temperature conditions of 100°F (38°C). The vapor pressure limitation of 40 pounds per square inch absolute (psia) (276 kPa) at 100°F (38°C) is the threshold for the definition of what constitutes a liquid for the purposes of classifying the material as a flammable or combustible liquid. Flammable liquids are classified into three classes based on a combination of their flash point and boiling point. Class IA has a flash point below

73°F (23°C) and a boiling point below 100°F (38°C). Class IB has a flash point below 73°F (23°C) and a boiling point at or above 100°F (38°C). Class IC has a flash point above 73°F (23°C) and below 100°F (38°C). Flammable liquids do not include compressed gases or cryogenic fluids. Compressed gases are regulated in Chapter 53 and cryogenic fluids are regulated in Chapter 55.

**FLAMMABLE MATERIAL.** A material capable of being readily ignited from common sources of heat or at a temperature of 600°F (316°C) or less.

❖ The primary focus of this term is to classify solid materials that are more hazardous than normal combustibles because of their susceptibility to ignition as flammable materials. Additionally, any material that will readily ignite at or below 600°F (316°C) would be considered flammable. The term “flammable materials” should not be confused with combustible materials.

**FLAMMABLE SOLID.** A solid, other than a blasting agent or *explosive*, that is capable of causing fire through friction, absorption of moisture, spontaneous chemical change or retained heat from manufacturing or processing, or which has an ignition temperature below 212°F (100°C) or which burns so vigorously and persistently when ignited as to create a serious hazard. A chemical shall be considered a flammable solid as determined in accordance with the test method of CPSC 16 CFR Part 1500.44, if it ignites and burns with a self-sustained flame at a rate greater than 0.0866 inch (2.2 mm) per second along its major axis.

❖ Flammable solids include various materials that either ignite readily, burn vigorously or are difficult to extinguish. Materials that may not ignite easily or burn vigorously in bulk form may do so in finely divided form. This is especially true of most flammable metals. Ignition sources for flammable solids include frictional heat from machining or cutting operations; absorption of moisture from air (as opposed to water-reactive materials forming flammable vapors when mixed with water); spontaneous chemical changes such as sublimation (the chemical process through which solids emit vapors without first changing phase to liquids); and heat absorbed during manufacturing processes like oil quenching or heat treating. Solid materials with ignition temperatures below 212°F (100°C) that ignite before melting are also considered flammable solids, as are materials burning robustly and persistently when ignited, including magnesium and coal. CPSC has developed a standard test method (CPSC 16 CFR 1500.44) that is referenced for determining when a material complies with the definition. Commentary Figure 202-F2 depicts the equipment and test method. A material burning at a rate greater than 0.1 inch (2.5 mm) per second is considered a flammable solid for the purpose of applying the requirements of this chapter.

Commentary Figure 202-F3 lists both the melting points and ignition temperatures for several pure metals in bulk form. These materials may ignite at much

## DEFINITIONS

lower temperatures when finely divided. Moreover, many metals, such as calcium, hafnium, plutonium, sodium, thorium and zirconium, will ignite in air under certain conditions. Thorium and plutonium will

release radiation when they burn. Likewise, many metals react with each other in finely divided form. For example, iron or steel filings and fine magnesium particles, combined with frictional heat or cutting oil,

For SI: 1 inch = 25.4 mm.

**Figure 202-F2  
FLAMMABLE SOLID TEST METHOD**

Material	Melting point (°F)	Ignition temperature (°F)
Aluminum <sup>a</sup>	1,220	1,832
Barium	1,337	347
Calcium	1,548	1,300
Hafnium	4,032	—
Iron <sup>b</sup>	2,795	1,706
Lithium	367	356
Magnesium	1,202	1,153
Plutonium	1,184	1,112
Potassium <sup>c</sup>	144	156
Sodium	208	239
Strontium	1,425	1,328
Thorium	3,353	932
Titanium	3,140	2,900
Uranium <sup>d</sup>	2,070	6,900
Zinc	786	1,652
Zirconium	3,326	2,552

For SI: °C = [(°F)-32]/1.8.

- a. Above indicated temperature.
- b. Ignition in oxygen.
- c. Spontaneous ignition in moist air.
- d. Below indicated temperature.

**Figure 202-F3  
MELTING AND IGNITION TEMPERATURES OF SELECTED PURE METALS IN SOLID FORM**

can ignite in a thermite reaction. Aluminum, iron and steel are not usually recognized as combustible metals; however, aluminum, iron and steel can be ignited in powdered form. Rather than producing an open flame, both iron and steel produce a vigorous sparking reaction when ignited. On the other hand, aluminum may burn with explosive force.

Although the definition of “Flammable solid” could be literally interpreted as being applicable to a much wider variety of common materials (e.g., plastics, household items, toys, etc.) because ordinary combustible materials could fail the CPSC test, the definition text clearly limits its application to “chemicals.” It is not the intent of this chapter to regulate such common-place materials or items because, practically speaking, such a sweeping application could result in

many buildings, including Group R buildings, being classified or reclassified in Group H-3, which is certainly not the intent of the code. Commentary Figure 202-F4 describes fire hazards of selected common flammable solids that are regulated by this chapter.

**FLAMMABLE VAPOR AREA.** An area in which the concentration of flammable constituents (vapor, gas, fume, mist or dust) in air exceeds 25 percent of their lower flammable limit (LFL) because of the flammable finish processes operation. It shall include:

1. The interior of spray booths.
2. The interior of ducts exhausting from spraying processes.
3. Any area in the direct path of spray or any area containing dangerous quantities of air-suspended powder,

Material	Description
Carbon Carbon black	Carbon black is formed by combustion of certain gaseous hydrocarbons and hydrocarbon cracking. It is most hazardous after manufacture when particles may still be hot. Carbon black absorbs oxygen while cooling and smoldering may develop. After cooling, the material is not subject to spontaneous heating. A mixture of carbon black and oxidizable oils may produce heating.
Lamp black	Lamp black, a type of carbon black, is formed by incomplete burning of carbonaceous oils. It absorbs gases to some degree and has a strong affinity for liquids. It heats when in contact with drying oils and may ignite spontaneously soon after bagging begins.
Lead sulfocyanate	Burns slowly and decomposes to form flammable and toxic hydrogen disulfide and toxic carbon disulfide when heated.
Nitroaniline	Melts at 295°F with a flash point of 390°F. When in contact with organic materials, it may produce spontaneous ignition.
Nitrochlorobenzene	A solid material giving off flammable vapors when heated (sublimation).
Sulfides Antimony pentasulfide	Antimony pentasulfide is readily ignited when in contact with oxidizing materials and yields flammable and toxic hydrogen sulfide when in contact with strong acids.
Phosphorus pentasulfide	Phosphorus pentasulfide ignites readily and is subject to spontaneous heating in the presence of moisture. The ignition temperature is 287°F. Phosphorus pentasulfide produces toxic sulfur dioxide and phosphorus pentoxide when it burns, as well as flammable and toxic hydrogen sulfide when in contact with water.
Phosphorus sesquisulfide	Phosphorus sesquisulfide is highly flammable and ignites at 212°F to produce toxic sulfur dioxide.
Potassium and sodium sulfides	Both potassium and sodium sulfide are moderately flammable and they produce sulfur dioxide when burning and hydrogen sulfide comes in contact with acids.
Sulfur	The melting point is 234°F and the boiling point is 832°F with a flash point of 405°F. Sulfur vapors are highly flammable in air. Sulfur dust is a severe explosion hazard with ignition temperatures in the range of 274°F.
Naphthalene	Combustible in both solid and liquid form. Vapors and dusts form explosive mixtures in air.

For SI: °C = [(°F) - 32]/1.8.

**Figure 202-F4  
COMMON FLAMMABLE SOLIDS AND THEIR PROPERTIES**

## DEFINITIONS

combustible residue, dust, deposits, vapor or mists as a result of spraying operations.

4. The area in the vicinity of dip tanks, drain boards or associated drying, conveying or other equipment during operation or shutdown periods.

The *fire code official* is authorized to determine the extent of the flammable vapor area, taking into consideration the material characteristics of the flammable materials, the degree of sustained ventilation and the nature of the operations.

- ❖ The extent of the flammable vapor area should be determined by the fire code official based on an evaluation of the coating process, the liquid being used, the ventilation rate in the area and other variables that might increase the hazard.

**FLAMMABLE VAPORS OR FUMES.** The concentration of flammable constituents in air that exceeds 25 percent of their lower flammable limit (LFL).

- ❖ Vapors or fumes are only considered flammable when there is a high enough concentration for an ignition to occur if exposed to an ignition source. The code specifically defines “Flammable” as being greater than 25 percent of the LFL.

**FLASH POINT.** The minimum temperature in degrees Fahrenheit at which a liquid will give off sufficient vapors to form an ignitable mixture with air near the surface or in the container, but will not sustain combustion. The flash point of a liquid shall be determined by appropriate test procedure and apparatus as specified in ASTM D 56, ASTM D 93 or ASTM D 3278.

- ❖ The flash point is the characteristic used in the classification of flammable and combustible liquids. The flash point is the minimum temperature of a liquid at which it gives off sufficient vapor to form an ignitable mixture with air above its surface. The Tag Closed Tester (ASTM D56), the Pensky-Martens Closed Tester (ASTM D93) and the Small Scale Closed-Cup Apparatus (ASTM D3278) are the referenced test procedures for determining the flash points of liquids. The applicability of the three test methods depends on the viscosity of the test liquid and the expected flash point.

**FLEET VEHICLE MOTOR FUEL-DISPENSING FACILITY.** That portion of a commercial, industrial, governmental or manufacturing property where liquids used as fuels are stored and dispensed into the fuel tanks of motor vehicles that are used in connection with such businesses, by persons within the employ of such businesses.

- ❖ This is sometimes referred to as “you own the tanks, you own the vehicles” motor fuel-dispensing facility. The intent is to allow greater fuel storage tank capacities and reduced separation distances between the dispenser and above-ground tanks when the operator has control of the entire operation, including the vehicles being fueled. In other words, the person dispens-

ing the fuel is an employee of the facility operator. Motor fuel-dispensing facilities are classified in occupancy Group M by the IBC.

**[BE] FLIGHT.** A continuous run of rectangular treads, *winders* or combination thereof from one landing to another.

- ❖ Two points of clarification for stairways are addressed by the definition of “Flight.” First, a flight is made up of the treads and risers that occur between landings. Therefore, a stairway connecting two stories that includes an intermediate landing consists of two flights. Secondly, the inclusion of *winders* within a stairway does not create multiple flights. *Winders* are simply treads within a flight and are often combined with rectangular treads within the same flight.

**FLOAT.** A floating structure normally used as a point of transfer for passengers and goods, or both, for mooring purposes.

- ❖ A float is a deck section that lays on top of or is attached to (or both) a buoyant material in the water. The sections are attached to each other and held in place by methods that are designed to keep the floats in place.

**[BE] FLOOR AREA, GROSS.** The floor area within the inside perimeter of the *exterior walls* of the building under consideration, exclusive of vent shafts and courts, without deduction for *corridors*, *stairways*, *ramps*, closets, the thickness of interior walls, columns or other features. The floor area of a building, or portion thereof, not provided with surrounding *exterior walls* shall be the usable area under the horizontal projection of the roof or floor above. The *gross floor area* shall not include shafts with no openings or interior courts.

- ❖ Gross floor area is that area measured within the perimeter formed by the inside surface of the exterior walls. The area of all occupiable and nonoccupiable spaces, including mechanical and elevator shafts, toilet rooms, closets, and mechanical equipment rooms, are included in the gross floor area. This area could also include any covered porches, carports or other exterior space intended to be used as part of the building’s occupiable space. This gross and net floor areas are primarily used for the determination of occupant load in accordance with Table 1004.1.2.

**[BE] FLOOR AREA, NET.** The actual occupied area not including unoccupied accessory areas such as *corridors*, *stairways*, *ramps*, toilet rooms, mechanical rooms and closets.

- ❖ This net area is intended to be only the room areas that are used for specific occupancy purposes and does not include circulation areas, such as *corridors*, *ramps* or *stairways*, and service and utility spaces, such as toilet rooms and mechanical and electrical equipment rooms. Net floor area is typically measured between inside faces of walls within a room. Floor area, net and gross is utilized in Table 1004.1.2 to determine occupant load for a space.

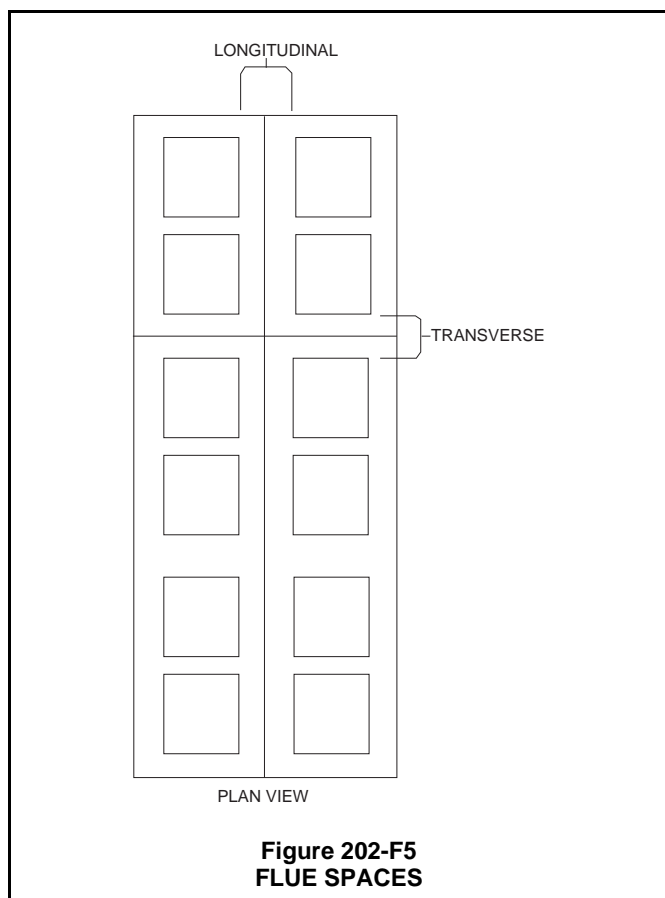

**FLUE SPACES.**

**Longitudinal flue space.** The flue space between rows of storage perpendicular to the direction of loading.

- ❖ The longitudinal flue space is a continuous open area between a double row- or multiple-row-type rack storage system. The flue space is to be clear for a set dimension, as required in Table 3208.3, from the floor to the top of the highest commodity for the entire length of the rack system. The flue spaces are an important feature for automatic sprinkler systems to effectively suppress and potentially control the fire. Reducing or eliminating such spaces will potentially reduce, if not eliminate, sprinkler effectiveness (see Commentary Figure 202-F5).

**Transverse flue space.** The space between rows of storage parallel to the direction of loading.

- ❖ The transverse flue space is a continuous open area between commodities in single-row-, double-row- and multiple-row-type rack storage systems. The flue space is to be clear for a set dimension, as required in Table 3208.3, from the floor to the top of the highest commodity for the entire width of the rack system. The flue spaces are an important feature for automatic sprinkler systems to effectively suppress and potentially control the fire. Reducing or eliminating such spaces will potentially reduce, if not eliminate, sprinkler effectiveness (see Commentary Figure 202-F5).

**FLUIDIZED BED.** A container holding powder coating material that is aerated from below so as to form an air-supported expanded cloud of such material through which the preheated object to be coated is immersed and transported.

- ❖ A fluidized bed differs from an electrostatic fluidized bed in that the fluidized bed uses an air stream instead of electrostatic charge. The air stream behaves like a fluid as the object is passed through it. Additionally, the object is preheated. In an electrostatic fluidized bed, the object is heated/cured in an oven after the coating process.

**FOAM-EXTINGUISHING SYSTEM.** A special system discharging a foam made from concentrates, either mechanically or chemically, over the area to be protected.

- ❖ Foam-extinguishing systems must be of an approved type and installed and tested to comply with NFPA 11, 11A and 16. All foams are intended to exclude oxygen from the fire, cool the area of the fire and insulate adjoining surfaces from heat caused by the fire. Foam systems are commonly used to extinguish flammable or combustible liquid fires (see commentary, Section 904.7). While water applied by an automatic sprinkler system can only act horizontally upon the surface that it reaches, foam-extinguishing agents have the ability to act vertically in addition to horizontally; and, unlike gaseous extinguishing agents, foam does not dissipate rapidly where there is no confined space. Thus, foam systems are also used where there is a need to fill a nonconfined space with extinguishing material as in the case of certain industrial applications.

**[BE] FOLDING AND TELESCOPIC SEATING.** Tiered seating having an overall shape and size that is capable of being reduced for purposes of moving or storing and is not a building element.

- ❖ Bleachers, folding and telescopic seating and grandstands are essentially unique forms of tiered seating that are supported on a dedicated structural system. All types are addressed in ICC 300, the safety standard for these types of seating arrangements. Folding and telescopic seating are commonly used in gymnasiums and sports arenas where the seating can be configured in a variety of ways for various types of events. "Building element" is a defined term in the IBC which is primarily used in conjunction with the structural elements regulated in Table 601 of the IBC. While telescopic seating may be attached to a wall, the system when pulled out or folded includes its main support system. Such seating is not considered a building element of the building or structure in which it is located (see Section 1029.1.1).

**[BG] FOSTER CARE FACILITIES.** Facilities that provide care to more than five children, 2<sup>1</sup>/<sub>2</sub> years of age or less.

- ❖ Foster care facilities are group homes where children live, not day care facilities. By being under 2<sup>1</sup>/<sub>2</sub> years of age, children are assumed not capable of self-preservation, thus there is a need for higher levels of active and passive protection in the building (see the

## DEFINITIONS

commentary to Occupancy Group I-2). Group homes with children over 2½ years of age would be Group R-4 or I-1, depending on the number of children housed in the facility. The “more than five children” is intended to clarify that a foster care family would not be considered a Group I-2 facility. See also the definitions for “24-hour basis,” “Custodial care,” “Group home,” “Incapable of self-preservation” and “Personal care service.”

**FUEL LIMIT SWITCH.** A mechanism, located on a tank vehicle, that limits the quantity of product dispensed at one time.

❖ This definition pertains to mobile fueling operations regulated by Section 5706.5.4.5 and describes a limit control that prevents more than a specified amount of liquid fuel from being dispensed at one time from a tank vehicle used in the mobile fueling operation (see commentary, Section 5706.5.4.5).

**FUMIGANT.** A substance which by itself or in combination with any other substance emits or liberates a gas, fume or vapor utilized for the destruction or control of insects, fungi, vermin, germs, rats or other pests, and shall be distinguished from insecticides and disinfectants which are essentially effective in the solid or liquid phases. Examples are methyl bromide, ethylene dibromide, hydrogen cyanide, carbon disulfide and sulfuryl fluoride.

❖ Pesticides that are applied in gaseous form within a closed space and kill by inhalation are termed “fumigants.” The basic fumigant material may be a volatile solid, liquid or gas. An example of a volatile solid fumigant is paradichlorobenzene. This substance, by the process of sublimation, fills a closed space with gas. It is marketed either as moth balls or moth cakes. Sublimation refers to the changing state from a solid to a gas without entering a liquid state. Many fumigants are flammable or combustible and all are toxic, posing health hazards that range from simply hazardous to deadly with minimal exposure.

**FUMIGATION.** The utilization within an enclosed space of a fumigant in concentrations that are hazardous or acutely toxic to humans.

❖ Fumigation sites are usually contained within a building but may also be at an outdoor location, aboard a vessel or in a vehicle. Soil fumigation can also be successful. The key to any fumigation is applying the appropriate fumigant for the correct duration, usually at least 8 hours for proper soaking to occur. The fumigant gas must penetrate every nook and cranny of the fumigation space or area; therefore, proper enclosure and sealing of the space or area is critical. Rooms can be sealed easily by caulking or taping doors, windows and ventilation openings. Entire structures can be sealed by encapsulation in plastic sheeting. Even trees can be isolated with an air-tight tent and soils can be fumigated by covering the area with plastic covers. Other sections of this commentary discuss operational safeguards for fumigation operations.

**FURNACE CLASS A.** An oven or furnace that has heat utilization equipment operating at approximately atmospheric pressure wherein there is a potential explosion or fire hazard that could be occasioned by the presence of flammable volatiles or combustible materials processed or heated in the furnace.

**Note:** Such flammable volatiles or combustible materials can, for instance, originate from the following:

1. Paints, powders, inks, and adhesives from finishing processes, such as dipped, coated, sprayed and impregnated materials.
2. The substrate material.
3. Wood, paper and plastic pallets, spacers or packaging materials.
4. Polymerization or other molecular rearrangements.

Potentially flammable materials, such as quench oil, water-borne finishes, cooling oil or cooking oils, that present a hazard are ventilated according to Class A standards.

❖ Ovens may also use a low-oxygen atmosphere to evaporate solvent. This kind of equipment has potential hazards involving the process material and heat generation.

**FURNACE CLASS B.** An oven or furnace that has heat utilization equipment operating at approximately atmospheric pressure wherein there are no flammable volatiles or combustible materials being heated.

❖ Even though no flammable, volatile or combustible materials are heated in this kind of oven, the process can still be a serious fire and explosion hazard.

**FURNACE CLASS C.** An oven or furnace that has a potential hazard due to a flammable or other special atmosphere being used for treatment of material in process. This type of furnace can use any type of heating system and includes a special atmosphere supply system. Also included in the Class C classification are integral quench furnaces and molten salt bath furnaces.

❖ These are units in which there is an explosion hazard because a special flammable atmosphere is being used for treatment of material in process. Within this class, an integral quench tank is used, which is a container that holds a quench medium into which a metalwork is immersed for various heat treatment processes. A molten bath furnace is a heated container that holds a melt or fusion into which metalwork is immersed for various heat treatment processes.

**FURNACE CLASS D.** An oven or furnace that operates at temperatures from above ambient to over 5,000°F (2760°C) and at pressures normally below atmospheric using any type of heating system. These furnaces can include the use of special processing atmospheres.

❖ These are generally referred to as vacuum furnaces because they operate below normal atmospheric pressure. Vacuum furnaces are described as either cold-wall furnaces, hot-wall furnaces, or furnaces

used for casting or melting of metal at temperatures up to 5,000°F (2760°C) or higher.

**GAS CABINET.** A fully enclosed, ventilated, noncombustible enclosure used to provide an isolated environment for *compressed gas* cylinders in storage or use. Doors and access ports for exchanging cylinders and accessing pressure-regulating controls are allowed to be included.

❖ This term refers to an assembly constructed and designed to protect compressed gas cylinders and associated equipment.

**GAS DETECTION SYSTEM, CONTINUOUS.** See “Continuous gas detection system.”

**GAS ROOM.** A separately ventilated, fully enclosed room in which only *compressed gases* and associated equipment and supplies are stored or used.

❖ A gas room is an on-site built room that meets the construction requirements of the IBC. This room will require separation based on the amount of gases stored in the room.

**GAS ROOM, HYDROGEN FUEL.** See “Hydrogen fuel gas room.”

❖ See the commentary to “Hydrogen fuel gas room.”

**GASEOUS HYDROGEN SYSTEM.** An assembly of piping, devices and apparatus designed to generate, store, contain, distribute or transport a nontoxic, gaseous hydrogen-containing mixture having not less than 95-percent hydrogen gas by volume and not more than 1-percent oxygen by volume. Gaseous hydrogen systems consist of items such as *compressed gas* containers, reactors and appurtenances, including pressure regulators, pressure relief devices, manifolds, pumps, compressors and interconnecting piping and tubing and controls.

❖ This term includes the source of hydrogen and all piping and devices between the source and the equipment being used. The gas in a hydrogen system is above the upper flammable limit (UFL) and is therefore “too rich” to burn. Any leakage, however, can quickly create conditions that will be explosive under ambient conditions.

**[BG] GRADE FLOOR OPENING.** A window or other opening located such that the sill height of the opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening.

❖ Openings used for emergency escape or rescue are clearly easier to use the closer they are to grade. This definition specifies that the maximum sill height above the exterior adjacent grade must be no more than 44 inches (1118 mm) for an opening to qualify as a grade floor opening (see Section 1030.3).

**[BG] GRADE PLANE.** A reference plane representing the average of finished ground level adjoining the building at exterior walls. Where the finished ground level slopes away from the exterior walls, the reference plane shall be established by the lowest points within the area between the building and the *lot line* or, where the *lot line* is more than 6 feet

(1829 mm) from the building, between the building and a point 6 feet (1829 mm) from the building.

❖ This term is used in the definitions of “Basement” and “Story above grade plane.” It is critical in determining the height of a building and the number of stories above grade, which are regulated by Chapter 5 of the IBC, and in determining fire protection system requirements in Chapter 9. Since the finished ground surface adjacent to the building may vary (depending on site conditions), the mean average taken at various points around the building constitutes the grade plane.

Situations may arise where the ground adjacent to the building slopes away from the building because of site or landscaping considerations. In this case, the lowest finished ground level at any point between the building’s exterior wall and a point 6 feet (1829 mm) from the building [or the lot line, if closer than 6 feet (1829 mm)] comes under consideration.

In the context of the code, the term “grade” means the finished ground level at the exterior walls. While the grade plane is a hypothetical horizontal plane derived as indicated above, the grade is that which actually exists or is intended to exist at the completion of site work. The only situation where the grade plane and the grade are identical is when the site is perfectly level for a distance of 6 feet (1829 mm) from all exterior walls. See the commentary to this definition in Chapters 2 and 5 of the IBC for a more detailed discussion and illustrations of sloping grade scenarios.

**[BE] GRANDSTAND.** Tiered seating supported on a dedicated structural system and two or more rows high and is not a building element (see “*Bleachers*”).

❖ Bleachers, folding and telescopic seating and grandstands are essentially unique forms of tiered seating that are supported on a dedicated structural system. All types are addressed in the safety standard for these types of seating arrangements, ICC 300. Grandstands can be found at a county fair ground, along a parade route or within indoor facilities. Examples are sports arenas and public auditoriums, as well as places of religious worship and gallery-type lecture halls. “Building element” is a defined term in the IBC which is primarily used in conjunction with the structural elements regulated in Table 601 of the IBC. Grandstands have a separate structural system. Individual bench seats directly attached to a floor system are not a grandstand. The terms “bleacher” and “grandstand” are basically interchangeable. There is no cut-off in size or number of seats that separates bleachers and grandstands (see Section 1029.1.1).

**[BG] GROUP HOME.** A facility for social rehabilitation, substance abuse or mental health problems that contains a group housing arrangement that provides custodial care but does not provide medical care.

❖ The term “group home” is listed under Group I-1 and R-4 occupancies. See the commentary under “Custo-

## DEFINITIONS

dial care.” The number of occupants would differentiate which occupancy classification is applicable to the facility. Residents live in a supervised living arrangement. Facilities can be for persons with developmental, emotional, mental or physical difficulties or for persons recovering from drugs or alcohol abuse. The intent of these facilities is to promote recovery, community integration and improved quality of life. While there may be security restrictions, occupants are not restrained (see the definition of Occupancy Group I-3 for restrained conditions). The focus is the increase in an individual’s capacity to be successful in living, working, learning and social environments to the best of their ability. See also the commentary to “24-hour basis,” “Custodial care,” “Foster care facilities,” “Incapable of self-preservation.” “Personal care services” and “Nursing homes.”

**[BE] GUARD.** A building component or a system of building components located at or near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to a lower level.

❖ Guards are sometimes mistakenly referred to as “guardrails.” In actuality, the guard consists of the entire vertical portion of the barrier, not just the top rail (see commentary to “Handrail” and Section 1015). The purpose of guards is to minimize the potential for falls at dropoffs adjacent to walking surfaces. Loading requirements for guards are located in Section 1607.8 of the IBC.

**[BG] GUEST ROOM.** A room used or intended to be used by one or more guests for living or sleeping purposes.

❖ Lodging houses with five or fewer guest rooms are allowed by the IBC as Group R-3 occupancy. They are also permitted under the IRC. See the definitions of “Lodging house” and “Residential Group R-3” occupancies.

**[BS] GYPSUM BOARD.** Gypsum wallboard, gypsum sheathing, gypsum base for gypsum veneer plaster, exterior gypsum soffit board, predecorated gypsum board or water-resistant gypsum backing board complying with the standards listed in Tables 2506.2 and 2507.2 and Chapter 35 of the *International Building Code*.

❖ Gypsum board is the most commonly used material for interior wall covering. Gypsum board is also used for exterior sheathing, plaster lath and ceiling covering. Because it is installed in sheet form, it is less labor intensive and generally considered more cost effective than other wall and ceiling materials, such as plaster. Gypsum board requires a minimal amount of finishing and will readily accept paint, wallpaper, vinyl fabric, special textured paint and similar surface finish materials.

Gypsum board will be subject to severe failure when placed in direct contact with water or continuous moisture. For this reason, the code does not allow gypsum board to be used in wet areas unless it is provided with a finish material impervious to moisture.

**[BG] HABITABLE SPACE.** A space in a building for living, sleeping, eating or cooking. Bathrooms, toilet rooms, closets, halls, storage or utility spaces and similar areas are not considered habitable spaces.

❖ These spaces are normally considered inhabited in the course of residential living and provide the four basic characteristics associated with it: living, sleeping, eating and cooking. All habitable spaces are considered occupiable spaces, though other occupiable spaces, such as halls or utility rooms, are not considered habitable (see the definition of “Occupiable space” in the IBC).

**HALOGENATED EXTINGUISHING SYSTEM.** A fire-extinguishing system using one or more atoms of an element from the halogen chemical series: fluorine, chlorine, bromine and iodine.

❖ Halon is a colorless, odorless gas that inhibits the chemical reaction of fire. Halon extinguishing systems are useful in occupancies, such as computer rooms where an electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents presents a problem. The halon extinguishing system must be of an approved type and installed and tested to comply with NFPA 12A.

Halon extinguishing agents have been identified as a source of emissions resulting in the depletion of the stratospheric ozone layer. For this reason, production of new supplies of halon has been phased out. Alternative gaseous extinguishing agents, such as clean agents, have been developed as alternatives to halon.

**HANDLING.** The deliberate transport by any means to a point of storage or use.

❖ Handling is concerned with transporting hazardous materials within a building’s means of egress. A hazardous material that is not in either storage or use is essentially being handled.

**[BE] HANDRAIL.** A horizontal or sloping rail intended for grasping by the hand for guidance or support.

❖ Handrails are provided along walking surfaces that lead from one elevation to another, such as ramps, and stairways. Handrails may be any shape in cross section provided that they can be gripped by hand for support and guidance and for checking possible falls on the adjacent walking surface. In addition to being necessary in normal day-to-day use, handrails are especially needed in times of emergency when the pace of egress travel is hurried and the probability for occupant instability while traveling along the sloped or stepped walking surface is greater. Handrails, by themselves, are not intended to be used in place of guards to limit falls at drop-offs. Where guards and handrails are used together, the handrail is a separate element typically attached to the inside surface of the guard. The top guard cannot be used as a required handrail, except within dwelling units where the height is restricted to that of a handrail (see Sec-

tion 1014). See the commentary to the definition of “Guard.” For loading on handrails, see Section 1607.8 of the IBC.

**HAZARDOUS MATERIALS.** Those chemicals or substances which are *physical hazards* or *health hazards* as defined and classified in this chapter, whether the materials are in usable or waste condition.

❖ The term “hazardous materials” refers to materials posing either a physical or health hazard.

**HAZARDOUS PRODUCTION MATERIAL (HPM).** A solid, liquid or gas associated with semiconductor manufacturing that has a degree-of-hazard rating in health, flammability or instability of Class 3 or 4 as ranked by NFPA 704 and which is used directly in research, laboratory or production processes which have, as their end product, materials that are not hazardous.

❖ This definition identifies those specific materials that can be contained within an HPM facility. The restriction in the definition for only hazardous materials with a Class 3 or 4 rating is not intended to exclude materials that are less hazardous, but to clarify that materials of the indicated higher ranking are still permitted in an HPM facility without classifying the building as Groups H-1 through H-4. NFPA 704 is referenced to establish the degree of hazard ratings for all materials as related to health, flammability and instability risks. See Commentary Figure 202-H1 for a list of commonly used HPM and their hazard classifications.

**HEALTH HAZARD.** A classification of a chemical for which there is statistically significant evidence that acute or chronic health effects are capable of occurring in exposed persons. The term “health hazard” includes chemicals that are toxic, highly toxic and *corrosive*.

❖ Materials that pose risks to people from handling or exposure are considered health hazards. Even though the materials may also be flammable, those classified as health hazards either will not burn or will not pose a fire hazard similar to that of ordinary combustible materials. Materials that pose a health hazard may also pose a physical hazard and must comply with the requirements of the code applicable to both hazards. Toxins that attack specific organs are indicative of the other health-hazard materials regulated by this chapter. Hepatotoxins, such as carbon tetrachloride, are capable of causing liver damage and nephrotoxins, such as halogenated hydrocarbons, can cause kidney damage. Neurotoxins include mercury and calcium disulfide, which may produce toxic effects on the nervous system. Although the definition of “Health hazard” includes a reference to carcinogens, it is not the intent of this chapter to regulate carcinogens that are not otherwise classified as an irritant, sensitizer or other known health hazard, such as a target organ toxin. Federal regulations address the permitted workplace exposure conditions to known carcinogens.

**HEAT DETECTOR.** See “Detector, heat.”

**[BG] HEIGHT, BUILDING.** The vertical distance from grade plane to the average height of the highest roof surface.

❖ This definition establishes the two points of measurement that determine the height of a building. This measurement is used to determine compliance with the building height limitations of Sections 503.1 and 504 and Tables 504.3 and 504.4, which limit building height both in terms of the number of stories and the number of feet between the two points of measurement.

The lower point of measurement is the grade plane (see the definition of “Grade plane”). The upper point of measurement is the roof surface of the building, with consideration given to sloped roofs (such as a hip or gable roof). In the case of sloped roofs, the average height would be used as the upper point of measurement, rather than the eave line or the ridge line. The average height of the roof is the mid-height between the roof eave and the roof ridge, regardless of the shape of the roof.

This definition also indicates that building height is measured to the highest roof surface. In the case of a building with multiple roof levels, the highest of the various roof levels must be used to determine the building height. If the highest of the various roof levels is a sloped roof, then the average height of that sloped roof must be used. The average height of multiple roof levels is not to be used to determine the building height. Where structures are divided into multiple buildings by fire walls, building height is determinable for each building separately.

The distance that a building extends above ground also determines the relative hazards of that building. Simply stated, a taller building presents relatively greater safety hazards than a shorter building for several reasons, including fire service access and time for occupant egress. The code specifically defines how building height is measured to enable various code requirements, such as type of construction and fire suppression, to be consistent with those relative hazards.

The term “height” is also used frequently in the code for other limitations related to, and sometimes not related to, “building height.” For example, Section 1510 of the IBC limits the height of a penthouse above the top of the roof. Since a “Penthouse” is defined as a structure that is built above the roof of a building, it is above the point to which “Building height” is measured. Therefore a penthouse would not affect the measurement of building height and can be located above the maximum allowed roof height provided it complies with the limitations of Section 1510 of the IBC. Other provisions such as Section 1015 of the code and Section 1406 of the IBC specify requirements based on height, but such height is usually measured from a location other than grade plane and is not intended to be building height.

## DEFINITIONS

**HELIPORT.** An area of land or water or a structural surface that is used, or intended for use, for the landing and taking off of helicopters, and any appurtenant areas which are used, or intended for use, for heliport buildings and other heliport facilities.

- ❖ Heliports present special problems because they are frequently located in congested areas of cities, on

roofs of buildings, near hospitals and on piers adjacent to water.

**HELISTOP.** The same as “Heliport,” except that fueling, defueling, maintenance, repairs or storage of helicopters is not permitted.

- ❖ A helistop is a place for landing and taking off for helicopters with no procedures or operations occurring

Material	Description or Use	NFPA 704 Hazard Classification			
		Health	Flammability	Reactivity	Other
Acetic acid	Corrosive liquid used for wet etching (metal)	2	2	1	
Acetone	Flammable liquid used for wafer cleaning	1	3	0	
Ammonium fluoride	Corrosive for wet etching (oxide)	3	0	0	
Arsenic trichloride	Diffusion	3	0	1	W
Arsenic trioxide	Diffusion	4	0	0	
Arsine	Poison flammable gas used for epitaxial growth, diffusion and ion implantation	4	4	3	
Boron tribromide	Corrosive liquid used for diffusion	4	0	3	W
Boron trichloride	Nonflammable corrosive gas used for diffusion	4	0	1	W
Chlorine	Poison gas used for dry etching	3	0	0	0XY
Diborane	Highly reactive flammable gas used for diffusion	3	4	3	W
Dichlorosilane	Flammable liquefied gas used for epitaxial growth	4	4	4	
Gallium	Reactive metal used as a semiconductor crystal material	1	0	3	
Gallium arsenide	Reactive metal salt used as a semiconductor crystal material	3	0	0	
Gallium arsenide phosphide	Reactive metal salt used as a semiconductor crystal material	3	0	0	
Germanium	Reactive metal used as a semiconductor crystal material	0	0	3	
Hydrofluoric acid	Highly corrosive liquid or gas used for wet etching (oxide)	4	0	0	
Hydrogen peroxide <sup>a</sup>	Organic peroxide used for wafer cleaning	2	0	1	0XY
Isopropanol	Flammable liquid used for wafer cleaning	1	3	0	
Methanol	Flammable liquid used for wafer cleaning	1	3	0	
Nitric acid	Corrosive liquid used for wet etching (metal)	3	0	0	0XY
Oxygen (liquid)	Oxidizing gas used for oxidation	3	0	0	0XY
Phosphine	Flammable liquefied poison gas used for diffusion and ion implantation	4	4	4	
Phosphoric acid	Corrosive liquid used for wet etching (metal)	2	0	0	
Phosphorus oxychloride	Corrosive liquid used for diffusion	4	0	3	W
Phosphorus pentoxide	Corrosive solid sublimed for use in diffusion	4	0	3	W
Phosphorus tribromide	Corrosive liquid used for diffusion	4	0	3	W
Silane	Pyrophoric gas used for oxidation	2	4	4	
Silicon	Flammable solid (metal) used as a semiconductor crystal material	2	4	2	W
1, 1, 1-Trichloroethane	Mildly flammable solvent (difficult to ignite) used for wafer cleaning	2	1	0	
Tetrachlorosilane	Flammable liquid used for epitaxial growth	3	4	2	W

a. NFPA 704 values for 35 to 52 percent by weight (the most concentration) are listed. The reactivity hazard increases to 3 at concentrations above 52 percent.

**Figure 202-H1  
HAZARDOUS PRODUCTION MATERIALS (HPM) USED IN THE MANUFACTURE OF SEMICONDUCTORS**

other than loading or off-loading of passengers or freight.

**HI-BOY.** A cart used to transport hot roofing materials on a roof.

- ❖ A hi-boy, also known as a hot carrier, is a wheeled tank used on the roof deck to move hot asphalt around the work area. Hi-boys are available in either insulated or noninsulated models, and typically hold either 30 or 55 gallons (114 or 208 L).

**HIGH-PILED COMBUSTIBLE STORAGE.** Storage of combustible materials in closely packed piles or combustible materials on pallets, in racks or on shelves where the top of storage is greater than 12 feet (3658 mm) in height. Where required by the *fire code official*, *high-piled combustible storage* also includes certain high-hazard commodities, such as rubber tires, Group A plastics, flammable liquids, idle pallets and similar commodities, where the top of storage is greater than 6 feet (1829 mm) in height.

- ❖ High-piled combustible storage has two distinct features not common to other storage areas: the large quantity of commodities (or products) and storage in a compact arrangement (density). The height values used to distinguish high-piled storage from general or incidental storage were largely based on fire tests [12 feet (3638 mm) for Class I–IV and 6 feet (1829 mm) for high hazard]. These tests were conducted to determine the effects of various configurations, quantities and classes of commodities as well as various fire protection features.

**HIGH-PILED STORAGE AREA.** An area within a building which is designated, intended, proposed or actually used for *high-piled combustible storage*.

- ❖ This term defines the area or space where the combustible commodity is actually located. The intent of defining this area is to differentiate such a space from any of the other more traditionally defined occupan-

cies (for example, business, factory, etc.) and the amount of fire protection that is required in these unique spaces. Spaces not actually containing high-piled storage are not considered part of the high-piled storage area; thus, those areas would not need to be added into the aggregate area when applying Table 3206.2.

The definition is not clear as to how aisles are to be addressed. Section 3206.9 has several requirements related to aisles that are focused primarily upon access to exits and fire department access. NFPA 13, however, has specific aisle dimensions for rack storage, which are provided based upon testing of actual storage commodities and the performance of sprinkler systems. These aisles serve more as “fire breaks” to slow the spread of fire from storage array to storage array. Therefore, any aisles required by NFPA 13 would be required to be included when determining the actual high-piled storage area involving rack storage. See the commentary to Sections 3206.9 and 3206.3.2.1 for further discussion.

**[BG] HIGH-RISE BUILDING.** A building with an occupied floor located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access.

- ❖ Determining what qualifies as a high-rise building is a fairly unique measurement of height and is not based on the definition of “Building height.” The critical measurement is from the lowest ground location where a fire department will be able to set its fire-fighting equipment to a floor level of occupied floors as shown in Commentary Figure 202-H2. It is not a measurement from grade plane to top of the building. The basis of the measurement is analyzing the capability of fighting a fire and rescuing occupants from the outside of the building. Once past a height of 75 feet (22 860 mm) above ground level, ground-based fire fighting will not be sufficient. High-rise buildings must comply with the requirements of Section 403.

For SI: 1 foot = 304.8 mm.

**Figure 202-H2  
HIGH-RISE BUILDING**

## DEFINITIONS

**HIGH-VOLTAGE TRANSMISSION LINE.** An electrical power transmission line operating at or above 66 kilovolts.

❖ High-voltage transmission lines are used to carry large amounts of electrical power (66,000 volts or more) over long distances, usually from a main power generation station to main substations, because the line losses are much smaller than with lower-voltage lines. They may also be used for electric power transmission from one central station to another for load sharing. The term “high voltage transmission line” as used in the context of the code is referring only to overhead conductors that are made of either copper or aluminum. In other contexts, the term could include underground lines as well.

**HIGHLY TOXIC.** A material which produces a lethal dose or lethal concentration which falls within any of the following categories:

1. A chemical that has a median lethal dose (LD<sub>50</sub>) of 50 milligrams or less per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
2. A chemical that has a median lethal dose (LD<sub>50</sub>) of 200 milligrams or less per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.
3. A chemical that has a median lethal concentration (LC<sub>50</sub>) in air of 200 parts per million by volume or less of gas or vapor, or 2 milligrams per liter or less of mist, fume or dust, when administered by continuous inhalation for one hour (or less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

Mixtures of these materials with ordinary materials, such as water, might not warrant classification as highly toxic. While this system is basically simple in application, any hazard evaluation that is required for the precise categorization of this type of material shall be performed by experienced, technically competent persons.

❖ This definition, as does the definition of “Toxic,” gives very specific criteria in the form of lethal doses and lethal concentrations as administered to albino rats and albino rabbits. The lethal dosages are related to the ingestion and skin contact with materials, generally liquids and solids. The lethal concentrations are related to vapors, dusts, gases or mists as inhaled by albino rats. Inhalation can occur from either a gas, vapor or mist that is generated from highly toxic or toxic liquids. In some cases, a liquid may be considered highly toxic or toxic if ingested or if skin contact occurs, but vapors are not an inhalation hazard according to the criteria. These definitions give criteria to help determine what materials are regulated by this chapter and Chapter 50. Often, materials are listed as toxic or highly toxic, on MSDS, but may not necessarily meet these criteria. Instead, the terminology may be used to describe irritant characteristics of

the material. For a list of common highly toxic materials, see Commentary Figure 202-H3.

**HIGHLY VOLATILE LIQUID.** A liquefied *compressed gas* with a *boiling point* of less than 68°F (20°C).

❖ This definition provides criteria for the classification of a material as being highly volatile, and provides correlation with the defined terms “Liquid” and “Cryogenic fluid.” Basically, if the boiling point of a material is at room temperature or lower it would be considered volatile. The concern usually associated with highly volatile liquids is the volume of vapors released to the atmosphere. These vapors could be harmless, but many liquids, for example, may be corrosive, toxic or flammable. Additionally, vapors are more susceptible to ignition than liquids.

**HIGHWAY.** A public street, public alley or public road.

❖ Roads, alleys and similar thoroughfares or vehicular accessways on private property are not included in this definition. However, when private roadways adjacent to an explosives magazine or blasting site are commonly used for vehicular traffic by the public, the separation required should be the same as that required for public rights-of-way or public access should be suspended.

**[A] HISTORIC BUILDINGS.** Buildings that are listed in or eligible for listing in the National Register of Historic Places, or designated as historic under an appropriate state or local law.

❖ To be considered “historic,” a building needs to be designated as such through a federal, state or local law. In addition, there are buildings that have been reviewed for eligibility to be listed as a national historic building. Those listed as eligible for national listing also are considered historic for the purposes of the code. Buildings that are within a historic district are not necessarily, themselves, historic buildings. The determination of their designation as historic would depend on the specifics of the listing of the historic area. The IEBC provides specific provisions applying to historic buildings.

**HOGGED MATERIALS.** Wood waste materials produced from the lumber production process.

❖ This term refers to mill waste that may include a mixture of bark, chips or dust along with other byproducts of trees. Material designated as hogged fuel is included in this category.

**[M] HOOD.** An air-intake device used to capture by entrainment, impingement, adhesion or similar means, grease and similar contaminants before they enter a duct system.

**Type I.** A kitchen hood for collecting and removing grease vapors and smoke.

❖ A kitchen exhaust system, which includes the hood serving a commercial cooking appliance, is a specialized exhaust system. A commercial cooking appliance can generate large quantities of air contaminants, such as grease vapors, smoke and

combustion byproducts. The descriptor “Type I” used in conjunction with the term “hood” refers to an exhaust system that is required for all cooking appliances that are used for commercial purposes and that produce grease-laden vapors or smoke.

**Type II.** A general kitchen hood for collecting and removing steam vapor, heat, odors and products of combustion.

- ❖ A Type II exhaust hood is considered a light-duty hood that would typically be installed over steam kettles, conventional ovens, food warmers, some types of enclosed pizza ovens, steam tables and dishwashing machines. A Type II hood is not intended for grease or smoke removal. The primary purpose of a Type II hood is to capture and remove water vapor, waste heat and any products of combustion that might be associated with the heating of the appliance, such as from fuel gas combustion.

**[BF] HORIZONTAL ASSEMBLY.** A fire-resistance-rated floor or roof assembly of materials designed to restrict the spread of fire in which continuity is maintained.

- ❖ A horizontal assembly is a component for completing compartmentation. Horizontal assemblies have all

openings and penetrations protected equal to the rating for the fire-resistance-rated floor or roof assembly. Horizontal assemblies are regulated by Section 711 of the IBC.

**[BE] HORIZONTAL EXIT.** An *exit* component consisting of fire-resistance-rated construction and opening protectives intended to compartmentalize portions of a building thereby creating refuge areas that afford safety from fire and smoke from the area of fire origin.

- ❖ This term refers to a fire-resistance-rated wall that subdivides a structure into multiple compartments and provides an effective barrier to protect occupants from a fire condition within one of the compartments. After occupants pass through a horizontal exit, they must be provided not only with sufficient space to gather but also with access to another exit, such as an exterior door or exit stairway, through which they can exit the building. Commentary Figure 202-H4 depicts the exits serving a single building that is subdivided with a fire-resistance-rated wall (see Section 1026).

Material	Health	Flammability	Reactivity	Other	TLV/TWA Value <sup>a</sup>
Acrolein (CH <sub>2</sub> :CHCHO)	3	3	2		0.1 ppm TLV/TWA
Adiponitrile (NC[CH <sub>2</sub> ] <sub>4</sub> CN)	4	2	0		
Allyl Alcohol (CH <sub>2</sub> :CHCH <sub>2</sub> OH)	3	3	2		2 ppm TLV/TWA
Benzotrifluoride (C <sub>6</sub> H <sub>5</sub> CF <sub>3</sub> )	4	3	0		
Beryllium (Be)	4	1	0		2 mcg/m <sup>3</sup> TLV/TWA
Bromine (Br)	4	0	0	OXY	0.3 ppm TLV/TWA
Bromine Pentafluoride (BF <sub>5</sub> )	4	0	3	OXY/W	0.1 ppm TLV/TWA
Chloropicrin (CCl <sub>3</sub> NO <sub>2</sub> )	4	0	3		0.1 ppm TLV/TWA
Cyanogen (NCCN)	4	4	2		10 ppm TLV/TWA
Dimethyl Sulfate (CH <sub>3</sub> OSO <sub>2</sub> OCH <sub>3</sub> )	4	2	0		0.1 ppm TLV/TWA (skin—suspected carcinogen)
Ethylamine (C <sub>2</sub> H <sub>5</sub> NH <sub>2</sub> )	3	4	0		10 ppm TLV/TWA
Epichlorhydrin (chloromethyl oxirane) ([OCH <sub>2</sub> CH]CH <sub>2</sub> Cl)	3	3	2		0.1 ppm TLV/TWA (skin)
Hydrazine, anhydrous (H <sub>2</sub> NNH <sub>2</sub> )	3	3	2		0.1 ppm TLV/TWA (skin—suspected carcinogen)
Hydrogen Cyanide, anhydrous (HCN)	4	4	2		10 ppm TLV-C
Hydrogen Fluoride (HF)	4	0	0		3 ppm TLV-C
Parathion ([C <sub>2</sub> H <sub>5</sub> O] <sub>2</sub> PSOC <sub>6</sub> H <sub>4</sub> NO <sub>2</sub> )	4	1	2		0.1 mg/m <sup>3</sup> TLV/TWA
Phenol (C <sub>6</sub> H <sub>5</sub> OH)	3	2	0		5 ppm TLV/TWA (skin)
Sodium Hydride (NaH)	3	3	2	W	
Sodium Peroxide (Na <sub>2</sub> O <sub>2</sub> )	3	0	2	W	
1,1,2-Trichloroethane (CHCl <sub>2</sub> CH <sub>2</sub> Cl)—Not to be confused with 1,1,1-Trichloroethane	3	1	0		10ppm TLV/TWA (skin)

a. TLV/TWA means Threshold Limit Value/Time-weighted Average. See definition in Chapter 2 of the *International Mechanical Code*.

**Figure 202-H3  
COMMON HIGHLY TOXIC MATERIALS AND THEIR HAZARDS**

## DEFINITIONS

### [BG] HOSPITALS AND PSYCHIATRIC HOSPITALS.

Facilities that provide care or treatment for the medical, psychiatric, obstetrical, or surgical treatment of inpatient care recipients that are incapable of self-preservation.

- ❖ Persons in hospital facilities may be physically incapable of self-preservation or at least extremely limited in their ability to evacuate. In psychiatric hospitals they may be confined within an area of a building for care or security purposes. In consideration of occupants' health, as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies. See the commentary to Occupancy Group I-2 and Section 407 of the IBC.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both passive and active. See also the definitions for "24-hour basis," "Care suite," "Custodial care," "Detoxification facilities," "Incapable of self-preservation," "Medical care" and "Nursing homes."

**HOT WORK.** Operations including cutting, welding, Thermit welding, brazing, soldering, grinding, thermal spraying, thawing pipe, installation of torch-applied roof systems or any other similar activity.

- ❖ This term describes the scope of what would be considered hot work as it is regulated in this chapter. The scope is broad and would include any activity that produces sparks, slag or other waste products. This would include both gas and electric methods. Torch-applied roof systems are also included.

**HOT WORK AREA.** The area exposed to sparks, hot slag, radiant heat, or convective heat as a result of the hot work.

- ❖ This definition helps to locate which areas would be considered part of the hot work area to better understand the level of susceptibility to ignition.

**HOT WORK EQUIPMENT.** Electric or gas welding or cutting equipment used for hot work.

- ❖ In the past, chapters dealing with hot work focused primarily on gas welding. Electric welding, though it

does not deal with oxygen and fuel gases, still presents ignition hazards (see Commentary Figure 202-H5).

**HOT WORK PERMITS.** Permits issued by the responsible person at the facility under the hot work permit program permitting welding or other hot work to be done in locations referred to in Section 3503.3 and prepermitted by the *fire code official*.

- ❖ As applied in Chapter 35, this permit differs from a typical permit in that it is not directly issued by the fire code official. Instead, a hot work operations facility is given permission to designate a person, perhaps the

Figure 202-H5  
TYPICAL WELDING CART

Figure 202-H4  
HORIZONTAL EXIT

safety officer, to issue permits as needed. This results in flexibility for facilities where hot work is a common occurrence. These permits are issued under what is called a hot work program, which is also defined in this section.

**HOT WORK PROGRAM.** A permitted program, carried out by *approved* facilities-designated personnel, allowing them to oversee and issue permits for hot work conducted by their personnel or at their facility. The intent is to have trained, on-site, responsible personnel ensure that required hot work safety measures are taken to prevent fires and fire spread.

- ❖ This kind of program is described in the definition for “Hot work permits.” This program allows someone on site to control the issuing of permits for hot work. The person who is charged with this responsibility must be trained in hot work operations and have the necessary authority. Having such a program at a facility encourages a better understanding of fire safety and perhaps more incentive to play an active role in the prevention of fires. This program reduces the administrative burden on the fire department and ensures that hot work operations can proceed as needed.

**HPM FACILITY.** See “Semiconductor fabrication facility.”

**HPM ROOM.** A room used in conjunction with or serving a Group H-5 occupancy, where HPM is stored or used and which is classified as a Group H-2, H-3 or H-4 occupancy.

- ❖ An HPM room in a Group H-5 facility is used for the storage and use of HPM in excess of the MAQs permitted in Table 5003.1.1(1) or (2). The rooms are, therefore, considered a Group H-2, H-3 or H-4 occupancy, depending on the type of hazardous material (see Commentary Figure 202-S3).

**HYDROGEN FUEL GAS ROOM.** A room or space that is intended exclusively to house a *gaseous hydrogen system*.

- ❖ This term refers to an enclosed space used exclusively for a gaseous hydrogen system that requires construction and protection that are unique to the hazards associated with this use. The room itself may be considered as an incidental accessory occupancy or a Group H occupancy, depending on the amount of hydrogen in such rooms. The definition itself should not be interpreted to prevent hydrogen piping systems from serving distributed hydrogen-using equipment and appliances located elsewhere on site or in the building; however, the amount of hydrogen within such piping needs to be evaluated with respect to the MAQs in Table 5003.1.1(1).

**IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).** The concentration of air-borne contaminants that poses a threat of death, immediate or delayed permanent adverse health effects, or effects that could prevent escape from such an environment. This contaminant concentration level is established by the National Institute of Occupational Safety and Health (NIOSH) based on both toxicity and flammability. It generally is expressed in parts per million by volume (ppm v/v) or milligrams per cubic meter (mg/

m<sup>3</sup>). Where adequate data do not exist for precise establishment of IDLH concentrations, an independent certified industrial hygienist, industrial toxicologist, appropriate regulatory agency or other source *approved* by the *fire code official* shall make such determination.

- ❖ There are three general atmospheres that make up an IDLH toxic condition. These are toxic, flammable and oxygen deficient. In the absence of an IDLH value, the fire code official may consider using an estimated IDLH of 10 times the lower explosive limit (LEL) while an IDLH oxygen-deficient atmosphere is 19.5-percent oxygen or lower. The EPA has determined that 10 percent of the IDLH value is an acceptable level of concern for evaluating hazmat release concentrations and public protective options.

**IMPAIRMENT COORDINATOR.** The person responsible for the maintenance of a particular *fire protection system*.

- ❖ To minimize the time a fire protection system is out of service, the building owner or other designee is required to monitor impairment procedures (see commentary Section 901.7.1). This person has the responsibility for performing the actions necessary during the impairment and is the single point of contact for issues relating to the impairment; thus, it should be a person who has both authority and knowledge of the facility under consideration.

**[BG] INCAPABLE OF SELF-PRESERVATION.** Persons who, because of age, physical limitations, mental limitations, chemical dependency or medical treatment, cannot respond as an individual to an emergency situation.

- ❖ Patients/residents of nursing homes and hospitals may be in situations where they are unable to self-evacuate due to physical limitations arising from, for example, medication, operation, injury or connection to medical equipment.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both active and passive. See also the definitions for “24-hour basis,” “Custodial care,” “Detoxification facilities,” “Foster care facilities,” “Group home,” “Hospitals and psychiatric hospitals,” “Medical care,” “Nursing home” and “Personal care services.”

**INCOMPATIBLE MATERIALS.** Materials that, when mixed, have the potential to react in a manner which generates heat, fumes, gases or byproducts which are hazardous to life or property.

- ❖ Incompatible materials constitute a dangerous chemical combination whether in storage or in use. Determining which chemicals in combination pose a hazard is not always easy. MSDS may not provide all of the necessary information. When in doubt, the fire

## DEFINITIONS

code official should seek additional information from the manufacturer of the chemicals involved, the building owner or experts who are knowledgeable in industrial hygiene or chemistry. NFPA's *Fire Protection Guide to Hazardous Materials* also contains useful information on hazardous chemical reactions.

**INERT GAS.** A gas that is capable of reacting with other materials only under abnormal conditions such as high temperatures, pressures and similar extrinsic physical forces. Within the context of the code, inert gases do not exhibit either physical or *health hazard* properties as defined (other than acting as a simple asphyxiant) or hazard properties other than those of a *compressed gas*. Some of the more common inert gases include argon, helium, krypton, neon, nitrogen and xenon.

❖ The term "inert gas" is used in a number of sections throughout the code. For example, it is used in the exception to Section 2501.1, Sections 2906.4 and 2309.6.2, as well as in Chapters 50, 53, 57 and 64. The term "inert gas" is also used in the IMC and the IFGC without definition. This definition is not in conflict with the provisions found in either of these companion codes.

While inert gases do not present a physical hazard or health hazard as regulated by Chapter 50, inert gases are hazardous materials in the sense that they are simple asphyxiants that can cause injury or death by displacing oxygen. Any atmosphere containing 19.5 percent or less by volume of oxygen is considered oxygen deficient and inert gases can create such an environment. Inert gases are colorless, odorless, tasteless and are not irritating. As a result, the only means of detecting an oxygen-deficient atmosphere is through the use of gas detection equipment. Inert gases include argon, nitrogen, helium and carbon dioxide. Inert compressed gases and cryogenic fluids have other hazards, such as the potential energy within their containers. Because of these hazards, the provisions in Chapter 53 for compressed gases and Chapter 55 for cryogenic fluids are applicable regardless if the stored gas or cryogenic fluid is inert.

The definition includes an explanatory sentence intended to inform the user that inert gases do not react readily with other materials under normal temperatures and pressures, but it is possible for a reaction to occur. For example, even nitrogen combines with some of the more active metals such as lithium and magnesium to form nitrides, and at high temperatures it will also combine with hydrogen, oxygen and other elements. The inert gases neon, krypton and xenon are considered rare due to their scarcity. Although these gases are commonly referred to as inert gases, the formation of compounds is possible. For example, xenon combines with fluorine to form various fluorides, and with oxygen to form oxides. The compounds thus formed are crystalline solids.

By defining the term the likelihood of using gases that are not inert, including carbon dioxide, will be reduced.

**INHABITED BUILDING.** A building regularly occupied in whole or in part as a habitation for people, or any place of religious worship, schoolhouse, railroad station, store or other structure where people are accustomed to assemble, except any building or structure occupied in connection with the manufacture, transportation, storage or use of *explosive materials*.

❖ Building use need not conform to regular intervals or schedules to be considered inhabited if people routinely occupy the building. Those buildings at a storage or blasting site used for the manufacture, transportation or storage of explosive materials must be considered as magazines rather than inhabited buildings for the purpose of applying the provisions of Section 5604.

**INITIATING DEVICE.** A system component that originates transmission of a change-of-state condition, such as in a smoke detector, manual fire alarm box, or supervisory switch.

❖ All fire protection systems consist of devices, which upon use or actuation, will initiate the intended operation. A manual fire alarm box, for example, upon actuation will transmit a fire alarm signal. In the case of a single-station device, the initiating device and the notification appliance are one in the same.

**INSECTICIDAL FOGGING.** The utilization of insecticidal liquids passed through fog-generating units where, by means of pressure and turbulence, with or without the application of heat, such liquids are transformed and discharged in the form of fog or mist blown into an area to be treated.

❖ Insecticidal fogging as a means of pest control was developed during World War II as part of a program to use smoke-screen techniques for control of malaria-bearing mosquitos. The product of the fog-generating process is an aerosol, which is a suspension of liquid particles in air. Many insecticides used in the fogging process are flammable and pose a fire hazard requiring safeguards, such as the securing of all ignition sources during fogging and for up to 24 hours afterward.

Aerosol insecticides also pose a toxicity hazard; therefore, proper entry precautions for the fogged area should be observed.

**[BE] INTERIOR EXIT RAMP.** An exit component that serves to meet one or more means of egress design requirements, such as required number of exits or exit access travel distance, and provides for a protected path of egress travel to the exit discharge or public way.

❖ To qualify as an interior exit ramp the ramp must be enclosed with a fire-resistance-rated enclosure in order to provide a protected path between the exit access and exit discharge. This enclosure must extend directly to the exterior at grade; extend through an exit passageway to grade; or comply with one of the allowances for exit discharge through a lobby, vestibule or horizontal exit. Travel distance is measured to the entrance to the enclosure for the interior exit ramp. Ramps that are utilized by occupants for evacuation, but do not meet the provisions for exits, are considered exit access elements (see

“Exit access ramp”). For exterior exit ramp requirements, see Section 1027.

**[BE] INTERIOR EXIT STAIRWAY.** An exit component that serves to meet one or more means of egress design requirements, such as required number of exits or exit access travel distance, and provides for a protected path of egress travel to the exit discharge or public way.

❖ To qualify as an interior exit stairway, the ramp must be enclosed with a fire-resistance-rated enclosure in order to provide a protected path between the exit access and exit discharge. This enclosure must extend directly to the exterior at grade; extend through an exit passageway to grade; or comply with one of the allowances for exit discharge through a lobby, vestibule or horizontal exit. Travel distance is measured to the entrance to the enclosure for the interior exit stairway. Stairways that are utilized by occupants for evacuation, but do not meet the provisions for exits, are considered exit access elements (see “Exit access stairway”). For exterior exit stairway requirements, see Section 1027.

**[BG] INTERIOR FINISH.** Interior finish includes interior wall and ceiling finish and interior floor finish.

❖ This is a more general term that addresses all exposed surfaces, which includes walls, ceilings and floors. Interior finish material is exposed to the interior space enclosed by these building elements.

**[BG] INTERIOR FLOOR-WALL BASE.** Interior floor finish trim used to provide a functional or decorative border at the intersection of walls and floors.

❖ This definition, which addresses interior floor-wall base trim materials, provides an understanding and clarification of these types of products versus other interior trim materials. In many cases, floor covering material is just seamlessly turned-up or used at the intersection of the floor and the wall thus becoming the floor-wall base trim. Because of their location at the floor-line, floor-wall base materials are not likely to be involved in a fire until the floor covering is also involved, usually at room flashover. See also the commentary to Section 804.4.

**[BG] INTERIOR WALL AND CEILING FINISH.** The exposed interior surfaces of buildings, including but not limited to: fixed or movable walls and partitions; toilet room privacy partitions; columns; ceilings; and interior wainscoting, paneling or other finish applied structurally or for decoration, acoustical correction, surface insulation, structural *fire resistance* or similar purposes, but not including trim.

❖ A material that is applied to ceilings as well as walls, columns, partitions (including the privacy partitions in bathrooms that could pose a significant threat in larger bathrooms if unrated) and other vertical interior surfaces whether fixed or movable. The application of this material may be for structural, decorative, acoustical, structural fire resistance and other similar reasons. Trim, such as baseboard, door or window

casing, is not considered interior wall and ceiling finish. Interior wall and ceiling finish is regulated by Section 803.

**IRRITANT.** A chemical which is not *corrosive*, but which causes a reversible inflammatory effect on living tissue by chemical action at the site of contact. A chemical is a skin irritant if, when tested on the intact skin of albino rabbits by the methods of CPSC 16 CFR Part 1500.41 for an exposure of four or more hours or by other appropriate techniques, it results in an empirical score of 5 or more. A chemical is classified as an eye irritant if so determined under the procedure listed in CPSC 16 CFR Part 1500.42 or other *approved* techniques.

❖ Materials classified as irritants include a wide range of materials that pose a health hazard with acute effects caused by short-term exposure. Exposure to irritants may result in a minor, troublesome injury at the point of contact; however, the injury usually heals without leaving a scar. In comparison, corrosives can cause permanent destruction of tissue at the point of contact—with a scar the likely result. Many household insecticides and pesticides are common irritants. The definition is derived from DOL 29 CFR 1910.1200.

**[A] JURISDICTION.** The governmental unit that has adopted this code under due legislative authority.

❖ The governmental unit such as a town, township, county or state that has the legal authority under state statutes to adopt a building code.

**KEY BOX.** A secure device with a lock operable only by a fire department master key, and containing building entry keys and other keys that may be required for access in an emergency.

❖ The key box is part of an emergency entry system. The building owner/manager places a key box or key vault in an approved location on the exterior of the building or at the entrance to a facility, placing keys, access cards or security codes inside the box. The emergency responders can use their special fire department master key to enter the box, retrieve the contents and gain access to the building or facility. There are several different brands of highly secure key boxes available that are tested and listed as anti-theft devices. See the commentary to the definition of “Fire department master key” and Section 506.1 for further discussion.

**[A] LABELED.** Equipment, materials or products to which have been affixed a label, seal, symbol or other identifying mark of a nationally recognized testing laboratory, *approved* agency or other organization concerned with product evaluation that maintains periodic inspection of the production of the labeled items and whose labeling indicates either that the equipment, material or product meets identified standards or has been tested and found suitable for a specified purpose.

❖ The term “labeled” is not to be confused with the term “listed.” A label is a marking or other identifying mark

## DEFINITIONS

that indicates approval from a nationally recognized testing laboratory, approved agency or other organization that evaluates products. A label is used to identify materials and assemblies that must bear the identification of the manufacturer, as well as a third-party quality control agency. The quality control agency allows the use of its label based on the results of periodic audits and inspections of the manufacturer's plant. This is one form of quality control. The code often requires labeled equipment and systems (see the definition for "Listed").

**LEVEL OF EXIT DISCHARGE.** See "Exit discharge, level of."

**LIMITED SPRAYING SPACE.** An area in which operations for touch-up or spot painting of a surface area of 9 square feet (0.84 m<sup>2</sup>) or less are conducted.

❖ This definition is applicable only to small touch-up-type operations. The requirements in this chapter for limited spraying operations are for an occasional user of flammable/combustible liquids, as opposed to an area used continuously for spraying. An example of such an operation is a furniture distributor that uses a limited spraying space to touch up scratches on products before sale. The limited application method could utilize dedicated spray-finishing equipment or simply an aerosol can (see commentary, Section 2404.9).

**LIQUEFIED NATURAL GAS (LNG).** A fluid in the liquid state composed predominantly of methane and which may contain minor quantities of ethane, propane, nitrogen or other components normally found in natural gas.

❖ Liquefied natural gas (LNG) for motor vehicle fuel comes from the same source as compressed natural gas (CNG). Unlike liquefied petroleum gas (LP-gas), which changes from vapor to a liquid at room temperature by application of pressure, LNG has to be cooled for it to liquefy. LNG is usually in a liquid state at the dispensing station (see Section 2308).

**LIQUEFIED PETROLEUM GAS (LP-gas).** A material which is composed predominantly of the following hydrocarbons or mixtures of them: propane, propylene, butane (normal butane or isobutane) and butylenes.

❖ The definition of LP-gas is consistent with that found in NFPA 58, with one exception: NFPA 58 requires that the vapor pressure of an LP-gas mixture be less than or equal to that of commercial propane.

**LIQUID.** A material having a melting point that is equal to or less than 68°F (20°C) and a *boiling point* which is greater than 68°F (20°C) at 14.7 pounds per square inch absolute (psia) (101 kPa). Where not otherwise identified, the term "liquid" includes both flammable and *combustible liquids*.

❖ In dealing with liquids, two areas are important to check on the MSDS:

1. What is the specific gravity of the liquid? The specific gravity is the chemical's weight compared to the weight of an equal volume of

water. If the specific gravity is lower than 1.0 (which is the specific gravity of water), the chemical will float. If it is higher than 1.0, it will sink. A flammable liquid that has a specific gravity lower than 1.0 will float on top of any fire-fighting water that is applied. It can then become a running fire as it floats on top of the water that is running off from the scene.

2. Will the chemical mix with water? If a chemical will mix with water, it limits the fire-fighting ability of water and another method of extinguishment should be considered.

**LIQUID OXYGEN AMBULATORY CONTAINER.** A container used for liquid oxygen not exceeding 0.396 gallons (1.5 liters) specifically designed for use as a medical device as defined by 21 USC Chapter 9 that is intended for portable therapeutic use and to be filled from its companion base unit, a liquid oxygen home care container.

❖ These containers are a smaller, portable version of the liquid oxygen (LOX) home care container defined elsewhere in this section. They are used by patients in need of continuous oxygen therapy to enhance their mobility and, thus, improve their lifestyle. See the commentary to the definition of "Liquid oxygen home care container" for a technical description of LOX containers. A key aspect in this definition is that these containers are considered medical devices by the U.S. Food and Drug Administration under the Code of Federal Regulations, Title 21— Federal Food, Drug and Cosmetic Act. LOX containers used as medical devices are unique in that they are intended for therapeutic use only and not for use in industrial applications. These containers include in their design all appurtenances, such as regulators, gauges, piping and controls, and require no external piping other than the application of disposable breathing apparatus (see Commentary Figure 202-L1).

**LIQUID OXYGEN HOME CARE CONTAINER.** A container used for liquid oxygen not exceeding 15.8 gallons (60 liters) specifically designed for use as a medical device as defined by 21 USC Chapter 9 that is intended to deliver gaseous oxygen for therapeutic use in a home environment.

❖ A LOX home care container is a cryogenic container equipped with a vaporizer, a pressure control system and a means of pressure relief. The container is constructed similar to a thermos bottle with the inner container generally constructed of stainless steel and installed within an outer container constructed of carbon steel or aluminum. The space between the inner and outer vessel is filled with an insulating material or may be placed in a negative pressure (vacuum). The insulation and space limits the heat transfer to the inner container. A vaporizer converts the LOX to oxygen gas, which flows through a pressure control system so the flow rate of oxygen is regulated. These containers can be used for stationary home oxygen therapy or, as indicated in the definition of "Liquid

oxygen ambulatory container,” to refill the LOX ambulatory container. A key aspect in this definition is that these containers are also considered medical devices by the U.S. Food and Drug Administration under the Code of Federal Regulations, Title 21—Federal Food, Drug and Cosmetic Act. LOX containers used as medical devices are unique in that they are intended for therapeutic use only and not for use in industrial applications (see Commentary Figure 202-L2).

**LIQUID STORAGE ROOM.** A room classified as a Group H-3 occupancy used for the storage of flammable or *combustible liquids* in a closed condition.

- ❖ The Group H-3 occupancy classification for storage of flammable or combustible liquids in closed containers recognizes the hazardous nature of these materials.

**LIQUID STORAGE WAREHOUSE.** A building classified as a Group H-2 or H-3 occupancy used for the storage of flammable or *combustible liquids* in a closed condition.

- ❖ This definition clarifies both the occupancy group (Group H-2 or H-3, depending on the pressure of vessels stored) and that a liquid storage warehouse is a building as described in Section 5704.3.8. The term “liquid storage warehouse” is used in the code in Tables 903.2.11.6, 5704.3.6.3(2) and 5704.3.6.3(3) and Sections 2306.2.2, 5104.6, 5704.3.4.3 and 5704.3.1.1 through 5704.3.8.5. Note that the term “liquid storage warehouse” is not used in the IBC. See the commentary to Section 5704.3 for further information on these unique buildings.

**[A] LISTED.** Equipment, materials, products or services included in a list published by an organization acceptable to the *fire code official* and concerned with evaluation of products or services that maintains periodic inspection of produc-

tion of listed equipment or materials or periodic evaluation of services and whose listing states either that the equipment, material, product or service meets identified standards or has been tested and found suitable for a specified purpose.

- ❖ The term “listed,” which is not to be confused with “labeled,” is a form of quality control. Essentially, a particular product, piece of equipment or system is evaluated or tested and the results are published in a list by agencies, such as approved testing laboratories and inspection agencies. Listed products and equipment are periodically inspected to maintain the listing. The code often requires listed equipment or systems (see also the definition for “Labeled”).

The question is often asked whether the listing of a product can be voided or violated. The use of a listing mark applied to a product is authorized by the listing agency and is a “statement” by the product manufacturer that the product, as manufactured, met all appropriate requirements (such as the criteria contained in a test standard) at the time of manufacture and shipment to a point-of-use or point-of-sale. After that point in time, any alteration or modification may make it difficult for the fire code official or the listing agency to determine if the product meets the criteria by which its listing was originally attained. Listed products are subject to the review and approval of the fire code official. Where the fire code official determines that a field modification or alteration to the product is significant enough to call its impact on the listing into question, an evaluation in the field by the listing agency may be required in order to verify the compliance of the product with the original listing cri-

## DEFINITIONS

teria. Such field evaluations or tests would be the responsibility of the owner with no expense to the jurisdiction (see the commentary to Section 104.9.2).

**LOCKDOWN.** An emergency situation, in other than a Group I-3 occupancy, requiring that the occupants be sheltered and secured in place within a building when normal evacuation would put occupants at risk.

❖ Buildings are developing “lockdown” plans in response to such security threats as terrorist attacks or shootings such as the events that have occurred at Columbine High School or Virginia Tech and other venues. In such incidents, security authorities recommend that building occupants be kept inside of the building behind locked doors until authorized to move by safety authorities. Sometimes, lockdown procedures can work in direct opposition to traditional life safety safeguards, particularly as pertains to maintaining a viable means of egress. Requirements have been added to the code on lockdown plans, lockdown drills and lockdown operations, not only in schools, but in all buildings where a lockdown plan is desired in order to reduce the conflicts between security and life safety (see Section 406.4).

**[BG] LODGING HOUSE.** A one-family dwelling where one or more occupants are primarily permanent in nature and rent is paid for guest rooms.

❖ The code establishes a lodging house as a Group R-3 occupancy where there are five or fewer guest rooms. This definition provides a distinction from Group R-1 occupancies where the occupants are expected to be transient. A lodging house has one or more occupants who are permanent; this is their home.

**LONGITUDINAL FLUE SPACE.** See “Flue space—longitudinal.”

**[A] LOT.** A portion or parcel of land considered as a unit.

❖ A lot is a legally recorded parcel of land, the boundaries of which are described on a deed. When code requirements are based on some element of a lot (such as yard area or lot line location), it is the physical attributes of the parcel of land that the code is addressing, not issues of ownership. Adjacent lots owned by the same party are treated as if they were owned by different parties because ownership can change at any time. However, a group of platted lots or subdivision lots could be joined together and “considered as a unit” for the purposes of the code. For example, a collection of platted lots could be used as a single building lot for the construction of a covered mall and its associated anchor buildings. Local jurisdictions may require for taxing or other purposes that the lots be legally joined, or merged, as well.

A condominium form of building ownership, whether a residential or a commercial condominium, does not create separate lots (i.e., parcels of land) and such unit owners are treated as separate tenants, not separate lot owners. The lines separating one part of a condominium from another are not lot

lines but lines indicating the limits of ownership. As such, walls constructed on lines separating condominium ownership would not need to be fire (or party) walls.

Legal property lines do not always constitute site boundaries (i.e., malls, condominiums, townhouses). A site could contain multiple legal “lot” divisions.

**[A] LOT LINE.** A line dividing one lot from another, or from a street or any public place.

❖ Lot lines are legally recorded divisions between two adjacent land parcels or lots. They are the reference point for the location of buildings for exterior separation and other code purposes (see the definition of “Lot”).

**[BE] LOW ENERGY POWER-OPERATED DOOR.** Swinging door which opens automatically upon an action by a pedestrian such as pressing a push plate or waving a hand in front of a sensor. The door closes automatically, and operates with decreased forces and decreased speeds. See also “Power-assisted door” and “Power-operated door.”

❖ There are basically three different doors that provide some type of power assistance for entry – low energy power-operated doors, power-assisted doors and power-operated doors. The low energy power-operated door is typically a side-swinging door that also operates as a manual door. However, the door has the additional feature of automatic operation when a person pushes on a plate or sensor located on a wall or post near the door [See IBC Commentary Figures 202(31), 202(32) and 202(33)]. The low energy power-assisted door and power-assisted door are operated by the user touching something; therefore, they both must comply with BMHA156.19.

**LOW-PRESSURE TANK.** A storage tank designed to withstand an internal pressure greater than 0.5 pound per square inch gauge (psig) (3.4 kPa) but not greater than 15 psig (103.4 kPa).

❖ This definition makes a differentiation between what is considered a low-pressure tank and what is considered a high-pressure tank. Low-pressure tanks are generally less hazardous than high-pressure tanks because the rate of release of cryogenic fluids is much lower.

**LOWER EXPLOSIVE LIMIT (LEL).** See “Lower flammable limit.”

❖ See the commentary for the definition of “Lower flammable limit (LFL).”

**LOWER FLAMMABLE LIMIT (LFL).** The minimum concentration of vapor in air at which propagation of flame will occur in the presence of an ignition source. The LFL is sometimes referred to as LEL or lower explosive limit.

❖ LFL or LEL is the bottom limit on a flammability range, which is the range in which a flammable vapor is mixed with air in just the right percentages to allow combustion. This is an important concept because the requirement for ventilation is based on keeping the vapor concentrations outside of the flammability

range. The upper portion of the range is called the UEL, or upper explosive limit; another term that carries the same meaning is UFL, or upper flammable limit. As long as flammable vapors are not within the range between UFL and LFL, combustion is unlikely.

**LP-GAS CONTAINER.** Any vessel, including cylinders, tanks, portable tanks and cargo tanks, used for transporting or storing LP-gases.

- ❖ The definition of LP-gas container provides consistency with NFPA 58 and makes it clear that the containers being regulated in Chapter 61 of the code are specifically those used for the storage or transport of LP-gas, not the generic, 60 gallon (227.1 L) or less containers defined in Section 202 of the code.

An LP-gas container can be constructed as a cylinder, portable tank, stationary tank or as a cargo tank vehicle. Cylinders are generally constructed to the requirements of the DOT while stationary tanks, portable tanks and cargo tanks are generally constructed to the requirements of the ASME *Boiler and Pressure Vessel Code* for unfired pressure vessels. In addition to these requirements, LP-gas containers must also be constructed in accordance with the requirements in NFPA 58.

All LP-gas containers must meet the requirements contained in Chapter 5 of NFPA 58, which addresses all components used in the construction of container assemblies or complete LP-gas systems. These requirements include general provisions that are applicable to all containers, visual inspection requirements for DOT cylinders in stationary service, container service pressures, required openings for DOT cylinders and ASME containers, container markings and container appurtenances. A container appurtenance is a device installed in container openings for safety, control, or operating purposes. Appurtenances include a pressure relief device, one or more pressure regulators, an overfill prevention device, a manual shutoff valve, and a means of gauging the liquid level and the pressure inside the container. The types of appurtenances required for LP-gas containers are based on whether the container is constructed as a cylinder or tank. For stationary tanks, its volumetric capacity will dictate the required container appurtenances.

**MAGAZINE.** A building, structure or container, other than an operating building, *approved* for storage of *explosive materials*.

- ❖ Structures for the storage of explosive materials are not considered inhabited buildings for the purpose of applying Section 5604. Explosives, a necessary part of our industrialized society, must be transported from places of manufacture to a location of use. Somewhere along the line, they will probably have to be stored. This type of storage place is called a magazine.

**Indoor.** A portable structure, such as a box, bin or other container, constructed as required for Type 2, 4 or 5 maga-

zines in accordance with NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55 so as to be fire resistant and theft resistant.

- ❖ These magazines are sometimes found inside warehouses, wholesale houses and retail establishments on wheels or casters to allow easy movement when needed.

**Type 1.** A permanent structure, such as a building or igloo, that is bullet resistant, fire resistant, theft resistant, weather resistant and ventilated in accordance with the requirements of NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55.

- ❖ The walls of a Type 1 magazine should be constructed of either masonry, metal or wood. The foundation should consist of brick, concrete, cement, block, stone or wood post. The floors should be constructed of nonsparking material and be strong enough to bear the weight of the maximum quantity to be stored. The listed standards give the sizes of material for each type of construction material.

**Type 2.** A portable or mobile structure, such as a box, skid-magazine, trailer or semitrailer, constructed in accordance with the requirements of NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55 that is fire resistant, theft resistant, weather resistant and ventilated. If used outdoors, a Type 2 magazine is also bullet resistant.

- ❖ Construction of a Type 2 magazine may be either:

1. Wood [having sides, bottoms, and covers or doors constructed of 2-inch (51 mm) hardwood, well braced at corners and covered with sheet metal (not less than 26 gauge) with exposed nails countersunk].
2. Metal [having sides, bottoms and covers or doors constructed of 12-gauge (0.1046 inch) metal and lined inside with a nonsparking material. Edges of metal shall overlap sides at least 1 inch (25 mm)].

**Type 3.** A fire resistant, theft resistant and weather resistant “day box” or portable structure constructed in accordance with NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55 used for the temporary storage of *explosive materials*.

- ❖ Construction of a Type 3 magazine may be of not less than 12-gauge (0.1046 inch) steel, lined with 1/2-inch (12.7 mm) plywood or 1/2-inch (12.7 mm) hardboard. The door or lid must overlap the door opening by at least 1 inch (25 mm).

**Type 4.** A permanent, portable or mobile structure such as a building, igloo, box, semitrailer or other mobile container that is fire resistant, theft resistant and weather resistant and constructed in accordance with NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55.

- ❖ Construction of a Type 4 magazine may be of masonry, metal-covered wood, fabricated metal or a combination of these materials.

**Type 5.** A permanent, portable or mobile structure such as a building, igloo, box, bin, tank, semitrailer, bulk trailer,

## DEFINITIONS

tank trailer, bulk truck, tank truck or other mobile container that is theft resistant, which is constructed in accordance with NFPA 495, NFPA 1124 or DOTy 27 CFR Part 55.

- ❖ Restrictions on Type 5 outdoor storage facilities:
  - Ground around the storage facility must slope away for drainage. Wheels must be removed from vehicles used as unattended storage facilities or they must be immobilized by kingpin locking devices.
- ❖ Restrictions on Type 5 indoor storage facilities:
  - Blasting agents are not to be stored in any kind of indoor storage facility in a residence or dwelling.

**MAGNESIUM.** The pure metal and alloys, of which the major part is magnesium.

- ❖ Magnesium is a silvery-white combustible metal weighing only two-thirds as much as aluminum and having good structural properties when suitably alloyed. For this reason, magnesium alloys are used to a great extent in the construction of aircraft; automobiles and trucks; household appliances; furniture; office equipment, machine parts and numerous other applications. Powdered magnesium is used in signal flares and other fireworks to produce an intense white light.

The melting point of pure magnesium is 1,202°F (650°C). The ignition temperature is generally considered to be very close to the melting point, but ignition of magnesium in certain forms may occur at lower air temperatures. Magnesium ribbon and fine magnesium shavings can be ignited under some conditions at temperatures of 950°F (510°C), and very finely divided magnesium powder has been ignited at an air temperature below 900°F (482°C).

The ease of ignition of magnesium depends to a large extent upon the size and shape of the material as well as the intensity of the ignition source. The flame of a match may be sufficient to ignite magnesium ribbon, shavings or chips with thin feather edges, and a spark will ignite fine dust such as is produced in grinding operations. Heavier pieces, such as ingots or thick-walled castings, are difficult to ignite because heat is rapidly conducted away from a localized ignition source. If the entire piece of metal can be raised to the ignition temperature, however, self-sustained burning will occur.

Because the melting point of magnesium is low, the metal melts as it burns and, after some minutes of burning, produces puddles of molten magnesium. The production of molten metal will depend to a considerable extent on the physical condition of the material. Finely divided magnesium, such as shavings, dust and small scraps, will burn more rapidly and produce less molten metal than will an equal quantity of magnesium in the more solid form of ingots or castings.

Metal products marketed under a variety of trade names and designations and commonly referred to as “magnesium” may, in fact, be one of a large number of alloys containing widely differing percentages of magnesium, aluminum, zinc and manganese. Some of these alloys have melting points and ignition temperatures considerably lower than that of pure magnesium.

**MALL.** See “Covered mall building.”

**MANUAL FIRE ALARM BOX.** A manually operated device used to initiate an alarm signal.

- ❖ Manual fire alarm boxes are commonly known as pull stations. Manual fire alarm boxes include all manual devices used to activate a manual fire alarm system and have many configurations, depending on the manufacturer. All manual fire alarm devices, however, must be approved and installed in accordance with NFPA 72 for the particular application. Manual fire alarm boxes may be combined in guard tour boxes.

**MANUAL STOCKING METHODS.** Stocking methods utilizing ladders or other nonmechanical equipment to move stock.

- ❖ Manual stocking methods do not require the use of mechanical means to stock and retrieve commodities. Commodities may be stocked or retrieved on foot where the commodity is accessible from a floor or landing, or through the use of a portable ladder or portable stair.

**MARINA.** Any portion of the ocean or inland water, either naturally or artificially protected, for the mooring, servicing or safety of vessels and shall include artificially protected works, the public or private lands ashore, and structures or facilities provided within the enclosed body of water and ashore for the mooring or servicing of vessels or the servicing of their crews or passengers.

- ❖ A marina is a protected area where the mooring of marine vessels occurs along with the associated operations to service the vessels, such as fueling, maintenance and repair facilities, ship chandlers, stores and restaurants, the launching of vessels and the loading of vessels with cargo or persons. Marine vessels moored in a marina are usually in close proximity to each other with floats of minimal widths, usually enough for people to walk on, and small carts to carry supplies that are to be loaded onto the vessels. The marina may offer out-of-water-storage, which is useful out of season and important in climates susceptible to freezing waters. Dry storage or “dry stacking” boat storage stores boats vertically in double, triple or even quadruple rack systems. Boats are placed into and retrieved from the storage racks with a forklift.

**MARINE MOTOR FUEL-DISPENSING FACILITY.** That portion of property where flammable or *combustible liquids* or gases used as fuel for watercraft are stored and dis-

pensed from fixed equipment on shore, piers, wharves, floats or barges into the fuel tanks of watercraft and shall include all other facilities used in connection therewith.

- ❖ A marine motor fuel-dispensing facility is not to be confused with a bulk marine terminal, which transfers fuel by way of flange-to-flange connections. A marine motor fuel-dispensing facility uses automotive-type dispensing equipment. Motor fuel-dispensing facilities are classified in Occupancy Group M by the IBC.

**MATERIAL SAFETY DATA SHEET (MSDS).** Information concerning a hazardous material which is prepared in accordance with the provisions of DOL 29 CFR Part 1910.1200 or in accordance with the provisions of a federally approved state OSHA plan.

- ❖ To comply with right-to-know legislation, building owners are required to provide or prepare a MSDS for all hazardous materials that may be on the premises. The MSDS is the single best source of information in dealing with the requirements of the IBC and the code.

**MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA.** The maximum amount of a hazardous material allowed to be stored or used within a *control area* inside a building or an outdoor *control area*. The maximum allowable quantity per control area is based on the material state (solid, liquid or gas) and the material storage or use conditions.

- ❖ Exceeding this amount, also referred to as the MAQ, will place the use area or building into a hazardous occupancy classification. See Tables 5003.1.1(1), 5003.1.1(2), 5003.1.1(3), 5003.1.1(4) and 5003.8.3.2.

**[BE] MEANS OF EGRESS.** A continuous and unobstructed path of vertical and horizontal egress travel from any occupied portion of a building or structure to a *public way*. A means of egress consists of three separate and distinct parts: the *exit access*, the *exit* and the *exit discharge*.

- ❖ The means of egress is the path traveled by building occupants to leave the building and the site on which it is located. It includes all interior and exterior elements that the occupants must utilize as they make their way from every room and usable space within the building to a public way such as a street or alley. The elements that make up the means of egress create the lifeline that occupants utilize to travel out of the structure and to a safe distance from the structure. The means of egress provisions of the code strive to provide a reasonable level of life safety in every structure. The means of egress provisions are subdivided into three distinct portions (see the definitions of "Exit access," "Exit" and "Exit discharge").

**MECHANICAL STOCKING METHODS.** Stocking methods utilizing motorized vehicles or hydraulic jacks to move stock.

- ❖ Mechanical stocking methods are generally associated with rack storage. The mass of the commodity, the height of the rack storage or the shear quantity of commodity on any one pallet will normally put stocking or retrieval beyond human reach or strength.

Methods commonly employed for this type of operation are manned forklifts or unmanned mechanized storage and retrieval systems.

**[BG] MEDICAL CARE.** Care involving medical or surgical procedures, nursing or for psychiatric purposes.

- ❖ Persons who need medical care are likely to be incapable of self-preservation or at least extremely limited in their ability to evacuate. In consideration of occupants' health as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies rather than evacuation. See also the commentary to Occupancy Group I-2.

Care facilities encompass a full spectrum of occupant acuity and support services, and span a wide range of occupancy types, including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. On the lower end of the care spectrum, i.e., personal care, is when occupants are supervised but do not need custodial or medical care. But, where occupants may be elderly or impaired, i.e., custodial care, they may need occasional daily living assistance, such as cooking and cleaning. Persons who receive custodial care may or may not require assistance with evacuation depending on the occupancy and conditions of the occupancy. On the opposite end of the care spectrum, persons receiving care may be completely bedridden and dependant on medical gases and emergency power to maintain life (i.e., medical care). The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both active and passive. See also the definitions for "24-hour basis," "Custodial care," "Detoxification facilities," "Foster care facilities," "Group home," "Hospitals and psychiatric hospitals," "Incapable of self-preservation," "Nursing homes" and "Personal care services."

**MEMBRANE STRUCTURE.** An air-inflated, air-supported, cable or frame-covered structure as defined by the *International Building Code* and not otherwise defined as a tent. See Chapter 31 of the *International Building Code*.

- ❖ This definition is broadly inclusive of all types of membrane structures, regardless of the supporting mechanism or structure, as defined in Chapter 2 of the IBC as "Air-inflated structure," "Air-supported structure," "Cable-restrained, air supported structure," "Membrane-covered cable structure" and "Membrane-covered frame structure." Note that tents are not included. See the definitions of "Air-inflated structure," "Air supported structure" and "Tent."

**[BE] MERCHANDISE PAD.** A merchandise pad is an area for display of merchandise surrounded by *aisles*, permanent fixtures or walls. Merchandise pads contain elements such as nonfixed and moveable fixtures, cases, racks, counters and partitions as indicated in Section 105.2 of the *International Building Code* from which customers browse or shop.

- ❖ Merchandise pads would most likely be found in large stores with changing displays of clothes or furniture.

## DEFINITIONS

This is not a raised display-only area. These areas allow customers to move between displays or racks. In regards to means of egress, merchandise pads could be considered analogous to areas of fixed seating or groups of tables. The aisle accessways are within the merchandise pad and lead to the aisles on the outside edges of the merchandise pads. Not all stores will contain merchandise pads (e.g., a typical grocery store with fixed shelves and aisles).

**METAL HYDRIDE.** A generic name for compounds composed of metallic element(s) and hydrogen.

❖ Hydride is the name given to the negative ion of hydrogen. With the exception of inert gases, every element in the Periodic Table of Elements can form a hydride. The hazards of hydrides will vary based on the elemental molecule to which the -H ion attaches itself.

A metal hydride is a metallic alloy that will adsorb and release hydrogen molecules. (The term “adsorb” means a taking up by physical or chemical forces of the molecules of hydrogen gas by the surfaces of solids with which they are in contact.) With metal hydrides, adsorption occurs when the hydrogen molecules accumulate on the surface of metal. Many of the metals used in metal hydride storage systems (MHSS) are designed to be reversible, meaning they can adsorb and release hydrogen from the system. The adsorption and release occurs when heat is transferred within the MHSS, which upsets the equilibrium condition between the hydrogen, the hydrogen-adsorbing alloy and the metal hydride system.

**METAL HYDRIDE STORAGE SYSTEM.** A *closed system* consisting of a group of components assembled as a package to contain metal-hydrogen compounds for which there exists an equilibrium condition where the hydrogen-adsorbing metal alloy(s), hydrogen gas and the metal-hydrogen compound(s) coexist and where only hydrogen gas is released from the system in normal use.

❖ Metal hydride storage systems (MHSS) are another technological advancement in fuel-cell technology

that is becoming a commonly used method for storing hydrogen and is an alternative to traditional compressed or cryogenic fluid storage methods for supplying hydrogen to fuel cells. A MHSS will release or adsorb hydrogen gas when the equilibrium condition is changed. Changes in the equilibrium condition cause the system to either release heat (exothermic) or absorb heat (endothermic). MHSSs designed in compliance with Section 5807 are designed so only hydrogen is released from or introduced into the system during its discharge or filling. The requirements in Section 5807 provide guidance to fire code officials and design professionals in the design, construction, inspection and testing of systems and components used as a MHSS (see Commentary Figure 202-M1).

**[BG] MEZZANINE.** An intermediate level or levels between the floor and ceiling of any story and in accordance with Section 505 of the *International Building Code*.

❖ A common design feature in factories, warehouses and mercantile buildings is an intermediate loft, or platform, between the story levels of a building. This type of feature, or mezzanine, can be found in buildings of all occupancies. The IBC must deal with whether this intermediate level is another story of the building or whether it can simply be treated as part of the story in which it is contained. The basic rule is that the intermediate level must be less than one-third of the area of the story below (of the room in which it is located) in order to be considered a mezzanine. Requirements for mezzanines are found in Section 505 of the IBC.

**MOBILE FUELING.** The operation of dispensing liquid fuels from tank vehicles into the fuel tanks of motor vehicles. Mobile fueling may also be known by the terms “Mobile fleet fueling,” “Wet fueling” and “Wet hosing.”

❖ This definition pertains to the fueling process regulated by Section 5706.5.4.5, wherein fuel is dispensed from the tank vehicle directly to the fuel tank of a vehicle (see commentary, Section 5706.5.4.5).

**Figure 202-M1**  
**METAL HYDRIDE STORAGE CONTAINER AND ITS METAL HYDRIDE CONTENT**  
Photo courtesy of Ovanics Hydrogen Systems, LLC

**MORTAR.** A tube from which fireworks shells are fired into the air.

- ❖ Mortars must be inspected carefully for defects, such as dents, bent ends, damaged interiors and damaged plugs, prior to placement and use. Defective mortars must not be used. Careful inspection of mortars is of particular importance for paper mortars that can sustain undetected damage to their interiors that can result in serious malfunctions.

**MULTIPLE-STATION ALARM DEVICE.** Two or more single-station alarm devices that can be interconnected such that actuation of one causes all integral or separate audible alarms to operate. A multiple-station alarm device can consist of one single-station alarm device having connections to other detectors or to a manual fire alarm box.

- ❖ This definition refers to a combination of similar or different types of alarm devices that could be interconnected. The actuation of any two devices, whether a smoke detector or manual fire alarm box, will activate the required audible alarms at all interconnected devices.

**MULTIPLE-STATION SMOKE ALARM.** Two or more single-station alarm devices that are capable of interconnection such that actuation of one causes the appropriate alarm signal to operate in all interconnected alarms.

- ❖ In occupancies with sleeping areas, occupants must be notified in a fire so that they can promptly evacuate the premises. In accordance with the requirements of NFPA 72, multiple-station smoke alarms are self-contained, smoke-activated alarm devices built in accordance with UL 217 that can be interconnected with other devices so that all integral or separate alarms will operate when any one device is activated.

**NESTING.** A method of securing flat-bottomed *compressed gas* cylinders upright in a tight mass using a contiguous three-point contact system whereby all cylinders within a group have not less than three points of contact with other cylinders, walls or bracing.

- ❖ Nesting is the placement of cylinders in tightly packed groups in which three sides of the group are comprised of walls or barriers and each cylinder is in contact with a wall or another cylinder in at least three places. It is generally considered an alternative to chaining or otherwise physically securing compressed gas cylinders (as required by Section 5303.5.3) under conditions of occupancy where cylinders must be readily moveable, such as in a filling plant.

Placing cylinders in multipoint contact with one another can reduce cylinder instability while affording the ready mobility required by an operation being conducted by trained personnel. Such a configuration is relatively secure for all cylinders involved because even those cylinders on the open side would have to be displaced from behind, i.e., an area within the nest itself. This reduces the potential for damage to the cylinder valve since a knockdown of the cylinder

could result in leakage of hazardous gas or create a projectile situation.

One safety precaution that could reduce the likelihood of a cylinder on the face of the nest having a valve sheared is maintaining an open space in front of the nest, free of shelves, counters or other projections, which could act to break the valve on an overturning cylinder. Additionally, valve protection caps should be in place on the cylinders at all times when the cylinder is not connected, being filled or emptied (see Commentary Figure 202-N1).

**FIGURE 202-N1  
NESTING OF CYLINDERS**

**NET EXPLOSIVE WEIGHT (net weight).** The weight of *explosive material* expressed in pounds. The net explosive weight is the aggregate amount of *explosive material* contained within buildings, magazines, structures or portions thereof, used to establish quantity-distance relationships.

- ❖ This definition is included to correlate the use of the provisions of this chapter. The definition is based on Department of Defense (DOD) concepts; however, prescriptive requirements have been removed from the DOD definition and placed into the body of the code. The net explosive weight may vary depending on building construction; for example, in cases where appropriate barrier walls or appropriate distances have been employed to avoid propagation.

**NORMAL TEMPERATURE AND PRESSURE (NTP).** A temperature of 70°F (21°C) and a pressure of 1 atmosphere [14.7 psia (101 kPa)].

- ❖ Reaction by some chemicals is based on temperature and pressure. Understanding this relationship to normal room temperature and pressure (elevation) can provide information on the hazards for the chemical being considered.

**[BE] NOSING.** The leading edge of treads of *stairs* and of landings at the top of *stairway flights*.

- ❖ The front edge of the tread that is exposed to the users foot provides the visual clue for the placement of the foot in both ascent and descent. The nosings of a stair are a reference point for the measurement of as tread depth and riser height. The line connecting the nosings serves as the reference for the measurement of handrail and guard heights, as well as headroom. The code assures their uniformity by limiting

## DEFINITIONS

the projection of the tread and landing nosings that results in a stairway that is easy to use. If too large, they are a tripping hazard when walking up a stair. If too small in relation to tread depth, the effective tread depth required for heel clearance in descent is minimized. The code provides limits for both minimum and maximum nosing projections and establishes a minimum tread depth when no projection is required. An exception to these limits exists in the requirements for both alternating tread devices and ship ladders where an exaggerated projected tread depth, required to provide for reasonable foot room, is unique to the steeper gradient and functional use of these devices.

**NOTIFICATION ZONE.** See “Zone, notification.”

**NUISANCE ALARM.** An alarm caused by mechanical failure, malfunction, improper installation or lack of proper maintenance, or an alarm activated by a cause that cannot be determined.

❖ A nuisance alarm is essentially any alarm that occurs as a result of a condition that does not arise during the normal operation of the equipment. A nuisance alarm is not the same as a false alarm. A person who intentionally initiates an alarm by using a manual pull station or a person who accidentally initiates a smoke detector is not initiating a nuisance alarm. A nuisance alarm is, by nature, a factor of the system itself. See commentary to the definition of “False alarm.”

**[BG] NURSING HOMES.** Facilities that provide care, including both intermediate care facilities and skilled nursing facilities, where any of the persons are incapable of self-preservation.

❖ Persons in nursing homes may be physically incapable of self-preservation or at least extremely limited in their ability to evacuate. In dementia wards, they may be confined within an area of a building for care or security purposes. In consideration of occupants’ health as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies. See the commentary for Occupancy Group I-2 and Section 407 of the IBC.

Care facilities encompass a full spectrum of occupant acuity and support services, and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both passive and active. See also the definitions for “24-hour basis,” “Care suite,” “Custodial care,” “Detoxification facilities,” “Hospitals and psychiatric hospitals,” “Incapable of self-preservation” and “Medical care.”

**OCCUPANCY CLASSIFICATION.** For the purposes of this code, certain occupancies are defined as follows:

❖ The provisions of Sections 302 through 312 of the IBC control the classification of buildings and structures as to their use and occupancy. The purpose of those provisions is to provide rational criteria for the

classification of various occupancies into groups based on their relative fire hazard and life safety properties. This is necessary because the IBC, as well as many provisions of the code, utilize occupancy group classification as a fundamental principle for differentiating code requirements related to fire and life safety protection. By organizing occupancies with similar fire hazard and life safety properties into occupancy groups, the IBC and the code have adopted the means to differentiate occupancies such that various fire protection and life safety requirements can be rationally organized and applied. Each specific group has an individual classification and represents a different characteristic and level of fire hazard that requires special code provisions to lessen the associated risks. See Chapter 3 of the IBC commentary for further discussion of occupancy groups and examples of how they are applied.

**[BG] Assembly Group A.** Assembly Group A occupancy includes, among others, the use of a building or structure, or a portion thereof, for the gathering of persons for purposes such as civic, social or religious functions; recreation, food or drink consumption; or awaiting transportation.

❖ Because of the arrangement and density of the occupant load associated with occupancies classified in the Group A assembly category, the potential for multiple fatalities and injuries from fire is comparatively high. For example, no other use listed in Section 302.1 of the IBC contemplates occupant loads as dense as 5 square feet (0.46 m<sup>2</sup>) per person (see Table 1004.1.2). Darkened spaces in theaters, nightclubs and the like serve to increase hazards. In sudden emergencies, the congestion caused by large numbers of people rushing to exits can cause panic conditions. For these and many other reasons, there is a relatively high degree of hazard to life safety in assembly facilities. The relative hazards of assembly occupancies are reflected in the height and area limitations of Tables 504.3, 504.4 and 506.2 that are, in comparison, generally more restrictive than for buildings in other group classifications.

A room or space with an occupant load of 50 or more persons should not be automatically classified as a Group A; however, if a room or space is used for assembly purposes (i.e., gathering of persons for purposes such as civic, social or religious functions; recreation, food or drink consumption or awaiting transportation in accordance with Section 303.1) and the occupant load is 50 or more, Group A is likely to be the appropriate designation. Other uses can have an occupant load of more than 50 in a space or room; for example, a large office space, a grocery store or the main floor of a major retail business, but these are not assembly occupancies.

There are five specific assembly group classifications, Groups A-1 through A-5, described in this section. Where used in the code, the general term “Group A” is intended to include all five classifications.

The fundamental characteristics of all assembly occupancies are identified in this section. Structures that are designed or occupied for assembly purposes must be placed in one of the assembly group classifications. There are buildings and spaces which are used for assembly purposes, but are not classified as Assembly occupancies. These “exceptions” to this rule include small assembly buildings, tenant spaces and assembly spaces in mixed-use buildings. These exceptions to the Group A classification are addressed below.

**[BG] Small buildings and tenant spaces.** A building or tenant space used for assembly purposes with an *occupant load* of less than 50 persons shall be classified as a Group B occupancy.

- ❖ There are often small establishments that typically serve food and have a few seats that technically meet the definition of an assembly Group A occupancy but due to the low occupant load pose a lower risk than a typical assembly occupancy. These types of buildings and tenant spaces are to be considered as Group B occupancies when the occupant load is determined to be less than 50 persons. Examples of this include small “fast food” establishments and small “mom-and-pop” cafes or coffee shops.

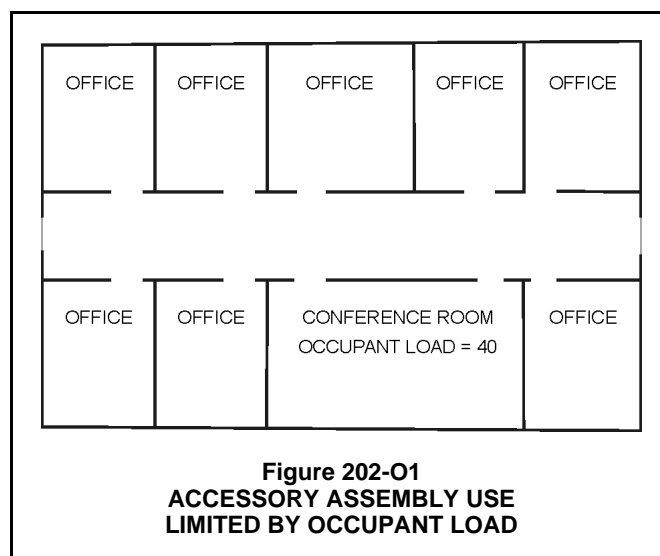

**[BG] Small assembly spaces.** The following rooms and spaces shall not be classified as assembly occupancies:

1. A room or space used for assembly purposes with an *occupant load* of less than 50 persons and accessory to another occupancy shall be classified as a Group B occupancy or as part of that occupancy.
2. A room or space used for assembly purposes that is less than 750 square feet (70 m<sup>2</sup>) in area and accessory to another occupancy shall be classified as a Group B occupancy or as part of that occupancy.

- ❖ Assembly rooms or spaces within larger buildings that house other uses are classified based upon their occupant loads. Where the occupant load of the assembly space is less than 50, or where the floor area of the space used for assembly purposes is less than 750 square feet (65 m<sup>2</sup>), a classification of other than Group A is permitted. In both cases, the purpose of the assembly space must be accessory to the principal occupancy of the structure (i.e., the activities in the assembly space are subordinate and secondary to the primary occupancy). If either the occupant load or floor area requirement is satisfied and the purpose of the assembly space is accessory to the principal occupancy, the space is permitted to either be classified as a Group B occupancy or as part of the principal occupancy. In either case, the assembly space is not required to be less than 10 percent of the area of the story on which it is located as is specified for accessory occupancies in Section 508.2 of the IBC (IBC Interpretation No. 20-04).

The allowances given to assembly spaces in buildings containing multiple uses are a practical code consideration that permits a mixed-use condition to exist without requiring compliance with the provisions for mixed occupancies (see Section 508 of the IBC). Although the term “accessory” is used in describing the relationship of the uses, the intent of the term here is that the use of the space is related to, or part of, the main use of the space. These exceptions are not limited by the accessory use requirements found in Section 508.2 of the IBC.

**Example 1:** An office building, classified as a Group B occupancy, has a conference room used for staff meetings with an occupant load of 40 (see Commentary Figure 202-O1). The occupancy classification of a conference room is generally considered a Group A-3. Since the occupant load of the conference room is less than 50 and its function is clearly accessory to the business area, the room is permitted to be classified the same as the main occupancy, Group B.

**Example 2:** A 749-square-foot (70 m<sup>2</sup>) assembly area is located adjacent to a mercantile floor area of 5,000 square feet (465 m<sup>2</sup>) (see Commentary Figure 202-O2). Although the assembly use area occupies 15 percent of the 5,000-square-foot (465 m<sup>2</sup>) floor area, it does not exceed 750 square feet (70 m<sup>2</sup>) and is not considered a Group A occupancy, but rather is classified as part of the Group M occupancy.

**[BG] Associated with Group E occupancies.** A room or space used for assembly purposes that is associated with a Group E occupancy is not considered a separate occupancy.

- ❖ A typical educational facility for students in the 12th grade and below invariably contains many types of assembly spaces other than classrooms, such as auditoriums, cafeterias, gymnasiums and libraries. Such assembly spaces in a Group E building are not

## DEFINITIONS

intended to be regulated as separate Group A occupancies, regardless of their floor area, but rather an extension of the Group E classification. It is worth mentioning, for such assembly functions to be considered part of the primary Group E occupancy, the assembly functions must be ancillary and supportive to the educational operation of the building. Otherwise, they would be classified into the appropriate Group A occupancy based upon their specific function. These assembly spaces, where classified as a portion of the Group E occupancy, are still considered as assembly in nature and must comply with assembly space requirements specified for accessibility and means of egress. However, often such school facilities are used for other functions, such as a meeting of a community service organization or a community crafts fair. These types of uses fall outside of the intent of this section and, therefore, such assembly spaces would need to be classified as a Group A.

**[BG] Accessory with places of religious worship.**

Accessory religious educational rooms and religious auditoriums with *occupant loads* of less than 100 per room or space are not considered separate occupancies

- ❖ Places of religious worship are listed as a Group A-3 occupancy. In addition to the worship hall, it is common for such facilities to contain smaller rooms used for educational activities. This provision allows such spaces to be considered as part of the Group A-3 classification rather than create a mixed-occupancy condition. For example, classrooms are normally classified as Group E if occupied by persons of ages through the 12th grade, or as Group B if the educa-

tion is provided to adults. These types of classrooms could be considered as a part of the Group A-3 occupancy under the provisions of this section. Where such rooms are used at certain times for other than as a religious auditorium or for religious education, Section 302 of the IBC requires that the requirements of each occupancy be applied.

**[BG] Assembly Group A-1.** Group A occupancy includes assembly uses, usually with fixed seating, intended for the production and viewing of performing arts or motion pictures including, but not limited to:

- Motion picture theaters
- Symphony and concert halls
- Television and radio studios admitting an audience
- Theaters

- ❖ Some of the characteristics of Group A-1 occupancies are large, concentrated occupant loads; low lighting levels; above-normal sound levels; and a moderate fuel load.

Group A-1 is characterized by two basic types of activities. The first type is one in which the facility is occupied for the production and viewing of theatrical or operatic performances. Facilities of this type ordinarily have fixed seating; a permanent raised stage; a proscenium wall and curtain; fixed or portable scenery drops; lighting devices; dressing rooms; mechanical appliances or other theatrical accessories and equipment (see Commentary Figure 202-O3).

The second type is one in which the structure is primarily occupied for the viewing of motion pictures. Facilities of this type ordinarily have fixed seating, no stage, a viewing screen, motion picture projection

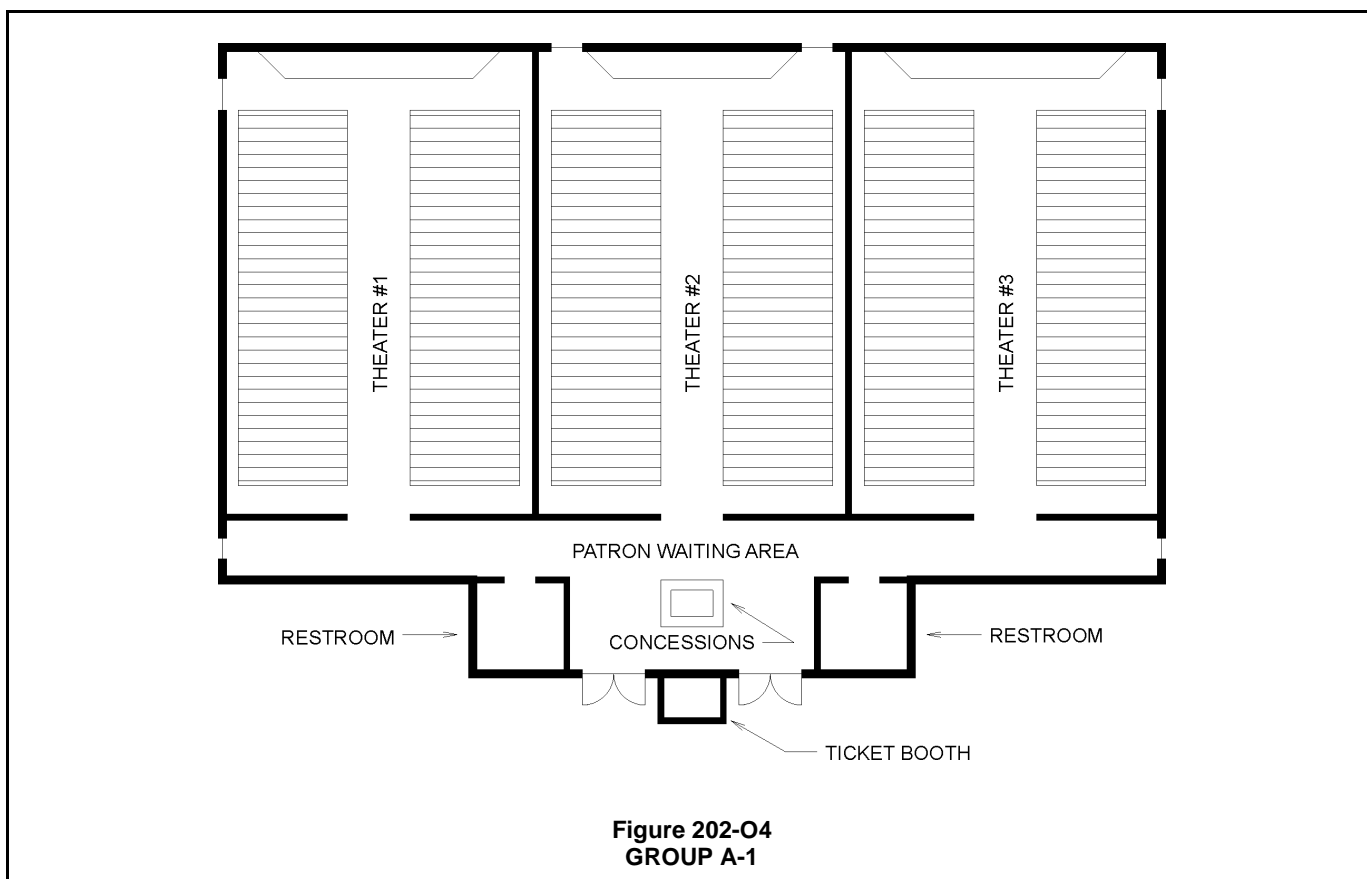

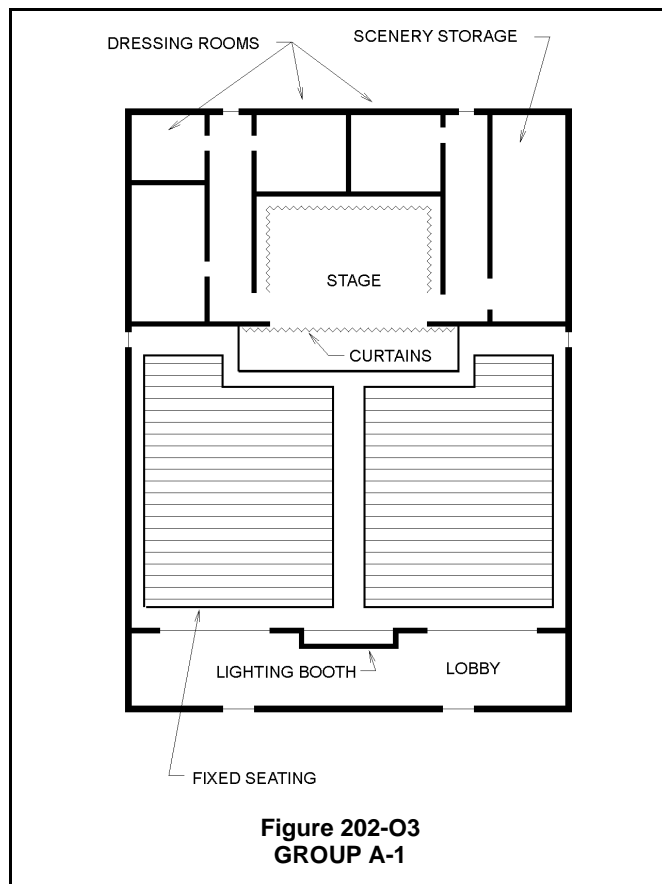

booths and equipment (see Commentary Figure 202-04).

Group A-1 presents a significant potential life safety hazard because of the large occupant loads and the concentration of people within confined spaces. The means of egress is an important factor in the design of such facilities. Theaters for the performing arts that require stages are considered particularly hazardous because of the amount of combustibles, such as curtains, drops, scenery, construction materials and other accessories normally associated with stage operation. As such, special protection requirements applicable to stages and platforms are provided in Section 410 of the IBC and Chapter 10 of the code.

**[BG] Assembly Group A-2.** Group A-2 occupancy includes assembly uses intended for food and/or drink consumption including, but not limited to:

- Banquet halls
- Casinos (gaming areas)
- Night clubs
- Restaurants, cafeterias and similar dining facilities (including associated commercial kitchens)
- Taverns and bars

❖ Group A-2 includes occupancies in which people congregate in high densities for social entertainment, such as drinking and dancing (e.g., nightclubs, dance halls, banquet halls, cabarets, etc.) and food and drink consumption (e.g., restaurants). The unique-

## DEFINITIONS

ness of these occupancies is characterized by some or all of the following:

- Low lighting levels;
- Entertainment by a live band or recorded music generating above-normal sound levels;
- No theatrical stage accessories;
- Later-than-average operating hours;
- Tables and seating arranged or positioned so as to create ill-defined aisles;
- A specific area designated for dancing;
- Service facilities for alcoholic beverages and food; and
- High occupant load density.

The fire records are very clear in identifying that the characteristics listed above often cause a delayed awareness of a fire situation and confuse the appropriate response, resulting in an increased egress time and sometimes panic. Together, these factors may result in extensive life and property losses. These characteristics are only advisory in determining whether Group A-2 is the appropriate classification. Often, there are additional characteristics that are unique to a project, which also must be taken into consideration when a classification is made.

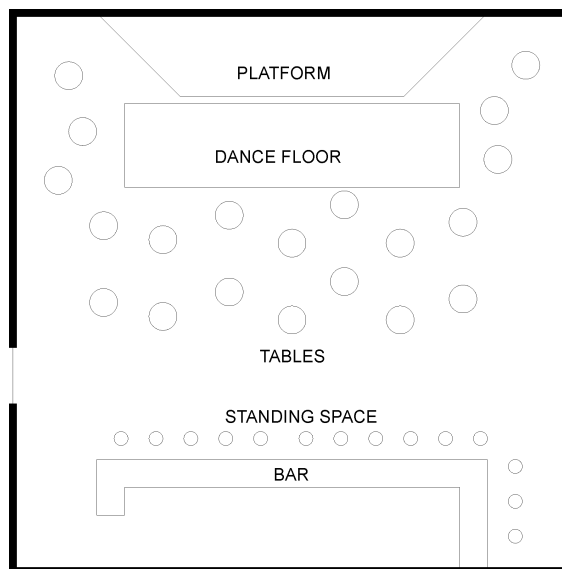

**Example:** The Downtown Club, a popular local nightclub/dance hall, features a different band every weekend (see Commentary Figure 202-O5). It is equipped with a bar and basic kitchen facilities so that beverages and appetizers can be served. There is a platform for a band to perform, a dance floor in front of the platform and numerous cocktail tables and chairs. The tables and chairs are not fixed, resulting in a

hazardous arrangement because there are no distinct aisles. When the band performs, the house lights are dimmed and spotlights are keyed in on the performers. The club is equipped with a sound system that is used at loud levels. The club is open until 3:00 a.m.—the latest time the local jurisdiction will allow.

From this description of the Downtown Club, one can readily see that the appropriate classification is Group A-2. Sometimes, however, it is not this easy to determine the appropriate classification. In such cases, the building official must seek additional information regarding the functions of the building and each area within the building.

Two of the specific uses listed as Group A-2 occupancies are typically not considered as facilities primarily used for food and/or drink consumption, however, their classification as such has been deemed appropriate for varying reasons. The placement of casino gaming areas in the Group A-2 classification is because they share many hazard characteristics with night clubs and, to some extent, the other uses in the category. The presence of distracting lights, sounds and decorations, along with the potential for alcohol consumption, create an assembly environment that is best addressed under the Group A-2 provisions. The classification is specific to the gaming areas of a casino, therefore, other related uses, such as administrative, storage and lodging areas are to be individually classified based upon their specific use.

Although commercial kitchens do not pose the same conditions and concerns as the other uses classified as Group A-2, their classification as such recognizes the relationship that exists between the

**Figure 202-O5**  
**GROUP A-2**

dining and cooking areas. Providing a physical fire-resistive separation between the kitchen and the dining area that it serves is often found to be impractical. Assigning a single occupancy classification for both the commercial kitchen and its associated dining area eliminates any potential for an unnecessary mixed-occupancy condition. This single classification approach can also be applied where the occupant load of the dining area is below 50, allowing for a Group B classification. Under such circumstances, the kitchen would be considered an extension of the Group B dining facility.

**[BG] Assembly Group A-3.** Group A-3 occupancy includes assembly uses intended for worship, recreation or amusement and other assembly uses not classified elsewhere in Group A, including, but not limited to:

- Amusement arcades
- Art galleries
- Bowling alleys
- Community halls
- Courtrooms
- Dance halls (not including food or drink consumption)
- Exhibition halls
- Funeral parlors
- Gymnasiums (without spectator seating)
- Indoor swimming pools (without spectator seating)
- Indoor tennis courts (without spectator seating)
- Lecture halls
- Libraries
- Museums
- Places of religious worship
- Pool and billiard parlors
- Waiting areas in transportation terminals

- ❖ Structures in which people assemble for the purpose of social activities (such as entertainment, recreation and amusement) that are neither classified in Group A-1 or A-2 nor appropriately classified in Group A-4 or A-5 are to be classified in Group A-3. Exhibition halls, libraries, dance halls (not including food and drink), places of religious worship, museums, gymnasiums, recreation centers, health clubs, fellowship halls, indoor shooting galleries, bowling centers and billiard halls are among the facilities often classified in Group A-3. Also, since they most nearly resemble this occupancy classification, public and private spaces used for assembly are often classified in Group A-3. These include large courtrooms, meeting rooms and conference centers. Similarly, lecture rooms located in colleges, universities or in schools for students above the 12th grade that have an occupant load of 50 or more are also classified in Group A-3, as well as structures in which people gather exclusively for worship and other religious purposes. Although such worship and religious purposes are without restriction to any particular sect or creed, the intent of the code is to limit Group A-3 classification to occupancies that are specifically related to worship services, devotions and religious rituals.

The fire hazard in terms of combustible contents (fuel load) in structures classified in Group A-3 is most often expected to be moderate to low. Since structures classified in Group A-3 vary widely as to the purpose for which they are used, the range of fuel load varies widely. For example, the fuel load in a library or an exhibition hall usually is considerably greater than that normally found in a gymnasium.

**[BG] Assembly Group A-4.** Group A-4 occupancy includes assembly uses intended for viewing of indoor sporting events and activities with spectator seating including, but not limited to:

- Arenas
- Skating rinks
- Swimming pools
- Tennis courts

- ❖ Structures provided with spectator seating in which people assemble to watch an indoor sporting event are to be classified as Group A-4. Arenas, skating rinks, swimming pools and tennis courts are among the facilities often classified as Group A-4. The distinguishing factor between Group A-4 and A-5 structures is whether the event is indoors or outdoors. Group A-4 facilities are limited to indoor structures only. The distinguishing factor between Group A-3 and A-4 facilities is the presence of a defined seating area. While Group A-3 facilities are indoors (i.e., tennis courts, swimming pools), they typically do not have a defined seating area in which to view the event. Only facilities that are both indoors and have a defined seating area are to be classified as Group A-4.

**[BG] Assembly Group A-5.** Group A-5 occupancy includes assembly uses intended for participation in or viewing outdoor activities including, but not limited to:

- Amusement park structures
- Bleachers*
- Grandstands
- Stadiums

- ❖ Structures classified in Group A-5 are outdoor facilities where people assemble to view or participate in social and recreational activities (e.g., stadiums, grandstands, bleachers, coliseums). In order to qualify as an outdoor facility, the structure must be one where the products of combustion are freely and rapidly vented to the atmosphere (i.e., a structure without enclosures that would prevent the free movement of smoke from the occupied area to the outside). Any recreation facility that has exterior walls that enclose the facility and a roof that fully covers the area would not be classified in Group A-5, but rather in Group A-3 or A-4 depending on whether a seating area has been provided. In the case of a structure with a retractable roof, the more stringent occupancy classification (i.e., Group A-4) would be required.

Since occupancies classified in Group A-5 are primarily viewing and sports participation areas, the fuel load associated with them is very low (i.e., the structure itself and seats). Since the fuel load present is

## DEFINITIONS

relatively low and the expectation is that smoke will be quickly evacuated from the structure, the relative fire hazard of occupancies classified in Group A-5 is expected to be low. The life safety hazard from panic that might occur in an emergency, however, is a serious concern; hence, the capability of large crowds to exit the structure quickly and orderly during emergencies is an important design consideration (see Section 1029).

Both A-4 and A-5 occupancies will include a variety of uses that support the viewing of sports and similar activities. There will likely be luxury seating suites, locker rooms, toilet facilities and press boxes, which are clearly part of the overall uses of the facility. There may also be offices, food concession stands and merchandise stands which by their use are different occupancies, but are probably within the accessory occupancy limits established in Section 508.2 of the IBC. Because of the multitiered design of most Group A-4 and A-5 occupancies, the limit for accessory occupancies of 10 percent of the story will need to be creatively applied. There may be full-fledged restaurants that are in the same building, but may be open to guests not limited to those attending an event. A Group A-2 occupancy designation is likely the most appropriate classification, and the mixed occupancy conditions would most typically be addressed under the accessory occupancy provisions of Section 508.2 of the IBC.

**[BG] Business Group B.** Business Group B occupancy includes, among others, the use of a building or structure, or a portion thereof, for office, professional or service-type transactions, including storage of records and accounts. Business occupancies shall include, but not be limited to, the following:

- Airport traffic control towers
- Ambulatory care facilities
- Animal hospitals, kennels and pounds
- Banks
- Barber and beauty shops
- Car wash
- Civic administration
- Clinic-outpatient
- Dry cleaning and laundries: pick-up and delivery stations and self-service
- Educational occupancies for students above the 12th grade
- Electronic data processing
- Food processing establishments and commercial kitchens not associated with restaurants, cafeterias and similar dining facilities not more than 2,500 square feet (232 m<sup>2</sup>) in area.
- Laboratories: testing and research
- Motor vehicle showrooms
- Post offices
- Print shops
- Professional services (architects, attorneys, dentists, physicians, engineers, etc.)
- Radio and television stations

Telephone exchanges

Training and skill development not in a school or academic program (This shall include, but not be limited to, tutoring centers, martial arts studios, gymnastics and similar uses regardless of the ages served, and where not classified as a Group A occupancy).

- ❖ The risks to life safety in the business occupancy classification are relatively low. Exposure to the potential effects of fire is limited because business-type facilities most often have low fuel loads, are normally occupied only during the daytime and, with some exceptions, are usually occupied for a set number of hours. The occupants, because of the nature of the use, are typically alert, ambulatory, conscious, aware of their surroundings and generally familiar with the building's features, particularly the means of egress. Historically, this occupancy has one of the better fire safety records for the protection of life and property.

This section identifies the general characteristics and lists examples of occupancies that are classified in Group B. Note that the description recognizes the need for limited storage spaces that are incidental to office occupancies. The accessory storage classified as a Group B occupancy is limited by Section 311.1.1 of the IBC to be no more than 10 percent of a given story of a building. Colleges (educational occupancies for students above grade 12) may have spaces that have an occupant load of more than 50 in a room, but are ancillary to the place of education and used only for programs directly associated with training and education programs (see Section 303.4 of the IBC). For college buildings, similar to other office buildings, if there are spaces with occupant loads of greater than 50, such as cafeterias or lecture halls, by the character of the space and the level of fire hazard, they would be appropriately classified as Group A-2 or A-3, respectively (see IBC Section 302.1). When lecture facilities for large groups (i.e., occupant load of 50 or more) are located within the same building where classrooms with an occupant load less than 50 are found, the building is a mixed occupancy (Groups A-3 and B) and is subject to the provisions of Section 508.

While civic administration covers a broad range of state and local government buildings, many such buildings will have a variety of uses and need to be considered under mixed occupancy provisions. Frequently police stations will include jails or holding cells. Fire stations will be a mix of offices, parking and maintenance facilities for the fire engines and living spaces for the fire fighters. Often a meeting room that is open to the public is also included. This type of facility is a mix of Group A, B, R and S occupancies.

Ambulatory care facilities are those used to provide medical, or similar care, on less than a 24-hour basis to patients who are rendered incapable of self-preservation (see the definition of that term). Frequently

called “day surgery centers” or “ambulatory surgical centers,” ambulatory care facilities perform procedures that render care recipients (patients) temporarily incapable of self-preservation due to the use of nerve blocks, sedation or anesthesia. Due to the condition of the care recipients, the need for medical staff to stabilize the patients before evacuation and the use of medical gases, such as oxygen and nitrous oxide, these types of facilities pose greater fire and life safety hazards than other business occupancies. Accordingly, additional fire protection and means of egress requirements specific to ambulatory care are provided in Section 422 of the IBC.

Facilities that provide medical services for inpatient care where the care recipients (patients) stay for more than 24 hours would be classified as Group I-2. Buildings used as sleep clinics would be classified as Group B since these spaces are not typical dwelling or sleeping units where people live, the occupants are assumed to be capable of self-preservation and the occupants are not living in a supervised environment. Although the patients in a sleep clinic may be sleeping, they can be easily awakened and alerted to an emergency as compared to the patients at an ambulatory care facility.

The code distinguishes between food processing operations that are not directly associated with a restaurant based on size. Those operations 2,500 square feet or smaller fall under the Group B classification. A small catering business would fall under this classification. Other food-related businesses that don't provide a space for their product to be eaten on site, such as a take-out pizza store and neighborhood bakery, would also fall under this classification. A commercial kitchen or food processing facility larger than 2,500 square feet would be classified as a Group F occupancy.

Training and skill development is classified as a Group B occupancy due to the similarity in use of spaces to education above the 12th grade and with professional consultation. Often unions provide training facilities for their members so they can keep up with new materials and updates of regulations. Other facilities can provide one-on-one tutoring such as remedial reading or math skills for students. Training or skill development can include those whose ages are typically associated with grades 12 or earlier. The determination of the appropriate classification requires the building official to consider whether the training is given as part of a traditional educational program. Examples provided by the code allow a range of size in the numbers receiving the training from a one-on-one tutoring situation to large classes of children learning martial arts or ballet. The presence of children does not automatically mean a classification as a Group E. Where the occupant load of a training classroom or space exceeds 50 occupants, a Group A classification may be appropriate for the space, especially if the space is to be used for different activities at different times. If the training room is

used for a martial arts competition, with spectators, on an evening or weekend, then a Group A designation should also be considered.

**[BG] Educational Group E.** Educational Group E occupancy includes, among others, the use of a building or structure, or a portion thereof, by six or more persons at any one time for educational purposes through the 12th grade.

- ❖ The risks to life safety in this occupancy vary with the composition of the facilities and also with the ages of the occupants. In general, children require more safeguards than do older, more mature persons.

This section identifies the criteria for classification of a building in Group E. The two fundamental characteristics of a Group E facility are as follows:

1. The facility is occupied by more than five persons (excluding the instructor); and
2. The purpose of the facility is for educating persons at the 12th-grade level and below, but not including more than five occupants 2<sup>1</sup>/<sub>2</sub> years of age or younger.

It is common for a school to also have gymnasiums (Group A-3), auditoriums (Group A-1), libraries (Group A-3) and offices (Group B). Storage rooms might be classified as either a Group S-1 occupancy, or if less than 10 percent of a story, Group E (see Section 311.1.1 of the IBC). When this occurs, the building is considered as a mixed occupancy condition and is subject to the provisions of Section 508. In accordance with Section 303.1.3 of the IBC, assembly spaces, such as the gymnasium, auditorium, library and cafeteria, do not have to be considered separate occupancies if used for school purposes (see commentary below). For such assembly functions to be considered part of the primary Group E occupancy, the assembly functions must be ancillary and supportive to the educational operation of the building.

Occupancies used for the education of persons above the 12th grade level are not included in Group E. These facilities are occupied by adults who are not expected to require special supervision, direction or instruction in a fire or other emergency.

**[BG] Accessory to places of religious worship.** Religious educational rooms and religious auditoriums, which are accessory to places of religious worship in accordance with Section 508.3.1 of the *International Building Code* and have *occupant loads* of less than 100 per room or space shall be classified as Group A-3 occupancies.

- ❖ In places of religious worship, worship halls, religious educational rooms and religious auditoriums are often all provided in the same building complex. Such religious educational rooms and auditoriums are not to be considered separate occupancies (i.e., Group E). Where such rooms are used at certain times for other than as a religious auditorium or for religious

## DEFINITIONS

education, Section 302 requires that the requirements of each occupancy be applied.

**[BG] Group E, day care facilities.** This group includes buildings and structures or portions thereof occupied by more than five children older than 2½ years of age who receive educational, supervision or *personal care services* for less than 24 hours per day.

- ❖ Group E day care occupancies include facilities intended to be used for the care and supervision of more than five children older than 2½ years of age where individual care is for a period of less than 24 hours per day. Day care centers are a special concern since they are generally occupied by preschool children who are less capable of responding to an emergency. The hazards found in a day care center are far greater than in normal educational facilities, not so much because of the occupant or fuel load, but because of the inability of the occupants to respond.

Children 2½ years of age or younger usually are not able to recognize an emergency situation, respond appropriately or simply be able to egress without assistance; thus, facilities that have more than five children 2½ years of age or younger are classified as child care facilities and considered to be Group I-4 unless the provisions of one of the sub-classifications of that group allow for a different classification.

Locations where child care may be provided that would not be considered Group E, I-4 or I-2 are addressed in Sections 305.2.1 through 305.2.3 of the IBC.

**[BG] Within places of worship.** Rooms and spaces within places of worship providing such care during religious functions shall be classified as part of the primary occupancy.

- ❖ Cry rooms and other types of child care areas within places of worship that are used for this purpose during a religious function need not be classified as Group E day care facilities. Such rooms and spaces may take on the classification of the primary occupancy, which in most cases would be Group A-3. The limited occupant load makes the need for classification as a Group E occupancy unnecessary. If the child care areas are used when there is not a service or other religious function going on simultaneously, such as for child day care during the week, the religious facility would be a mixed use building (see IBC commentary, Section 305.2 or 308.6).

**[BG] Five or fewer children.** A facility having five or fewer children receiving such care shall be classified as part of the primary occupancy.

- ❖ Where a child care facility has no more than five children receiving care at any one time, the classification of the main occupancy may extend to the child care use. The limited number of occupants requiring care

services does not warrant classification as a separate and distinct occupancy from that of the major use.

**[BG] Five or fewer children in a dwelling unit.** A facility such as the above within a dwelling unit and having five or fewer children receiving such care shall be classified as a Group R-3 occupancy or shall comply with the *International Residential Code*.

- ❖ Where the child care services are performed within a single-family dwelling or within a dwelling unit of a two-family dwelling, residential provisions are applicable provided the number of children receiving care does not exceed five. The facility may be classified under the IBC as a Group R-3 occupancy or may be regulated under the provisions of the IRC. Where such a use occurs within a dwelling unit of a Group R-2 multifamily building, it is expected that the child care facility be considered as an extension of the primary Group R-2 classification as with five or fewer children.

**[BG] Factory Industrial Group F.** Factory Industrial Group F occupancy includes, among others, the use of a building or structure, or a portion thereof, for assembling, disassembling, fabricating, finishing, manufacturing, packaging, repair or processing operations that are not classified as a Group H high-hazard or Group S storage occupancy.

- ❖ The purpose of this definition is to identify the characteristics of occupancies that are classified in the factory industrial group and to differentiate Groups F-1 and F-2. Because of the vast number of diverse manufacturing and processing operations in the industrial community, it is more practical to classify such facilities by their level of hazard rather than by their function. In industrial facilities, experience has shown that the loss of life or property is most directly related to fire hazards, particularly the fuel load contributed by the materials being fabricated, assembled or processed.

Statistics show that property losses are comparatively high in factory and industrial occupancies, but the record of fatalities and injuries from fire has been remarkably low. This excellent life safety record can, in part, be attributed to fire protection requirements of the code.

This definition requires that all structures that are used for fabricating, finishing, manufacturing, packaging, assembling or processing products or materials are to be classified in either Group F-1 (moderate hazard) or F-2 (low hazard). These classifications are based on the relative level of hazard for the types of materials that are fabricated, assembled or processed. Where the products and materials in a factory present an extreme fire, explosion or health hazard, such facilities are classified in Group H. It should be noted that the term "Group F" is not a specific occupancy, but is a term that collectively applies to Groups F-1 and F-2.

**[BG] Factory Industrial F-1 Moderate-hazard occupancy.** Factory industrial uses that are not classified as Factory Industrial F-2 Low Hazard shall be classified as F-1 Moderate Hazard and shall include, but not be limited to, the following:

Aircraft (manufacturing, not to include repair)  
 Appliances  
 Athletic equipment  
 Automobiles and other motor vehicles  
 Bakeries  
 Beverages; over 16-percent alcohol content  
 Bicycles  
 Boats  
 Brooms or brushes  
 Business machines  
 Cameras and photo equipment  
 Canvas or similar fabric  
 Carpets and rugs (includes cleaning)  
 Clothing  
 Construction and agricultural machinery  
 Disinfectants  
 Dry cleaning and dyeing  
 Electric generation plants  
 Electronics  
 Engines (including rebuilding)  
 Food processing and commercial kitchens not associated with restaurants, cafeterias and similar dining facilities more than 2,500 square feet (232 m<sup>2</sup>) in area.  
 Furniture  
 Hemp products  
 Jute products  
 Laundries  
 Leather products  
 Machinery  
 Metals  
 Millwork (sash and door)  
 Motion pictures and television filming (without spectators)  
 Musical instruments  
 Optical goods  
 Paper mills or products  
 Photographic film  
 Plastic products  
 Printing or publishing  
 Refuse incineration  
 Shoes  
 Soaps and detergents  
 Textiles  
 Tobacco  
 Trailers  
 Upholstering  
 Wood; distillation  
 Woodworking (cabinet)

- ❖ Structures classified in Group F-1 (moderate hazard) are occupied for the purpose of the fabrication, finishing, manufacturing, packaging, assembly or processing of materials that are combustible or that use

combustible products in the production process. Food processing facilities and commercial kitchens that are 2,500 square feet or smaller in area fall under the Group B occupancy category (see Section 304.1 of the IBC).

**[BG] Factory Industrial F-2 Low-hazard Occupancy.** Factory industrial uses involving the fabrication or manufacturing of noncombustible materials that, during finishing, packaging or processing do not involve a significant fire hazard, shall be classified as Group F-2 occupancies and shall include, but not be limited to, the following:

Beverages; up to and including 16-percent alcohol content  
 Brick and masonry  
 Ceramic products  
 Foundries  
 Glass products  
 Gypsum  
 Ice  
 Metal products (fabrication and assembly)

- ❖ Structures classified in Group F-2 (low hazard) are occupied for the purpose of the fabrication, manufacturing or processing of noncombustible materials. It is acceptable for noncombustible products to be packaged in a combustible material, provided that the fuel load contributed by the packaging is negligible when compared to the amount of noncombustible product. The use of a significant amount of combustible material to package or finish a noncombustible product, however, will result in a Group F-1 (moderate-hazard factory and industrial) classification.

To distinguish when the presence of combustible packaging constitutes a significant fuel load, possibly requiring the reclassification of the building or structure as Group F-1, a reasonable guideline to follow is the "single-thickness" rule, which is when a noncombustible product is put in one layer of packaging material.

Examples of acceptable conditions in Group F-2 are:

- Vehicle engines placed on wood pallets for transportation after assembly;
- Washing machines in corrugated cardboard boxes; and
- Soft-drink glass bottles packaged in pressed paper boxes.

Occupancies involving noncombustible items packaged in more than one layer of combustible packaging material are most appropriately classified in Group F-1.

Typical examples of packaging that would result in a Group F-1 classification are:

- Chinaware wrapped in corrugated paper and placed in cardboard boxes;
- Glassware set in expanded foam forms and placed in cardboard boxes; and

## DEFINITIONS

- Fuel filters individually packed in pressed paper boxes, placed by the gross in a cardboard box and stacked on a pallet for transportation.

Factories and industrial facilities often have offices and areas where large quantities of materials are kept in the same building as manufacturing operations, fabrication processes and assembly processes. The stock areas are classified as either Group S-1 or S-2, depending on the combustibility of the materials stored. Areas used for offices that do not qualify as accessory occupancies (see Section 508.2 of the IBC) are classified in Group B. When these combinations of occupancies occur, as well as other combinations of occupancies, the building is subject to the mixed occupancy provisions in Section 508 of the IBC.

**High-hazard Group H.** High-hazard Group H occupancy includes, among others, the use of a building or structure, or a portion thereof, that involves the manufacturing, processing, generation or storage of materials that constitute a physical or health hazard in quantities in excess of those allowed in *control areas* complying with Section 5003.8.3, based on the maximum allowable quantity limits for *control areas* set forth in Tables 5003.1.1(1) and 5003.1.1(2). Hazardous occupancies are classified in Groups H-1, H-2, H-3, H-4 and H-5 and shall be in accordance with this code and the requirements of Section 415 of the *International Building Code*. Hazardous materials stored or used on top of roofs or canopies shall be classified as outdoor storage or use and shall comply with this code.

- ❖ This occupancy classification identifies the various types of facilities contained in the high-hazard occupancy groups, e.g., those facilities where the storage of materials or the operations are deemed to be extremely hazardous to life and property, especially when they involve the use of significant amounts of highly combustible, flammable or explosive materials, regardless of their composition (i.e., solids, liquids, gases or dust). Although they are not explosive or highly flammable, other hazardous materials, such as corrosive liquids, highly toxic materials and poisonous gases, still present an extreme hazard to life. Many materials possess multiple hazards, whether physical or health related.

There is a wide range of high-hazard operations in the industrial community; therefore, it is more practical to categorize such facilities in terms of the degree of hazard they present, rather than attempt to define a facility in terms of its function. This method is similar to that used to categorize Group F factory and Group S storage occupancies.

Group H is handled as a separate classification because it represents an unusually high degree of hazard that is not found in the other occupancies. It is important to isolate those industrial or storage operations that pose the greatest dangers to life and property and to reduce such hazards by providing systems or elements of protection through the regula-

tory provisions of building codes. There are numerous provisions and exceptions throughout the code that cannot be used when one or more Group H occupancies are present.

Operations that, because of the materials utilized or stored, cause a building or portion of a building to be classified as a high-hazard occupancy are identified in this section. While buildings classified as Group H may not have a large occupant load, the unstable chemical properties of the materials contained on the premises constitute an above-average fuel load and serve as a potential danger to the surrounding area.

The dangers created by the high-hazard materials require special consideration for the abatement of the danger. The classification of a material as high hazard is based on information derived from National Fire Protection Association (NFPA) standards and the Code of Federal Regulations (DOL 29 CFR).

The wide range of materials utilized or stored in buildings creates an equally wide range of hazards to the occupants of the building, the building proper and the surrounding area. Since these hazards range from explosive to corrosive conditions, the high-hazard occupancy has been broken into four subclassifications: Groups H-1 through H-4. A fifth category, Group H-5, is used to represent structures that contain hazardous production material (HPM) facilities. Each of these subclassifications addresses materials that have similar characteristics and the protection requirements attempt to address the hazard involved. These subclassifications are defined by the properties of the materials involved with only occasional reference to specific materials. This performance-based criterion may involve additional research to identify a hazard, but it is the only way to remain current in a rapidly changing field. MSDS will be a major source for information.

Additional information on hazardous materials can be found in Section 415 as well as the commentary to the code.

This definition and Section 307.1 of the IBC acknowledge that a building is not classified as a high-hazard occupancy unless the MAQs per control area as prescribed in Tables 5003.1.1(1) and 5003.1.1(2) [IBC Tables 307.1(1) and 307.1(2)] are exceeded, subject to the applicable control area provisions of Section 5003.8.3 (IBC Section 414.2). The maximum quantity limitations per control area prescribed in Tables 5003.1.1(1) and 5003.1.1(2) [IBC Tables 307.1(1) and 307.1(2)] have been determined to be relatively safe when maintained in accordance with the code. Therefore, a building containing less than the MAQs specified would not be classified as a Group H occupancy but, rather, as the occupancy group it most nearly resembles. The materials in these tables are defined in detail in this chapter.

Section 5003.8.3 (IBC Section 414.2) establishes the control area concept for regulating hazardous materials. This concept would allow the maximum

allowable quantities of hazardous materials per control area in Tables 5003.1.1(1) and 5003.1.1(2) [IBC Tables 307.1(1) and 307.1(2)] to be exceeded within a given building without classifying the building as a high-hazard occupancy by utilizing a multiple control area approach. The permitted number of control areas, maximum percentage of allowable quantities of hazardous materials per control area and degree of fire separation between control areas are regulated by Section 5003.8.3 (IBC Section 414.2) (see the definition of "Control area" and the commentary to Section 5003.8.3).

This definition and Section 307.1 of the IBC also clarify that hazardous materials outside of the building envelope should be classified as outdoor storage. As such, hazardous material quantities on roofs or canopies are not included in evaluating the occupancy classification of a building or structure. Canopies used to support gaseous hydrogen systems must comply with Section 406.7.2.1 of the IBC.

**Uses other than Group H.** The storage, use or handling of hazardous materials as described in one or more of the following items shall not cause the occupancy to be classified as Group H, but it shall be classified as the occupancy that it most nearly resembles:

1. Buildings and structures occupied for the application of flammable finishes, provided that such buildings or areas conform to the requirements of Chapter 24 of this code and Section 416 of the *International Building Code*.
  2. Wholesale and retail sales and storage of flammable and *combustible liquids* in mercantile occupancies conforming to Chapter 57.
  3. Closed piping system containing flammable or *combustible liquids* or gases utilized for the operation of machinery or equipment.
  4. Cleaning establishments that utilize *combustible liquid* solvents having a *flash point* of 140°F (60°C) or higher in *closed systems* employing equipment *listed* by an *approved* testing agency, provided that this occupancy is separated from all other areas of the building by 1-hour *fire barriers* in accordance with Section 707 of the *International Building Code* or 1-hour *horizontal assemblies* in accordance with Section 711 of the *International Building Code*, or both.
  5. Cleaning establishments that utilize a liquid solvent having a *flash point* at or above 200°F (93°C).
  6. Liquor stores and distributors without bulk storage.
  7. Refrigeration systems.
  8. The storage or utilization of materials for agricultural purposes on the premises.
  9. Stationary batteries utilized for facility emergency power, uninterruptible power supply or telecommunication facilities, provided that the batteries are equipped with safety venting caps and ventilation is provided in accordance with the *International Mechanical Code*.
  10. *Corrosive* personal or household products in their original packaging used in retail display.
  11. Commonly used *corrosive* building materials.
  12. Buildings and structures occupied for aerosol storage shall be classified as Group S-1, provided that such buildings conform to the requirements of Chapter 51.
  13. Display and storage of nonflammable solid and nonflammable or noncombustible liquid hazardous materials in quantities not exceeding the *maximum allowable quantity per control area* in Group M or S occupancies complying with Section 5003.8.3.5.
  14. The storage of black powder, smokeless propellant and small arms primers in Groups M and R-3 and special industrial explosive devices in Groups B, F, M and S, provided such storage conforms to the quantity limits and requirements of this code.
- ❖ The exceptions list indicates uses and conditions that are exempt from a high-hazard (Group H) classification because of the building's construction, use, the packaging of materials, the quantity of materials or the precautions taken to prevent fire. Even if a high-hazard material meets one of the exceptions, its storage and use must comply with the applicable provisions of the code and Section 414 of the IBC.
- There are 14 cases where facilities would not be classified a Group H because of the specific type of material; how it is expected to be used or stored, or both; the building's construction and use; the packaging of materials; the quantity of materials or the precautions taken to prevent fire. Even if a high-hazard material meets one of these 14 cases, its storage and use must comply with the applicable provisions of Section 414 of the IBC and this code.
- Item 1 exempts spray painting and similar operations within buildings from being classified as a high-hazard occupancy. This exception requires that all such operations, as well as the handling of flammable finishes, are in accordance with the provisions of Section 416 of the IBC and Chapter 24 of the code; therefore, an adequately protected typical paint spray booth in a factory (Group F-1) would not result in a high-hazard occupancy classification for either the building or the paint spray area.
- Item 2 relies on the provisions of Section 5704.3.4.1 to regulate the storage of flammable and combustible liquids for wholesale and retail sales and storage in mercantile occupancies. The overall permitted amount of flammable and combustible liquids is dependent on the class of liquid, storage arrangement, container size and level of sprinkler protection. For nonsprinklered buildings, the maximum allowable quantity per control area permitted by Table

## DEFINITIONS

5704.3.4.1 is 1,600 gallons (6057 L) of Class IB, IC, II, and IIIA liquids with a maximum of 60 gallons (227 L) of Class IA liquids. Depending on storage and ceiling heights, buildings equipped with a sprinkler system with a minimum design density for an Ordinary Hazard Group 2 occupancy may have an aggregate total of 7,500 gallons (28 391 L) of Class IB, IC, II, and IIIA liquids with a maximum of 60 gallons (227 L) of Class IA liquids. The quantities of Class IB, IC, II and IIA liquids could be further increased depending on the potential storage conditions and enhanced degree of sprinkler protection (see Section 5703.3.4.1 for additional design information). Again, it should be noted, that despite the increased quantities which far exceed the base quantity limitations of Table 5003.1.1(1) [IBC Table 307.1(1)], compliance with this item would result in the building not being classified as a Group H occupancy.

Item 3 exempts from Group H classification closed systems that are used exclusively for the operation of machinery or equipment. The closed piping systems, which are essentially not open to the atmosphere, keep flammable or combustible liquids from direct exposure to external sources of ignition as well as prevent the users from coming in direct contact with liquids or harmful vapors. This item would include systems such as oil-burning equipment, piping for diesel fuel generators and LP-gas cylinders for use in forklift trucks.

Item 4 allows cleaning establishments that utilize a closed system for all combustible liquid solvents with a flash point at or above 140°F (60°C) to be classified as something other than Group H. The reference to using equipment listed by an approved testing laboratory does not mean that the entire system needs to be approved, but rather the individual pieces of equipment. As with any mechanical equipment or appliance, it should bear the label of an approved agency and be installed in accordance with the manufacturer's installation instructions (see the IMC).

Item 5 covers cleaning establishments that use solvents that have very high flash points [at least 200°F (93°C)] and that are exceedingly difficult to ignite. Such liquids can be used openly, but with due care.

Item 6 exempts all retail liquor stores and liquor distribution facilities from the high-hazard occupancy classification, even though most of the contents are considered combustible liquids. The item takes into account that alcoholic beverages are packaged in individual containers of limited size.

Item 7 refers to refrigeration systems that utilize refrigerants that may be flammable or toxic. Refrigeration systems do not alter the occupancy classification of the building, provided they are installed in accordance with the IMC. The IMC has specific limitations on the quantity and type of refrigerants that can be used, depending on the occupancy classification of the building.

Item 8 addresses materials that are used for agri-

cultural purposes, such as fertilizers, pesticides, and fungicides, when used on the premises. Agricultural materials stored for direct or immediate use are not usually of large enough quantity that would constitute a large fuel load or an exceptionally hazardous condition. A group H classification is not appropriate for these situations.

Item 9 addresses battery storage rooms when used as part of an operating system, such as for providing standby power. The batteries used in installations of this type do not represent a significant health, safety or fire hazard. The electrolyte and battery casing contribute little fuel load to a fire. The release of hydrogen gas during the operation of battery systems is minimal. Ventilation in accordance with the IMC will disperse the small amounts of liberated hydrogen. This exception also assumes that rooms containing stationary storage battery systems are in compliance with Section 608 and the enclosure requirements of Table 509 of the IBC.

Without Item 10, certain products that technically are corrosive could cause grocery stores and other mercantile occupancies to be inappropriately classified as Group H-4. This item allows the MAQ in Table 5003.1.1(2) [IBC Table 307.1(2)] for corrosives to be exceeded in the retail display area. This would include such things as bleaches, detergents and other household cleaning supplies in normal-size containers.

Item 11 exempts the storage or manufacture of commonly used building materials, such as Portland cement, from being inappropriately classified as Group H.

Item 12 exempts from a Group H classification those buildings and structures used for the storage of aerosol products, provided they are protected in accordance with the provisions of Chapter 51 and NFPA 30B and the code. The aerosol storage requirements of the code referred to in this item are based on the provisions of NFPA 30B. Compliance with this item exempts buildings from complying with the code provisions for Group H, provided the storage of aerosol products complies with the applicable separation, storage limitations and sprinkler design requirements specified in the code and NFPA 30B.

Item 13 permits certain products found in mercantile and storage occupancies, which may be comprised of hazardous materials, to exceed the MAQ of Tables 5003.1.1(1) and 5003.1.1(2) [IBC Tables 307.1(1) and 307.1(2)]. The products, however, must be comprised of nonflammable solids or liquids that are nonflammable or noncombustible. Materials could include swimming pool chemicals, which are typically Class 2 or 3 oxidizers or industrial corrosive cleaning agents (see commentary, Section 5003.8.3.5).

Item 14 permits the base maximum allowable quantity per control area of black powder, smokeless propellant and small arms primers in Group M and R-3 occupancies to be exceeded, provided the material is stored in accordance with Chapter 56. The require-

ments are based on the provisions in NFPA 495. Similarly, special industrial explosive devices are found in a number of occupancies other than Group H (Groups B, F, M and S). Storage of these devices in accordance with the code is not required to have a high-hazard occupancy classification. Power drivers are commonly used in the construction industry, and there are stocks of these materials maintained for sale and use by the trade. The automotive airbag industry has evolved with the use of these devices, and they are located in automotive dealerships and personal use vehicles throughout society. The code currently exempts up to 50 pounds (23 kg) of these materials from regulation under Chapter 56.

**High-hazard Group H-1.** Buildings and structures containing materials that pose a *detonation* hazard shall be classified as Group H-1. Such materials shall include, but not be limited to, the following:

Detonable pyrophoric materials

Explosives:

Division 1.1

Division 1.2

Division 1.3

Division 1.4

Division 1.5

Division 1.6

Organic peroxides, unclassified detonable

Oxidizers, Class 4

Unstable (reactive) materials, Class 3 detonable, and Class 4

- ❖ The contents of occupancies in Group H-1 present a detonation hazard. Examples of materials that create this hazard are listed in the definition. The definitions for Group H-1 materials are listed in Section 5602 and defined in Chapter 2. Because of the explosion hazard potential associated with Group H-1 materials, occupancies in Group H-1, which exceed the MAQ indicated in Table 5003.1.1(1) [IBC Table 307.1(1)], are required to be located in detached one-story buildings without basements (see commentary to Section 5003.8.2 and IBC Sections 415.6.2, 415.7 and 508.3). Group H-1 occupancies cannot be located in a mixed occupancy building.

**Occupancies containing explosives not classified as H-1.** The following occupancies containing explosive materials shall be classified as follows:

1. Division 1.3 explosive materials that are used and maintained in a form where either confinement or configuration will not elevate the hazard from a mass fire hazard to mass explosion hazard shall be allowed in Group H-2 occupancies.
2. Articles, including articles packaged for shipment, that are not regulated as a Division 1.4 explosive under Bureau of Alcohol, Tobacco, Firearms and Explosives regulations, or unpackaged articles used in process operations that do not propagate a *detona-*

*tion* or deflagration between articles shall be allowed in H-3 occupancies.

- ❖ There are certain explosive materials that pose a hazard level less than that anticipated for a Group H-1 occupancy. A Group H-2 classification is permitted for Division 1.3 explosive materials used or maintained under conditions where the hazard level will not rise from that of a mass fire hazard to a mass explosion hazard. A Group H-3 occupancy classification is permitted for packaged and unpackaged articles not regulated as Division 1.4 explosives by the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF), as well as unpackaged articles used in process operations, provided there is no concern regarding the propagation of a detonation or deflagration between the articles during process operations.

**High-hazard Group H-2.** Buildings and structures containing materials that pose a *deflagration* hazard or a hazard from accelerated burning shall be classified as Group H-2. Such materials shall include, but not be limited to, the following:

Class I, II or IIIA flammable or *combustible liquids* that are used or stored in normally open containers or systems, or in closed containers or systems pressurized at more than 15 pounds per square inch gauge (103.4 kPa)

*Combustible dusts* where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 414.1.3 of the *International Building Code*

*Cryogenic fluids*, flammable

Flammable gases

Organic peroxides, Class I

Oxidizers, Class 3, that are used or stored in normally open containers or systems, or in closed containers or systems pressurized at more than 15 pounds per square inch gauge (103.4 kPa)

Pyrophoric liquids, solids and gases, nondetonable

Unstable (reactive) materials, Class 3, nondetonable

Water-reactive materials, Class 3

- ❖ The contents of occupancies in Group H-2 present a deflagration or accelerated burning hazard. Examples of materials that create this hazard are listed. The definitions for Group H-2 materials are contained in Chapter 2 also. Because of the severe fire or reactivity hazard associated with these types of materials, proper classification is essential in determining the applicable requirements with regard to the mitigation of these hazards.

**High-hazard Group H-3.** Buildings and structures containing materials that readily support combustion or that pose a *physical hazard* shall be classified as Group H-3. Such materials shall include, but not be limited to, the following:

Combustible fibers, other than densely packed baled cotton, where manufactured, generated or used in

## DEFINITIONS

such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 414.1.3 of the *International Building Code*

Consumer fireworks, 1.4G (Class C, Common)

Cryogenic fluids, oxidizing

Flammable solids

Organic peroxides, Class II and III

Oxidizers, Class 2

Oxidizers, Class 3, that are used or stored in normally closed containers or systems pressurized at 15 pounds per square inch gauge (103 kPa) or less

Oxidizing gases

Unstable (reactive) materials, Class 2

Water-reactive materials, Class 2

- ❖ The contents of occupancies in Group H-3 present a hazard inasmuch as they contain materials that readily support combustion or that present a physical hazard. Examples of materials that create this hazard are listed in the definition. The definitions for Group H-3 materials are contained in Chapter 2 also. While Group H-3 materials are generally less of a fire or reactivity hazard than Group H-2 materials, they still present a greater physical hazard than materials not currently regulated as high hazard.

**High-hazard Group H-4.** Buildings and structures containing materials that are *health hazards* shall be classified as Group H-4. Such materials shall include, but not be limited to, the following:

*Corrosives*

Highly toxic materials

Toxic materials

- ❖ The contents of occupancies in Group H-4 present a hazard inasmuch as they contain materials that are health hazards. Examples of these hazards are listed in this definition. The definitions for Group H-4 materials are contained in Chapter 2 also. While reference is made to chemicals that cause these hazards, the MSDS for these chemicals, which are furnished by the applicant, will need considerable subjective evaluation.

Some materials falling into the category of health hazard may also present a physical hazard and would, therefore, require the structure to be designed for multiple hazards in accordance with Section 5001.1 of the code and Section 307.8 of the IBC.

**High-hazard Group H-5.** Semiconductor fabrication facilities and comparable research and development areas in which hazardous production materials (HPM) are used and the aggregate quantity of materials is in excess of those listed in Tables 5003.1.1(1) and 5003.1.1(2) shall be classified as Group H-5. Such facilities and areas shall be designed and constructed in accordance with Section 415.11 of the *International Building Code*.

- ❖ HPM includes flammable liquids and gases, corrosives, oxidizers and, in many instances, highly toxic materials (see the definition for "Hazardous production material"). In determining the applicable require-

ments of other sections of the code, HPM facilities are considered to be Group H-5 occupancies. It is intended that the quantities of materials permitted in Table 2704.2.2.1 will take precedence over Tables 5003.1.1(1) and 5003.1.1(2).

**[BG] Institutional Group I.** Institutional Group I occupancy includes, among others, the use of a building or structure, or a portion thereof, in which care or supervision is provided to persons who are or are not capable of self-preservation without physical assistance or in which persons are detained for penal or correctional purposes or in which the liberty of the occupants is restricted. Institutional occupancies shall be classified as Group I-1, I-2, I-3 or I-4.

- ❖ Institutional occupancies are comprised of two basic types. The first, Group I-1, I-2 and I-4, relates to facilities that provide personal care, custodial care or medical care for people who, due to age; physical limitations; diseases; mental disabilities; or other infirmities, need a supervised environment (see the commentary for the definitions of "Custodial care," "Medical care" and "Personal care service"). This includes persons who are ambulatory and are capable of self-preservation as well as those who are restricted in their mobility or are totally immobile to the extent that they are incapable of self-preservation and therefore may need assistance to evacuate during an emergency situation, such as a fire. The IFC also addresses the idea of a defend-in-place protection option for hospitals and nursing homes (see the commentary for the definition of "Incapable of self-preservation" and Sections 403 and 404). The second type, Group I-3, relates primarily to detention and correctional facilities. Since security is the major operational consideration in these kinds of facilities, the occupants (inmates) are under some form of supervision and restraint and may be rendered incapable of self-preservation without direct intervention from staff in emergency situations due to locked cells and exits.

The degree of hazards in each type of institutional facility identified in this section varies respective to each kind of occupancy. The code addresses each occupancy separately and the regulatory provisions throughout the code provide the proper means of protection so as to produce an acceptable level of safety to life and property.

Groups I-1, I-2 and I-3 are further divided into "conditions" relative to unique aspects of the respective occupancies. Group I-1 and R-4 are closely related and are primarily distinguished by the number of persons residing in the facility (see Section 308.3).

Another of the distinguishing characteristics between the different Group I occupancies and other occupancies is when care is provided for a length of time exceeding 24-hours. The intent is that this criteria is not specific to the hours of operation of the facility, but the length of time that care is provided for the patients, residents or those in day care. For example, an outpatient clinic that is open 24 hours a day is a

Group B occupancy provided care recipients are treated as outpatients and there are no in-patients that would stay at the facility 24 hours or longer. Another example would be a “day care” facility that is open 24 hours to serve workers who work any shift and need to have children in “day care” while they work. Provided that individual children receive care for less than 24 hours, the occupancy would be classified as a Group I-4 or possibly a Group E.

Each individual facility will have unique characteristics or a combination of characteristics that should be considered when classifying it to one occupancy and condition or another. For example, some of the newer care facilities are offering a combination of care levels to allow for persons to age-in-place within the same complex. A facility could easily have a mix of occupancies such as one wing providing full-time nursing care (Group I-2 Condition 1), a second wing may provide assisted living care for residents with dementia so they may need direct physical contact from staff to react to an emergency (Group I-1 Condition 2), and yet a third wing may provide custodial care where residents are capable of responding to an emergency on their own (Group I-2 Condition 1). Health care and custodial care facilities are subject to many state and some local regulations. Such regulations may be a determining factor in deciding which IBC occupancy classification is appropriate.

**[BG] Institutional Group I-1.** Institutional Group I-1 occupancy shall include buildings, structures or portions thereof for more than 16 persons, excluding staff, who reside on a 24-hour basis in a supervised environment and receive custodial care. Buildings of Group I-1 shall be classified as one of the occupancy conditions indicated below. This group shall include, but not be limited to, the following:

- Alcohol and drug centers
- Assisted living facilities
- Congregate care facilities
- Group homes
- Halfway houses
- Residential board and care facilities
- Residential board and custodial care facilities
- Social rehabilitation facilities

- ❖ Group I-4 and R-4 occupancies are similar facilities that differ only by the number of residents receiving care. Group I-1 and R-4 occupancies are based on four characterizations described in the occupancy classification: both are facilities where custodial care is provided, there is 24-hour-a day supervision and the occupancy is either Condition 1 or Condition 2. The difference is the number of persons receiving care and residing in such facilities: Group I-1 has greater than 16 residents; Group R-4 has six to 16 persons. Note that Group I-1 and R-4 occupancies are limited facilities where custodial care is provided and not where medical care is provided (see the commentary to “Custodial care” and “Medical care”). Both Group I-1 and R-4 occupancies list the same eight

generic uses as example uses falling under the Group I-1/R-4 umbrella. Of these eight, only “Group home” is defined (see commentary to this definition). Some of these terms may be used in state and local regulations of care facilities. Caution should be taken before assuming that a state-defined “assisted living” facility should be classified under the IBC as a Group I-1 and R-4 occupancy.

Both Groups I-1 and R-4 include “conditions” to cover the variety of acuity and ability levels of custodial care recipients. Group I-1 Condition 1 and Group R-4 Condition 1 occupancies match requirements for previous editions of the code for Groups I-1 and R-4, before conditions were included. The intent of the conditions was to address the concerns that some residents may need limited assistance or verbal direction to evacuate. The building protection offered for Groups I-1 and R-4 occupancies in previous editions of the code is maintained in Condition 1. Some additional requirements were added for Condition 2. Note that this is custodial care. Where nursing care is provided, the facility is a Group I-2 Condition 1. The Condition 1 care recipients may be slower during evacuation but all are capable of emergency evacuation without any physical assistance from others; however, they require no more than only minor verbal queuing from others during emergencies, as might be expected in the general population. Condition 2 custodial care recipients are also slower to evacuate and include any care recipients who may require limited assistance during evacuation. Group I-1 Condition 2 and Group R-4 Condition 2 integrates additional protection features, such as smoke barriers to subdivide the building and increased automatic sprinkler requirements.

In Group I-1 Condition 2 and Group R-4 Condition 2 facilities, assistance with evacuation can occur either because of care recipients’ physical or mental limitations, or both. The Condition 2 assistance with evacuation includes help getting out of bed into a wheelchair or walker, or help initiating ambulation. It includes continued physical assistance getting out of the building from a sleeping room, apartment or other rooms during an emergency. Assistance with evacuation includes assisting persons who may have resistance or confusion in response to an alarm, or require help with instructions. It can also include help for persons with short periods of impaired intermittent consciousness due to medications or illness. Custodial care Group I-1 Condition 2 and Group R-4 Condition 2 evacuation assistance is limited and does not include moving occupants in beds or stretchers during emergencies, as is allowed in Group I-2 medical care.

How individual state licensing agencies name, classify and regulate many of the uses listed in Groups I-1 and R-4 vary significantly from state to state and may not line up with the IBC classifications. It is for this reason that Group I-1 and R-4 lists of uses are included under the general occupancy classification and not under each “condition.” The building

## DEFINITIONS

permit applicant should confirm how the specific state licensing regulations correlate to the code's care type, occupancy, condition, evacuation capability and number of persons receiving care. The permit application drawings should identify the five criteria, while specifically noting that the state licensing regulations limit occupants to only include Condition 1 criteria or allow Condition 2 criteria. Most assisted living facilities and many residential board and care facilities will be classified as Group I-1 Condition 1 or R-4 Condition 1. Generally, almost all specially designated Alzheimer's/memory care facilities providing custodial care will be classified as Group I-1 Condition 2 or Group R-4 Condition 2, due to the inability of some residents to recognize how to respond to an emergency situation. Note that nursing facilities with specialized dementia wings that provide medical care would be classified as Group I-2 Condition 1. Also, it is important to keep in mind that facilities that may be classified initially as Group I-1 Condition 1 (capable of self-preservation) or R-4 Condition 1 can very easily need to be reclassified as a Group I-1/R-4 Condition 2 or as a Group I-2 Condition 1 if the abilities of the persons receiving care change over time. Therefore, it is essential for the proponents of a new facility to present to the building official information regarding the full range of patients and residents expected at a facility both initially and over time.

The occupant load for occupancy classification purposes refers to the number of care recipients only. The number of guests or staff is not included. Note however, that the number of guests and staff is included for means of egress purposes.

For clarification purposes, a dormitory or apartment complex that houses only elderly people and has a nonmedically trained live-in manager is not classified as an institutional occupancy but, rather, as a residential occupancy (see the Group R definitions). A critical phrase in the code to consider when evaluating this type of facility is "live in a supervised residential environment." Such dormitories or apartment complexes may contain features, such as special emergency call switches, that are located in each dwelling unit, and that are monitored by health center staff. These emergency call switches are a convenience and do not necessarily indicate infirmity of the care recipients.

**[BG] Condition 1.** This occupancy condition shall include buildings in which all persons receiving custodial care who, without any assistance, are capable of responding to an emergency situation to complete building evacuation.

- ❖ See the general commentary to Group I-1 occupancies.

**[BG] Condition 2.** This occupancy condition shall include buildings in which there are any persons receiving custodial care who require limited verbal or

physical assistance while responding to an emergency situation to complete building evacuation.

- ❖ See the general commentary to Group I-1 occupancies.

**[BG] Six to 16 persons receiving custodial care.** A facility housing not fewer than six and not more than 16 persons receiving custodial care shall be classified as Group R-4.

- ❖ Any building that has the characteristics of a Group I-1 occupancy but that has more than five and not more than 16 persons receiving custodial care is classified as Group R-4 (see Section 310.6). Ninety-eight percent of households in the U.S. have less than 16 occupants; thus the limit of 16 is considered appropriate for a residential occupancy. Similar to Group I-1, Group R-4 is also divided into a Condition 1 and Condition 2.

**[BG] Five or fewer persons receiving custodial care.** A facility with five or fewer persons receiving custodial care shall be classified as Group R-3 or shall comply with the *International Residential Code* provided an *automatic sprinkler system* is installed in accordance with Section 903.3.1.3 or with Section P2904 of the *International Residential Code*.

- ❖ Any building that has the characteristics of a Group I-1 occupancy (either Condition 1 or Condition 2, or both) but has five or fewer persons receiving custodial care is classified as Group R-3 (see Section 310.5) or may be constructed in accordance with the *International Residential Code*® (IRC®) (see IBC Section 310.5.1). When the code allows compliance in accordance with the IRC, the only requirements that would apply would be those of the IRC, including the installation of automatic sprinkler protection. The intent is to allow persons to be cared for in a residential or home environment, often under the care of family members. Please note similar provisions for Group E occupancies as well as Groups I-2 and I-4.

**[BG] Institutional Group I-2.** Institutional Group I-2 occupancy shall include buildings and structures used for medical care on a 24-hour basis for more than five persons who are not capable of self-preservation. This group shall include, but not be limited to, the following:

- Foster care facilities
- Detoxification facilities
- Hospitals
- Nursing homes
- Psychiatric hospitals

- ❖ An occupancy classified in Group I-2 is characterized by three conditions: it is a health care facility where the level of care offered is medical care, there is 24-hour-a-day medical supervision for the individuals receiving care and patients/residents require physical assistance by staff or others to reach safety in an emergency situation (see the definitions for "24-hour basis," "Custodial care" and "Medical care," and the

five facility examples listed). Where a facility offers medical care instead of custodial care, it is assumed that residents may not be capable of self-preservation. This assessment of the level of care provided needs to be taken with caution and reliance on other state and federal guidelines and associated regulations may be necessary. Also, it is important to keep in mind that facilities that may be classified initially as Group I-1 Condition 1 (capable of self-preservation) or R-4 Condition 1 can very easily need to be reclassified as a Group I-1/R-4 Condition 2 or as a Group I-2 Condition 1 if the abilities of the persons receiving care change over time. Therefore, it is essential for the proponents of a new facility to present information to the building official regarding the full range of patients and residents expected at a facility both initially and over time.

Due to the diversification of how medical care is provided in the five characteristic occupancies currently specified in the IBC for Group I-2 occupancies, the Group I-2 occupancy has been split into two basic conditions: Condition 1, long-term care (nursing homes) and Condition 2, short-term care (hospitals). Although both of these subsets are based on medical treatment and are occupancies within which the occupants are protected with a defend-in-place method of safety, changes in the delivery of care in the two different conditions has changed in the past 10-20 years. Some examples of these changes include:

- Within hospitals, there has been a general increase in the floor area per patient due to the increase in diagnostic equipment and the movement towards single-occupant patient rooms.
- Within nursing homes, there has been a trend to provide more residential-type accommodations, such as group/suite living, gathering areas and cooking facilities in residential areas.

The most common examples of facilities classified in Group I-2 are hospitals (Condition 2) and nursing homes (Condition 1). Other facilities included are detoxification facilities, foster care facilities and psychiatric hospitals. How individual state licensing agencies name, classify and regulate many of the uses listed in Groups I-2 varies significantly from state to state and may not line up with the IBC classifications. It is for this reason that the Group I-2 list of uses is included under the general occupancy classification and not under each “condition.”

The benefit to the “condition” concept is that a majority of code requirements will still apply to all Group I-2 occupancies such as mechanical systems, property maintenance and rehabilitation, but will provide for the opportunity for specific code requirements that apply to the different levels of care and acuity that are found in different facility types; thus allowing for the establishment of specific code

requirements that are based on the operation of the facility.

It is not uncommon to find dining rooms (Group A-2), staff offices (Group B), gift shops (Group M), laundries (Group F) and other nonmedically related areas in buildings otherwise classified as Group I-2. Where such other occupancies occur, the building is considered as a mixed occupancy and subject to the provisions of Section 508. In addition to the general requirements contained in this section, Section 407 contains specific requirements for Group I-2.

**[BG] Occupancy Conditions.** Buildings of Group I-2 shall be classified as one of the following occupancy conditions:

- ❖ A distinction is made between Condition 1 and Condition 2 for Group I-2 occupancies. Section 407 of the IBC provides many requirements that apply to both conditions under the Group I-2 occupancy.

**[BG] Condition 1.** This occupancy condition shall include facilities that provide nursing and medical care but do not provide emergency care, surgery, obstetrics, or in-patient stabilization units for psychiatric or detoxification, including, but not limited to, nursing homes and foster care facilities.

- ❖ The principal use in this category is nursing homes. Typically facilities providing long-term medical care but not the types of care typically found in hospitals. Foster care facilities, by Chapter 2 definition are those where children up to 2½ years old receive care. Foster care for more than five infants and toddlers would also be classified as Group I-2 Condition 1. Foster care facilities that provide care for five or more children older than 2½ would typically be Group I-1/R-4 Condition 1, based on supervised living and capability of the residents.

**[BG] Condition 2.** This occupancy condition shall include facilities that provide nursing and medical care and could provide emergency care, surgery, obstetrics, or inpatient stabilization units for psychiatric or detoxification, including, but not limited to, hospitals.

- ❖ Hospitals and psychiatric hospitals are both included in the Condition 2 category of the I-2 occupancy. Treatment is usually for periods longer than 24 hours and provides medical care not typically available in long-term nursing care facilities.

**[BG] Five or fewer persons receiving medical care.** A facility with five or fewer persons receiving medical care shall be classified as Group R-3 or shall comply with the *International Residential Code* provided an *automatic sprinkler system* is installed in accordance with Section 903.3.1.3 or with Section P2904 of the *International Residential Code*.

- ❖ Any facility that has the characteristics of a Group I-2 occupancy but does not have more than five persons receiving care at any one time is to be classified as a Group R-3 occupancy. As an option, the facility may

## DEFINITIONS

be designed and constructed under the provisions of the IRC, provided the building has a sprinkler system. The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members. The persons receiving the care do not need to be capable of self-preservation. The sprinkler system is to comply with the requirements for an NFPA 13D system or those of Section P2904 of the IRC. Please note similar provisions for Group E occupancies as well as Groups I-1 and I-4.

**[BG] Institutional Group I-3.** Institutional Group I-3 occupancy shall include buildings and structures which are inhabited by more than five persons who are under restraint or security. A Group I-3 facility is occupied by persons who are generally incapable of self-preservation due to security measures not under the occupants' control. This group shall include, but not be limited to, the following:

- Correctional centers
- Detention centers
- Jails
- Pre-release centers
- Prisons
- Reformatories

Buildings of Group I-3 shall be classified as one of the following occupancy conditions:

- ❖ An occupancy classified in Group I-3 is characterized by three conditions: it is a location where persons are under restraint or where security is closely supervised, there are more than five such persons and they are not capable of self-preservation because the conditions of confinement are not under their control (i.e., they require assistance by the facilities' staff to reach safety in an emergency situation). For occupancy classification purposes, the provision refers to the number of persons being secured or restrained only. The number of guests or staff is not included. Please note, however, that the number of guests and staff is included for means of egress purposes.

Buildings that have these characteristics but that contain no more than five persons who are being secured or restrained are to be classified based upon the function to which they are associated. For example, the small holding cell in a Group B police station having only the one cell would simply be classified as a portion of the Group B occupancy. Regardless of the occupancy classification, the means of egress provisions for places of restraint are still applicable (see Chapter 10).

It is recognized that not all Group I-3 occupancies have the same level of restraint; thus, to distinguish these different levels, the code defines five different conditions of occupancy based on the degree of access to the exit discharge.

**[BG] Condition 1.** This occupancy condition shall include buildings in which free movement is allowed from sleeping areas and other spaces where access or occupancy is permitted to the exterior via *means of*

*egress* without restraint. A Condition 1 facility is permitted to be constructed as Group R.

- ❖ Condition 1 areas are those where the occupants have unrestrained access to the exterior of the building. As such, a key or remote-control release device is not needed for any occupant to reach the exterior of the building (exit discharge) at any time. These types of buildings are referred to as "low-security facilities." A work-release center is a typical Condition 1 facility. Because of the lack of restraint associated with a Condition 1 building, it resembles a residential use more than a detention facility and, therefore, is permitted to be classified in Group R (see the definitions for "Group R" in this chapter).

**[BG] Condition 2.** This occupancy condition shall include buildings in which free movement is allowed from sleeping areas and any other occupied smoke compartment to one or more other smoke compartments. Egress to the exterior is impeded by locked *exits*.

- ❖ Condition 2 areas are those in which the movement of occupants is not controlled within the exterior walls of the building (i.e., the occupants have unrestrained access within the building). As such, there is free movement by the occupants between smoke compartments (as created by smoke barriers); however, the occupants must rely on someone else to allow them to exit the building to the area of discharge.

**[BG] Condition 3.** This occupancy condition shall include buildings in which free movement is allowed within individual smoke compartments, such as within a residential unit comprised of individual *sleeping units* and group activity spaces, where egress is impeded by remote-controlled release of *means of egress* from such smoke compartment to another smoke compartment.

- ❖ Condition 3 areas are those in which free movement by the occupants is permitted within an individual smoke compartment; however, movement of occupants from one smoke compartment (as created by smoke barriers) to another smoke compartment and from within the building to the exterior (exit discharge) is controlled by remote-release locking devices. As such, the occupants in the facility are dependent on the staff for their release from each smoke compartment or to the exterior (exit discharge).

**[BG] Condition 4.** This occupancy condition shall include buildings in which free movement is restricted from an occupied space. Remote-controlled release is provided to permit movement from *sleeping units*, activity spaces and other occupied areas within the smoke compartment to other smoke compartments.

- ❖ Condition 4 areas are those in which the movement of restrained persons from any room or space within a smoke compartment (as created by smoke barriers) to another smoke compartment or to the exterior (exit discharge) is controlled by remote release locking devices. Any movement within the facility requires

activation of a remote control lock system to release the designated area. The persons being restrained or secured within a Condition 4 area must rely on an activation system in the event of an emergency in order to evacuate the area.

Condition 4 facilities most often are penal facilities where the restrained persons are considered relatively safe to handle in large groups. As such, many persons can be released simultaneously from their individual sleeping areas when they need to travel to dining areas or move to another area.

**[BG] Condition 5.** This occupancy condition shall include buildings in which free movement is restricted from an occupied space. Staff-controlled manual release is provided to permit movement from *sleeping units*, activity spaces and other occupied areas within the smoke compartment to other smoke compartments.

- ❖ Condition 5 areas are those in which the persons being secured or restrained are not allowed free movement to any other room or space within a smoke compartment (as created by smoke barriers) to another smoke compartment or to the exterior (exit discharge) unless the locking device controlling their area of confinement is manually released by a staff member. Once released from an individual space, a staff member is responsible for unlocking all doors from that location to the next smoke compartment. This is the most restrictive occupancy condition, as each secured person must be released on an individual basis and escorted to other areas.

Condition 5 facilities are most often used for maximum security or solitary confinement areas where the persons are considered to be dangerous to others, including staff members, and cannot safely be handled in large groups.

**[BG] Institutional Group I-4, day care facilities.** Institutional Group I-4 shall include buildings and structures occupied by more than five persons of any age who receive custodial care for less than 24 hours by persons other than parents or guardians, relatives by blood, marriage, or adoption, and in a place other than the home of the person cared for. This group shall include, but not be limited to, the following:

Adult day care  
Child day care

- ❖ Facilities that contain provisions for the custodial care of more than five persons of any age are classified as Group I-4 (see definitions of “Custodial care” and “Personal care service”). Group I-4 facilities are less restrictive in some of the requirements (e.g., height and area) than the other Group I occupancies. Group I-4 facilities are intended to be used to provide care for less than 24 hours. Day care facilities are not intended to be a full-time residence for the people receiving care. The staff members are assumed not to be related to the individuals in the day care facilities. The premise of the provisions is that the numbers receiving care are exclusive of staff. The care

recipients in a Group I-4 occupancy are not expected to respond to an emergency without physical assistance from others. Group I-4 occupancies include both adult day care and child day care.

Adult care facilities are assumed to be for people other than children who require some type of custodial care (i.e., nonmedical). A facility where adults gather for social activities such as a community center or a YMCA is not an adult care facility (Group I) and would be regulated under other provisions of the code (Group A-3 or B). The classification of Group I-4 for an adult day care facility does not apply to facilities that provide personal care services for adults who are capable of responding to an emergency unassisted. In that case, the facility is simply classified into the occupancy group it most resembles. A facility providing a similar degree of custodial care for infants and toddlers on less than a 24-hour-per-day basis would be considered as a Group I-4 day care facility.

**[BG] Classification as Group E.** A child day care facility that provides care for more than five but not more than 100 children 2½ years or less of age, where the rooms in which the children are cared for are located on a *level of exit discharge* serving such rooms and each of these child care rooms has an *exit* door directly to the exterior, shall be classified as Group E.

- ❖ Children 2½ years of age or less (i.e., infants and toddlers) typically are not capable of independently responding to an emergency and must be led or carried to safety. Under such circumstances, the infants and toddlers are considered nonambulatory. Therefore, a Group I-4 classification is given to those facilities where six or more infants and toddlers receive custodial care for less than 24 hours per day. A similar condition is found in foster care facilities (Group I-2 Condition 1) where infants and toddlers stay for extended periods of time. The distinguishing factor between the two occupancies is the amount of time the facility provides care for each individual. Group I-2 facilities provide care on a 24-hour basis, while in Group I-4 facilities individual care must be less than 24 hours. It is also assumed that medical care is not present in Group I-4 facilities.

A child care facility in which the number of infants and toddlers is greater than five but not more than 100 is permitted to be classified as Group E, provided the infants and toddlers are all located in rooms on the level of exit discharge that serves such rooms and all of the rooms have exit doors directly to the exterior. This exception is only applicable to rooms and spaces used for child care and is not intended to apply to accessory spaces such as restrooms, offices and kitchens. Many day care facilities primarily catering to those under primary school age tend to divide the children into three general categories based on state laws and regulations. These include infant, toddler and preschool.

Some variations do occur in that larger day care

## DEFINITIONS

facilities will have transition rooms for mobile infants or pre-K oriented rooms for those entering kindergarten. But, basically, there is a mixture of children 2½ years or younger and older children. The older children can automatically be in a facility classified as a Group E occupancy, but for the younger children, the exception as discussed above would need to be applied to classify the entire occupancy as Group E. The total number of children can exceed 100 and the Group E classification is retained, provided that the number of children 2½ years or younger is limited to 100 or fewer. The infant and toddler rooms would need to have exits directly to the outside on the level of exit discharge. If the exception is not applied, the entire facility would need to be classified as Group I-4 or a mixed occupancy classification would be necessary.

By permitting the facility to be classified as Group E, the building would not be required to be sprinklered unless the fire area was greater than 12,000 square feet (115 m<sup>2</sup>). A Group I-4 facility would be required to be sprinklered regardless of the area. But as a Group E occupancy, panic hardware would be required in rooms and spaces exceeding 50 occupants.

**[BG] Within a place of religious worship.** Rooms and spaces within places of religious worship providing such care during religious functions shall be classified as part of the primary occupancy.

- ❖ The Group I-4 provisions do not apply to places of religious worship simply providing care services during worship and related religious functions. If the space is used at other times simply as a day care facility, then it would be classified as Group I-4 or E, as applicable.

**[BG] Five or fewer occupants receiving care.** A facility having five or fewer persons receiving custodial care shall be classified as part of the primary occupancy.

- ❖ Where five or fewer persons receive custodial care in a facility other than a dwelling unit, the classification of the care area is to be consistent with that of the primary occupancy. The limited number of care recipients reduces the hazard level to the point that classification as a Group I-4 occupancy is not warranted.

**[BG] Five or fewer occupants receiving care in a dwelling unit.** A facility such as the above within a *dwelling unit* and having five or fewer persons receiving custodial care shall be classified as a Group R-3 occupancy or shall comply with the *International Residential Code*.

- ❖ Buildings that have five or fewer persons receiving custodial care within a dwelling unit are to be classified as Group R-3, or shall be constructed in accordance with the IRC. The assumption is that this type of activity is possible in a residential environment

where one or more family members require the high level of care required by Group I-4. Please note similar provisions for Group E occupancies, as well as Groups I-1 and I-2.

**[BG] Mercantile Group M.** Mercantile Group M occupancy includes, among others, the use of a building or structure or a portion thereof, for the display and sale of merchandise, and involves stocks of goods, wares or merchandise incidental to such purposes and accessible to the public. Mercantile occupancies shall include, but not be limited to, the following:

- Department stores
- Drug stores
- Markets
- Motor fuel-dispensing facilities
- Retail or wholesale stores
- Sales rooms

- ❖ Group M (mercantile) occupancies normally involve the display and sale of large quantities of combustible merchandise, and the fuel load in such facilities can be relatively high, potentially exposing the occupants (customers and sales personnel) to a high degree of fire hazard. Mercantile operations often attract large crowds (particularly in large department stores and covered malls and especially during weekends and holidays). There are two factors that alleviate the risks to life safety: the occupant load normally has a low-to-moderate density and the occupants are alert, mobile and able to respond in an emergency situation. The degree of openness and the organization of the retail displays found in most mercantile occupancies is generally orderly and does not present an unusual difficulty for occupant evacuation.

Contained in the definition are general descriptions of the kinds of occupancies that are classified in Group M. Mercantile buildings most often have both a moderate occupant load and a high fuel load, which are in the form of furnishings and the goods being displayed, stored and sold.

The key characteristics that differentiate occupancies classified in Group M from those in Group B are the larger quantity of goods or merchandise available for sale and the lack of familiarity of the occupants with the building, particularly its means of egress. To be classified in Group M, the goods that are on display must be accessible to the public. If a patron sees an item for sale, then that item is generally available for purchase at that time (i.e., there is a large stock of goods). If a store allows people to see the merchandise but it is not available on the premises, such as an automobile showroom, then the occupancy classification of business (Group B) should be considered. A mercantile building is accessible to the public, many of whom may not be regular visitors. A business building, however, is primarily occupied by regular employees who are familiar with the building arrangement and, most importantly, the exits. This awareness of the building and the exits can be an important factor in a fire emergency.

Where storage rooms are limited to a maximum of 100 square feet in area, Section 311.1.1 of the IBC allows such rooms to still be considered part of the primary occupancy, provided that the aggregate of such rooms does not exceed 10 percent of the story. Therefore many mercantile stores with stockroom areas will be considered a mixed use building for height and area, construction type and sprinkler requirements. Note that Table 508.4 of the IBC does not require a fire-resistance rating on the separation between Group M and S-1.

Automotive, fleet-vehicle, marine and self-service motor fuel-dispensing facilities, also defined in this chapter of the code, are classified in the mercantile occupancy group, as are the convenience stores often associated with such occupancies. Quick-lube, tune-up, muffler and tire shops are not included in this classification. Those facilities that typically conduct automotive service and repair work are treated as a repair garage (Group S-1), also defined in this chapter of the code.

Simply because a building containing a mercantile-type occupancy has a dense occupant load does not necessitate the need to classify the building as an assembly occupancy unless the activity includes an assembly-type area where purchasing of goods is a group activity versus individual shoppers independently considering and purchasing merchandise. For example, a building in which auction sales occur may have a highly concentrated occupant load where the sales occur but the definition describes mercantile occupancies as “the use of a building or structure or portion thereof for the display and sale of merchandise and involves stocks of goods, wares or merchandise incidental to such purposes and accessible to the public.” However, in an auction, the activity is dominated by an assembly use of the space as people gather to conduct and participate in the auction. As such, auction spaces need to be assigned a Group A-3 occupancy (IBC Committee Interpretation No. 38-03). The presence of highly concentrated occupant loads does not in itself mandate an assembly use classification unless the activity is assembly in nature versus large numbers of people pursuing individual activities of acquisition.

**[BG] Residential Group R.** Residential Group R includes, among others, the use of a building or structure, or a portion thereof, for sleeping purposes when not classified as an Institutional Group I or when not regulated by the *International Residential Code* in accordance with Section 101.2 of the *International Building Code*.

❖ Residential occupancies represent some of the highest fire safety risks of any of the occupancies listed in Chapter 3 of the IBC. There are several reasons for this condition:

- Structures in the residential occupancy house the widest range of occupant types, i.e., from infants to the aged, for the longest periods of time. As such, residential occupancies are more

susceptible to the frequency of careless acts of the occupants; therefore, the consequences of exposure to the effects of fire are the most serious.

- Most residential occupants are asleep approximately one-third of every 24-hour period. When sleeping, they are not likely to become immediately aware of a developing fire. Also, if awakened from sleep by the presence of fire, the residents often may not immediately react in a rational manner which could delay their evacuation.
- The fuel load in residential occupancies is often quite high, both in quantity and variety. Also, in the construction of residential buildings, it is common to use extensive amounts of combustible materials.
- Another portion of the fire problem in residential occupancies relates to the occupants’ lack of vigilance in the prevention of fire hazards. In their own domicile or residence, people tend to relax and are often prone to allow fire hazards to go unabated; thus, in residential occupancies, fire hazards tend to accrue over an extended period of time and go unnoticed or are ignored.

Most of the nation’s fire problems occur in Group R buildings and, in particular, one- and two-family dwellings, which account for more than 80 percent of all deaths from fire in residential occupancies and about two-thirds of all fire fatalities in all occupancies. One- and two-family dwellings also account for more than 80 percent of residential property losses from fire and more than one-half of all property losses from fire.

Because of the relatively high fire risk and potential for loss of life in buildings classified in Groups R-1 (hotels and motels) and R-2 (apartments and dormitories), the code has stringent provisions for the protection of life in these occupancies. Group R-3 occupancies, however, are not generally considered to be in the same domain and, thus, are not subject to the same level of regulatory control as is provided in other occupancies. Group R-3 facilities are one- or two-family dwellings where the occupants are generally more familiar with their surroundings, and, because they are single units or duplexes, tend to pose a lower risk of injury or death.

Because of the growing trend to care for people in a residential environment, residential care/assisted living facilities are also classified as Group R. Specifically, these facilities are classified as Group R-4. “Mainstreaming” people who are recovering from alcohol or drug addiction and people who are developmentally disabled is reported to have therapeutic and social benefits. A residential environment often fosters this mainstreaming.

Buildings in Group R are described herein. A building or part of a building is considered to be a residential occupancy if it is intended to be used for

## DEFINITIONS

sleeping accommodations (including residential care/assisted living facilities) and is not an institutional occupancy. Institutional occupancies are similar to residential occupancies in many ways; however, they differ from each other in that institutional occupants are in a supervised environment and, in the case of Group 1-2 and 1-3 occupancies, are under some form of restraint or physical limitation that makes them incapable of complete self-preservation. The number of these occupants who are under supervision or are incapable of self-preservation is the distinguishing factor for being classified as an institutional or residential occupancy.

The term “Group R” refers collectively to the four individual residential occupancy classifications: Groups R-1, R-2, R-3 and R-4. These classifications are differentiated in the code based on the following criteria: (1) whether the occupants are transient or nontransient in nature; (2) the type and number of dwellings contained in a single building; and (3) the number of occupants in the facility.

**[BG] Residential Group R-1.** Residential Group R-1 occupancies containing *sleeping units* where the occupants are primarily transient in nature, including:

- Boarding houses (transient) with more than 10 occupants
- Congregate living facilities (transient) with more than 10 occupants
- Hotels (transient)
- Motels (transient)

❖ R-1: The key characteristic of Group R-1 that differentiates it from other Group R occupancies is the number of transient occupants (i.e., those whose length of stay is not more than 30 days).

The most common building types classified in Group R-1 are hotels, motels and boarding houses. Group R-1 occupancies do not typically have cooking facilities in the unit. When a unit is not equipped with cooking facilities, it does not meet the definition of a “Dwelling unit” in Chapter 2 of the code. When this occurs, such units are treated as sleeping units for the application of code provisions. Sleeping units are required to be separated from each other by fire partitions and horizontal assemblies (see IBC Sections 420, 708 and 711). A recent trend in development is the construction of “extended-stay hotels.” While these units may have all of the characteristics of a typical dwelling unit (i.e., cooking, living, sleeping, eating, sanitation), the length of stay is still typically not more than 30 days. As such, these buildings would still be classified as Group R-1. If the length of stay is more than 30 days, these buildings would be classified as Group R-2. If a hotel offers its rooms for short-term housing (i.e., more than 30 days), the facility must comply with the provision for both Group R-1 and R-2.

Other occupancies are often found in buildings classified in Group R-1. These occupancies include nightclubs (Group A-2), restaurants (Group A-2), gift

shops (Group M), health clubs (Group A-3) and storage facilities (Group S-1). When this occurs, the building is a mixed occupancy and is subject to the provisions of Section 508 of the IBC.

Transient congregate living facilities and boarding houses with 10 or fewer occupants can be constructed to the standards of Group R-3 occupancies rather than the general category of Group R-1. The primary intent of this provision is to permit bed and breakfast-type facilities to be established in existing single-family (one-family) structures. In comparison to the provision under Group R-2 which permits congregate living facilities with fewer than 16 nontransient occupants to be built as a Group R-3, the Group R-3 “transient” facility is limited to 10 or fewer occupants in reflection of the limited number of occupants.

Lodging houses, while transient in nature and potentially having more than 10 occupants, are specifically listed under Group R-3. Lodging houses are defined and are typically bed-and-breakfast-type facilities.

**[BG] Residential Group R-2.** Residential Group R-2 occupancies containing *sleeping units* or more than two *dwelling units* where the occupants are primarily permanent in nature, including:

- Apartment houses
- Boarding houses (nontransient) with more than 16 occupants
- Congregate living facilities (nontransient) with more than 16 occupants
- Convents
- Dormitories
- Fraternities and sororities
- Hotels (nontransient)
- Live/work units
- Monasteries
- Motels (nontransient)
- Vacation timeshare properties

❖ The length of the occupants’ stay plus the arrangement of the facilities provided are the basic factors that differentiate occupancies classified in Group R-2 from other occupancies in Group R. The occupants of facilities or areas classified in Group R-2 are primarily nontransient, capable of self-preservation and share their means of egress in whole or in part with other occupants outside of their sleeping area or dwelling unit. Building types ordinarily classified in Group R-2 include apartments, boarding houses (when the occupants are not transient) and nontransient congregate living facilities, such as dormitories, where there are more than 16 occupants.

Individual dwelling units in Group R-2 are either rented by tenants or owned by the occupants. The code does not make a distinction between either type of tenancy. Residential condominiums are treated in the code the same as Group R-2 apartments. Such condominiums are based on shared ownership of a building and related facilities. While an individual owner will have exclusive rights to a certain unit, the

building, the lot the building sits upon, parking, common recreational facilities and similar features are owned in common by all the owners of individual dwelling units. In most cases condominiums do not establish separate lots and the walls between units are not setting on lot lines. Another type of shared ownership is referred to as a “co-op,” short for cooperative. Occasionally a condominium will establish actual lots and lot lines distinguishing individual ownership. When the dwelling unit is located on a separate parcel of land, lot lines defining the parcel exist and the requirements for fire separation must be met.

Dormitories are generally associated with university or college campuses for use as student housing, but this is changing rapidly. Many dormitories are now being built as housing for elderly people who wish to live with other people their own age and who do not need 24-hour-a-day medical supervision. The only difference between the dormitory that has just been described and the dormitory found on a college campus is the age of its occupants. If the elderly people must have 24-hour-a-day medical supervision (i.e., a nurse or doctor on the premises), the building is no longer considered a residential occupancy but an institutional occupancy and would have to comply with the applicable provisions of the code for the appropriate Group I occupancy.

Similar to Group R-1, individual rooms in dormitories are sleeping units. When college classes are not in session, the rooms in dormitories are sometimes rented out for periods of less than 30 days to convention attendees and other visitors. When dormitories undergo this type of transient use, they more closely resemble Group R-1. A style of dormitory design that is being used more frequently is one where there are groups of sleeping units around a common living space, including shared bathrooms and sometimes a kitchen or kitchenette. At this time, the code does not indicate if these groups of rooms should be addressed as separate sleeping units or as a dwelling unit except for when counting units for determining the number of Accessible units required (see Section 1107.6.2.3.1 of the IBC).

Buildings containing dormitories often contain other occupancies, such as cafeterias or dining rooms (Group A-2), recreation rooms (Group A-3), offices (Group B) and meeting rooms (Group A-3). When this occurs, the building is considered a mixed occupancy and is subject to the provisions of Section 508 of the IBC.

Included in the listing of Group R-2 are live/work units. A live/work unit is a dwelling unit or sleeping unit in which a significant portion of the space includes a nonresidential use operated by the tenant. Reflecting a growing trend in urban neighborhoods and the reuse of existing buildings, live/work units must comply with the provisions of Section 419 of the IBC.

The intent of the congregate living facility reference is to better define when a congregate living facility is

operating as a single-family home. Blended families are now commonplace and not necessarily defined strictly by blood or marriage. Small boarding houses, convents, dormitories, fraternities, sororities, monasteries and nontransient hotels and motels may be small enough to operate as a single-family unit and would be permitted to be constructed as Group R-3 occupancies as intended by the code. The threshold of 16 persons is consistent with the results of the most recent census, which showed that 98 percent of households in the U.S. that identified themselves as a single family have less than 16-occupants. The 16 occupant limit is also consistent with the limits of an NFPA 13D sprinkler system.

**[BG] Residential Group R-3.** Residential Group R-3 occupancies where the occupants are primarily permanent in nature and not classified as Group R-1, R-2, R-4 or I, including:

- Boarding houses (nontransient) with 16 or fewer occupants
- Boarding houses (transient) with 10 or fewer occupants
- Buildings that do not contain more than two *dwelling units*
- Care facilities that provide accommodations for five or fewer persons receiving care
- Congregate living facilities (nontransient) with 16 or fewer occupants
- Congregate living facilities (transient) with 10 or fewer occupants
- Lodging houses with five or fewer guest rooms

- ❖ Group R-3 facilities include all detached one- and two-family dwellings and multiple (three or more) single-family dwellings (townhouses) more than three stories in height. Those buildings three or less stories in height are not classified as Group R-3 and are regulated by the IRC. Each pair of dwelling units in multiple single-family dwellings greater than three stories in height must be separated by fire walls (see Section 706 of the IBC) or by two exterior walls (see Table 602 of the IBC) in order to be classified as Group R-3. (Duplexes, buildings with two dwelling units, must be detached from other structures in order to be regulated by the IRC). A duplex attached to another duplex would be required to comply with the code and be classified as Group R-2 or R-3, depending on the presence of fire walls.

Buildings that are classified as Group R-3, while limited in height, are not limited in the allowable area per floor as indicated in Table 506.2.

Buildings that are one- and two-family dwellings and multiple single-family dwellings less than three stories in height and that contain another occupancy (e.g., Groups B, M, I-4) must be regulated as a mixed occupancy in accordance with the code and are not permitted to be regulated by the provisions of the IRC. However, some mixed use dwelling units may qualify as live/work units under Section 419 and be classified as a Group R-2 occupancy.

## DEFINITIONS

In addition, boarding houses and congregate living facilities with no more than 16 nontransient occupants or no more than 10 transient occupants are to be classified as Group R-3.

Group R-3 occupancies include small care facilities where care is provided to five or fewer persons. The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members that is typical within a single-family-type home. Allowances for the Group R-3 classification of smaller care facilities are established in Group E, Group I-1, Group I-2 and Group I-4. Because the intent is to accommodate persons who might otherwise be in other group occupancies, including Group I-2, the Group R-3 care facility is not limited to only persons who are capable of self-preservation. The only limit is the number receiving care, not the total number of occupants in the dwelling unit. If two people are receiving care, and the rest of the family includes four others, totaling six occupants in the dwelling does classify the dwelling as a Group R-3 occupancy.

Lodging houses with five or fewer guest rooms can be classified as a Group R-3 occupancy or, under Section 310.5.2 of the IBC, can be constructed under the provisions of the IRC. The definition of "Lodging house" allows the rental of guest rooms to transients, provided that there are one or more occupants who are permanent in nature. While Section 310.5.2 requires owner occupancy of the dwelling unit in order for it to be built in compliance with the IRC, there is no owner occupancy requirement for lodging houses that comply with Group R-3 requirements. The broad intent of the lodging house provisions is to allow bed-and-breakfast and similar facilities under the Group R-3 category, even though transient housing generally falls under the Group R-1 classification. The limit is set to the number of guest rooms. There is no specified limit on the number of guests, the number of residents, or the combination of both.

**[BG] Care facilities within a dwelling.** Care facilities for five or fewer persons receiving care that are within a single-family dwelling are permitted to comply with the *International Residential Code* provided an *automatic sprinkler system* is installed in accordance with Section 903.3.1.3 or Section P2904 of the *International Residential Code*.

- ❖ The Group R-3 definition already states that care facilities that accommodate five or fewer persons receiving care can be classified as a Group R-3 occupancy. The definitions of Group E, Group I-1, Group I-2 and Group I-4 each state the option of providing the care of five or fewer persons within a structure regulated under the IRC. The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members that is typical within a single-family-type home. As stated for those care facilities allowed within the Group R-3 occupancy, the persons receiving care in a building

designed according to the IRC are not limited to those who are capable of self-preservation. Similar to those for Groups I-1 and I-2, this definition specifies that such an IRC-regulated facility must be provided with an automatic sprinkler system.

**[BG] Lodging houses.** Owner-occupied *lodging houses* with five or fewer guest rooms shall be permitted to be constructed in accordance with the *International Residential Code*.

- ❖ This section allows bed-and-breakfast-type hotels that are both owner-occupied and have five or fewer rooms to rent to be constructed under the IRC. There is no occupant load limitations for this option as there are for boarding houses or congregate residences. See the commentary to the definition of "Group R-3 occupancies."

**[BG] Residential Group R-4.** Residential Group R-4 shall include buildings, structures or portions thereof for more than five but not more than 16 persons, excluding staff, who reside on a 24-hour basis in a supervised residential environment and receive custodial care. Buildings of Group R-4 shall be classified as one of the occupancy conditions indicated below. This group shall include, but not be limited to, the following:

- Alcohol and drug centers
- Assisted living facilities
- Congregate care facilities
- Group homes
- Halfway houses
- Residential board and care facilities
- Social rehabilitation facilities

Group R-4 occupancies shall meet the requirements for construction as defined for Group R-3, except as otherwise provided for in the *International Building Code*.

- ❖ Where five to 16 residents live in a supervised environment and receive custodial care, such a facility is classified as Group R-4. Ninety-eight percent of households in the U.S. that identified themselves as single family have less than 16 occupants. The 16-occupant limit is also consistent with the limits of an NFPA 13D sprinkler system. Thus the limit to the number of residents to 16 was established as an appropriate limit considering that this facility will operate similar to a single-family home. Under federal housing laws regarding nondiscrimination, families cannot be determined by blood or marriage. If a Group R-4 occupancy is expanded or allowed to have more than 16 care recipients, the facility needs to be reclassified as a Group I-1 occupancy. The number of persons used in the determination includes those who receive care and is not intended to include staff.

Similar to Group I-1, a Group R-4 occupancy is also one of two conditions. In a Condition 1 facility, care recipients may be slower during evacuation but are capable of self-preservation. In a Condition 2 facility, care recipients may require limited assistance with evacuation during emergency situations. See also the commentary in Section 308.3 for Group

I-1 for a further detailed explanation of both Group I-1 and R-4 custodial care occupancies (also see the definition of “Custodial care”).

Group R-4 facilities must satisfy the construction requirements of Group R-3. Facilities with five or fewer persons receiving care will be either a Group R-3 occupancy (see Section 310.5), or can be built under the IRC (see Section 310.5.1).

**[BG] Condition 1.** This occupancy condition shall include buildings in which all persons receiving custodial care, without any assistance, are capable of responding to an emergency situation to complete building evacuation.

- ❖ See the commentary to the definition of “Group R-4 occupancies.”

**[BG] Condition 2.** This occupancy condition shall include buildings in which there are any persons receiving custodial care who require limited verbal or physical assistance while responding to an emergency situation to complete building evacuation.

- ❖ See the commentary to the definition of “Group R-4 occupancies.”

**[BG] Storage Group S.** Storage Group S occupancy includes, among others, the use of a building or structure, or a portion thereof, for storage that is not classified as a hazardous occupancy.

- ❖ This definition requires that all structures (or parts thereof) designed or occupied for the storage of moderate- and low-hazard materials are to be classified in either Group S-1 (moderate hazard) or S-2 (low hazard). Small storage areas are inherent in almost any activity or occupancy.

The life safety problems in structures used for storage of moderate- and low-hazard materials are minimal because the number of people involved in a storage operation is usually small and normal work patterns require the occupants to be dispersed throughout the facility. The problems of fire safety, particularly as they relate to the protection of stored contents, are directly associated with the amount and combustibility of the materials (including packaging) that are housed on the premises.

Storage facilities typically contain significant amounts of combustible or noncombustible materials that are kept in a common area. Because of the combustion, flammability or explosive characteristics of certain materials, a structure (or portion thereof) that is used to store high-hazard materials which exceed the MAQs, or that does not meet one of the exceptions identified in Section 307.1 of the IBC, cannot be classified as Group S and is to be classified as Group H, high-hazard uses, and is to comply with Section 307 of the IBC.

Storage occupancies consist of two basic types: Groups S-1 and S-2, which are based on the properties of the materials being stored. The distinction between Groups S-1 and S-2 is similar to that

between Groups F-1 and F-2, as outlined in those definitions.

**[BG] Accessory storage spaces.** A room or space used for storage purposes that is less than 100 square feet (9.3 m<sup>2</sup>) in area and accessory to another occupancy shall be classified as part of that occupancy. The aggregate area of such rooms or spaces shall not exceed the allowable area limits of Section 508.2 of the *International Building Code*.

- ❖ This provision allows small storage rooms to be classified in the same occupancy group as the primary occupancy of a space. There are two limits, each space is limited to 100 square feet, and the aggregate of such spaces on any story is limited to 10 percent of the floor area. These small storage spaces could occur in any other occupancy, such as a Group B office building, a Group E classroom or a Group M retail store. Individual spaces in excess of 100 square feet would be classified as an S occupancy and the provisions of mixed occupancies (see Section 508) would come into play. Section 508.2 limits accessory occupancies on any story to 10 percent of the area of that story. The area of storage spaces would need to be totaled to determine if they can be classified as part of the main occupancy or may, in part, need to be classified as a Group S occupancy. As a separated mixed-use building, Table 508.4 does not require a separation between S-1 and F-1, B or M. Table 509 for incidental uses would require storage rooms in Group I-2 and ambulatory care facilities with an area over 100 square feet to be separated by fire barrier or horizontal assemblies with a fire-resistance rating of at least 1 hour.

**[BG] Moderate-hazard storage, Group S-1.** Storage Group S-1 occupancies are buildings occupied for storage uses that are not classified as Group S-2, including, but not limited to, storage of the following:

- Aerosols, Levels 2 and 3
- Aircraft hangar (storage and repair)
- Bags: cloth, burlap and paper
- Bamboos and rattan
- Baskets
- Belting: canvas and leather
- Books and paper in rolls or packs
- Boots and shoes
- Buttons, including cloth covered, pearl or bone
- Cardboard and cardboard boxes
- Clothing, woolen wearing apparel
- Cordage
- Dry boat storage (indoor)
- Furniture
- Furs
- Glues, mucilage, pastes and size
- Grains
- Horns and combs, other than celluloid
- Leather
- Linoleum
- Lumber

## DEFINITIONS

Motor vehicle repair garages complying with the maximum allowable quantities of hazardous materials listed in Table 5003.1.1(1) (see Section 406.8 of the *International Building Code*)

Photo engravings

Resilient flooring

Silks

Soaps

Sugar

Tires, bulk storage of

Tobacco, cigars, cigarettes and snuff

Upholstery and mattresses

Wax candles

- ❖ Buildings in which combustible materials are stored and that burn with ease are classified in Group S-1, moderate-hazard storage occupancies. Examples of the kinds of materials that, when stored, are representative of occupancies classified in Group S-1 are listed in the definition.

As defined by the code, a repair garage is any structure used for servicing or repairing motor vehicles. Therefore, regardless of the extent of work done (e.g., quick-lube, tune-up, muffler and tire shops, painting, body work, engine overhaul), repair garages are classified as Group S-1 and must be in compliance with Section 406.8 of the IBC. In addition, to avoid a Group H classification, the amounts of hazardous materials in the garage must be less than the MAQ indicated in Tables 5003.1.1(1) and 5003.1.1(2) [IBC Tables 307.1(1) and 307.1(2)] of the code.

Aircraft hangars for storage, repair or both would be classified as Group S-1. This classification correlates with the actual use of such hangars which very frequently would include some level of repair work and also works with the requirements of NFPA 409. Aircraft hangars accessory to one- and two-family structures remain a Group U occupancy.

**[BG] Low-hazard storage, Group S-2.** Storage Group S-2 occupancies include, among others, buildings used for the storage of noncombustible materials such as products on wood pallets or in paper cartons with or without single thickness divisions; or in paper wrappings. Such products are permitted to have a negligible amount of plastic trim, such as knobs, handles or film wrapping. Storage uses shall include, but not be limited to, storage of the following:

Asbestos

Beverages up to and including 16-percent alcohol in metal, glass or ceramic containers

Cement in bags

Chalk and crayons

Dairy products in nonwaxed coated paper containers

Dry cell batteries

Electrical coils

Electrical motors

Empty cans

Food products

Foods in noncombustible containers

Fresh fruits and vegetables in nonplastic trays or

containers

Frozen foods

Glass

Glass bottles, empty or filled with noncombustible liquids

Gypsum board

Inert pigments

Ivory

Meats

Metal cabinets

Metal desks with plastic tops and trim

Metal parts

Metals

Mirrors

Oil-filled and other types of distribution transformers

Parking garages, open or enclosed

Porcelain and pottery

Stoves

Talc and soapstones

Washers and dryers

- ❖ Buildings in which noncombustible materials are stored are classified as Group S-2, low-hazard storage occupancies. It is acceptable for stored noncombustible products to be packaged in combustible materials as long as the quantity of packaging is kept to an insignificant level.

As seen in Group F-1 and F-2 classifications, it is important to be able to distinguish when the presence of combustible packaging constitutes a significant fuel load. As such, a fuel load might require the building to be classified in Group S-1, moderate-hazard storage. A simple guideline to follow is the “single-thickness” rule, which is when a noncombustible product is put in one layer of packaging material.

Examples of materials qualified for storage in Group S-2 storage facilities are as follows:

- Vehicle engines placed on wood pallets for transportation after assembly.
- Washing machines in corrugated cardboard boxes.
- Soft-drink glass bottles packaged in pressed paper boxes.

Structures used to store noncombustible materials packaged in more than one layer of combustible packaging material are to be classified in Group S-1.

Examples of materials that, because of packaging, do not qualify for classification in Group S-2 are:

- Chinaware wrapped in corrugated paper and placed in cardboard boxes.
- Glassware set in expanded foam forms and placed in a cardboard box.
- Fuel filters individually packed in pressed paper boxes, placed by the gross in a cardboard box and then stacked on a wood pallet for transportation.

An area often related to Group S occupancies is Chapter 32, which regulates high-piled combustible

storage [storage over 12 feet (3658 mm) in height or 6 feet (1829 mm) if the material is considered high hazard]. Chapter 32 of the IFC is focused on not only the type of materials being stored but also the height and configuration of such storage. It is important to note that not all Group S occupancies will contain high-piled storage and that high-piled storage is not limited to Group S occupancies. High-piled storage can be found in occupancies such as Group H or F.

Open and enclosed parking garages are classified as Group S-2 occupancies as long as no repair activities occur in such buildings, as discussed in the commentary for this definition. A garage in a fire station, for example, that undertakes maintenance and repairs limited to cleaning, hose change, water fill, fire equipment upgrades or wheel removal for repair off premise would not constitute the same hazard associated with repair garages and would be appropriately classified as Group S-2.

**[BG] Miscellaneous Group U.** Buildings and structures of an accessory character and miscellaneous structures not classified in any specific occupancy shall be constructed, equipped and maintained to conform to the requirements of this code commensurate with the fire and life hazard incidental to their occupancy. Group U shall include, but not be limited to, the following:

Agricultural buildings

Aircraft hangar, accessory to a one- or two-family residence (see Section 412.5 of the *International Building Code*)

Barns

Carports

Fences more than 6 feet (1829 mm) high

Grain silos, accessory to a residential occupancy

Greenhouses

Livestock shelters

Private garages

Retaining walls

Sheds

Stables

Tanks

Towers

- ❖ This definition identifies the characteristics of occupancies classified in Group U. Structures that are classified in Group U are typically accessory to another building or structure and are not more appropriately classified in another occupancy. Miscellaneous storage buildings accessory to detached one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories in height, however, are intended to be designed and built in accordance with the IRC.

Structures classified as Group U, such as fences, equipment, foundations, retaining walls, etc., are somewhat outside the primary scope of the code (i.e., means of egress, fire resistance). They are not usually considered to be habitable or occupiable. Nevertheless, many code provisions do apply and need to

be enforced (e.g., structural design and material performance).

Structures housing accessory equipment that is part of a utility or communications system are often classified as Group U occupancies when there is no intent that these structures be occupied except for servicing and maintaining the equipment within the structure. A pumphouse for a water or sewage system or an equipment building at the base of a telecommunications tower are examples of such buildings.

Group U occupancies are subject to the same structural loadings such as snow loads as other occupancies. This definition establishes that occupancies classified as utility and miscellaneous structures shall be constructed, equipped and maintained to conform to the code requirements that are commensurate with the fire and life hazards incidental to their occupancy. The structural design requirements for roofs are the minimum deemed necessary to withstand such elements. Allowing construction of a building with an accessory occupancy that could reasonably be expected to collapse under the snow loads known to prevail in certain area is not in the best interest of public safety.

**[BG] OCCUPANT LOAD.** The number of persons for which the *means of egress* of a building or portion thereof is designed.

- ❖ In addition to the limitation on the maximum occupant load for a space, the code also requires the determination of the occupant load that is to be utilized for the design of the means of egress system. The number for the floor area per occupant (occupant load factor) in Table 1004.1.2 reflects common and traditional occupant densities based on the empirical data for the density of similar spaces. This occupant load is also utilized to determine the required number of plumbing fixtures (see Chapter 29 of the IBC) and when automatic sprinkler systems or fire alarm and detection systems are required (see Chapter 9).

**OPEN BURNING.** The burning of materials wherein products of combustion are emitted directly into the ambient air without passing through a stack or chimney from an enclosed chamber. Open burning does not include road flares, smudgepots and similar devices associated with safety or occupational uses typically considered open flames, *recreational fires* or use of portable outdoor fireplaces. For the purpose of this definition, a chamber shall be regarded as enclosed when, during the time combustion occurs, only apertures, ducts, stacks, flues or chimneys necessary to provide combustion air and permit the escape of exhaust gas are open.

- ❖ Open burning is any burning that takes place in an unenclosed space. Examples include burning of leaves or grass clippings, burning construction debris and fires built on the ground for warmth in cold weather. The burning of wood scraps in a steel drum or in a piece of culvert over which a supply of construction sand can be dumped and kept thawed is

## DEFINITIONS

common practice on construction sites in cold climates and could be evaluated by the fire code official as being an allowable “occupational use” as mentioned in the definition. The definition has also been revised to clarify that the use of portable outdoor fireplaces (also known as patio fireplaces) is specifically excluded, thus eliminating the confusion that previously existed as to how to treat those devices. See also the definition of “Recreational fire.”

**[BE] OPEN-ENDED CORRIDOR.** An interior *corridor* that is open on each end and connects to an exterior *stairway* or *ramp* at each end with no intervening doors or separation from the *corridor*.

❖ Breezeway configurations are common in hotels and apartment buildings, especially in areas where being open to the outside air is considered an amenity. By essentially being open to the outside, the intent and level of safety is similar to an exterior egress balcony (see Section 1027.6, Exception 4 for requirements).

**OPEN MALL.** See “Covered mall building.”

**OPEN MALL BUILDING.** See “Covered mall building.”

**[BG] OPEN PARKING GARAGE.** A structure or portion of a structure with the openings as described in Section 406.5.2 of the *International Building Code* on two or more sides that is used for the parking or storage of private motor vehicles as described in Section 406.5 of the *International Building Code*.

❖ Open parking garages are defined as having uniformly distributed openings on no less than two sides totaling no less than 40 percent of the building perimeter. The aggregate area of the openings is to be a minimum of 20 percent of the total wall area of all perimeter walls (see the commentary to Section 406.5.2 of the IBC).

**OPEN SYSTEM.** The use of a solid or liquid hazardous material involving a vessel or system that is continuously open to the atmosphere during normal operations and where vapors are liberated, or the product is exposed to the atmosphere during normal operations. Examples of open systems for solids and liquids include dispensing from or into open beakers or containers, dip tank and plating tank operations.

❖ This definition is related primarily to hazardous materials use. Generally, an open system is one that will normally be open to the atmosphere; for example, a dip tank or dispensing or mixing of hazardous materials. Open systems are inherently more hazardous than closed systems. When evaluating the MAQs of hazardous materials and the associated requirements, open systems are more heavily regulated.

**OPERATING BUILDING.** A building occupied in conjunction with the manufacture, transportation or use of *explosive materials*. Operating buildings are separated from one another with the use of intraplant or intraline distances.

❖ Magazines are used for storage of explosive materials. Manufacturing or operating buildings used for the storage of explosives are not magazines and are not intended to be used for storage, although at times

there may be storage incidental to the manufacturing function. This definition is included here to clarify this difference.

**OPERATING LINE.** A group of buildings, facilities or workstations so arranged as to permit performance of the steps in the manufacture of an *explosive* or in the loading, assembly, modification and maintenance of ammunition or devices containing *explosive materials*.

❖ This term is used by those engaged in the storage and manufacture of explosive materials, as well as with the regulators of these materials, including the DOD. The term is also consistent with terminology used by the DOD and the Institute of Makers of Explosives (IME). The term “operating line” is defined in relationship to operating buildings that may be grouped in such a manner so as to create a manufacturing process.

**OPERATING PRESSURE.** The pressure at which a system operates.

❖ This term is self-explanatory and is used in Chapters 9, 31, 55 and 60 of the code.

**ORGANIC COATING.** A liquid mixture of binders such as alkyd, nitrocellulose, acrylic or oil, and flammable and combustible solvents such as hydrocarbon, ester, ketone or alcohol, which, when spread in a thin film, convert to a durable protective and decorative finish.

❖ “Organic coatings” are defined as flammable and combustible paints and other protective or decorative coatings.

**ORGANIC PEROXIDE.** An organic compound that contains the bivalent -O-O- structure and which may be considered to be a structural derivative of hydrogen peroxide where one or both of the hydrogen atoms have been replaced by an organic radical. Organic peroxides can present an explosion hazard (*detonation* or *deflagration*) or they can be shock sensitive. They can also decompose into various unstable compounds over an extended period of time.

**Class I.** Describes those formulations that are capable of *deflagration* but not *detonation*.

**Class II.** Describes those formulations that burn very rapidly and that pose a moderate reactivity hazard.

**Class III.** Describes those formulations that burn rapidly and that pose a moderate reactivity hazard.

**Class IV.** Describes those formulations that burn in the same manner as ordinary combustibles and that pose a minimal reactivity hazard.

**Class V.** Describes those formulations that burn with less intensity than ordinary combustibles or do not sustain combustion and that pose no reactivity hazard.

**Unclassified detonable.** Organic peroxides that are capable of *detonation*. These peroxides pose an extremely high-explosion hazard through rapid explosive decomposition.

❖ The chemical structure of organic peroxides differs from that of hydrogen peroxide (an oxidizer) in that an

organic radical replaces the hydrogen atoms. Commentary Figure 202-O6 shows an example of this chemical structure in which a benzoyl radical ( $C_6H_5CO$ ) in the widely used Class I organic peroxide benzoyl peroxide replaces the hydrogen atoms in hydrogen peroxide ( $H_2O_2$ ). Organic chemicals are all carbon based. As a result, organic peroxides pose varying degrees of fire or explosion hazards in addition to their oxidizing properties.

The classification system in this chapter (see Commentary Figure 202-O7) is derived from a system developed by the Society of the Plastics Industry (Bulletin 19A).

**OUTDOOR CONTROL AREA.** An outdoor area that contains hazardous materials in amounts not exceeding the maximum allowable quantities of Table 5003.1.1(3) or Table 5003.1.1(4).

❖ This term refers to a storage area that is exposed to the elements (wind, rain, snow, etc.) that cannot exceed the MAQ listed in the code and the IBC. See Tables 5003.1.1(3), 5003.1.1(4) and Sections 5001 and 5003 of the code, and Section 414.6 in the IBC.

**OUTPATIENT CLINIC.** See “Clinic, outpatient.”

**OVERCROWDING.** A condition that exists when either there are more people in a building, structure or portion thereof than have been authorized or posted by the *fire code official*, or when the *fire code official* determines that a threat exists to the safety of the occupants due to persons sitting and/or standing in locations that may obstruct or impede the use of *aisles*, passages, *corridors*, *stairways*, *exits* or other components of the *means of egress*.

❖ This definition notes that an unsafe condition exists when the actual number of people present in a building or a building space exceeds the maximum allowable occupant load of that building or space as determined and posted on the premises by the fire code official. Section 1004 of the code would allow a maximum occupant load of one person per every 5 square feet ( $0.5 \text{ m}^2$ ) of building area, as long as the egress components provide sufficient capacity for such a load. When that egress capacity is exceeded, then overcrowding exists. The definition also recognizes that, even though the number of occupants in a building or space may not be excessive, the inability of occupants to use the egress elements due to blockage by patrons is also a life safety hazard.

**[A] OWNER.** Any person, agent, operator, entity, firm or corporation having any legal or equitable interest in the property; or recorded in the official records of the state, county or municipality as holding an interest or title to the property; or otherwise having possession or control of the property, including the guardian of the estate of any such person, and the executor or administrator of the estate of such person if ordered to take possession of real property by a court.

❖ This term defines the person or other legal entity who is responsible for a building and its compliance with code requirements.

**OXIDIZER.** A material that readily yields oxygen or other oxidizing gas, or that readily reacts to promote or initiate combustion of combustible materials and, if heated or contaminated, can result in vigorous self-sustained decomposition.

**Class 4.** An oxidizer that can undergo an explosive reaction due to contamination or exposure to thermal or physical shock and that causes a severe increase in the burning

IFC	DOTn 49 CFR, PART 173.128(b)	HAZARD DESCRIPTION
Unclassified detonatable	Type A	Detonation hazard when confined
Class I	Type B	Deflagration hazard when confined
Class II	Type C and Type D	Mass fire hazard similar to flammable liquid <sup>a</sup>
Class III	Type E	Fire hazard similar to combustible liquid
Class IV	Type F	Little or no fire or reactivity hazard
Class V	Type G	No fire or reactivity hazard

a. Moderate detonation or deflagration hazard when heated under confinement.

**Figure 202-O7**  
**COMPARISON OF ORGANIC PEROXIDE CLASSIFICATION SYSTEMS**

## DEFINITIONS

rate of combustible materials with which it comes into contact. Additionally, the oxidizer causes a severe increase in the burning rate and can cause spontaneous ignition of combustibles.

**Class 3.** An oxidizer that causes a severe increase in the burning rate of combustible materials with which it comes in contact.

**Class 2.** An oxidizer that will cause a moderate increase in the burning rate of combustible materials with which it comes in contact.

**Class 1.** An oxidizer that does not moderately increase the burning rate of combustible materials.

- ❖ The classification of oxidizers had its origins in the provisions of NFPA 430 and is consistent with Department of Transportation (DOT) hazardous materials regulations. Oxidizers, whether a solid, liquid or gas, yield oxygen or another oxidizing gas during a chemical reaction or readily react to oxidize combustibles and increase their burning rate. This characteristic is a result of the enrichment of the air to more than 21-percent oxygen content.

This enrichment is a hazard because an ordinary combustible material that will burn freely at the atmospheric oxygen level of 21 percent will burn more rapidly at higher concentrations of oxygen. The rate of reaction varies with the class of oxidizer. Specific classification of oxidizers is important because of the varying degree of hazard. Examples of oxidizers include liquid hydrogen peroxide, nitric acid, sulfuric acid and solids, such as sodium chlorite, chromic acid and calcium hypochlorite. Many commercially available swimming pool chemicals are examples of Class 2 or 3 oxidizers.

**OXIDIZING CRYOGENIC FLUID.** An oxidizing gas in the cryogenic state.

- ❖ This definition is provided to correlate with the title of Chapter 63 and Section 6304.2.1.1, which is consistent with code-style improvement of providing hazard-specific requirements in material-specific chapters in addition to the general material chapters, in this case Chapter 55. The primary focus of the oxidizing cryogenic fluid provisions in this chapter is liquid oxygen.

**OXIDIZING GAS.** A gas that can support and accelerate combustion of other materials more than air does.

- ❖ Oxidizing gases present essentially the same hazard characteristics as solids and liquids. Examples of oxidizing gases are oxygen, ozone and the oxides of nitrogen, fluorine and chlorine.

**OZONE-GAS GENERATOR.** Equipment which causes the production of ozone.

- ❖ Ozone is considered a highly toxic gas. Ozone generators are addressed separately in Section 6005 because the code has traditionally dealt with the storage and use of hazardous materials, but not the generation.

**[BE] PANIC HARDWARE.** A door-latching assembly incorporating a device that releases the latch upon the application of a force in the direction of egress travel. See also "Fire exit hardware."

- ❖ Panic hardware is commonly used in educational and assembly-type spaces where the number of occupants who would use a doorway during a short time frame in an emergency is high in relation to an occupancy with a less dense occupant load, such as an office building. The hardware is required so that the door can be easily opened during an emergency when pressure on a door from a crush of people could render normal hardware inoperable. Not all types of panic hardware are permitted on doors required to be fire-protection rated (see the definition for "Fire exit hardware" and Section 1010.1.10).

**PASS-THROUGH.** An enclosure installed in a wall with a door on each side that allows chemicals, HPM, equipment, and parts to be transferred from one side of the wall to the other.

- ❖ A pass-through is similar to a sally port and is used to store and receive HPM for the fabrication area. The pass-through must be separated from the exit access corridor by fire-resistance-rated construction, including a fire-resistance-rated, self-closing fire door on each side, and be sprinklered.

**[BG] PENTHOUSE.** An enclosed, unoccupied rooftop structure used for sheltering mechanical and electrical equipment, tanks, elevators and related machinery, and vertical shaft openings.

- ❖ Any enclosed structure that is located above the surrounding roof surfaces can be considered a penthouse as long as it meets the criteria within Section 1510.2 of the IBC. By complying with these requirements, the penthouse is considered to not contribute to the height of the building, either in number of stories or feet above grade plane. If the proposed penthouse does not meet these requirements, it must be considered as an additional story of the building or structure.

**PERMISSIBLE EXPOSURE LIMIT (PEL).** The maximum permitted 8-hour time-weighted-average concentration of an air-borne contaminant. The exposure limits to be utilized are those published in DOL 29 CFR Part 1910.1000. The Recommended Exposure Limit (REL) concentrations published by the U.S. National Institute for Occupational Safety and Health (NIOSH), Threshold Limit Value-Time Weighted Average (TLV-TWA) concentrations published by the American Conference of Governmental Industrial Hygienists (ACGIH), Workplace Environmental Exposure Level (WEEL) Guides published by the American Industrial Hygiene Association (AIHA), and other *approved*, consistent measures are allowed as surrogates for hazardous substances not *listed* in DOL 29 CFR Part 1910.1000.

- ❖ The PEL is a maximum time-weighted concentration at which 95 percent of exposed, healthy adults suffer no adverse effects over a 40-hour workweek. The lower the PEL, the more toxic the substance.

**[A] PERMIT.** An official document or certificate issued by the *fire code official* that authorizes performance of a specified activity.

- ❖ The permit constitutes a license issued by the fire code official to proceed with a specific activity, such as construction of a building or conducting a certain type of business, in accordance with all applicable laws.

For the IBC and IRC, the “building official” is identified as the person responsible for issuing the permit. For the IFC, the “fire code official” is identified as the person responsible. For other I-Codes, the “code official” is identified as the person responsible.

**[A] PERSON.** An individual, heirs, executors, administrators or assigns, and also includes a firm, partnership or corporation, its or their successors or assigns, or the agent of any of the aforesaid.

- ❖ Corporations and other organizations listed in the definition are treated as persons under the law. Also, when the code provides for a penalty (see Section 109.4), the definition makes it clear that the individuals responsible for administering the activities of these various organizations are subject to these penalties.

**[BG] PERSONAL CARE SERVICE.** The care of persons who do not require medical care. Personal care involves responsibility for the safety of the persons while inside the building.

- ❖ Persons who need personal care may need supervision, but they are capable of self-preservation. See the commentary to Occupancy Group E day care.

Care facilities encompass a full spectrum of occupant acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. On the lower end of the care spectrum (i.e., personal care) is when occupants are supervised but do not need custodial or medical care. Where occupants may be elderly or impaired (i.e., custodial care), they may need occasional daily living assistance, such as cooking and cleaning. While occupants may take longer to evacuate than average, they are capable of self-preservation. On the opposite end of the care spectrum, persons receiving care may be completely bedridden and dependant on medical gases and emergency power to maintain life (i.e., medical care). The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems and building. See also the definitions for “24-hour basis,” “Custodial care,” “Detoxification facilities,” “Foster care facilities,” “Group home,” “Hospitals and psychiatric hospitals,” “Medical care,” “Nursing home” and “Incapable of self-preservation.”

**PESTICIDE.** A substance or mixture of substances, including fungicides, intended for preventing, destroying, repelling

or mitigating pests and substances or a mixture of substances intended for use as a plant regulator, defoliant or desiccant. Products defined as drugs in the Federal Food, Drug and Cosmetic Act are not pesticides.

- ❖ Typically, pesticides are ranked in the toxic category of health hazards. They are primarily used to control a variety of pests.

**[BE] PHOTOLUMINESCENT.** Having the property of emitting light that continues for a length of time after excitation by visible or invisible light has been removed.

- ❖ Examples of photoluminescent material are paint and tape that are charged by exposure to light. When the lights are turned off, the product will “glow” in the dark. Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Section 403.5.5 of the IBC and Section 1025) or exit signs (see Section 1013.5) may be photoluminescent or self-luminous. A variety of materials can comply with the referenced standards for egress path markings—UL 1994, *Standard for Safety of Low Level Path Marking and Lighting Systems* and ASTM E 2072, *Standard Specification for Photoluminescent (Phosphorescent) Safety Markings—and for signs—UL 924, Standard for Safety Emergency Lighting and Power Equipment.*

**PHYSICAL HAZARD.** A chemical for which there is evidence that it is a *combustible liquid, cryogenic fluid, explosive, flammable* (solid, liquid or gas), *organic peroxide* (solid or liquid), *oxidizer* (solid or liquid), *oxidizing gas, pyrophoric* (solid, liquid or gas), *unstable (reactive) material* (solid, liquid or gas) or *water-reactive material* (solid or liquid).

- ❖ Materials posing a detonation or deflagration hazard, or materials that readily support combustion, are considered physical hazards. Structures containing materials posing a physical hazard exceeding maximum allowable quantities are classified in Group H-1, H-2 or H-3. Materials posing a physical hazard may also present a health hazard.

**PHYSIOLOGICAL WARNING THRESHOLD.** A concentration of air-borne contaminants, normally expressed in parts per million (ppm) or milligrams per cubic meter (mg/m<sup>3</sup>), that represents the concentration at which persons can sense the presence of the contaminant due to odor, irritation or other quick-acting physiological responses. When used in conjunction with the permissible exposure limit (PEL), the physiological warning threshold levels are those consistent with the classification system used to establish the PEL. See the definition of “Permissible exposure limit (PEL).”

- ❖ The term “physiological warning properties” is not defined. From a practical standpoint, the physiological warning properties are represented by a concentration of a contaminant that allows the average individual to sense its presence by a body warning signal including, but not limited to, odor, irritating effects such as stinging sensations, coughing, scratchy feeling in the throat, running of the eyes or nose and similar signals.

## DEFINITIONS

There may be a wide variability reported for some of the more common threshold levels including that of olfactory perception. Variations that may be encountered are due to a number of factors including the methods used in their determination, the population exposed and others. The requirements for gas detection established in the code are tied to the permissible exposure limit (PEL), and there are several methods for determining the PEL inherent in the definition of that term. Including this definition intends to link the determination of the physiological warning threshold level to the data used to determine the PEL. For example, the PEL as established by 29 CFR is primarily based on data developed by the American Conference of Governmental Industrial Hygienists (ACGIH) called “threshold limit values (TLVs)” as referenced in the definition of “Permissible exposure limit (PEL)”. To substantiate the TLVs (PELs), the ACGIH publishes the Documentation of the Threshold Limit Values (TLVs®) and Biological Exposure Indices (BEIs®) where the user is provided with data used in their establishment. The significant commercially available toxic and highly toxic gases with published TLVs are listed by ACGIH, and perception thresholds are provided. These warning properties are considered, as evidenced by the documentation when the TLV and hence the PEL is established. It is appropriate that the data used in the base documents be used as the basis for determining the threshold level when such data is available. The use of data from other sources may be used in the absence of data within the system used for the establishment of the PEL, but where such data has been considered in determining the PEL such data should take precedent. By providing a definition for physiological warning threshold level and guidance as to how it is to be applied, the code user is given guidance that carries out the intent of the provisions for gas detection that have been established in the code. See the commentary to Section 6004.2.2.10 for further discussion of gas detection.

**PIER.** A structure built over the water, supported by pillars or piles, and used as a landing place, pleasure pavilion or similar purpose.

❖ A pier extends from land over the water to facilitate the loading and unloading of marine vessels with both people and cargo. Many piers also have commercial operations located on them. Piers are typically longer than they are wide and may be constructed of concrete, wood or other combustible materials. When wood materials are used, they are usually heavily coated or pressure treated with preservatives. Exposure to weather will cause the wood materials to dry out and be susceptible to ignition. Wood piers, being elevated structures, will burn freely due to the configuration and amount of exposed material available to burn.

**PLACE OF RELIGIOUS WORSHIP.** See “Religious worship, place of.”

**[M] PLENUM.** An enclosed portion of the building structure, other than an occupiable space being conditioned, that is designed to allow air movement and thereby serve as part of an air distribution system.

❖ A plenum is part of an air distribution system and is usually concealed within the building construction. Plenums can be used for supply, return, exhaust, relief and ventilation air. They can occur in ceiling, attic or under-floor spaces, in mechanical equipment rooms (air handler rooms) and in stud and joist cavities. The definition clarifies that plenums are uninhabitable, unoccupiable cavities and interstitial spaces only; an unoccupiable room or space is not a plenum (see the commentary to Section 602 of the IMC for restrictions on the use of plenums).

**PLOSOPHORIC MATERIAL.** Two or more unmixed, commercially manufactured, prepackaged chemical substances including oxidizers, flammable liquids or solids, or similar substances that are not independently classified as *explosives* but which, when mixed or combined, form an *explosive* that is intended for blasting.

❖ Plosophoric materials, or plosophors, also are known as two-component or binary explosives. When plosophoric materials are mixed or combined at the point of use, the procedures recommended by the manufacturer should be strictly enforced. Mixed or combined plosophoric materials must be transported, stored and used in the same manner as explosives.

**PLYWOOD AND VENEER MILLS.** Facilities where raw wood products are processed into finished wood products, including waferboard, oriented strandboard, fiberboard, composite wood panels and plywood.

❖ Veneer mills are unique because the milling is done with knives rather than saws. Veneer logs are often air dried for an extended period of time before processing.

**PORTABLE OUTDOOR FIREPLACE.** A portable, outdoor, solid-fuel-burning fireplace that may be constructed of steel, concrete, clay or other noncombustible material. A portable outdoor fireplace may be open in design, or may be equipped with a small hearth opening and a short chimney or chimney opening in the top.

❖ This definition describes a fairly recent innovation that has often been treated as open burning. These devices function similar to a masonry or factory-built indoor fireplace except that they are portable, solid fuel-burning fireplaces designed to provide ambience and warmth in outdoor settings. They come in many styles and designs, both open and enclosed. Some designs are constructed of steel with screening around the firebox while others are made of concrete or clay with a small hearth opening and are equipped

with a short chimney or simply a chimney opening. Still others function as a fire pit on legs. The design will typically include a stand or legs to elevate the fire-box above the surface upon which it is placed to provide clearance to combustible materials. Sections 307.4.3 and 307.5 of the code contain specific clearance and attendance requirements for these devices. See also the definitions of “Open burning” and “Recreational fire.”

**POWERED INDUSTRIAL TRUCK.** A forklift, tractor, platform lift truck or motorized hand truck powered by an electrical motor or internal combustion engine. Powered industrial trucks do not include farm vehicles or automotive vehicles for highway use.

❖ This kind of vehicle includes forklift trucks and other similar vehicles used to move stock in warehouses, industrial buildings, large retail spaces, storage yards and loading docks. These vehicles are not licensed for highway travel and do not include farm machinery.

**[BE] POWER-ASSISTED DOOR.** Swinging door that opens by reduced pushing or pulling force on the door-operating hardware. The door closes automatically after the pushing or pulling force is released, and functions with decreased forces. See also “Low energy power-operated door” and “Power-operated door.”

❖ There are basically three different types of doors that provide some type of power assistance for entry: low energy power-operated doors, power-assisted doors and power-operated doors. The power-assisted door is typically a side-swinging door that has the additional feature of powered assistance to move the door to the open position. When a door has power assistance, the force or effort it takes to open the door while it is being pushed or pulled is reduced as long as a user maintains pressure on the hardware. When the hardware is released, the door will move to the closed position. Power-assisted doors are typically used when a door is an unusual size or weight. The low-energy power-assisted door and power-assisted door both are operated by the user touching something; therefore, they both must comply with BMHA156.19.

**[BE] POWER-OPERATED DOOR.** Swinging, sliding, or folding door that opens automatically when approached by a pedestrian or opens automatically upon an action by a pedestrian. The door closes automatically and includes provisions such as presence sensors to prevent entrapment. See also “Low energy power-operated door” and “Power-assisted door.”

❖ There are basically three different types of doors that provide some type of power assistance for entry: low energy power-operated doors, power-assisted doors and power-operated doors. The power-operated door can be a sliding, hinged or side-swinging door that operates automatically by either a motion sensor or sensor mat when someone approaches the door. Power-operated doors are most commonly installed at the busy entrances of commercial buildings. As a

door with hands-free operation, the power-operated door must comply with BMHA156.10.

**PRESSURE VESSEL.** A closed vessel designed to operate at pressures above 15 psig (103 kPa).

❖ A pressure vessel used to contain hazardous materials must comply with the ASME *Boiler and Pressure Vessel Code* (BPVC), in accordance with Section 5003.2.1. Pressure vessels are constructed as cylindrical or spherical structures because such a design is safer, more economical, and it is easier to construct a vessel in these shapes to control axial and circumferential stresses. Pressure vessels can be constructed for either a horizontal (see Commentary Figure 202-P1) or vertical orientation (see Commentary Figure 202-P2). The design, construction and examination requirements for pressure vessels that are used for hazardous materials are contained in Section VIII, Division 1, of the BPVC, which sets forth requirements for unfired pressure vessels with design pressures up to 3,000 pounds per square inch gauge (psig) (20 685 kPa). For pressures over 3,000 psig (20 685 kPa), the alternative design rules in Division 2 or 3 of BPVC Section VIII must be applied. Pressure vessels are not listed by nationally recognized testing laboratories. Instead, when a pressure vessel is fabricated in accordance with the BPVC, the fabricator will employ an authorized inspector to perform examinations of the vessel to ensure it is constructed in accordance with the BPVC and the approved design drawings. The authorized inspector also verifies the proper materials of construction are selected, that welders have the appropriate certifications based on the welding methods used and that welds are performed in accordance with the approved welding procedures. The BPVC requires that all pressure vessels be equipped with a nameplate welded at a conspicuous location directly onto the shell of the vessel (or

**Figure 202-P1**  
**INSULATED HORIZONTAL PRESSURE VESSEL**

## DEFINITIONS

onto a welded bracket if the pressure vessel will be insulated) that demonstrates the vessel was constructed in accordance with the requirements of ASME. In addition to the pressure vessel's nameplate, ASME also requires that a Manufacturer's Data Report for Pressure Vessels (ASME Form U-1) be prepared by the manufacturer to document the construction of the vessel and its compliance with the applicable edition of the BPVC. It is quite common in the establishment of new construction processes to purchase and install used pressure vessels. Given the safety factors required by the BPVC, properly selected and maintained pressure vessels can easily perform for decades provided they are operated within their design temperature and pressures, and are properly designed for external loads. Fire code officials should utilize the nameplate in conjunction with ASME Form U-1 to confirm that the installed vessel is constructed to the BPVC and use this documentation to demonstrate compliance with Section 5003.2.1. Pressure vessels that are not equipped with a nameplate should not be approved unless they are evaluated by a qualified engineer. In such instances, a technical report and opinion should be obtained in accordance with Section 104.7.2.

Figure 202-P2  
VERTICAL PRESSURE VESSEL

**PRIMARY CONTAINMENT.** The first level of containment, consisting of the inside portion of that container which

comes into immediate contact on its inner surface with the material being contained.

- ❖ In most cases, this definition pertains to those components of tanks, portable tanks and containers that are the main mechanism for the containment of liquid (the basic walls of the tank, portable tank or container). The term "secondary containment" refers to the containment provided when the primary containment fails.

**[BG] PRIVATE GARAGE.** A building or portion of a building in which motor vehicles used by the tenants of the building or buildings on the premises are stored or kept, without provisions for repairing or servicing such vehicles for profit.

- ❖ In Section 406 of the IBC, the code regulates two types of garages: private and public. Public garages are further separated into open or enclosed garages. Private garages are limited in size by Section 406.3 of the IBC and can be accessory to either residential or nonresidential uses. The definition is intended to help distinguish private garages from public garages. Carports are also addressed in Section 406.3 of the IBC.

**PROCESS TRANSFER.** The transfer of flammable or *combustible liquids* between tank vehicles or tank cars and process operations. Process operations may include containers, tanks, piping and equipment.

- ❖ The transfer of flammable or combustible liquids during any process operation may include the introduction of the flammable or combustible liquids into or within the process operation.

**PROPELLANT.** The liquefied or *compressed gas* in an aerosol container that expels the contents from an aerosol container when the valve is actuated. A propellant is considered flammable if it forms a flammable mixture with air, or if a flame is self-propagating in a mixture with air.

- ❖ The amount of flammable propellant content is important in properly classifying aerosol products, since it affects the overall chemical heat of combustion value. Common flammable propellants are hydrocarbons, such as butane, propane, isobutane or a combination of these.

**PROXIMATE AUDIENCE.** An audience closer to pyrotechnic devices than allowed by NFPA 1123.

- ❖ The separation distance of the pyrotechnic devices and the audience permitted by NFPA 1123 is in relationship to the shell size of the mortar. NFPA 1126 addresses the requirements for proximate audiences.

**[B] PSYCHIATRIC HOSPITALS.** See "Hospitals."

**PUBLIC TRAFFIC ROUTE (PTR).** Any public street, road, highway, navigable stream or passenger railroad that is used for through traffic by the general public.

- ❖ See the commentary to the definition of "Quantity-Distance (Q-D)."

**[BE] PUBLIC-USE AREAS.** Interior or exterior rooms or spaces that are made available to the general public.

❖ This term is utilized to describe all interior and exterior spaces or rooms that may be occupied by the general public for any amount of time. Spaces that are utilized by the general public may be located in facilities that are publicly or privately owned. Examples include the lobby in an office building, a high-school gymnasium with assembly seating, an open-air stadium, a multipurpose room, an exposition hall, a restaurant dining room, a health club, etc. (see also the commentary to the definitions of “Common use” and “Employee work area”).

**[A] PUBLIC WAY.** A street, alley or other parcel of land open to the outside air leading to a street, that has been deeded, dedicated or otherwise permanently appropriated to the public for public use and which has a clear width and height of not less than 10 feet (3048 mm).

❖ The public way marks the termination of the exit discharge portion of the means of egress system. It is the final destination for occupants, and is presumed to be safe from the emergency occurring in the structure or it will directly connect to other routes so that occupants can move a distance away from the danger. The 10-foot (3048 mm) width is consistent with the exit discharge requirements in Section 1028.

**PYROPHORIC.** A chemical with an autoignition temperature in air, at or below a temperature of 130°F (54°C).

❖ The definition is derived from DOL 29 CFR Part 1910.1200. Pyrophoric materials, whether in a gas, liquid or solid form, are capable of spontaneous ignition at low temperatures. Pyrophoric materials, regardless of their physical state, may spontaneously ignite when exposed to air at normal or slightly elevated temperatures, even in small quantities. Many pyrophoric materials are also highly reactive with water. While even moist air may increase the possibility of ignition, the application of water may cause an explosive reaction (see commentary, Chapter 67).

**PYROTECHNIC ARTICLE.** A pyrotechnic device for use in the entertainment industry, which is not classified as fireworks.

❖ This definition refers to articles containing substances or a mixture of substances designed to produce heat, light, sound or smoke or a combination of such effects for theatrical purposes.

**PYROTECHNIC COMPOSITION.** A chemical mixture that produces visible light displays or sounds through a self-propagating, heat-releasing chemical reaction which is initiated by ignition.

❖ This definition parallels the definition in NFPA 1124, referenced in Section 5605.1. The term is used in the definition of “Display, 1.3G fireworks,” and is the basis for establishing the allowable amounts in Table 5604.3.

**PYROTECHNIC SPECIAL EFFECT.** A visible or audible effect for entertainment created through the use of pyrotechnic materials and devices.

❖ Pyrotechnic special effects are widely used in motion-picture production to create all types of effects involving explosions, fires, light, smoke and sound concussions. The types of pyrotechnic materials used include flash powder, flash paper, gun cotton, black powder (gunpowder), smokeless powder, detonator explosives and many more. They are used in bullet hits (squibs), blank cartridges, flash pots, fuses, mortars, smoke pots, sparkle pots, etc.

The main problems of pyrotechnics include prematurely triggering the pyrotechnic effect; use of larger quantities or more dangerous materials than needed; causing a fire; lack of adequate fire-extinguishing capabilities and, of course, inadequately trained and experienced pyrotechnic operators. As a result of these risks, all pyrotechnic special effects are regulated at the federal, state and local level.

**PYROTECHNIC SPECIAL-EFFECT MATERIAL.** A chemical mixture used in the entertainment industry to produce visible or audible effects by combustion, *deflagration* or *detonation*. Such a chemical mixture predominantly consists of solids capable of producing a controlled, self-sustaining and self-contained exothermic chemical reaction that results in heat, gas sound, light or a combination of these effects. The chemical reaction functions without external oxygen.

❖ Pyrotechnic special effects materials are Division 1.3 explosives. They will burn but not explode, unless confined. Examples are black powder and pellet powder, safety fuses, igniters, igniter cord, fuse lighters, Division 1.3 special fireworks and Division 1.3 composite solid propellants.

**PYROTECHNICS.** Controlled exothermic chemical reactions timed to create the effects of heat, hot gas, sound, dispersion of aerosols, emission of visible light or a combination of such effects to achieve the maximum effect from the least volume of pyrotechnic composition.

❖ This definition describes special devices that are used to create entertainment, exhibition, demonstration or simulation through the controlled use of flame, sounds, aerosols or other special effects before a proximate audience (see Section 5608 and NFPA 1126).

**QUANTITY-DISTANCE (Q-D).** The quantity of *explosive material* and separation distance relationships providing protection. These relationships are based on levels of risk considered acceptable for the stipulated exposures and are tabulated in the appropriate Q-D tables. The separation distances specified afford less than absolute safety:

**Inhabited building distance (IBD).** The minimum separation distance between an operating building or magazine containing *explosive materials* and an inhabited building or site boundary.

## DEFINITIONS

**Intermagazine distance (IMD).** The minimum separation distance between magazines.

**Intraline distance (ILD) or Intraplant distance (IPD).** The distance to be maintained between any two operating buildings on an *explosives* manufacturing site when at least one contains or is designed to contain *explosives*, or the distance between a magazine and an operating building.

**Minimum separation distance ( $D_o$ ).** The minimum separation distance between adjacent buildings occupied in conjunction with the manufacture, transportation, storage or use of *explosive materials* where one of the buildings contains *explosive materials* and the other building does not.

- ❖ This definition (with subdefinitions) correlates with tables to be used for distance determination, and also with the terminology used by those engaged in the storage and manufacture of explosive materials as well as with the regulators of these materials, including the DOD. The term is also consistent with terminology used by the DOD and the IME. The terms will bring a consistent set of terminologies to the code.

The definition “Quantity-Distance (Q-D)” is the relationship between a quantity of explosive material and the minimum separation distances required. The use of Q-D relationships to establish building siting is fundamentally used in the planning and occupancy of buildings used to contain explosive materials. Section 5601.2.3 (permit restrictions) authorizes the fire code official to limit the quantity of explosives at any given location. The limitations on quantity are typically derived based on the location of the explosives. The distances required vary depending on the sensitivity of the receptor. Distances are generally greater where the public or those not engaged in the manufacturing process are involved.

The subelements of the definition include terms that typically appear (or should appear) on building and site plans that are used to confirm that the siting for the structure used to contain the explosive material (building or magazine) is properly located. Acronyms (e.g., IBD, ILD, IMD, etc.) are typically used to describe the distance used to separate the explosives from receptors such as inhabited buildings, public traffic or transportation routes (highways), other storage (magazines) and the like.

Notwithstanding the tabular distance established by the Q-D tables integral to the explosives industry, there are occasions where ancillary buildings are needed to be constructed that do not contain explosive materials per se, where the ancillary building will encroach on the building containing explosive materials.  $D_o$  is a fire separation distance, and not unlike that used by the IBC to determine the location of “detached buildings.” As the buildings regulated by the Q-D tables are required to be detached, a minimum separation distance is established. This distance is noted in Tables 5601.8.1(1) through 5601.8.1(3) with 50 feet (15 240 mm) established as

the minimum for buildings containing materials with mass fire and fire hazards, and 60 feet (18 288 mm) established as the minimum for buildings containing materials with mass explosion hazards. From a practical standpoint, the  $D_o$  distances will apply only to facilities where the explosive quantities are near the minimums as the distances are increased rapidly with increases in material content.

The term “intraline” is used in this chapter in the definition of “Operating, building,” and in Note a to Table 5605.3. The term “intraline distance (ILD)” (intra = within the line) is used synonymously with intraplant distance (IPD), although there are differences applied on military sites for the purpose of separating different operating lines. For example, on military sites, it is common to separate one operating line from another by the inhabited building distance. On the other hand, on commercial sites, it is common to produce multiple product lines within an associated building group and to separate the various buildings within the group by IPD. By equating the terms “IPD” and “ILD,” commercial uses are provided with a level of protection that is designed to address building safety that is not product specific, but is designed to address the explosive nature of materials involved.

The term “intraplant” is used in the title of Section 5605.3, Table 5605.3 and in the definition of “Operating building.” It is a unique term, and as such requires the supporting definition included here.

**RAILWAY.** A steam, electric or other railroad or railway that carries passengers for hire.

- ❖ The definition of “Railway” is intended to minimize the exposure of passengers to danger if an explosion occurs involving an explosives magazine.

**[BE] RAMP.** A walking surface that has a running slope steeper than one unit vertical in 20 units horizontal (5-percent slope).

- ❖ This definition is needed to determine the threshold at which the ramp requirements apply to a walking surface. Walking surfaces steeper than specified in the definition are subject to the ramp requirements in Sections 1012 and 1029.

**RAMP, EXIT ACCESS.** See “Exit access ramp.”

**RAMP, EXTERIOR EXIT.** See “Exterior exit ramp.”

**RAMP, INTERIOR EXIT.** See “Interior exit ramp.”

**RAW PRODUCT.** A mixture of natural materials such as tree, brush trimmings, or waste logs and stumps.

**READY BOX.** A weather-resistant container with a self-closing or automatic-closing cover that protects fireworks shells from burning debris. Tarpaulins shall not be considered as ready boxes.

- ❖ After delivery and prior to the display, shells must be separated according to size and their designation as salutes. Any display fireworks that will be temporarily stored at the display site during the fireworks display must be stored in ready boxes separated according to size and their designation as salutes.

**[A] RECORD DRAWINGS.** Drawings (“as built”) that document the location of all devices, appliances, wiring, sequences, wiring methods and connections of the components of a fire alarm system as installed.

- ❖ To verify that the system has been installed to comply with the code and applicable referenced standards, complete as-built drawings of the fire alarm system must be available on site for review.

**RECREATIONAL FIRE.** An outdoor fire burning materials other than rubbish where the fuel being burned is not contained in an incinerator, outdoor fireplace, portable outdoor fireplace, barbeque grill or barbeque pit and has a total fuel area of 3 feet (914 mm) or less in diameter and 2 feet (610 mm) or less in height for pleasure, religious, ceremonial, cooking, warmth or similar purposes.

- ❖ This kind of fire includes ordinary campfires and other small fires used for the activities listed. The definition has also been revised to clarify that the use of portable outdoor fireplaces (also known as patio fireplaces) is specifically included thus eliminating the confusion that previously existed as to how to treat those devices. See also the definition of “Open burning.”

**REDUCED FLOW VALVE.** A valve equipped with a restricted flow orifice and inserted into a *compressed gas* cylinder, portable tank or stationary tank that is designed to reduce the maximum flow from the valve under full-flow conditions. The maximum flow rate from the valve is determined with the valve allowed to flow to atmosphere with no other piping or fittings attached.

- ❖ This is a valve that allows the maximum flow rate from a container to be reduced. For the reduction to be accurate, the maximum flow rate of a container must be known. The maximum flow rate must be determined without any piping or fittings attached to the container. This ensures that the reduction valve can actually achieve what is intended.

**REFINERY.** A plant in which flammable or *combustible liquids* are produced on a commercial scale from crude petroleum, natural gasoline or other hydrocarbon sources.

- ❖ A refinery is the facility that produces flammable or combustible liquids from raw materials.

**REFRIGERANT.** The fluid used for heat transfer in a refrigeration system; the refrigerant absorbs heat and transfers it at a higher temperature and a higher pressure, usually with a change of state.

- ❖ The refrigerant is the working fluid in refrigeration and air-conditioning systems. In vapor refrigeration cycles, refrigerants absorb heat from the load side at the evaporator and reject heat at the condenser. Aside from having suitable thermodynamic properties, the selection of a refrigerant must also take into consideration chemical stability, flammability, toxicity and environmental compatibility. Refrigeration is a result of the physical laws of vaporization (evaporation) of liquids. Basically, evaporation of liquid refrigerant is an endothermic process and condensing of vapors is an exothermic process.

erant is an endothermic process and condensing of vapors is an exothermic process.

**[M] REFRIGERATING (REFRIGERATION) SYSTEM.** A combination of interconnected refrigerant-containing parts constituting one closed refrigerant circuit in which a refrigerant is circulated for the purpose of extracting heat.

- ❖ Such systems include, at minimum, a pressure-imposing element or generator, an evaporator, a condenser and interconnecting piping. A single piece of equipment can contain multiple refrigeration systems (circuits).

**[A] REGISTERED DESIGN PROFESSIONAL.** An architect or engineer, registered or licensed to practice professional architecture or engineering, as defined by the statutory requirements of the professional registration laws of the state in which the project is to be constructed.

- ❖ This term is used throughout the code where a special level of expertise and knowledge is required. The definition clearly notes that each state defines its own professional registration laws. Legal qualifications for engineers and architects are established by the state having jurisdiction. Licensing and registration of engineers and architects are accomplished by written or oral examinations offered by states or by reciprocity (licensing in other states).

**[BG] RELIGIOUS WORSHIP, PLACE OF.** A building or portion thereof intended for the performance of religious services.

- ❖ This term has been added to the code for the purpose of making the code more broadly applicable to the worship facilities of all religions. Major religions for the world include Christianity, Islam, Hinduism, Buddhism and Judaism, which use different terms to describe the main space used for religious services. The intent in the code is for the same application for all similar types of religious facilities. The term also makes it clear that it defines the room or sanctuary for the performance of religious worship services and not retreat complexes, rectories, convents and classroom or office areas.

**REMOTE EMERGENCY SHUTOFF DEVICE.** The combination of an operator-carried signaling device and a mechanism on the tank vehicle. Activation of the remote emergency shutoff device sends a signal to the tanker-mounted mechanism and causes fuel flow to cease.

- ❖ This definition describes an important safety device used in the mobile fueling operation regulated by Section 5706.5.4.5 and describes a portable device that a tank vehicle driver may use to prevent an overfill spill during mobile fueling when the driver is out of immediate reach of the tanker shutoff controls (see commentary, Section 5706.5.4.5).

**REMOTE SOLVENT RESERVOIR.** A liquid solvent container enclosed against evaporative losses to the atmosphere during periods when the container is not being utilized, except for a solvent return opening not larger than 16 square

## DEFINITIONS

inches (10 322 mm<sup>2</sup>). Such return allows pump-cycled used solvent to drain back into the reservoir from a separate solvent sink or work area.

- ❖ A remote solvent reservoir is the storage of flammable or combustible liquid in a container that is not in the same control area as the machine using the flammable or combustible liquid. The remote solvent reservoir is connected to the machine by piping or tubing.

**REMOTELY LOCATED, MANUALLY ACTIVATED SHUTDOWN CONTROL.** A control system that is designed to initiate shutdown of the flow of gases or liquids that is manually activated from a point located some distance from the delivery system.

- ❖ See the commentary to the definitions for “Emergency shutoff valves.”

**REPAIR GARAGE.** A building, structure or portion thereof used for servicing or repairing motor vehicles.

- ❖ A repair garage may be part of a motor fuel-dispensing facility. The fuel-dispensing area will comply with the motor fuel-dispensing facility sections of this chapter and the repair garage area will comply with the repair garage section (see Section 2311) of this chapter. A marine pleasure craft dealership with a boat repair area will be classified as a repair garage. Motor vehicle repair garages are classified in occupancy Group S-1 by the IBC.

**RESIN APPLICATION AREA.** An area where reinforced plastics are used to manufacture products by hand lay-up or spray-fabrication methods.

- ❖ Glass fiber is used for reinforcement of plastics or polymers, and the resulting products are typically called glass fiber reinforced plastics or polymers (GFRP). It is common to use the acronym FRP (fiber reinforced polymers), which is applicable to all fiber-reinforced plastics or polymers.

**RESPONSIBLE PERSON.** A person trained in the safety and fire safety considerations concerned with hot work. Responsible for reviewing the sites prior to issuing permits as part of the hot work permit program and following up as the job progresses.

- ❖ This is the person designated to administer the hot work program (see that term’s definition in this section) in Section 3503. Without this definition, the term “responsible person” is a vague descriptor. The definition includes the scope of responsibilities for this person.

**RETAIL DISPLAY AREA.** The area of a Group M occupancy open for the purpose of viewing or purchasing merchandise offered for sale. Individuals in such establishments are free to circulate among the items offered for sale which are typically displayed on shelves, racks or the floor.

- ❖ Products containing aerosol propellants range from hair spray to paint to pesticides, lubricants and adhesives. Most often, products of this kind are grouped on shelves, but may also be set out in aisle displays

of stacked cartons with the top carton being “display cut” to show the product. A display cut carton, according to Section 3.3.26.2 of NFPA 30B, is a type of packaging in which the top and portions of the sides and front of the carton are removed to expose the product to the consumer.

**ROLL COATING.** The process of coating, spreading and impregnating fabrics, paper or other materials as they are passed directly through a tank or trough containing flammable or *combustible liquids*, or over the surface of a roller revolving partially submerged in a flammable or *combustible liquid*.

- ❖ Roll-coating methods apply material to flat work pieces, usually paper, cardboard, cloth or thin metals, using liquid-coated cylinders or rollers. Coating material may be applied to the rollers by rotating them in an open trough or pan or applying liquid to the space between two rollers. Please note that for this term to apply anywhere in the code, the tank or trough must contain flammable or combustible liquids.

The requirements in this chapter are for protection against, and mitigation in case of, a fire. In this case, the flammable vapors are typically heavier than air and may travel and spread a long distance unnoticed before reaching a potential ignition source and causing a vapor explosion or fire. In case of a fire within the tank or trough, there are additional concerns. The liquids are typically not water miscible and may overflow when the sprinkler system is activated or during the manual fire-fighting stages. This could spread the fire and liquids even farther.

**RUBBISH (TRASH).** Combustible and noncombustible waste materials, including residue from the burning of coal, wood, coke or other combustible material, paper, rags, cartons, tin cans, metals, mineral matter, glass crockery, dust and discarded refrigerators, and heating, cooking or incinerator-type appliances.

- ❖ The term “rubbish” is normally associated with combustible waste. In this code the term is much broader and would include noncombustible waste, such as metals. Generally, the scope of this definition includes anything that has been discarded.

**SAFETY CAN.** An *approved* container of not more than 5-gallon (19 L) capacity having a spring-closing lid and spout cover so designed that it will relieve internal pressure when subjected to fire exposure.

- ❖ Safety cans are commonly used where limited quantities of flammable and combustible liquids are required for manufacturing or research. The basic purpose of a safety can is to provide a safe and convenient means of transporting, dispensing and storing up to 5 gallons (19 L) of flammable and combustible liquids. All listed safety cans, regardless of material of construction, are required to be constructed as leak-tight containers. They must automatically vent any vapor if subjected to fire exposure at a pressure of 3 to 5 psig (20 685 to 34 475 kPa gauge) to prevent the container from being subjected to a deflagration

resulting from the increased vapor pressure of the liquid. Openings on safety cans must close automatically after being filled or dispensing a liquid. Finally, all listed safety cans must be designed so that a two-dimensional fire that could occur during dispensing cannot reach the pour opening and potentially extend into the safety can. This is commonly prevented by installing a flame arrestor in the container's inlet and outlet openings.

UL (Underwriters Laboratories) lists safety cans using UL 30 for metallic cans and UL 1313 for non-metallic cans. Factory Mutual (FM) Global also issues listings and approvals for metallic and nonmetallic safety cans. UL and FM both limit the volume of metallic safety cans to 5 gallons (19 L) or less—non-metallic safety cans are permitted to have a volume of 6.6 gallons (25 L). UL assigns a designation to safety cans based on the number of openings at the top of the container and container appurtenances. A Type I safety can, as shown in Commentary Figure 202-S1, is commonly a single-spout can designed for filling containers or tanks with large receiving openings. A Type II safety can, as shown in Commentary Figure 202-S2, has an integral flexible dispensing hose to control the transfer of the liquid. These safety cans have a second opening that serves as a pressure-vacuum vent which is also used to fill the safety can with liquid. Also see the commentary to Table 5003.1.1(1) and Section 5003.9.10.

**[BE] SCISSOR STAIRWAY.** Two interlocking *stairways* providing two separate paths of egress located within one *exit* enclosure.

- ❖ A scissor or interlocking stairway is sometimes used in high-rise buildings or to increase exit capacity of a stairwell enclosure. In this configuration, two independent stairway paths are located within the same exit

enclosure and may or may not be visually open to one another. When interlocking stairways are separated from each other with compliant fire barriers and horizontal assemblies, they are not considered scissor stairways (see Section 1007.1.1).

**SECONDARY CONTAINMENT.** That level of containment that is external to and separate from primary containment.

- ❖ If a spill or leak from the primary means of containment occurs, an additional level of containment may be necessary to isolate the hazardous materials from adjoining areas or the environment.

**SEED COTTON.** See “Cotton.”

**SEGREGATED.** Storage in the same room or inside area, but physically separated by distance from *incompatible materials*.

- ❖ The mixture of two or more chemicals can create a toxic or explosive chemical that is more dangerous than any of the individual chemicals. When chemicals are stored in the same room or storage area it is important to segregate them either by distance or by curbs that will prevent the chemicals from mixing in the case of a discharge.

**[BF] SELF-CLOSING.** As applied to a fire door or other opening, means equipped with an *approved* device that will ensure closing after having been opened.

- ❖ A self-closing opening protective refers to a fire or smoke door assembly equipped with a listed closer for doors that must be maintained in the normally closed position. When the door is opened and released, the self-closing feature returns the door to the closed position. It is important to distinguish between the terms “self-closing” and “automatic closing” because they are not interchangeable. “Automatic closing” refers to an opening protective that is

**Figure 202-S1

## DEFINITIONS

normally in the open position (see Section 716.5.9.2 of the IBC). Opening protectives with automatic closers are often held open and then returned to the closed position upon activation of fire detectors or smoke detectors or loss of power, which automatically releases the hold-open device allowing the door to close.

**[BE] SELF-LUMINOUS.** Illuminated by a self-contained power source, other than batteries, and operated independently of external power sources.

❖ Self-luminous products do not need an outside light source to charge them like photoluminescent materials do. Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Section 403.5.5 of the IBC and Section 1025) or exit signs (see Section 1011.5) may be photoluminescent or self-luminous. A variety of materials can comply with the referenced standards, for egress path markings—UL 1994 and ASTM E2072—and for signs—UL 924.

**SELF-PRESERVATION, INCAPABLE OF.** See “Incapable of self-preservation.”

**SELF-SERVICE MOTOR FUEL-DISPENSING FACILITY.** That portion of motor fuel-dispensing facility where liquid motor fuels are dispensed from fixed *approved* dispensing equipment into the fuel tanks of motor vehicles by persons other than a motor fuel-dispensing facility attendant.

❖ A self-service motor fuel-dispensing facility may be attended or, with the approval of the fire code official, unattended. A self-service motor fuel-dispensing facility is a facility where the fuel is dispensed by

someone other than an employee of the facility operator. Motor fuel-dispensing facilities are classified in occupancy Group M by the IBC.

**SEMICONDUCTOR FABRICATION FACILITY.** A building or a portion of a building in which electrical circuits or devices are created on solid crystalline substances having electrical conductivity greater than insulators but less than conductors. These circuits or devices are commonly known as semiconductors.

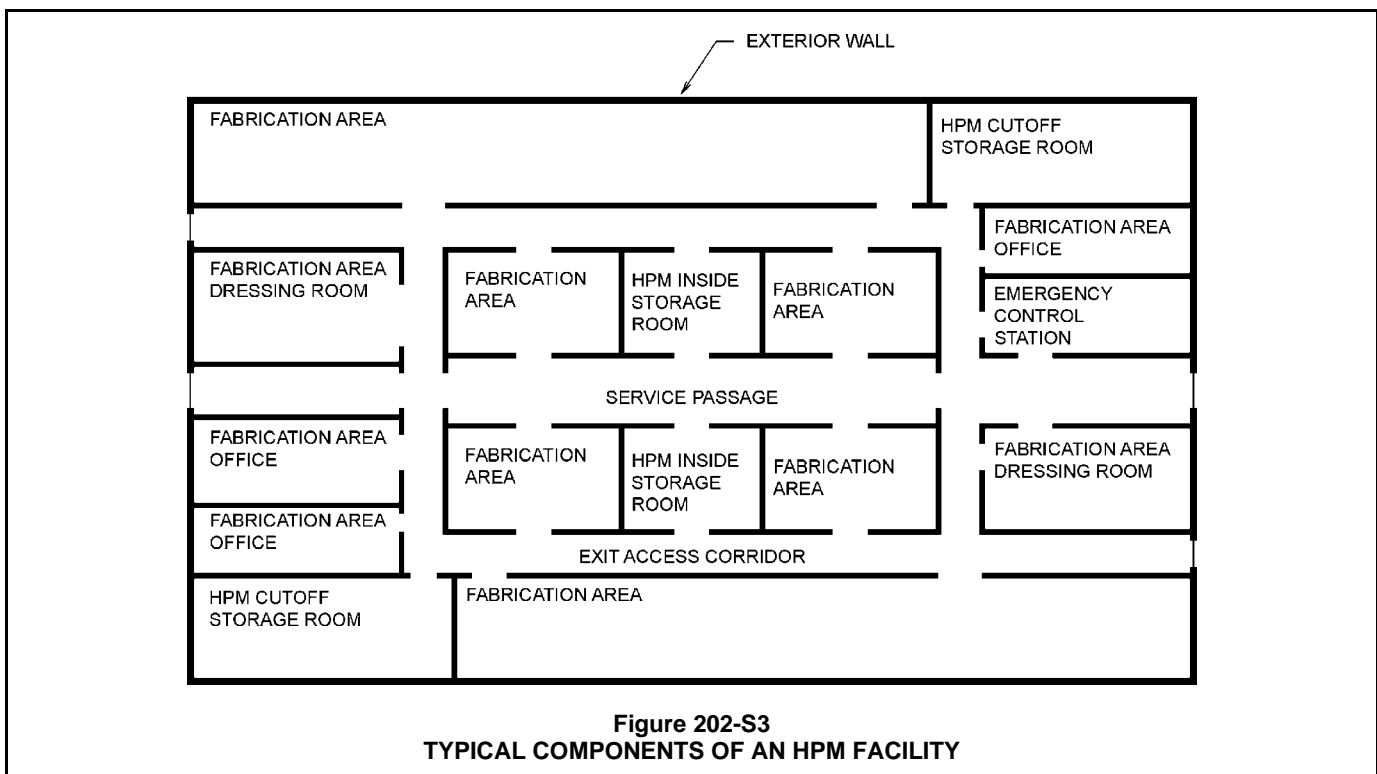

❖ A semiconductor fabrication facility is a building or a portion of a building where semiconductors are produced. See Commentary Figure 202-S3 for an example of a typical floor plan of a semiconductor fabrication facility.

**SERVICE CORRIDOR.** A fully enclosed passage used for transporting HPM and purposes other than required *means of egress*.

❖ Though HPM facility occupants may be exposed to limited HPM quantities during the course of their employment, their means of egress are protected from the HPM hazards by confining the HPM being transferred to its own passageway. A service corridor is required only when the HPM must be carried from a storage room or external area to a fabrication area through a passageway.

**SHELF STORAGE.** Storage on shelves less than 30 inches (762 mm) deep with the distance between shelves not exceeding 3 feet (914 mm) vertically. For other shelving arrangements, see the requirements for rack storage.

❖ To be considered shelf storage, the shelving must be no deeper than 30 inches (762 mm) and must be sep-

**Figure 202-S3**  
**TYPICAL COMPONENTS OF AN HPM FACILITY**

arated by no more than 3 feet (914 mm) vertically. Further, shelf storage units must be separated horizontally by aisles not less than 30 inches (762 mm) wide to reduce the transfer of fire from one shelf unit across the aisle to another. The aisles also allow convenient access for fire department personnel to combat a fire and for salvage and debris removal after an incident.

**SINGLE-STATION SMOKE ALARM.** An assembly incorporating the detector, the control equipment and the alarm-sounding device in one unit, operated from a power supply either in the unit or obtained at the point of installation.

❖ A single-station smoke alarm is a self-contained alarm device that detects visible or invisible particles of combustion. Its function is to detect a fire in the immediate area of the detector location. Single-station smoke alarms are individual units with the capability to stand alone. Where the single-station smoke alarms are interconnected with other single-station devices they would be considered a multiple-station smoke alarm system. Single-station smoke alarms are not capable of notifying or controlling any other fire protection equipment or systems. They may be battery powered, directly connected to the building power supply or a combination of both. Single-station smoke alarms must be built to comply with UL 217 and are to be installed as required by Section 907.2.11.

**[BG] SITE.** A parcel of land bounded by a *lot line* or a designated portion of a public right-of-way.

❖ This definition establishes, for application of code requirements, the property within the boundaries of the site that is under the control of the owner. The owner can be held responsible for code compliance of the site and all facilities on it. Note that legal property lines do not always constitute site boundaries (i.e., malls, condominiums, townhouses). A site could contain multiple legal “lot” divisions.

**[BG] SITE-FABRICATED STRETCH SYSTEM.** A system, fabricated on site and intended for acoustical, tackable or aesthetic purposes, that is composed of three elements:

1. A frame constructed of plastic, wood, metal or other material used to hold fabric in place;
2. A core material (infill, with the correct properties for the application); and
3. An outside layer, comprised of a textile, fabric or vinyl, that is stretched taut and held in place by tension or mechanical fasteners via the frame.

❖ Site-fabricated stretch systems are interior finish materials that are pulled taut across walls or ceilings with a frame that holds a fabric and core. These systems are now being used extensively because they can stretch to cover decorative walls and ceilings with unusual looks and shapes. The systems consist of three parts: a fabric (or vinyl), a frame and an infill core material. This type of product is not exclusive to

any particular manufacturer. It is important to point out that these materials are not curtains or drapes because they are not free hanging like curtains. See the commentary to Section 803.10.

**SKY LANTERN.** An unmanned device with a fuel source that incorporates an open flame in order to make the device airborne.

❖ This definition coordinates with Section 308.1.6, which prohibits the use of sky lanterns. This definition simply clarifies what is considered a sky lantern. Sky lanterns have the potential to start structure fires and wildfires. The two aspects of sky lanterns that are cause for concern are the open flame and that they freely float in the air without the ability for control from the ground. Typically they are also made of combustible materials such as paper.

**[BG] SLEEPING UNIT.** A room or space in which people sleep, which can also include permanent provisions for living, eating, and either sanitation or kitchen facilities but not both. Such rooms and spaces that are also part of a *dwelling unit* are not sleeping units.

❖ This definition is included to coordinate the Fair Housing Act Guidelines with the code. The definition for “Sleeping unit” clarifies the differences between sleeping units and dwelling units. In addition, using the term “sleeping unit” for spaces where people sleep will replace a multitude of other terms (i.e., patient room, cell, guest room) so that there is consistent application across occupancies. Some examples of sleeping units are hotel guestrooms, dormitories, bedrooms in boarding houses, patient sleeping rooms in hospitals, nursing homes or assisted living facilities, or housing cells in a jail. Another example would be a studio apartment with a kitchenette (i.e., countertop microwave, sink, refrigerator). Since the cooking arrangements are not the traditional permanent appliances (i.e., a cooktop, range or oven), this configuration would be considered a sleeping unit, and not a dwelling unit. As defined in the code, a dwelling unit must contain permanent facilities for living, sleeping, eating, cooking and sanitation.

**SMALL ARMS AMMUNITION.** A shotgun, rifle or pistol cartridge and any cartridge for propellant-actuated devices. This definition does not include military ammunition containing bursting charges or incendiary, trace, spotting or pyrotechnic projectiles.

❖ Small arms ammunition consists of cylindrical casings containing a small amount of smokeless powder. These items are usually designed to propel a missile or bullet at a target, but they may also be used in explosive actuated devices, such as nail guns and riveters. Individual cartridges are typically packed in paperboard boxes shipped in cardboard cartons. In a fire, these articles pose no mass detonation hazard and only a moderate (low-velocity) projectile hazard. The ATF definition of “Ammunition” also includes percussion caps and  $\frac{3}{32}$ -inch (2.4 mm) and other external burning pyrotechnic hobby fuses. Black powder

## DEFINITIONS

ammunition and black powder are not included in this definition.

**SMALL ARMS PRIMERS.** Small percussion-sensitive *explosive* charges, encased in a cap, used to ignite propellant powder.

❖ “Small arm primers” and “percussion caps” mean primers used for small arms ammunition.

**SMOKE ALARM.** A single- or multiple-station alarm responsive to smoke. See also “Single-station smoke alarm” and “Multiple-station smoke alarm.”

❖ This is a general term that applies to both single- and multiple-station smoke alarms that are not part of an automatic fire detection system. It is the generic term for any device that both detects the products of combustion and initiates an alarm signal for occupant notification.

**[BF] SMOKE BARRIER.** A continuous membrane, either vertical or horizontal, such as a wall, floor, or ceiling assembly, that is designed and constructed to restrict the movement of smoke.

❖ A smoke barrier is a fire-resistance-rated assembly that is different from a fire partition, fire barrier or fire wall. Smoke barriers include walls and floor/ceiling assemblies that are constructed with a 1-hour fire-resistance rating and are one of the components in a smoke compartment. In Group I-2 and I-3 occupancies, smoke barriers are intended to create adjacent smoke compartments to which building occupants can be safely and promptly relocated during a fire, thus preventing the need to have complete and immediate egress from the building. For these occupancies, complete egress from the building would not be practical in most cases, due to restrictions on the mobility of the occupants. To maintain tenability in the adjacent smoke compartment, the smoke barrier is therefore intended to resist the spread of fire and hinder the movement of smoke. Smoke barriers are also used to compartment a building into separate smoke control zones when using the provisions of Section 909. The construction requirements for a smoke barrier provide resistance to the transmission of smoke.

**[BG] SMOKE COMPARTMENT.** A space within a building enclosed by *smoke barriers* on all sides, including the top and bottom.

❖ Smoke compartments create spaces that protect occupants from the products of combustion produced by a fire in an adjacent smoke compartment and to restrict smoke to the compartment of fire origin.

**[BF] SMOKE DAMPER.** A *listed* device installed in ducts and air transfer openings designed to resist the passage of smoke. The device is installed to operate automatically, controlled by a smoke detection system, and where required, is capable of being positioned from a *fire command center*.

❖ Similar to a fire damper, smoke dampers are intended to restrict the passage of smoke through ducts or openings in structural assemblies such as

smoke barriers and corridor walls. They are also installed in smoke control systems. The smoke leakage rates of these devices are used to classify them in accordance with UL 555S. See also the commentary to the definitions of “Damper” and “Fire damper.”

**SMOKE DETECTOR.** A *listed* device that senses visible or invisible particles of combustion.

❖ These devices are considered early warning devices and have saved many people from smoke inhalation and burns. Smoke detectors have a wide range of uses, from sophisticated fire detection systems for industrial and commercial uses to residential. A smoke detector is a device, typically listed in accordance with UL 268, that activates a fire alarm system. These system smoke detectors contain only the components required to detect the products of combustion and activate a fire alarm system and are, therefore, different from single- and multiple-station smoke alarms.

Smoke detectors typically consist of two types: ionization and photoelectric. An ionization detector contains a small amount of radioactive material that ionizes the air in a sensing chamber and causes a current to flow through the air between two charged electrodes. When smoke enters the chamber, the particles cause a reduction in the current. When the level of conductance decreases to a preset level, the detector responds with an alarm.

A photoelectric smoke detector consists primarily of a light source, a light beam and a photosensitive device. When smoke particles enter the light beam, they reduce the light intensity in the photosensitive device. When obscuration reaches a preset level, the detector initiates an alarm.

**[BG] SMOKE-DEVELOPED INDEX.** A comparative measure, expressed as a dimensionless number, derived from measurements of smoke obscuration versus time for a material tested in accordance with ASTM E 84.

❖ The ASTM E84 test method of measuring the density of smoke emitted from combustible materials determines the smoke-developed index. This value is only comparative and provides only a relative understanding of smoke generation potential. The smoke-developed index is sometimes abbreviated as SDI.

**[BE] SMOKE-PROTECTED ASSEMBLY SEATING.** Seating served by means of egress that is not subject to smoke accumulation within or under a structure.

❖ An example of smoke-protected assembly seating is an open outdoor grandstand or an indoor arena with a smoke control system. The code has less stringent requirements for certain aspects of smoke-protected assembly seating than for seating that is not smoke protected, since occupants are subject to less hazard from the accumulation of smoke and fumes during a fire event. For example, an assembly dead-end aisle is permitted to be longer for a smoke-protected assembly area. For smoke control system requirements, see Section 909.

**SMOKELESS PROPELLANTS.** Solid propellants, commonly referred to as smokeless powders, used in small arms ammunition, cannons, rockets, propellant-actuated devices and similar articles.

- ❖ This term refers to a propellant explosive from which there is little or no smoke when fired, including smokeless powder for cannons and smokeless powder for small arms.

**[BF] SMOKEPROOF ENCLOSURE.** An *interior exit stairway* designed and constructed so that the movement of the products of combustion produced by a fire occurring in any part of the building into the enclosure is limited.

- ❖ A smokeproof enclosure is intended to provide an effective barrier to the entry of smoke into an exit stairway, thereby offering an additional level of protection for occupants of high-rise and underground structures.

**SOLID.** A material that has a melting point and decomposes or sublimates at a temperature greater than 68°F (20°C).

- ❖ One of the three states of matter, solids must decompose (pyrolysis) before they can produce vapors that will support combustion. The surface area of a solid in relation to the heat source is a concern for fire fighters; the greater the surface being subjected to a heat source, the more rapid the pyrolysis.

**SOLID BIOFUEL.** Densified biomass made in the form of cubiform, polyhedral, polyhydric or cylindrical units, produced by compressing milled biomass.

- ❖ This definition coordinates with the definition of “Biomass” and the application of this term in Section 2809. Essentially these materials need to be treated the same as materials such as finished lumber. The materials are compressed biomass materials. Section 2809.4 exempts the solid biofuel inside of buildings from the fencing requirements in the same way traditional lumber is exempted. Without these terms it makes it difficult to know how to regulate such materials.

**SOLID BIOMASS FEEDSTOCK.** The basic materials of which solid biofuel is composed, manufactured or made.

- ❖ This explains the types of materials that make up solid biofuel. This clarifies how the requirements of Section 2809 are to be applied. In addition, these materials need to be treated in accordance with Section 2808 prior to becoming a “solid biofuel.” These materials are processed in agro-industrial facilities (see the definition for “Agro-industrial”).

**SOLID SHELVING.** Shelving that is solid, slatted or of other construction located in racks and which obstructs sprinkler discharge down into the racks.

- ❖ Solid shelving generally consists of nominal wood (lumber), plywood, particleboard or metal shelves that span between the supports of the storage system to support the commodities. Solid shelving creates a condition where the rack storage system is effectively divided into areas by the shelving. The shelving can

potentially act as a protective barrier for a fire and from fire service hose streams by preventing the penetration of water into the fire area. As a result, the sprinkler system design will require an in-rack sprinkler system, in addition to the ceiling sprinkler system for water distribution, to penetrate the shelving barriers.

**SOLVENT DISTILLATION UNIT.** An appliance that receives contaminated flammable or *combustible liquids* and which distills the contents to remove contaminants and recover the solvents.

- ❖ A solvent distillation unit recycles flammable and combustible liquids by the condensation and collection of the vapors that are produced as the mixture is heated. The solvent distillation unit processes waste solvents in a separate, stand-alone batch, on-line batch or continuous systems. The distillation units heat the waste solvent to its boiling point. This causes the solvent to evaporate and the solvent vapors are then condensed in a separate container. The basic components of a distillation unit are the process chamber or boiler, the encapsulated heaters, a water-cooled chamber and associated piping and instrumentation. Temperature sensors monitor the temperature and help maintain the required distillation temperature. Disposable vessel liners can be used for simple collection and disposal of still bottoms. Vacuum pumps that can distill high-boiling solvents at lower temperatures are also available. Solvent distillation units having a distillation chamber capacity of 60 gallons (227 L) or less are listed under UL 2208. Solvent distillation units having a distillation chamber capacity greater than 60 gallons (227 L) must comply with Section 5705.4.2.

**SOLVENT OR LIQUID CLASSIFICATIONS.** A method for classifying solvents or liquids according to the following classes:

**Class I solvents.** Liquids having a *flash point* below 100°F (38°C).

**Class II solvents.** Liquids having a *flash point* at or above 100°F (38°C) and below 140°F (60°C).

**Class IIIA solvents.** Liquids having a *flash point* at or above 140°F (60°C) and below 200°F (93°C).

**Class IIIB solvents.** Liquids having a *flash point* at or above 200°F (93°C).

**Class IV solvents.** Liquids classified as nonflammable.

- ❖ These dry cleaning solvent classifications parallel the flammable and combustible liquid classifications defined in Chapter 57, with a notable exception that, while flammable liquids (Class I) are divided into three subclasses (Class IA, IB and IC) based on flash point and boiling point, Class I solvents are not. Solvent classifications, on the other hand, include a classification (Class IV) for those solvents considered to be nonflammable, whereas the flammable and combustible liquid classifications have no comparable category.

## DEFINITIONS

**SPECIAL AMUSEMENT BUILDING.** A building that is temporary, permanent or mobile that contains a device or system that conveys passengers or provides a walkway along, around or over a course in any direction as a form of amusement arranged so that the egress path is not readily apparent due to visual or audio distractions or an intentionally confounded egress path, or is not readily available because of the mode of conveyance through the building or structure.

❖ In general, a special amusement building is a building or portion thereof in which people gather (thus, an assembly occupancy) and in which egress is either not readily apparent due to distractions, is intentionally confounded (i.e., a maze) or is not readily available or where the occupants are moved through the building by way of a people mover system or are specifically directed through a walkway. Because of the nature of their use, these buildings contain special effects and other features that make it more difficult for occupants to determine when an emergency exists and where exits are located. The definition includes all such facilities, including portable and temporary structures. The hazard associated with such buildings is not related to the permanence or length of use; therefore, seasonal uses (such as “haunted houses” at Halloween) and portable uses (carnival attractions) are included if they meet the criteria in the definition. See also Section 411 of the IBC which regulates special amusement buildings.

**SPECIAL INDUSTRIAL EXPLOSIVE DEVICE.** An explosive power pack containing an *explosive* charge in the form of a cartridge or construction device. The term includes but is not limited to explosive rivets, explosive bolts, *explosive* charges for driving pins or studs, cartridges for *explosive*-actuated power tools and charges of *explosives* used in automotive air bag inflators, jet tapping of open hearth furnaces and jet perforation of oil well casings.

❖ Special industrial explosive devices are explosive-actuated power devices and propellant-actuated power devices. “Explosive-actuated device” means a tool or special mechanized device that is actuated by explosives. Examples of explosive-actuated power devices are jet tappers and jet perforators. “Propellant-actuated device” means a tool or special mechanized device or gas generator system that is actuated by a smokeless propellant or that releases and directs work through a smokeless propellant charge (also see commentary, Section 5601.1, Exception 6).

**SPRAY BOOTH.** A mechanically ventilated appliance of varying dimensions and construction provided to enclose or accommodate a spraying operation and to confine and limit the escape of spray vapor and residue and to exhaust it safely.

❖ Spray booths vary in construction, size and design. The definition is clear in that it can be a fully enclosed structure or it can be designed to contain the flammable or combustible vapors. An example of a fully enclosed structure is a spray booth where products are carried/carted into the booth for spraying operation and carted out once the operation is complete.

This definition, however, also allows for what is typically described as “open-face booths,” where the spray booth is enclosed on three sides and ventilated on the open side to confine the vapors to the spray booth area (see Commentary Figure 202-S4). An example of this is wood furniture finishing, where products such as wood tables are sprayed with stains and coating.

**SPRAY ROOM.** A room designed to accommodate spraying operations, constructed in accordance with the *International Building Code* and separated from the remainder of the building by a minimum 1-hour *fire barrier*.

❖ When spray booths cannot accommodate the spraying processes, because of size or for economic reasons, an entire room is dedicated to the process. In many cases, the oversprayed flammable/combustible liquids are allowed to remain on the floor until cleaned. These rooms have specific ventilation requirements to prevent the accumulation of vapors at the floor. See the commentary to Section 2404.3.1 for further discussion of spray rooms.

**SPRAYING SPACE.** An area in which dangerous quantities of flammable vapors or combustible residues, dusts or deposits are present due to the operation of spraying processes. The *fire code official* is authorized to define the limits of the spraying space in any specific case.

❖ Spraying spaces generally occur in one or a combination of three forms. The least desirable form is open floor area spraying, where the spraying area consists of an entire floor of a building without isolating the spraying operation. A better form is the spray room that isolates the spray operation by construction to less than an entire floor of the facility. The optimum form is a specially designed spray booth that isolates the operational hazards of spraying to an appropriately regulated space. Regardless of the form, all require special safeguards to address hazards, including adequate ventilation, fire suppression and management of overspray.

Figure 202-S4  
TYPICAL PAINT SPRAY BOOTH

**[BE] STAIR.** A change in elevation, consisting of one or more risers.

- ❖ All steps, even a single step, are defined as a stair. This makes the stair requirements applicable to all steps unless specifically exempt in the code.

**[BE] STAIRWAY.** One or more *flights of stairs*, either exterior or interior, with the necessary landings and platforms connecting them, to form a continuous and uninterrupted passage from one level to another.

- ❖ It is important to note that this definition characterizes a stairway as connecting one level to another. The term “level” is not to be confused with “story.” Steps that connect two levels, one of which is not considered a “story” of the structure, would be considered a stairway. For example, a set of steps between the basement level in an areaway and the outside ground level would be considered a stairway. A series of steps between the floor of a story and a mezzanine within that story would also be considered a stairway (see definitions for “Flight,” “Stairway, exterior,” “Stairway, interior” and “Interior exit stairway,” and Sections 1011, 1019, 1023 and 1027).

**STAIRWAY, EXIT ACCESS.** See “Exit access stairway.”

**STAIRWAY, EXTERIOR EXIT.** See “Exterior exit stairway.”

**STAIRWAY, INTERIOR EXIT.** See “Interior Exit Stairway.”

**STAIRWAY, SCISSOR.** See “Scissor stairway.”

**[BE] STAIRWAY, SPIRAL.** A *stairway* having a closed circular form in its plan view with uniform section-shaped treads attached to and radiating from a minimum-diameter supporting column.

- ❖ Spiral stairways are permitted as part of a means of egress in limited circumstances given in Section 1011.10. Spiral staircases could be used for supplemental/convenience stairways in other locations. Spiral stairways are commonly used where a small number of occupants use the stairway and the floor space for the stair is very limited. Spiral stairways are typically supported by a center pole. Requirements are found with stairways in Section 1011.10.

**STANDBY POWER SYSTEM.** A source of automatic electric power of a required capacity and duration to operate required building, hazardous materials or ventilation systems in the event of a failure of the primary power. Standby power systems are required for electrical loads where interruption of the primary power could create hazards or hamper rescue or fire-fighting operations.

- ❖ This definition is intended to provide clarity for the fire code official as to exactly what systems are considered to be standby power systems and is consistent with definitions in NFPA 110 and NFPA 111. However, since the list of systems in the definition is not exhaustive, reference must be made to Section 604 of the code which provides the “where required” provisions. When the normal power supply to any of the

indicated systems, or other systems designated by the code, fails, the standby power system is to provide a specified degree and duration systems and equipment that are essential for life safety such as elevators and platform lifts, emergency responder radio coverage and smoke control systems. See the commentary to Section 604 for more detailed discussion on the difference between standby and emergency power.

**STANDPIPE SYSTEM, CLASSES OF.** Standpipe system classes are as follows:

- ❖ A standpipe system is typically an arrangement of vertical piping located in exit stairways that allows fire-fighting personnel to connect hand-carried hoses at each level to manually extinguish fires. Section 905 and NFPA 14 recognize three different classes of standpipe systems. For a further discussion of standpipe classes and types, see the commentary to Section 905.3.1.

**Class I system.** A system providing 2½-inch (64 mm) hose connections to supply water for use by fire departments and those trained in handling heavy fire streams.

- ❖ A Class I standpipe system is intended for use by trained fire service personnel as a readily available water source for manual fire-fighting operations. A Class I standpipe system is equipped with only 2½-inch (64 mm) hose connections to allow the fire service to attach the appropriate hose and nozzles. A Class I standpipe system is not equipped with hose stations, which include a cabinet, hose and nozzle.

**Class II system.** A system providing 1½-inch (38 mm) hose stations to supply water for use primarily by the building occupants or by the fire department during initial response.

- ❖ A Class II standpipe system is intended for use by building occupants or by the fire department for manual suppression. The hose stations defined in NFPA 14 as part of the Class II standpipe system include a hose rack, hose nozzle, hose and hose connection. The intent of providing the hose is for use by properly trained personnel. Occupant-use hose stations should only be provided where they can be used by people who have been properly trained in the use of the hose and nozzle.

**Class III system.** A system providing 1½-inch (38 mm) hose stations to supply water for use by building occupants and 2½-inch (64 mm) hose connections to supply a larger volume of water for use by fire departments and those trained in handling heavy fire streams.

- ❖ A Class III standpipe system is intended for use by building occupants as well as trained fire service personnel. The 1½-inch (38 mm) hose station is for use by the building occupants or fire department for manual fire suppression and the 2½-inch (64 mm) hose connection is intended for use primarily by fire service personnel or those who have received training in the use of the larger hoses. Class III systems allow the

## DEFINITIONS

fire department to select the types of hose necessary based on the fire hazard present. If the fire is effectively controlled by an automatic sprinkler system, the smaller hose size may be all that is necessary for fire department mop up operations.

**STANDPIPE, TYPES OF.** Standpipe types are as follows:

- ❖ Section 905 recognizes five types of standpipe systems. The use of each type of system depends on specific occupancy conditions and the presence of an automatic sprinkler system. For a further discussion of standpipe classes and types, see the commentary to Section 905.3.1.

**Automatic dry.** A dry standpipe system, normally filled with pressurized air, that is arranged through the use of a device, such as a dry pipe valve, to admit water into the system piping automatically upon the opening of a hose valve. The water supply for an automatic dry standpipe system shall be capable of supplying the system demand.

- ❖ A typical automatic dry standpipe system has an automatic water supply retained by a dry pipe valve. The dry pipe valve clapper is kept in place by air placed in the standpipe system under pressure. Once a standpipe hose valve is opened, the air is released from the system, allowing water to fill the system through the dry pipe valve. This system is traditionally used in areas where the temperature falls below 40°F (4°C); where a wet system could freeze and possibly burst the pipe or simply not be available when needed.

**Automatic wet.** A wet standpipe system that has a water supply that is capable of supplying the system demand automatically.

- ❖ An automatic wet standpipe system is used in locations where the entire system would remain above 40°F (4°C). Because the system is pressurized with water, an immediate release of water occurs when a hose connection valve is opened. This is the most generally preferred type of standpipe but it is not necessarily the required type unless so stipulated.

**Manual dry.** A dry standpipe system that does not have a permanent water supply attached to the system. Manual dry standpipe systems require water from a fire department pumper to be pumped into the system through the fire department connection in order to supply the system demand.

- ❖ A manual dry standpipe system is filled with water only when the fire service is present. Typically, the fire service connects the discharge from a water source, such as a pumper truck, to the fire department connection of a manual dry standpipe system. When the fire service has suppressed the fire and is preparing to leave, the system is drained of the remaining water. Manual dry standpipe systems are commonly installed in open parking structures.

**Manual wet.** A wet standpipe system connected to a water supply for the purpose of maintaining water within the

system but which does not have a water supply capable of delivering the system demand attached to the system. Manual wet standpipe systems require water from a fire department pumper (or the like) to be pumped into the system in order to supply the system demand.

- ❖ A manual wet standpipe system is connected to an automatic water supply, but the supply is not capable of providing the system demand. The manual wet system could be one that is connected with the sprinkler system such that it is capable of supplying the demand for the sprinkler system but not for the standpipe. The standpipe system demand is met when the fire service provides additional water through the fire department connection from the discharge of a water source, such as a pumper truck.

**Semiautomatic dry.** A dry standpipe system that is arranged through the use of a device, such as a deluge valve, to admit water into the system piping upon activation of a remote control device located at a hose connection. A remote control activation device shall be provided at each hose connection. The water supply for a semiautomatic dry standpipe system shall be capable of supplying the system demand.

- ❖ This type of dry standpipe is a special design that uses a solenoid-activated valve to retain the automatic water supply. Once the standpipe hose valve is opened, a signal is sent to the deluge valve retaining the automatic water supply to allow water to fill the system. This kind of system is used in areas where the temperature falls below 40°F (4°C), where a wet system would otherwise freeze. As such, there is no semiautomatic wet system type.

**STATIC PILES.** Piles in which processed wood product or solid biomass feedstock is mounded and is not being turned or moved.

- ❖ Static piles are long-term bulk storage piles that must be monitored for internal heat buildup. This term includes processed wood products but also addresses solid biomass feedstock. See the definition for "Solid biomass feedstock."

**STEEL.** Hot- or cold-rolled as defined by the *International Building Code*.

- ❖ This is a basic definition that clarifies that steel is either cold- or hot-rolled as defined by the IBC; however, the IBC does not specifically define cold- or hot-rolled steel but describes how it must be used.

**STORAGE, HAZARDOUS MATERIALS.** The keeping, retention or leaving of hazardous materials in closed containers, tanks, cylinders, or similar vessels; or vessels supplying operations through closed connections to the vessel.

- ❖ Storage of hazardous materials in a structure is governed either by the occupancy group that it is accessory to or by the hazard group that it is associated with. The determination of the occupancy class is based on the MAQs and the exceptions found in the IBC and the code.

**[BG] STORY.** That portion of a building included between the upper surface of a floor and the upper surface of the floor or roof next above (see “Basement,” “Building height,” “Grade plane” and “Mezzanine”). A story is measured as the vertical distance from top to top of two successive tiers of beams or finished floor surfaces and, for the topmost story, from the top of the floor finish to the top of the ceiling joists or, where there is not a ceiling, to the top of the roof rafters.

❖ All levels in a building that conform to this description are stories, including basements. A mezzanine is considered part of the story in which it is located. See Chapter 5 of the IBC for code requirements regarding limitations on the number of stories in a building as a function of the type of construction.

**[BG] STORY ABOVE GRADE PLANE.** Any story having its finished floor surface entirely above grade plane, or in which the finished surface of the floor next above is:

1. More than 6 feet (1829 mm) above grade plane; or
2. More than 12 feet (3658 mm) above the finished ground level at any point.

❖ The determination of the allowed height of a building under Section 504 of the IBC is based on the number of stories above grade plane. (See definitions of “Basement,” “Building height” and “Grade plane.”) The code establishes by this definition which stories of a building are those above grade plane. Clearly it includes those stories that are fully above grade plane. It also includes stories that may be partially below finished ground level, but the finished floor level is more than 6 feet (1829 mm) above grade plane. It also includes those floor levels that, due to an irregular terrain, have a finished floor level more than 12 feet (3658 mm) above finished ground level at any point surrounding the building. Any building level not qualifying as a story above grade plane is, by definition, a basement.

**SUPERVISING STATION.** A facility that receives signals and at which personnel are in attendance at all times to respond to these signals.

❖ The supervising station is the location where all fire protection-system-related signals are sent and where trained personnel are present to respond to an emergency. The supervising station may be an approved central station, a remote supervising station, a proprietary supervising station or other constantly attended location approved by the fire code official. Each type of supervising station must comply with the applicable specific provisions described in NFPA 72.

**SUPERVISORY SERVICE.** The service required to monitor performance of guard tours and the operative condition of fixed suppression systems or other systems for the protection of life and property.

❖ The supervisory service is responsible for maintaining the integrity of the fire protection system by notifying the supervising station of a change in protection system status.

Guard tours are recognized as a nonrequired (voluntary) system. If a guard tour is provided, the signals from that system can be transmitted through the supervisory service to the supervision station. Guard tours are not a required part of a fire alarm system.

**SUPERVISORY SIGNAL.** A signal indicating the need of action in connection with the supervision of guard tours, the fire suppression systems or equipment, or the maintenance features of related systems.

❖ Activation of a supervisory signal-initiating device transmits a signal indicating that a change in the status of the fire protection system has occurred and that action must be taken. These signals are the basis for the actions taken by the attendant at the supervising station. These signals do not indicate an emergency condition but indicate that a portion of the system is not functioning in the manner in which it should and that if the condition is not corrected it could impair the ability of the fire protection system to perform properly. A supervisory signal is also a part of the nonrequired guard tour system.

**SUPERVISORY SIGNAL-INITIATING DEVICE.** An initiating device such as a valve supervisory switch, water level indicator, or low-air pressure switch on a dry-pipe sprinkler system whose change of state signals an off-normal condition and its restoration to normal of a fire protection or life safety system; or a need for action in connection with guard tours, fire suppression systems or equipment, or maintenance features of related systems.

❖ The supervisory signal-initiating device detects a change in protection system status. Examples of a supervisory signal-initiating device include a flow switch to detect movement of water through the system and a tamper switch to detect when someone shuts off a water control valve.

**SYSTEM.** An assembly of equipment consisting of a tank, container or containers, appurtenances, pumps, compressors and connecting piping.

❖ As with tanks or containers, a system can be either open or closed. The difference between a closed system and an open system is whether the hazardous material involved in a process is exposed to the atmosphere. Materials in closed or open systems are assumed to be “in use” as opposed to “in storage.” Gases are always assumed to be in closed systems, since they would be immediately dispersed in an open system if exposed to the atmosphere without some means of containment.

**TANK.** A vessel containing more than 60 gallons (227 L).

❖ This definition establishes the distinction between containers and tanks for purposes of code application, with a container being defined as a vessel of 60 gallons (227 L) or less capacity (see commentary to the definition of “Container”).

**TANK, ATMOSPHERIC.** A storage tank designed to operate at pressures from atmospheric through 1.0 pound per

## DEFINITIONS

square inch gauge (760 mm Hg through 812 mm Hg) measured at the top of the tank.

- ❖ This type of tank is not designed for an internal pressure that exceeds atmospheric pressure. Most require some type of emergency venting system to assist in the relief of pressure in a fire.

**TANK, PORTABLE.** A packaging of more than 60-gallon (227 L) capacity and designed primarily to be loaded into or on or temporarily attached to a transport vehicle or ship and equipped with skids, mountings or accessories to facilitate handling of the tank by mechanical means. It does not include any cylinder having less than a 1,000-pound (454 kg) water capacity, cargo tank, tank car tank or trailers carrying cylinders of more than 1,000-pound (454 kg) water capacity.

- ❖ A portable tank must be movable without having to detach permanently mounted electrical controls for the pumping or dispensing systems.

**TANK, PRIMARY.** A *listed* atmospheric tank used to store liquid. See “Primary containment.”

- ❖ The primary tank is the principal storage vessel for flammable and combustible liquids. The tank may use a secondary containment system or be installed in a dike area to control leaks and spills.

**TANK, PROTECTED ABOVE GROUND.** A tank *listed* in accordance with UL 2085 consisting of a primary tank provided with protection from physical damage and fire-resistive protection from a high-intensity liquid pool fire exposure. The tank may provide protection elements as a unit or may be an assembly of components, or a combination thereof.

- ❖ A protected above-ground tank is a shop-fabricated above-ground storage tank that has been subjected to a fire test that replicates an exposure to a 2-hour flammable liquid pool fire. Such tanks are constructed with integral secondary containment and are evaluated for vehicle impact and bullet resistance. All openings on a protected above-ground tank are located at the top of the storage tank which further limits the potential for liquid leaks—openings below the liquid level in these tanks are prohibited by the code. These tanks are listed as meeting the requirements of UL 2085, *Standard for Protected Above-ground Tanks for Flammable and Combustible Liquids*. Section 5704.2.9.7 has a number of requirements for protected above-ground tanks, including overfill protection that limits the volume of fuel oil to 95 percent of the tank’s capacity, an informational sign that explains how the tank is to be filled and that the tank volume must be verified before the tank is filled, and a minimum 5-gallon (19 L) spill container at the tank fill connection to capture any fuel trapped in the fuel delivery hose. If the liquid piping extends below the top of the tank, Section 5704.2.9.7.9 requires the installation of an antisiphon valve. An antisiphon valve is designed to prevent the siphoning of liquid from the tank in the event a pipe or fitting fails and leaks liquid.

**TANK, STATIONARY.** Packaging designed primarily for stationary installations not intended for loading, unloading or attachment to a transport vehicle as part of its normal operation in the process of use. It does not include cylinders having less than a 1,000-pound (454 kg) water capacity.

- ❖ This type of tank is placed in a permanent location and typically has electrically mounted controls attached to a permanent power source.

**TANK VEHICLE.** A vehicle other than a railroad tank car or boat, with a cargo tank mounted thereon or built as an integral part thereof, used for the transportation of flammable or *combustible liquids*, LP-gas or hazardous chemicals. Tank vehicles include self-propelled vehicles and full trailers and semitrailers, with or without motive power, and carrying part or all of the load.

- ❖ Tank vehicles used for storage and transportation of hazardous chemicals over public roadways are governed by the DOTn.

**TEMPORARY STAGE CANOPY.** A temporary ground-supported membrane-covered frame structure used to cover stage areas and support equipment in the production of outdoor entertainment events.

- ❖ There were four high-profile temporary stage canopy collapses during the 2011 summer concert season: August 7 at Brady District Block Party, Tulsa Oklahoma; July 17 at the Cisco Ottawa Blues Festival in Ottawa, Canada; August 13 at the Indiana State Fairgrounds, which resulted in seven dead and 50 injured; and August 18 at the Pukkelpop Festival in Kiewit, Belgium. In the summer of 2012, a life was lost at a Radiohead concert in Toronto. All resulted in tremendous property damage and two in multiple fatalities. The obvious concern is for the safety of the performers and audiences, stage-hands, lighting technicians, security personnel and every other individual in proximity to a temporary stage.

Temporary stage canopies are very specialized and complex. The nature of the structures must accommodate a wide variety of changing components such as audio equipment, video walls and scenery. The entertainment industry is continually evolving with new ways to improve shows, creating larger and more complex spectacles.

Due to the unique design of temporary stage canopies, very specific requirements for these structures are necessary.

**[BG] TENT.** A structure, enclosure or shelter, with or without sidewalls or drops, constructed of fabric or pliable material supported by any manner except by air or the contents that it protects.

- ❖ Tents can be temporary or permanent structures. When permanent, they are regulated by Section 3104. When erected as temporary enclosures, they are regulated by Sections 3103 and 3104 (see also Chapter 31 of the IBC). Commentary Figure 202-T1 illustrates a tent.

**THEFT RESISTANT.** Construction designed to deter illegal entry into facilities for the storage of *explosive materials*.

- ❖ Theft-resistant designs are intended to provide security against illegal or unauthorized entry into magazines containing explosives. Security measures specified in this and subsequent sections require special tools, keys or excessive force to compromise the security measure.

**TIMBER AND LUMBER PRODUCTION FACILITIES.**

Facilities where raw wood products are processed into finished wood products.

- ❖ Wood is still our most used structural material. With the ever increasing demand for wood products, growth of the forest products industry continues. Some woodworking facilities are a “one-man” shop while others employ as many as several thousand people.

**TIRES, BULK STORAGE OF.** Storage of tires where the area available for storage exceeds 20,000 cubic feet (566 m<sup>3</sup>).

- ❖ This definition describes a storage space that is larger than what would be found in most typical mercantile and storage occupancies. Because of its size and the volume of combustible material it would house, it poses an extraordinary hazard for fire protection.

The volume is based on the legacy code definition which was based on 10,000 passenger vehicle tires weighing an average of 25 pounds (11 kg) each rather than the volume of the stored tires. Assuming a 24-inch by 24-inch space (610 mm by 610 mm) for an average passenger vehicle tire and a 6-inch (152 mm) thickness, the result is 20,000 cubic feet (566 m<sup>3</sup>):

$$10,000 \text{ tires} \times 2 \text{ ft} \times 2 \text{ ft} \times 0.5 \text{ ft} = 20,000 \text{ ft}^3$$

The 20,000 cubic feet (566 m<sup>3</sup>) represents the actual volume of stored materials based on an equivalent height and area for passenger vehicle tires as shown in the calculation above and does not

include circulation area or other portions of the building. Rather, it focuses on how much of the material is present. Although the definition uses the term “area” rather than “volume,” it is the volume that becomes the threshold consideration. Still, the area where the tires are stored implies the footprint used for storage. It is not the intent to apply this to areas outside of those used for bulk tire storage.

Buildings used for the bulk storage of tires are classified as Group S-1 occupancies in accordance with Section 311.2 of the IBC. All Group S-1 occupancies, regardless of square footage, must be equipped with an NFPA 13 automatic sprinkler system if used for the bulk storage of tires as required by Section 903.2.9.2. Chapter 34 of the code also requires that bulk tire storage buildings be further designed to comply with NFPA 13, and Chapter 32 of the code includes additional requirements for high-piled rubber tire storage as a high-hazard commodity (see commentary, Chapters 32 and 34).

**TOOL.** A device, storage container, workstation or process machine used in a fabrication area.

- ❖ A tool is basically any device or piece of equipment, including a workstation, in a fabrication area where hazardous materials are used, stored or handled.

**TORCH-APPLIED ROOF SYSTEM.** Bituminous roofing systems using membranes that are adhered by heating with a torch and melting asphalt back coating instead of mopping hot asphalt for adhesion.

- ❖ This is a very specific operation that relates to hot work that uses a torch to adhere the materials. It is not considered welding, but still falls within the definition of “Hot work” (see Commentary Figure 6104.3.1).

**[A] TOWNHOUSE.** A single-family *dwelling unit* constructed in a group of three or more attached units in which each unit extends from the foundation to roof and with open space on not less than two sides.

- ❖ This specific configuration of construction is called different things in different parts of the country, such

Figure 202-T1  
EXAMPLE OF TENT STRUCTURE

## DEFINITIONS

as a rowhouse. A townhouse structure that meets the following four criteria is not regulated by the code but is regulated by the IRC. Those criteria are:

1. Each unit extends from foundation to roof with no vertical overlap of any parts of adjoining units.
2. Each unit must have open space on at least two sides (either two opposite or two adjoining sides).
3. Each unit must have a separate means of egress.
4. The building must not exceed three stories above grade plane.

If all of these criteria are met, then according to the exception to Section 101.2 of the IBC, the structure is within scope of the IRC. (It should also be noted that townhouses within the IRC must be separated by a wall or walls meeting specific criteria.) If a structure does not meet these four criteria, it will need to be regulated under the code and will either be classified as a Group R-2 or Group R-3 structure, depending on how the units are separated. A building containing three or more dwelling units is regulated as a Group R-2 occupancy. To be considered a Group R-3, the structure must have one or two dwelling units, or be subdivided by fire walls between every unit or every two units (see the definitions for "Area, building," "Dwelling" and "Dwelling unit"). Finally, the definition of "Townhouse" is not dependent on the presence of individual lots. A townhouse structure could be built with any number of attached units on the same lot, or it could be developed such that a property line lies at each common wall separating two units (see definition for "Lot").

**TOXIC.** A chemical falling within any of the following categories:

1. A chemical that has a median lethal dose ( $LD_{50}$ ) of more than 50 milligrams per kilogram, but not more than 500 milligrams per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
2. A chemical that has a median lethal dose ( $LD_{50}$ ) of more than 200 milligrams per kilogram but not more than 1,000 milligrams per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.
3. A chemical that has a median lethal concentration ( $LC_{50}$ ) in air of more than 200 parts per million but not more than 2,000 parts per million by volume of gas or vapor, or more than 2 milligrams per liter but not more than 20 milligrams per liter of mist, fume or dust, when administered by continuous inhalation for 1 hour (or

less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

❖ See the commentary to the definition of "Highly toxic."

**TRAFFIC CALMING DEVICES.** Traffic calming devices are design elements of fire apparatus access roads such as street alignment, installation of barriers, and other physical measures intended to reduce traffic and cut-through volumes, and slow vehicle speeds.

❖ The definition for traffic calming is based on the definition provided by the Institute of Transportation Engineers. Many communities are facing increased traffic volumes. Both new and existing streets are experiencing higher vehicular volumes and speeds as drivers attempt to find "short cuts" to ease their commutes. Designers, planning departments and traffic engineering departments are increasingly turning to traffic calming measures to preserve the quality and enjoyment of life for their citizens.

In many communities a concern of home owners is the use of residential streets as an alternative route to minor and major thoroughfares. They are concerned about pedestrian safety, reducing vehicle speeds and the traffic volume on residential streets. On the other hand, property owners also want the lowest response time that is practical in the event of an emergency that requires a response by the fire or police department. In fact, response time is the primary measurement for quality of service used by the public. The installation of traffic calming devices competes with these two goals.

A number of studies have been conducted to evaluate the impact of traffic calming devices on the response time of fire and emergency medical services (EMS) apparatus. These studies found that traffic calming devices have no real impact on law enforcement vehicles because of their size however, depending on the method of traffic calming used (e.g., "roundabouts," "speed bumps," "speed pillows," narrowing of streets, winding roads rather than straight roads, etc.) and the vehicle type, response times for fire and emergency services generally are increased by these devices by 2 to 10 seconds. Studies have also found that the vehicle frames of fire and EMS apparatus can be damaged and emergency services personnel have been injured while responding over certain traffic calming devices. See the commentary to Section 503.4.1 for further discussion of traffic calming devices. See also Commentary Figures 202-T2 and 202-T3 for illustrations of several typical traffic calming devices.

**[BG] TRANSIENT.** Occupancy of a dwelling unit or sleeping unit for not more than 30 days.

❖ The intent of this definition is to establish a time parameter to differentiate between transient and non-transient as listed under Groups R-1 and R-2. Real estate law dictates that a lease must be created after

30 days and time periods greater than 30 days are typically how extended-stay hotels and motels rent to people.

Such a time period enables the occupant to become familiar with the surroundings and, therefore, become more accustomed to any hazards of the built environment than an overnight guest or a guest who stays for just a few days would be. Since nontransient occupancies do not have the same level of protection in the code as transient occupancies, it is important to

determine what makes an occupancy transient so as to provide consistency in enforcement.

**[BG] TRANSIENT AIRCRAFT.** Aircraft based at another location and that is at the transient location for not more than 90 days.

- ❖ In place of the undefined term “private aircraft” previously used in the code, a defined term, “transient aircraft,” was added in the 2009 edition. Transient aircraft are those that are merely visiting an airport as compared to those which are based at that location.

**Figure 202-T2**  
**SPEED PILLOW TRAFFIC CALMING DEVICE**

**Figure 202-T3**  
**ROUNDBOUT TRAFFIC CALMING DEVICE**

## DEFINITIONS

The definition is used in conjunction with Section 914.8.3 to establish the level of fire suppression needed in various aircraft hangars. Fixed base operators, especially at larger airports, will have distinct hangars that are used for repair and maintenance of aircraft. The hangars used by transient aircraft are primarily a storage place for aircraft based at another location. This better identifies the intent of this type of aircraft hangar. Most frequently, the owner that wants to develop an aircraft hangar that fits the Group II category, will do no "major maintenance" and will only "store" airplanes in their hangar (see the commentary, Section 914.8.3).

**TRANSVERSE FLUE SPACE.** See "Flue space—Transverse."

**TRASH.** See "Rubbish."

**TROUBLE SIGNAL.** A signal initiated by the fire alarm system or device indicative of a fault in a monitored circuit or component.

❖ This type of signal indicates that there has been an abnormal change in the normal status of the fire detection system or devices and that a response is required to determine the nature of the fault condition. The trouble signal is only associated with electronic portions of a fire protection system. Physical conditions such as a closed valve are monitored electronically and would report as a supervisory signal rather than a trouble signal. A valve supervisory switch or "tamper switch," for example, would perform such a function.

**TUBE TRAILER.** A semitrailer on which a number of tubular gas cylinders have been mounted. A manifold is typically provided that connects the cylinder valves enabling gas to be discharged from one or more tubes or cylinders through a piping and control system.

❖ Tube trailers are a common method of supplying compressed gases to a variety of industrial processes, and it is not uncommon to have more than one tube trailer on a site. Depending on the cylinder's length and maximum allowable working pressure (MAWP), a trailer may have as few as six or as many as 18 to 24 cylinders varying in length from 20 feet (6096 mm) for small tube trailers to 38 feet (11 582 mm) on jumbo tube trailers. The vessels are generally designed for MAWP between 2,800 to approximately 3,800 pounds per square inch (psi) (19 305 to 26 200 kPa), depending on the storage pressure. At such pressures, each cylinder can hold anywhere from 5,000 to 20,000 standard cubic feet (scf) (142 to 566 m<sup>3</sup>), depending on the gas being stored. Tube trailers are subject to periodic inspections in accordance with U.S. Department of Transportation (DOTn) regulations and each new or substantially modified tube is required to successfully pass a substantial hydrostatic pressure test.

The transport of compressed gases by these road trailers, which are regulated by the DOTn as a bulk

compressed gas source, is an established distribution method used widely in the industrial gas industry for the transport over short distances of relatively small volumes of inert, flammable, oxidizer, corrosive or toxic compressed gases and gas mixtures, including hydrogen, methane, oxygen, nitrogen, argon, helium, many fluorocarbons, hydrogen sulfide and hydrogen

**Figure 202-T4  
TUBE TRAILER**

chloride.

At one end of the trailer is a manifold to which each cylinder valve is connected so that one or more tubes can discharge gas into a piping and control system. The tube trailer is connected via the manifold to the building or process using the compressed gas [see Commentary Figure 202-T4 and commentary, Section 5303.7.11)].

**TWENTY-FOUR HOUR BASIS.** See "24-hour basis" before the "A" entries.

**UNAUTHORIZED DISCHARGE.** A release or emission of materials in a manner which does not conform to the provisions of this code or applicable public health and safety regulations.

❖ Remember that hazardous chemicals pose a threat to life and property only when release is not authorized, controlled or properly protected.

**UNSTABLE (REACTIVE) MATERIAL.** A material, other than an *explosive*, which in the pure state or as commercially produced, will vigorously polymerize, decompose, condense or become self-reactive and undergo other violent chemical changes, including explosion, when exposed to heat, friction or shock, or in the absence of an inhibitor, or in the presence of contaminants, or in contact with *incompatible materials*. Unstable (reactive) materials are subdivided as follows:

**Class 4.** Materials that in themselves are readily capable of *detonation* or explosive decomposition or explosive reaction at *normal temperatures and pressures*. This class includes materials that are sensitive to mechanical or localized thermal shock at *normal temperatures and pressures*.

**Class 3.** Materials that in themselves are capable of *detonation* or of explosive decomposition or explosive reaction

but which require a strong initiating source or which must be heated under confinement before initiation. This class includes materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures.

**Class 2.** Materials that in themselves are normally unstable and readily undergo violent chemical change but do not detonate. This class includes materials that can undergo chemical change with rapid release of energy at *normal temperatures and pressures*, and that can undergo violent chemical change at elevated temperatures and pressures.

**Class 1.** Materials that in themselves are normally stable but which can become unstable at elevated temperatures and pressure.

- ❖ The definition of an “Unstable (reactive) material” is based on NFPA 704. The different classes of unstable (reactive) material reflect the degree of susceptibility of the materials to release energy. Unstable (reactive) materials polymerize, decompose or become self-reactive when exposed to heat, air, moisture, pressure or shock. Separation from incompatible materials is essential to minimizing the hazards. Examples of unstable (reactive) materials include acetaldehyde, ammonium nitrate, ethylene oxide, hydrogen cyanide, nitromethane, perchloric acid, sodium perchlorate, vinyl acetate and acetic acid.

**UNWANTED FIRE.** A fire not used for cooking, heating or recreational purposes or one not incidental to the normal operations of the property.

- ❖ For the purposes of applying the code, a clarification is provided to note that certain fires present in buildings would be acceptable; for example, the normal operation of a water heater, a gas stove or a fireplace. The definition does not address whether a fire is intentional or unintentional (arson versus a welding accident, for example).

**USE (MATERIAL).** Placing a material into action, including solids, liquids and gases.

- ❖ This term refers to when a chemical or material is used in a process that forms another substance, whether it is hazardous or not, and when the chemical is used independently.

**VAPOR PRESSURE.** The pressure exerted by a volatile fluid as determined in accordance with ASTM D 323.

- ❖ Vapor pressure is a characteristic property of liquids and varies with their temperature. As the temperature of the liquid increases, more and more of the liquid enters the vapor stage. This increased pressure can cause an emergency vent to release, or, if the conditions are serious enough, can result in a BLEVE.

**[M] VENTILATION.** The natural or mechanical process of supplying conditioned or unconditioned air to, or removing such air from, any space.

- ❖ Ventilation is the process of moving air to or from building spaces. Ventilation requirements are used in the code to establish minimum levels of air movement within a building for the purposes of providing a healthful interior environment. Ventilation would include both natural (openable exterior windows and doors for wind movement) and mechanical (forced air with mechanical equipment) methods.

**VESSEL.** A motorized watercraft, other than a seaplane on the water, used or capable of being used as a means of transportation. Nontransportation vessels, such as houseboats and boathouses, are included in this definition.

- ❖ Vessels, in this definition, are motorized watercraft, but by dictionary definition, a vessel is “...a watercraft or structure with its equipment, whether self-propelled or not, that is used or capable of being used as a means of transportation in navigation or commerce on water...” The definition could include small rowboats and sailboats. No minimum or maximum length is specified. Houseboats and boathouses that would be occupied as dwelling or sleeping units are also included in the definition.

**VISIBLE ALARM NOTIFICATION APPLIANCE.** A notification appliance that alerts by the sense of sight.

- ❖ Visible alarm notification appliances are located anywhere an occupant notification system is required, in occupancies where occupants may be hearing impaired and in sleeping accommodations of Group I-1 and R-1 occupancies. These alarm notification devices must be located and oriented so that they will display alarm signals throughout the required space. Visible alarms, when provided, are typically installed in the public and common areas of buildings (see the commentary, Section 907.5.2.3).

**WATER MIST SYSTEM, AUTOMATIC.** See “Automatic water mist system.”

**WATER-REACTIVE MATERIAL.** A material that explodes; violently reacts; produces flammable, toxic or other hazardous gases; or evolves enough heat to cause autoignition or ignition of combustibles upon exposure to water or moisture. Water-reactive materials are subdivided as follows:

**Class 3.** Materials that react explosively with water without requiring heat or confinement.

**Class 2.** Materials that react violently with water or have the ability to boil water. Materials that produce flammable, toxic or other hazardous gases, or evolve enough heat to cause autoignition or ignition of combustibles upon exposure to water or moisture.

**Class 1.** Materials that react with water with some release of energy, but not violently.

- ❖ Class 2 and 3 water-reactive materials can liberate significant quantities of heat and hazardous gases when reacting with water. Combustible water-reactive materials are capable of self-ignition. Even noncom-

## DEFINITIONS

bustible water-reactive materials pose a hazard because of the heat released during their reaction with water, which may be sufficient to ignite surrounding combustible materials. The description of each of the subdivisions is consistent with the approach used for the determination of water hazards in NFPA 704.

**WET-CHEMICAL EXTINGUISHING AGENT.** A solution of water and potassium-carbonate-based chemical, potassium-acetate-based chemical or a combination thereof, forming an extinguishing agent.

❖ This extinguishing agent is a suitable alternative to the use of a dry chemical, especially when protecting commercial kitchen range hoods. There is less cleanup time after system discharge. Wet chemical solutions are considered to be relatively harmless and normally have no lasting effect on the skin or respiratory system. These solutions may produce temporary irritation, which is usually mild and disappears when contact is eliminated. These systems must be pre-engineered and labeled. NFPA 17A applies to the design, installation, operation, testing and maintenance of wet-chemical extinguishing systems.

**WET FUELING.** See “Mobile fueling.”

**WET HOSING.** See “Mobile fueling.”

**WHARF.** A structure or bulkhead constructed of wood, stone, concrete or similar material built at the shore of a harbor, lake or river for vessels to lie alongside of, and to anchor piers or floats.

❖ A wharf is constructed along the shore and does not project significantly into the body of water as a pier would. Piers or floats may be attached to and project out from a wharf. Wharves may also have structures on them that support the use of the wharf.

**WILDFIRE RISK AREA.** Land that is covered with grass, grain, brush or forest, whether privately or publicly owned, which is so situated or is of such inaccessible location that a fire originating upon it would present an abnormally difficult job of suppression or would result in great or unusual damage through fire or such areas designated by the *fire code official*.

❖ This defined term provides clarification to Sections 105.6.24, Item 4, 105.6.32, 308.1.6 and 308.1.6.1 where the undefined term “hazardous fire area” had been used in previous editions of the code, leaving the fire code official with little or no guidance as to the code's intent. The source for this definition was a definition for the term “hazardous fire area” in the legacy *Uniform Fire Code*. However, in order to avoid conflict and confusion with the already-defined term “fire area,” the new term and the indicated section texts were changed to “wildfire risk area.”

**[BE] WINDER.** A tread with nonparallel edges.

❖ Winders are used as components of stairways that change direction, just as “fliers” (rectangular treads) are components in straight stairways. A winder performs the same function as a tread, but its shape

allows the additional function of a gradual turning of the stairway direction. The tread depth of a winder at the walkline and the minimum tread depth at the narrow end control the turn made by each winder. Winders are not landings. Winder treads are limited to curved or spiral stairways with all groups but are all stairways within dwelling units (see Section 1011.5.3).

**WIRELESS PROTECTION SYSTEM.** A system or a part of a system that can transmit and receive signals without the aid of wire.

❖ These systems use radio frequency transmitting devices that comply with the special requirements for supervision of low-power wireless systems in NFPA 72. Wireless devices have the advantage of flexibility in positioning. Consequently, portable wireless notification devices are frequently used in existing facilities where visual devices are not present throughout.

**WORKSTATION.** A defined space or an independent principal piece of equipment using HPM within a fabrication area where a specific function, laboratory procedure or research activity occurs. *Approved* or *listed* hazardous materials storage cabinets, flammable liquid storage cabinets or gas cabinets serving a workstation are included as part of the workstation. A workstation is allowed to contain ventilation equipment, fire protection devices, detection devices, electrical devices and other processing and scientific equipment.

❖ In HPM facilities, workstations further subdivide a fabrication area and provide relatively self-contained, specialized areas where HPM processes are conducted. Workstation controls limit the quantity of materials and impose limitations on the design of these processes to include, but not be limited to, protection by local exhaust; sprinklers; automatic and emergency shutoffs; construction materials and HPM compatibility. Excess materials are prohibited and must be contained in storage rooms designed to accommodate such hazards.

**[BG] YARD.** An open space, other than a *court*, unobstructed from the ground to the sky, except where specifically provided by the *International Building Code*, on the lot on which a building is situated.

❖ This definition is used, similar to the definition of “Court,” to establish the applicability of code requirements when yards are utilized for natural light or natural ventilation purposes (see Section 1206.1 of the IBC). Whereas a court is bounded on three or more sides with the building or structure, a yard is bounded on two or less sides by the building or structure. See also the definition of “Egress court.”

**ZONE.** A defined area within the protected premises. A zone can define an area from which a signal can be received, an area to which a signal can be sent or an area in which a form of control can be executed.

❖ Zoning a system is important to emergency personnel in locating a fire. When an alarm is designated to a specific zone, it allows the fire service to immediately respond to the area where the fire is in progress

instead of searching the entire building for the origin of an alarm.

**ZONE, NOTIFICATION.** An area within a building or facility covered by notification appliances which are activated simultaneously.

❖ This definition is provided to clarify the code by making a clear distinction between fire alarm system initiation device zones required by Section 907.6.4 and the zones that may be designed into occupant notification device systems in a building. The term is used primarily in the exceptions for sprinkler systems found in the manual fire alarm system requirements in Section 907.2 and its subsections. Note that the code does not require audible and visible occupant notification device systems to be zoned; if such zones are provided, it is a matter of the system design engineers judgment. The voice paging component in high-rise building emergency voice/alarm communication systems are, however, required to be zoned in accordance with Section 907.5.2.2.

## Part II—General Safety Provisions

# Chapter 3: General Requirements

### General Comments

Fire is always a concern, whether a building is under construction, is occupied for normal use or is undergoing renovation, restoration, expansion or demolition. But careful planning combined with common sense can make buildings and premises much safer, regardless of the occupancy or other activities at the site.

The primary focus of the requirements in this chapter is making sure the three elements necessary for a fire—ignition source, fuel and oxygen—do not come in contact with one another. NFPA 550 describes in great detail the features of fire safety systems and includes a logic tree called “The Fire Safety Concepts Tree” to graphically show all the possible means of achieving user-defined fire safety objectives. A portion of that tree is reproduced here as Commentary Figure 3 to show how to avoid fire ignition. Activities on this diagram that follow a plus sign (+), also known as an “or” gate, may be undertaken independently of each other to arrive at the desired goal. Alternatives following a dot (·), also known as an “and”

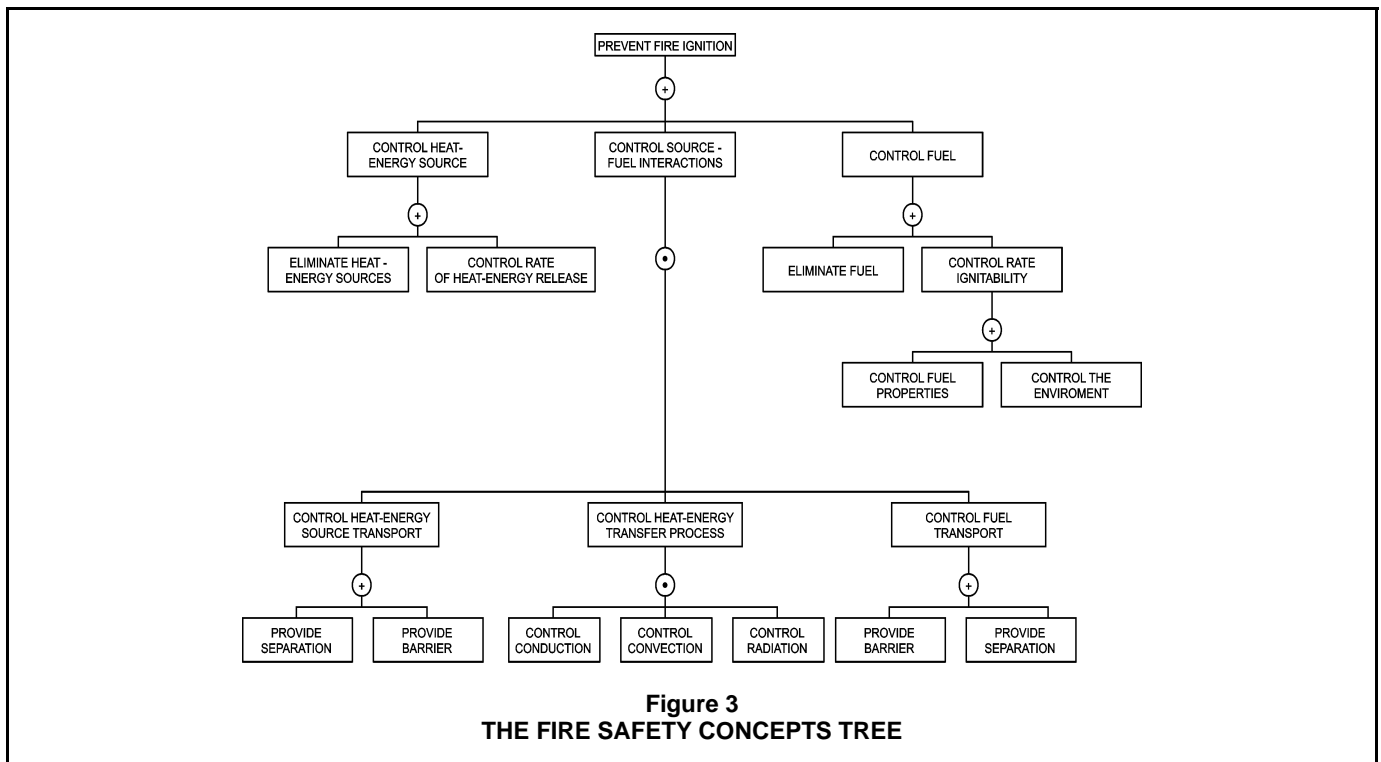

gate, must be combined to achieve the desired result.

Commentary Figure 3 shows that eliminating any one of the three elements required for a fire to occur will prevent a fire from happening. If there is no ignition source, a fuel load of any size should not catch fire. If there is no fuel load, there is nothing for an ignition source to ignite. If there is little or no air available to sustain combustion, any fire ignited in a fuel load will quickly die.

The requirements and precautions outlined in this chapter, when applied using good judgment and the common sense mentioned above, will help to foster safety for everyone.

### Purpose

The requirements and precautions contained in this chapter are intended to improve premises safety for everyone, including construction workers, tenants, operations and maintenance personnel and emergency response personnel.

## GENERAL REQUIREMENTS

### SECTION 301 GENERAL

**301.1 Scope.** The provisions of this chapter shall govern the occupancy and maintenance of all structures and premises for precautions against fire and the spread of fire and general requirements of fire safety.

- ❖ The requirements of Chapter 3 prescribe fire safety precautions for conditions that are likely to cause or contribute to the spread of fire in any building or structure or on any premises, regardless of occupancy.

**301.2 Permits.** Permits shall be required as set forth in Section 105.6 for the activities or uses regulated by Sections 306, 307, 308 and 315.

- ❖ Issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Applicants for permits should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit.

### SECTION 302 DEFINITIONS

**302.1 Definitions.** The following terms are defined in Chapter 2:

**BONFIRE.**

**HI-BOY.**

**HIGH-VOLTAGE TRANSMISSION LINE.**

**OPEN BURNING.**

**PORTABLE OUTDOOR FIREPLACE.**

**POWERED INDUSTRIAL TRUCK.**

**RECREATIONAL FIRE.**

**SKY LANTERN.**

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 303 ASPHALT KETTLES

**303.1 Transporting.** Asphalt (tar) kettles shall not be transported over any highway, road or street when the heat source for the kettle is operating.

**Exception:** Asphalt (tar) kettles in the process of patching road surfaces.

- ❖ The hazards of hauling a fired kettle of molten asphalt over public ways are obvious. Most asphalt kettles for roofing, paving and similar uses are currently liquefied petroleum gas (LP-gas) fired. Contractors often wish to keep asphalt in a liquid state to save time between jobs and when work is interrupted. Once asphalt is transformed from a solid to a liquid by heating, it retains much of its heat for some time, and although it becomes increasingly viscous as it cools, it remains fluid for a considerable time. Maintaining a fire under a kettle during transport is usually unnecessary and, therefore, prohibited, since little additional heat is required to return the asphalt to a usable consistency. An accident, flat tire or anything else that could cause the kettle to overturn, spilling the molten asphalt in the presence of an open flame, could lead to a serious fire. Even hitting potholes or other bumps in the road could cause the molten asphalt to splash out of the kettle, causing injury to people nearby or damage to property.

The exception for asphalt being used for road repair is necessary for efficient operations for work crews sealing pavement joints and performing similar roadway repairs.

**303.2 Location.** Asphalt (tar) kettles shall not be located within 20 feet (6096 mm) of any combustible material, combustible building surface or any building opening and within a controlled area identified by the use of traffic cones, barriers or other *approved* means. Asphalt (tar) kettles and pots shall not be utilized inside or on the roof of a building or structure. Roofing kettles and operating asphalt (tar) kettles shall not block *means of egress*, gates, roadways or entrances.

- ❖ Asphalt kettles sometimes catch fire. Having one located inside a building would present a serious smoke problem, as well as the fire hazards of asphalt spills flowing to lower floors or the release of LP-gas inside the building. Having one located next to quantities of combustible materials would also represent a fire hazard, as well as the possibility that splashes and splatters could damage construction materials beyond use. Keeping egress pathways and other travel lanes free of obstructions provides a needed

immediate exit from an area where an asphalt kettle-related incident might occur and enhances access to such areas for the fire department.

**303.3 Location of fuel containers.** Fuel containers shall be located not less than 10 feet (3048 mm) from the burner.

**Exception:** Containers properly insulated from heat or flame are allowed to be within 2 feet (610 mm) of the burner.

- ❖ This section reduces the likelihood that any gas or vapors escaping from fuel containers would be ignited by the open flame of the kettle burner and that the heat of the burner would cause overheating of the fuel containers.

The exception acknowledges the greater safety of insulated containers.

**303.4 Attendant.** An operating kettle shall be attended by not less than one employee knowledgeable of the operations and hazards. The employee shall be within 100 feet (30 480 mm) of the kettle and have the kettle within sight. Ladders or similar obstacles shall not form a part of the route between the attendant and the kettle.

- ❖ Having a trained attendant watch the kettle helps to create a safe operation. The attendant is usually responsible for making sure the asphalt is at the proper temperature, the level of liquid in the kettle is maintained at the required level and the fuel supply for the kettle burner is adequate. The attendant should watch for any change in the kettle that would signal the potential for a safety hazard, and adjust the burner output or other factors to keep the kettle in safe operating condition. The attendant is also often responsible for keeping the area surrounding the kettle free of combustible materials and other construction debris that could become a safety hazard.

**303.5 Fire extinguishers.** There shall be a portable fire extinguisher complying with Section 906 and with a minimum 40-B:C rating within 25 feet (7620 mm) of each asphalt (tar) kettle during the period such kettle is being utilized. Additionally, there shall be one portable fire extinguisher with a minimum 3-A:40-B:C rating on the roof being covered.

- ❖ This section defines the type and size of extinguisher that must be available for use, both on the ground near the kettle and on the roof level to which the asphalt is being applied. In the event of a kettle fire, water should not be used as an extinguishing agent because it could cause the molten asphalt to froth and possibly overflow the kettle or spatter over anything or anyone in the surrounding area. See also the commentary to Section 3317.3 for roofing operations during construction.

**303.6 Lids.** Asphalt (tar) kettles shall be equipped with tight-fitting lids.

- ❖ A tight-fitting lid on a hot kettle limits the air supply available to feed a kettle fire. Any fire that might start in a closed kettle will quickly burn itself out because of the limited amount of air available for combustion. The lid also helps prevent splashes and splatters that could cause personal injury.

**303.7 Hi-boys.** Hi-boys shall be constructed of noncombustible materials. Hi-boys shall be limited to a capacity of 55 gallons (208 L). Fuel sources or heating elements shall not be allowed as part of a hi-boy.

- ❖ Hi-boys are used on the roof of a building to transport hot asphalt from a point of supply near the edge of the roof to the site of the roofing application. Due to the hazards of molten asphalt discussed in Section 303.1, hi-boys are limited in size to control the maximum amount of potential spills on the roof, which could ignite and pose a high-challenge fire-suppression operation for the fire department. A limited size also enhances the movability and stability of the hi-boy, thus reducing the potential for a tip over. As a further safeguard against a fire incident, hi-boys are prohibited from being fired or equipped with a fuel source for firing. Hi-boys must also be constructed of noncombustible materials to enhance their durability and prevent the container from contributing fuel to a fire. Hi-boys should be well-maintained, including the frame; steering mechanism; tires or wheels; faucets and fill connections (see commentary, Section 202 for the definition of “Hi-boy”).

**303.8 Roofing kettles.** Roofing kettles shall be constructed of noncombustible materials.

- ❖ The requirement for noncombustible materials represents sound safety practice as well as good business practice. Portions of kettles constructed of combustible materials can be easily destroyed and could lead to larger fires. Replacement of destroyed kettles would be expensive. Paying for other fire damage would be even more costly.

Also note that roofing mops soaked in asphalt or pitch must never be left inside a building, near heating equipment or near combustible materials. These mops are subject to spontaneous heating no matter what material they are made of.

**303.9 Fuel containers under air pressure.** Fuel containers that operate under air pressure shall not exceed 20 gallons (76 L) in capacity and shall be *approved*.

- ❖ Limiting the size of pressurized fuel containers limits the probability of a container becoming a major fuel

## GENERAL REQUIREMENTS

source in case of a kettle fire. Requiring the use of approved containers gives the fire code official more control over the type and suitability of the vessel to be used under pressure.

### SECTION 304 COMBUSTIBLE WASTE MATERIAL

**304.1 Waste accumulation prohibited.** Combustible waste material creating a fire hazard shall not be allowed to accumulate in buildings or structures or upon premises.

❖ Accumulated waste, trash, construction debris and other natural materials, such as grass clippings, leaves and shrubbery cuttings, can become a serious fire hazard. The three subsections that follow this general statement address the most common situations.

**304.1.1 Waste material.** Accumulations of wastepaper, wood, hay, straw, weeds, litter or combustible or flammable waste or rubbish of any type shall not be permitted to remain on a roof or in any *court*, yard, vacant lot, alley, parking lot, open space, or beneath a grandstand, *bleacher*, pier, wharf, manufactured home, recreational vehicle or other similar structure.

❖ This section considers the kind of waste material that is most likely to accumulate during construction, renovation, additions or demolition and is often referred to as “the housekeeping section.” It prohibits disorderly, unkempt storage or accumulation of trash, waste rags, wastepaper, scrub brush and weeds, litter and other combustible materials. Litter and trash represent a serious fire hazard because of their ease of ignition and rapid heat release once ignited. The importance of maintaining property and buildings in good order seems obvious, but sloppy housekeeping still occurs and can be the cause of serious fires. In one of the most serious fires in recent years, improper storage of linseed-oil-soaked rags used to refinish paneling in a high-rise office building caused a fire that destroyed eight floors of the building and killed three fire fighters.

**304.1.2 Vegetation.** Weeds, grass, vines or other growth that is capable of being ignited and endangering property, shall be cut down and removed by the *owner* or occupant of the premises. Vegetation clearance requirements in urban-wildland interface areas shall be in accordance with the *International Wildland-Urban Interface Code*.

❖ Accumulations of natural waste, such as grass clippings, weed growth and shrubbery cuttings, are not only unsightly, but also represent a serious fire hazard. All too often these accumulations occur at or near fence lines that are adjacent to streets or alleys. This makes accidental ignition by a cigarette butt tossed from a passing vehicle a good possibility. Common sense tells us that removal of this kind of waste is beneficial. The rules of nearly all jurisdictions make waste control and removal the responsibility of the building or property owner, his or her agent, the

tenant or the contractor if work is being done on the site. Uncontrolled vegetation growth poses substantial risk to areas designated as wildland-urban interface areas. Accordingly, such areas must comply with the provisions of the *International Wildland-Urban Interface Code*<sup>®</sup> (IWUIC<sup>®</sup>).

**304.1.3 Space underneath seats.** Spaces underneath grandstand and bleacher seats shall be kept free from combustible and flammable materials. Except where enclosed in not less than 1-hour fire-resistance-rated construction in accordance with the *International Building Code*, spaces underneath grandstand and bleacher seats shall not be occupied or utilized for purposes other than *means of egress*.

❖ Numerous fires in grandstands and stadiums have shown over the years that the accumulation of flammable or combustible materials under grandstand seating areas can lead to fire disasters. Except as noted in the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), areas under grandstand seating must be kept free of flammable materials, including accumulations of waste or trash. One of the best ways to prevent a fire is to make certain there is no fuel to feed one.

The IBC does allow space under the stands to be used for purposes other than means of egress if that space is separated from the seating area by construction having at least a 1-hour fire-resistance rating. The separation is intended to allow time for occupants in the seating to vacate if a fire should occur. The fire code official would usually have to approve plans for use of space under the stands for concession stands, sales areas or storage areas.

**304.2 Storage.** Storage of combustible rubbish shall not produce conditions that will create a nuisance or a hazard to the public health, safety or welfare.

❖ Storage of combustible rubbish either indoors or outdoors must be approved by the fire code official. Combustibles should be accumulated in noncombustible containers, such as metal trash cans with tight lids, steel barrels or steel dumpster bins, which should be removed from the site regularly. The use of plastic waste containers should be discouraged due to the extremely high fuel content of such materials, which can sometimes be several times the fuel content of the waste material they contain. Such containers could, under fire conditions, cause rapid fire spread and overtax sprinkler systems, where installed. This section mentions public health as well as safety and welfare, indicating concern over retention of decomposing organic waste as well as flammable and combustible materials.

**304.3 Containers.** Combustible rubbish, and waste material kept within or near a structure shall be stored in accordance with Sections 304.3.1 through 304.3.4.

❖ Proper containers must be used to improve the safety of indoor or outdoor storage (in close proximity to buildings) of trash and isolate readily combustible materials. This section introduces the more detailed requirements in Sections 304.3.1 through 304.3.4.

**304.3.1 Spontaneous ignition.** Materials susceptible to spontaneous ignition, such as oily rags, shall be stored in a *listed* disposal container. Contents of such containers shall be removed and disposed of daily.

❖ Disposal containers, often called “waste cans” or “oily rag cans,” used for storage of materials that might auto-ignite as a result of the spontaneous combustion process must be tested and listed for that use by a recognized testing laboratory or agency and must bear a label showing that they have been tested, along with the name of the testing agency. Such containers are most commonly round and generally available in sizes ranging from 5 to 40 gallons (19 to 151 L). They are equipped with a manual or foot treadle-operated lid that opens to a maximum angle of 60 degrees (1.05 rad) and closes by gravity. These containers are designed to prevent continuing combustion of the contents if ignition occurs. Container design includes features that keep the can body containing waste from coming into contact with combustible surfaces of walls or floors (see commentary, Section 202, for the definition of “Listed”). Daily disposal of container contents reduces the amount of time that oily materials will lie dormant, generating internal heat that can lead to ignition. UL 32 provides further information on the construction, testing and listing of these containers.

**304.3.2 Capacity exceeding 5.33 cubic feet.** Containers with a capacity exceeding 5.33 cubic feet (40 gallons) (0.15 m<sup>3</sup>) shall be provided with lids. Containers and lids shall be constructed of noncombustible materials or of combustible materials with a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> where tested in accordance with ASTM E1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation.

**Exception:** Wastebaskets complying with Section 808.

❖ Requiring larger containers to meet stricter conditions is common sense. The larger the volume of waste each container holds, the larger the fire hazard. Isolating the containers from one another with lids helps reduce the possibility that a fire in one container will spread to nearby containers. The lid also helps to smother a fire within the container by limiting the oxygen available to feed it. Additionally, closed containers protect flammable and combustible materials from potential external ignition sources.

Combustible materials, used in such containers, must meet the performance criteria stated when tested in accordance with ASTM E1354. Most non-metallic waste containers are manufactured from polyethylene, which has a fuel value of 20,050 Btu per pound (46 636 kJ/kg). In comparison, the fuel value of newsprint paper is 9,000 Btu per pound (20 934 kJ/kg). To contain combustible waste in another combustible material that has twice the fuel potential value makes little sense. This section will prohibit the use of larger, nonfire-retardant polyethylene trash

containers within a structure. Several manufacturers have had the formulation for years to make a fire-retardant polyethylene.

The exception to this general provision points to more specific requirements for waste containers in Group I-3 facilities contained in Section 808.1.

**304.3.3 Capacity exceeding 1.5 cubic yards.** Dumpsters and containers with an individual capacity of 1.5 cubic yards [40.5 cubic feet (1.15 m<sup>3</sup>)] or more shall not be stored in buildings or placed within 5 feet (1524 mm) of combustible walls, openings or combustible roof eave lines.

**Exceptions:**

1. Dumpsters or containers in areas protected by an *approved automatic sprinkler system* installed throughout in accordance with Section 903.3.1.1, 903.3.1.2 or 903.3.1.3.
2. Storage in a structure shall not be prohibited where the structure is of Type I or IIA construction, located not less than 10 feet (3048 mm) from other buildings and used exclusively for dumpster or container storage.

❖ Although waste containers of this size are nearly always constructed of welded steel because of the weight of the waste load, the very fact that the waste load is large makes the containers a large fire hazard. Keeping these large containers in the open and away from combustible construction is the obvious way to keep the fire hazard low.

Exception 1 permits storage of these large containers indoors if the area is protected by an approved sprinkler system. It would be up to the fire code official to determine the maximum quantities that could be stored under these conditions.

Exception 2 applies only to buildings that are of fire-resistance-rated construction and are used exclusively for container storage. Such facilities might be found in scrap yards or at recycling centers, but rarely, if ever, in other occupancies.

**304.3.4 Capacity of 1 cubic yard or more.** Dumpsters with an individual capacity of 1.0 cubic yard [200 gallons (0.76 m<sup>3</sup>)] or more shall not be stored in buildings or placed within 5 feet (1524 mm) of combustible walls, openings or combustible roof eave lines unless the dumpsters are constructed of noncombustible materials or of combustible materials with a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> where tested in accordance with ASTM E1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation.

**Exceptions:**

1. Dumpsters in areas protected by an *approved automatic sprinkler system* installed throughout in accordance with Section 903.3.1.1, 903.3.1.2 or 903.3.1.3.
2. Storage in a structure shall not be prohibited where the structure is of Type I or IIA construction, located

## GENERAL REQUIREMENTS

not less than 10 feet (3048 mm) from other buildings and used exclusively for dumpster or container storage.

- ❖ Medium-density polyethylene dumpsters up to 9 cubic yards [27 ft<sup>3</sup> (0.76 m<sup>3</sup>)] in capacity and that have a fuel content of 20,020 Btu per pound (46 567 kJ/kg) [by comparison, municipal solid waste averages 4,500 Btu/lb (10 467 kJ/kg)] are now being distributed and used. Medium-density polyethylene is essentially equal to the fuel value for gasoline and becomes a burning liquid that spreads and flows when involved in a fire. As such, placing them 5 feet (1524 mm) away from a nearby structure will be of little value unless their flammability hazard is mitigated. This section does that by limiting container heat release rate and heat flux using the test parameters of ASTM E1354. The peak rate of heat release criterion is consistent with the one in Sections 304.3.2 and 808.1.

Exception 1 permits storage of these containers indoors if the area is protected by an approved sprinkler system. It would be up to the fire code official to determine the maximum quantities that could be stored under these conditions.

Exception 2 applies only to buildings that are of fire-resistance-rated construction and are used exclusively for waste container storage. Such facilities might be found in scrap yards or at recycling centers, but rarely, if ever, in other occupancies.

### SECTION 305 IGNITION SOURCES

**305.1 Clearance from ignition sources.** Clearance between ignition sources, such as luminaires, heaters, flame-producing devices and combustible materials, shall be maintained in an *approved* manner.

- ❖ Establishing safe clearances will usually mean following the requirements of the IBC or other codes adopted by the jurisdiction as well as having the approval of the fire code official.

**305.2 Hot ashes and spontaneous ignition sources.** Hot ashes, cinders, smoldering coals or greasy or oily materials subject to spontaneous ignition shall not be deposited in a combustible receptacle, within 10 feet (3048 mm) of other combustible material including combustible walls and partitions or within 2 feet (610 mm) of openings to buildings.

**Exception:** The minimum required separation distance to other combustible materials shall be 2 feet (610 mm) where the material is deposited in a covered, noncombustible receptacle placed on a noncombustible floor, ground surface or stand.

- ❖ This section covers two different, but equally serious, ignition source problems. First, hot ashes, embers and cinders from fireplaces, stoves or other fireboxes must never be placed in a combustible container. This point seems almost too obvious to be mentioned, but every year fires are started when someone carelessly scoops ashes containing glowing

embers into paper bags or cardboard cartons. It is also not uncommon to see construction scrap being burned in steel drums on construction sites in cold weather. Care must be taken when emptying ashes from those containers to make sure no hot coals get dumped on paper waste or other combustible materials.

The second problem, greasy or oily materials subject to spontaneous combustion, is addressed by requiring such materials to be placed in listed containers (see commentary, Section 304.3.1).

In both cases, safe distances must be maintained from combustible construction and building openings for added protection.

The exception recognizes the added protection of tight-fitting covers on noncombustible trash containers as well as the reduced fire hazard when the containers are placed on a noncombustible surface.

**305.3 Open-flame warning devices.** Open-flame warning devices shall not be used along an excavation, road, or any place where the dislodgment of such device might permit the device to roll, fall or slide on to any area or land containing combustible material.

- ❖ Open-flame warning devices other than fusees used to mark road accidents or other short-term emergencies are rarely used today. The old-fashioned kerosene pots used to mark construction hazards in dark areas have been largely replaced by “sawhorse” barriers with battery-powered flashing lights. But, even though use may be limited, the warning in this section is nonetheless real. One fusee not firmly fixed in the ground or on another stable surface can fall into a roadside ditch filled with dry weeds and cause a roadside fire that could spread into dry woodland or cropland, causing enormous fire damage. Likewise, a burned-out hand-held fusee that is carelessly tossed aside while still hot could ignite dry refuse.

**305.4 Deliberate or negligent burning.** It shall be unlawful to deliberately or through negligence set fire to or cause the burning of combustible material in such a manner as to endanger the safety of persons or property.

- ❖ The deliberate setting of fires, whether in a structure or in a waste container located where it could endanger a structure or its occupants, is normally considered arson, which is a felony that is punishable by a lengthy prison sentence. Fortunately, arson is not that common. More likely, a fire would be caused by carelessness or by someone not considering the consequences of his or her actions.

Regardless of the circumstances, fires must be avoided. Following the requirements in the code as well as those in the IBC will help to maintain a safe, fire-free site. On construction or demolition sites, secure fencing around the site and its waste containers is good protection. Following good housekeeping practices, including routine disposal of combustible materials, is also an excellent first line of protection against fire. An ignition source cannot cause damage

to property or endanger life unless there is a fuel load to be ignited.

**305.5 Unwanted fire ignitions.** Acts or processes that have caused repeated ignition of unwanted fires shall be modified to prevent future ignition.

- ❖ Many industrial processes have the potential to produce frequent nuisance fires that generate unwanted alarms necessitating emergency responses that risk the health and safety of fire fighters and citizens. This section empowers the fire code official to alter such processes to mitigate nuisance fires.

### SECTION 306

#### MOTION PICTURE PROJECTION ROOMS AND FILM

**306.1 Motion picture projection rooms.** Electric arc, xenon or other light source projection equipment that develops hazardous gases, dust or radiation and the projection of ribbon-type cellulose nitrate film, regardless of the light source used in projection, shall be operated within a motion picture projection room complying with Section 409 of the *International Building Code*.

- ❖ The requirements in this section are specific to spaces housing equipment used to project cellulose acetate film, also called safety film, which is in common use today. This film has about the same fire hazard characteristics as paper of the same thickness and form. The equipment used to project the film, however, may also present fire or health hazards that can be minimized by proper construction of the room. Section 409 of the IBC covers these construction requirements in detail.

The older type of motion picture film was made of cellulose nitrate, which is also called pyroxylin, which presents a significantly greater fire hazard and, therefore, calls for stricter construction requirements, including sprinklers. These requirements are contained in Sections 6504 and 903.2.5.3. The greater hazard of cellulose nitrate film, which today is found mainly in museum collections and other archives or film preservation facilities, comes from the characteristic of the material to begin degrading at temperatures below its ignition temperature, causing a chemical reaction that can lead to spontaneous combustion. The combustion products of cellulose nitrate are both flammable and extremely toxic because they include oxides of nitrogen. Cellulose nitrate film burns at a rate that is as much as 15 times the rate of common combustibles.

**306.2 Cellulose nitrate film storage.** Storage of cellulose nitrate film shall be in accordance with NFPA 40.

- ❖ NFPA 40 contains minimum requirements for a reasonable level of protection for the storage and handling of cellulose nitrate film. The standard does not address the manufacture of the film because it has not been made in the United States since 1951.

### SECTION 307 OPEN BURNING, RECREATIONAL FIRES AND PORTABLE OUTDOOR FIREPLACES

**307.1 General.** A person shall not kindle or maintain or authorize to be kindled or maintained any *open burning* unless conducted and *approved* in accordance with Sections 307.1.1 through 307.5.

- ❖ To control the hazards associated with it, open burning may not be authorized or undertaken without the approvals specified in Section 307. See the commentary to Section 202 for the definition of “Open burning” for a discussion of the types of burning intended to be regulated by this section.

**307.1.1 Prohibited open burning.** Open burning shall be prohibited when atmospheric conditions or local circumstances make such fires hazardous.

**Exception:** Prescribed burning for the purpose of reducing the impact of wildland fire when authorized by the *fire code official*.

- ❖ This section is intended to protect the public from irresponsible burning when it endangers the safety, health or welfare of persons near the burn site. The terms “offensive” and “objectionable” in the previous code edition were undefined and unreasonably subjective, making the prohibition of open burning due to smoke emissions unenforceable. Also, there is not a referenced standard that provides a method for measuring or otherwise determining when smoke emissions are “offensive or objectionable.” In the absence of such guidance, the legal requirements for consistency of enforcement were unattainable.

Fundamentally and historically, the code has regulated fire hazards and not poor air quality caused by smoke from fires. Experience strongly suggests that the previous wording encouraged citizens to request intervention by the fire code official to resolve neighborhood disputes regarding smoke emissions from many forms of outdoor fires that citizens correctly or incorrectly believed to be “open burning” (e.g., recreational fires, bonfires, charcoal burners, etc.); such situations should be civil matters rather than unlawful acts subject to the penalties prescribed in Section 109.

The revised wording empowers the fire code official to prohibit open burning when such fires would, in fact, be hazardous because of measurable environmental factors, such as weather (e.g., wind, temperature, relative humidity) or fuel characteristics (e.g., fuel moisture content).

The exception allows for prescribed burning that is conducted in an effort to minimize the fuel load in wildland and interface areas. Such prescribed burning is a common practice and is done with great planning and forethought and includes safeguards for proper fire control. Annually, several million wildland acres are subjected to prescribed burning in the U.S. to eliminate hazardous fuels, alter vegetation to pro-

## GENERAL REQUIREMENTS

mote the growth of fuels that produce less heat and burn slower, improve the habitat for wildlife and vegetation, control nuisance pests, and improve access for replanting and other recreational activities. The ability for a fire agency to utilize prescribed burning operations in a season when the fire can be more easily controlled reduces the personnel and resources needed to control a wildland fire when it occurs, and increases the likelihood that fewer structures and lives will be lost to wildland fire.

**307.2 Permit required.** A permit shall be obtained from the *fire code official* in accordance with Section 105.6 prior to kindling a fire for recognized silvicultural or range or wildlife management practices, prevention or control of disease or pests, or a bonfire. Application for such approval shall only be presented by and permits issued to the *owner* of the land upon which the fire is to be kindled.

❖ This section defines a rather narrow range of purposes for which permits will be issued. Section 105.6.30 covers open-burning permits in general. This section restricts permissible fires to those used for silviculture (the cultivation of forests and shade trees); range or wildlife management; pest control; and bonfires as defined in the code. This section further restricts the permitting process to owners of the land on which the fire is to be kindled (see commentary, Section 301.2).

**307.2.1 Authorization.** Where required by state or local law or regulations, *open burning* shall only be permitted with prior approval from the state or local air and water quality management authority, provided that all conditions specified in the authorization are followed.

❖ This section requires permit applicants to comply with state and local regulations covering air and water quality as well as safety regulations established by the jurisdiction having authority.

**307.3 Extinguishment authority.** Where open burning creates or adds to a hazardous situation, or a required permit for open burning has not been obtained, the *fire code official* is authorized to order the extinguishment of the open burning operation.

❖ When the fire code official finds that open burning creates a hazardous condition such as the potential for igniting exposures or is unsafe because of atmospheric conditions, this section establishes the authority of the fire code official to order that the open burning fire be extinguished. Note that the fire department is not included in the extinguishment scenario but, rather, the section relies on the provisions of Section 109.3.2, which establishes who must comply with the extinguishment order, i.e., "...the owner, operator, occupant or other person responsible for the condition or violation...." This enhances public safety by not requiring the commitment of a piece of fire apparatus to extinguish an open-burning fire that is not an emergency (see commentary, Section 109.3.2).

**307.4 Location.** The location for *open burning* shall be not less than 50 feet (15 240 mm) from any structure, and provisions shall be made to prevent the fire from spreading to within 50 feet (15 240 mm) of any structure.

### Exceptions:

1. Fires in *approved* containers that are not less than 15 feet (4572 mm) from a structure.
2. The minimum required distance from a structure shall be 25 feet (7620 mm) where the pile size is 3 feet (914 mm) or less in diameter and 2 feet (610 mm) or less in height.

❖ The 50-foot (15 240 mm) restriction applies to large fires in large open areas, such as those defined in Section 307.2. Exception 1 refers to fires that generally would be considerably smaller or would be controlled by the container in which they burn, presenting a reduced exposure risk to nearby buildings. Exception 2 allows a reduction in clearance from buildings based on the lesser hazard of fires that are limited in size.

**307.4.1 Bonfires.** A bonfire shall not be conducted within 50 feet (15 240 mm) of a structure or combustible material unless the fire is contained in a barbecue pit. Conditions that could cause a fire to spread within 50 feet (15 240 mm) of a structure shall be eliminated prior to ignition.

❖ Bonfires usually are large and associated with some kind of planned event (for example, a school pep rally, holiday celebration or camp celebration). This section restricts the location of these large fires to open areas in which sparks and burning embers would be unlikely to endanger structures and smoke would not be a significant hazard to public health. Allowing a bonfire in a barbecue pit automatically restricts the size of the fire to the fuel load that can be contained within the noncombustible fire pit.

**307.4.2 Recreational fires.** *Recreational fires* shall not be conducted within 25 feet (7620 mm) of a structure or combustible material. Conditions that could cause a fire to spread within 25 feet (7620 mm) of a structure shall be eliminated prior to ignition.

❖ Recreational fires are usually fairly small, but can still represent a significant fire hazard if the area in which they are kindled is not kept free of combustible trash and debris. Basic fire safety practices followed by campers make good guidelines. No fire should ever be kindled in a location where it would endanger structures or would be likely to ignite combustible materials close by.

**307.4.3 Portable outdoor fireplaces.** Portable outdoor fireplaces shall be used in accordance with the manufacturer's instructions and shall not be operated within 15 feet (3048 mm) of a structure or combustible material.

**Exception:** Portable outdoor fireplaces used at one- and two-family *dwellings*.

❖ Portable outdoor fireplaces (also known as patio fireplaces) designed to burn solid fuel are available at

retailers ranging from local grocery stores to big box retailers. Their widespread availability and use created considerable confusion for citizens and the fire service regarding if or how they were regulated by the code since Sections 307 and 308 were essentially silent on the use of this specific type of device. Fires in portable outdoor fireplaces could not be considered a “recreational fire” because critical to that definition is the concept that the fire is not contained in an incinerator, outdoor fireplace, barbecue grill or barbecue pit. It could then have been suggested that a portable outdoor fireplace is merely a type of “outdoor fireplace,” but the code did not contain any references pertaining to where an outdoor fireplace could be located or operated. Since the use and hazards associated with operating such fireplaces are more consistent with the type of activities regulated in Section 307 than other types of open flames addressed in Section 308, specific regulations are now provided in Section 307.

This section makes it clear that the use of portable outdoor fireplaces is specifically regulated by the code. It prohibits the use of these devices within 15 feet (3048 mm) of any structure and is consistent with Section 307.4, Exception 1. Also, consistent with regulations for other appliances, this section relies upon compliance with the manufacturer’s instructions for additional safeguards.

The exception exempts one- and two-family dwellings from the requirements of this section. In those occupancies, the level of familiarity and control exercised by the building occupants is recognized as offsetting the hazards of using these devices. There are practical difficulties involved in enforcing such regulations in one- and two-family dwellings as well.

**307.5 Attendance.** *Open burning, bonfires, recreational fires* and use of portable outdoor fireplaces shall be constantly attended until the fire is extinguished. A minimum of one portable fire extinguisher complying with Section 906 with a minimum 4-A rating or other *approved* on-site fire-extinguishing equipment, such as dirt, sand, water barrel, garden hose or water truck, shall be available for immediate utilization.

❖ This section reiterates basic common sense, but tends to be ignored quite often. Having one or more individuals responsible for keeping watch on a fire, even one of small size, is the first line of fire prevention. All too often news articles tell of wooden decks burning because hot embers from a charcoal grill fell unobserved onto the unprotected wooden surface, or of a huge brush or forest fire being caused by careless individuals who did not watch their campfires.

For practical purposes as well as for fire safety, some means of extinguishing a kindled fire should be kept close at hand. For small fires, a shovelful of dirt may be sufficient. For large fires, such as bonfires, large volumes of water may be necessary; however, no matter how much extinguishing equipment is available, it may prove useless unless someone is tending the fire and can sound an alarm.

## SECTION 308 OPEN FLAMES

**308.1 General.** Open flame, fire and burning on all premises shall be in accordance with Sections 308.1.1 through 308.4.1 and with other applicable sections of this code.

❖ This section establishes the scope of the requirements of Section 308 as being applicable to both indoor and outdoor situations involving open flames.

**308.1.1 Where prohibited.** A person shall not take or utilize an open flame or light in a structure, vessel, boat or other place where highly flammable, combustible or explosive material is utilized or stored. Lighting appliances shall be well-secured in a glass globe and wire mesh cage or a similar *approved* device.

❖ This section intends to maintain separation between ignitable combustible materials and ignition sources that involve an open flame in any vessel, structure or occupancy.

**308.1.2 Throwing or placing sources of ignition.** A person shall not throw or place, or cause to be thrown or placed, a lighted match, cigar, cigarette, matches, or other flaming or glowing substance or object on any surface or article where it can cause an unwanted fire.

❖ This section recognizes the hazard caused by carelessness in disposing of smoking materials and other flaming or glowing objects. Smoking in bed or in situations where the smoker could forget about lighted smoking materials has caused large numbers of fires and fatalities over the years. Lack of attention to fireplaces and ash pits has caused great property loss as well. As one example, a three-story fraternity house at Iowa State University in Ames, Iowa, was completely destroyed by the fire that resulted from a burning log tumbling from an overflowing ash pit onto a combustible floor surface.

Lighted cigarettes discarded through the windows of moving vehicles each year cause grass, brush and forest fires that consume huge acreage in open country as well as dwellings and other structures.

**308.1.3 Torches for removing paint.** A person utilizing a torch or other flame-producing device for removing paint from a structure shall provide not less than one portable fire extinguisher complying with Section 906 and with a minimum 4-A rating, two portable fire extinguishers, each with a minimum 2-A rating, or a water hose connected to the water supply on the premises where such burning is done. The person doing the burning shall remain on the premises 1 hour after the torch or flame-producing device is utilized.

❖ Any time an open flame is used to soften old paint in preparation for removal, there is a risk of fire that must be covered by having approved fire extinguishers or a water source readily available. The requirement for a 1-hour fire watch after discontinuing the use of the open flame covers the possibility that paint fragments could still be hot enough to ignite flammable or combustible materials that might be lying around. It also considers the possibility that the flame used to remove

## GENERAL REQUIREMENTS

paint from a combustible base material could heat that material to its ignition temperature and leave an almost undetectable smolder that might burst into flames later. Safe and effective means for removing paint at lower temperatures, such as warm-air heat devices capable of generating high-temperature convection air, are readily available for sale or rent and far less likely to result in an ignition of combustible materials.

**308.1.4 Open-flame cooking devices.** Charcoal burners and other open-flame cooking devices shall not be operated on combustible balconies or within 10 feet (3048 mm) of combustible construction.

### Exceptions:

1. One- and two-family *dwelling*s.
  2. Where buildings, balconies and decks are protected by an *automatic sprinkler system*.
  3. LP-gas cooking devices having LP-gas container with a water capacity not greater than 2<sup>1</sup>/<sub>2</sub> pounds [nominal 1 pound (0.454 kg) LP-gas capacity].
- ❖ This section contains a strict prohibition on the use of charcoal-burning grills and other open-flame cooking devices in the locations described. Its intent is to mitigate the potential for hot embers to fall from the firebox of the cooking device and ignite a combustible surface, such as a wooden balcony or deck. The 10-foot (3048 mm) separation also reduces the likelihood that fire-starting or cooking flare-ups will come in contact with combustible wall construction that is easily ignited.

Since this section appears to regulate only the operation of the cooking devices, it is often asked if the devices can even be located or stored in the locations described. In the case of LP-gas fired grills using containers larger than those described in Exception 3, the answer is generally no, based on Section 6.20.11.2 of NFPA 58, which does not allow larger containers to be transported through an occupied building. See Sections 6101.1 and 6104.1 of the code for references to NFPA 58.

In the case of locating non-LP-gas-fired cooking devices, the location would have to be approved by the fire code official. Note that the prohibition in this section would also apply to gas grills connected to the building's fuel gas piping system since they are still open flame cooking devices. See also Section 603.4.2.1.1.

Exception 1 exempts one- and two-family dwellings from the requirements of this section and would allow the use of LP-gas barbeque grills of any size on balconies of such buildings. In those occupancies, the level of familiarity and control exercised by the building occupants is recognized as offsetting the hazards of using open-flame cooking devices. There are practical difficulties involved in enforcing such regulations in one- and two-family dwellings as well. Exception 2 recognizes the added protection pro-

vided by sprinklers. Exception 3 allows small LP-gas burning devices such as the tabletop grills or units that might be used in cooking within residential occupancies.

**308.1.5 Location near combustibles.** Open flames such as from candles, lanterns, kerosene heaters and gas-fired heaters shall not be located on or near decorative material or similar combustible materials.

❖ Each year in nearly every county and community in the country at least one house fire occurs that is caused by a gas-fired space heater igniting nearby combustibles. Accidents involving candles and lanterns used in both outdoor and indoor settings are not at all uncommon. In nearly all of these incidents, the exercise of common sense and the practice of keeping ignition sources and fuel packages well separated could have prevented property damage or loss of life.

**308.1.6 Open-flame devices.** Torches and other devices, machines or processes liable to start or cause fire shall not be operated or used in or upon wildfire risk areas, except by a permit in accordance with Section 105.6 secured from the *fire code official*.

**Exception:** Use within inhabited premises or designated campsites that are not less than 30 feet (9144 mm) from grass-, grain-, brush- or forest-covered areas.

❖ This section establishes the fire code official's authority to control through the permitting process the use of open flames in areas susceptible to fires. The term "wildfire risk area" is defined in Chapter 2 of the code and is applied to land covered with grass, grain, brush, forest or similar vegetation that, if ignited, could pose a severe fire danger to surrounding areas. The exception recognizes open ground that is free of combustible materials as an acceptable barrier to fire spread [see the *International Wildland-Urban Interface Code*<sup>®</sup> (IWUIC<sup>®</sup>) for further information].

**308.1.6.1 Signals and markers.** Flame-employing devices, such as lanterns or kerosene road flares, shall not be operated or used as a signal or marker in or upon wildfire risk areas.

**Exception:** The proper use of fusees at the scenes of emergencies or as required by standard railroad operating procedures.

❖ This section prohibits the use of flame-producing devices as signal or marker devices except for the use of fusees to mark the scene of an emergency or where routinely employed in railroad procedures, such as when a train is stopped across a roadway not protected by permanent signal lights.

**308.1.6.2 Portable fueled open-flame devices.** Portable open-flame devices fueled by flammable or combustible gases or liquids shall be enclosed or installed in such a manner as to prevent the flame from contacting combustible material.

### Exceptions:

1. LP-gas-fueled devices used for sweating pipe joints or removing paint in accordance with Chapter 61.

2. Cutting and welding operations in accordance with Chapter 35.
3. Torches or flame-producing devices in accordance with Section 308.4.
4. Candles and open-flame decorative devices in accordance with Section 308.3.

❖ This section prohibits the use of portable devices in situations where they might be placed on unstable platforms or where they could be knocked over by human contact. The exceptions list the types of open-flame or heat-producing operations not regulated by this section but regulated elsewhere in the code.

**308.1.6.3 Sky lanterns.** A person shall not release or cause to be released an untethered sky lantern.

❖ Sky lanterns, variously known as Kongming lanterns, Chinese lanterns, fire balloons or fire parachutes, are typically made of paper and contain an open flame used to heat the air inside the device to make it airborne, similar to but on a much smaller scale than a hot air balloon. Once airborne, if these devices are untethered and their movement is thus unrestricted, they are subject to winds and other atmospheric conditions such that the location of the final landfall is completely unknown and uncontrolled by the user. Obviously, uncontrolled open flame devices descending out of the sky have a significant potential to start wildfires and structure fires.

**308.1.7 Religious ceremonies.** When, in the opinion of the *fire code official*, adequate safeguards have been taken, participants in religious ceremonies are allowed to carry hand-held candles. Hand-held candles shall not be passed from one person to another while lighted.

❖ This section has a very narrow application. As stated, only religious ceremonies are covered and the judgment of the fire code official is required for final approval. Prohibiting the passing of lighted candles from person to person is intended to minimize the opportunities for the candles to be dropped where they could become an ignition source for flammable or combustible materials or come into contact with clothing or hair. Spiritual significance may be attached to the use of candles in places of worship; therefore, the local fire code official should work closely with religious groups when enforcing this section.

**308.1.7.1 Aisles and exits.** Candles shall be prohibited in areas where occupants stand, or in an *aisle* or *exit*.

❖ This prohibition is intended to prevent accidents caused by lighted candles being knocked from their holders onto combustible furniture, carpeting or decorative materials. Candles are commonly found at seasonal religious observances where attendance often exceeds the norm. In case of an emergency, people must be able to move through the aisles toward the

exits without risking the ignition of clothing, hair or decorations.

**308.1.8 Flaming food and beverage preparation.** The preparation of flaming foods or beverages in places of assembly and drinking or dining establishments shall be in accordance with Sections 308.1.8.1 through 308.1.8.5.

❖ The regulations in this section of the code are necessary to give the fire code official guidance in allowing the preparation of flaming food and beverages to be conducted in restaurants in a safe manner. These types of foods, sometimes referred to as “flambé foods,” are prepared by adding a small amount of flammable or combustible liquid in the form of alcoholic beverages to the food and igniting it. Many restaurants prepare popular selected dishes, such as cherries jubilee, brandied peaches and flaming bananas, in this manner, usually tableside within close proximity of the customers. The proximity plus the intentional ignition of flammable liquids in a Group A occupancy make regulation of this process appropriate. Note that the regulations in this section are not intended to address a fuel source, such as Sterno, used to keep food warm.

**308.1.8.1 Dispensing.** Flammable or *combustible liquids* used in the preparation of flaming foods or beverages shall be dispensed from one of the following:

1. A 1-ounce (29.6 ml) container.
2. A container not exceeding 1-quart (946.5 ml) capacity with a controlled pouring device that will limit the flow to a 1-ounce (29.6 ml) serving.

❖ These dispensing provisions limit the amount of flammable or combustible liquid being transported around the restaurant for use in flaming food or beverage preparation in order to minimize the fuel potential in a fire incident involving such operations. Item 1 could be referring to a typical shot glass. Item 2 could be referring to a “jigger-pourer,” which is a device that fits into the neck of a bottle and is intended to limit the per-pour quantity to 1 ounce.

**308.1.8.2 Containers not in use.** Containers shall be secured to prevent spillage when not in use.

❖ Securing the containers used in flaming food or beverage preparation while not in use reduces the likelihood of an accidental spill.

**308.1.8.3 Serving of flaming food.** The serving of flaming foods or beverages shall be done in a safe manner and shall not create high flames. The pouring, ladling or spooning of liquids is restricted to a maximum height of 8 inches (203 mm) above the receiving receptacle.

❖ Limiting the height from which flammable or combustible liquids are poured reduces the likelihood of a spill or overpour that might miss the target dish and be ignited by a table candle, smoking materials or another ignition source.

## GENERAL REQUIREMENTS

**308.1.8.4 Location.** Flaming foods or beverages shall be prepared only in the immediate vicinity of the table being serviced. They shall not be transported or carried while burning.

❖ This section prohibits movement or transport of “flambé foods” while they are burning in order to reduce the potential for incidents wherein the tray or dish might be dropped or tipped causing a spill of burning liquid, which, while limited in size, could lead to a panic reaction by restaurant patrons or, if spilled on a patron, could cause serious burn injuries.

**308.1.8.5 Fire protection.** The person preparing the flaming foods or beverages shall have a wet cloth towel immediately available for use in smothering the flames in the event of an emergency.

❖ Flaming-food preparation is a cooking hazard much the same as stovetop preparation. An efficient method for extinguishing a stovetop fire in a frying pan or similar utensil is to put the cover on the utensil to exclude oxygen. In flambé preparation, the food is prepared in a relatively small pan or even in the dish in which it will be served and in which the flames can be easily smothered by a wet towel. Note that this precautionary measure is in addition to the portable fire extinguishers to be provided in accordance with Section 906.

**308.2 Permits required.** Permits shall be obtained from the *fire code official* in accordance with Section 105.6 prior to engaging in the following activities involving open flame, fire and burning:

1. Use of a torch or flame-producing device to remove paint from a structure.
2. Use of open flame, fire or burning in connection with Group A or E occupancies.
3. Use or operation of torches and other devices, machines or processes liable to start or cause fire in or upon wild-fire risk areas.

❖ This section establishes the authority of the fire code official to control the hazards of using open flames through the permitting process. The restrictions here do not prohibit the use of open-flame devices in the listed activities, but they do allow the fire code official to inspect plans and ongoing activities to make certain they are safe for the occupancy in which they are held. Permit applicants should be required to demonstrate that their regulated activities comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Sections 105.6.33 and 105.6.34 for a discussion of specific operational permits for the indicated regulated activities. The permit process also serves to notify the fire department of the increased hazard at particular locations.

**308.3 Group A occupancies.** Open-flame devices shall not be used in a Group A occupancy.

### Exceptions:

1. Open-flame devices are allowed to be used in the following situations, provided *approved* precautions are taken to prevent ignition of a combustible material or injury to occupants:
  - 1.1. Where necessary for ceremonial or religious purposes in accordance with Section 308.1.7.
  - 1.2. On stages and platforms as a necessary part of a performance in accordance with Section 308.3.2.
  - 1.3. Where candles on tables are securely supported on substantial noncombustible bases and the candle flames are protected.
2. Heat-producing equipment complying with Chapter 6 and the *International Mechanical Code*.
3. Gas lights are allowed to be used provided adequate precautions satisfactory to the *fire code official* are taken to prevent ignition of combustible materials.

❖ The use of open-flame devices in Group A occupancies where large numbers of people gather for entertainment, instruction, food or drink consumption, deliberation, awaiting transportation or social or religious functions increases the likelihood of the occupants coming into contact with these devices and is, therefore, prohibited. Safe alternatives to open-flame devices should be used where practical, especially in restaurants and other assembly occupancies where the focus is on atmosphere rather than symbolism or religious significance.

Exception 1 refers to Sections 308.1.7 and 308.3.2 for use in religious and theatrical settings as well as permitting use on tabletops when properly secured and protected.

Exception 2 refers to building service heat-producing equipment that meets other code requirements.

Exception 3 covers gas lights installed with proper flame safeguards and with the approval of the fire code official. This kind of lighting is often a permanent installation that would be covered by additional code requirements.

**308.3.1 Open-flame decorative devices.** Open-flame decorative devices shall comply with all of the following restrictions:

1. Class I and Class II liquids and LP-gas shall not be used.
2. Liquid- or solid-fueled lighting devices containing more than 8 ounces (237 ml) of fuel must self-extinguish and not leak fuel at a rate of more than 0.25 teaspoon per minute (1.26 ml per minute) if tipped over.
3. The device or holder shall be constructed to prevent the spillage of liquid fuel or wax at the rate of more

than 0.25 teaspoon per minute (1.26 ml per minute) when the device or holder is not in an upright position.

4. The device or holder shall be designed so that it will return to the upright position after being tilted to an angle of 45 degrees (0.79 rad) from vertical.

**Exception:** Devices that self-extinguish if tipped over and do not spill fuel or wax at the rate of more than 0.25 teaspoon per minute (1.26 ml per minute) if tipped over.

5. The flame shall be enclosed except where openings on the side are not more than 0.375-inch (9.5 mm) diameter or where openings are on the top and the distance to the top is such that a piece of tissue paper placed on the top will not ignite in 10 seconds.
6. Chimneys shall be made of noncombustible materials and securely attached to the open-flame device.

**Exception:** A chimney is not required to be attached to any open-flame device that will self-extinguish if the device is tipped over.

7. Fuel canisters shall be safely sealed for storage.
8. Storage and handling of *combustible liquids* shall be in accordance with Chapter 57.
9. Shades, where used, shall be made of noncombustible materials and securely attached to the open-flame device holder or chimney.
10. Candelabras with flame-lighted candles shall be securely fastened in place to prevent overturning, and shall be located away from occupants using the area and away from possible contact with drapes, curtains or other combustibles.

- ❖ This class of open-flame devices includes items such as wall-mounted candles or torch sconces; bug-repellant candles in glass jars or metal cans; tabletop candles and oil lamps; free-standing torch holders and candelabras. The criteria for the use of this kind of device are all intended to enhance safety.

**308.3.2 Theatrical performances.** Where *approved*, open-flame devices used in conjunction with theatrical performances are allowed to be used when adequate safety precautions have been taken in accordance with NFPA 160.

- ❖ Theatrical performances typically occur on stages and involve large quantities of combustible materials. Hazards associated with stages can include: combustible scenery and lighting suspended overhead; scenic elements, contents and acoustical treatment on the back and sides of the stage; workshops, scene docks and dressing rooms located around the stage perimeter, and storage areas and property rooms located underneath the stage. Because of the inherent dangers associated with the introduction of open flames into such a fuel-rich environment, the use of open-flame devices in theatrical performances requires review, evaluation and the approval of the fire code official on a case-by-case basis and must be safeguarded in accordance with the provisions of

NFPA 160. For further discussion of the special hazard nature of stages, see the commentary for Section 410 of the IBC.

**308.4 Group R occupancies.** Open flame, fire and burning in Group R occupancies shall comply with the requirements of Sections 308.1 through 308.1.6.3 and Section 308.4.1.

- ❖ This section establishes the applicability of the indicated requirements of Section 308 to open flame activities in Group R occupancies.

**308.4.1 Group R-2 dormitories.** Candles, incense and similar open-flame-producing items shall not be allowed in sleeping units in Group R-2 dormitory occupancies.

- ❖ This section provides the fire code official with the needed authority to control the introduction of potential ignition sources into Group R-2 dormitory occupancies and help to stop dorm fires before lives are endangered and potentially lost. Fire represents a significant risk to life and property in dormitory occupancies, particularly at residential schools, colleges and universities. The large number of young people living in close proximity to one another creates the potential for a relatively small fire to have serious and possibly fatal consequences.

Candle and incense use presents a significant life safety risk in the close confines of a typical residence hall. According to NFPA fire loss data, there is an average of 1,425 fires each year in dormitories, causing \$6.3 million in direct property damage. The data show that candle fires alone cause a staggering \$2.3 million in direct property damage each year in these occupancies, which makes them the most costly type of fire in a residence hall. Prohibiting the use of candles, incense and similar open flame items reduces the potential ignition sources for a fire, providing for a safer living environment.

## SECTION 309

### POWERED INDUSTRIAL TRUCKS AND EQUIPMENT

**309.1 General.** Powered industrial trucks and similar equipment including, but not limited to, floor scrubbers and floor buffers, shall be operated and maintained in accordance with Section 309.2 through 309.6.

- ❖ This section establishes the fire safety requirements for control of the hazards associated with powered industrial trucks and industrial equipment. Because these trucks or equipment may have either battery-powered electric motors or internal combustion engines using liquid or gaseous fuel, Sections 309.2 through 309.6 cover the fire safety aspects of both.

**309.2 Battery chargers.** Battery chargers shall be of an *approved* type. Combustible storage shall be kept not less than 3 feet (915 mm) from battery chargers. Battery charging shall not be conducted in areas accessible to the public.

- ❖ Battery chargers offer several safety challenges if they are not properly housed and operated. A battery that is connected to the charger with the poles

## GENERAL REQUIREMENTS

reversed can explode when charging power is turned on, which could result in corrosive liquid being sprayed over the charger room and anyone who happens to be in it. Aside from the possibility of serious bodily injury from flying debris or corrosive spray, eye damage from the spray is a critical consideration. There is also the possibility of energized charging leads shorting, arcing or fusing and causing sparks to become an ignition source for combustibles if they are not kept out of the area.

When a charger is properly connected and energized, the charging process causes generation of hydrogen and oxygen gases as well as acid or alkali fumes. These gases must be vented to prevent them from reaching ignitable or detonable levels (see commentary, Section 309.3). A typical battery charger arrangement is illustrated in Commentary Figure 309.2. Note that these battery chargers are outside of the scope of Section 608 and thus not subject to its provisions.

**Figure 309.2**  
**BATTERY CHARGERS FOR**  
**POWERED INDUSTRIAL TRUCKS**

**309.3 Ventilation.** Ventilation shall be provided in an *approved* manner in battery-charging areas to prevent a dangerous accumulation of flammable gases.

❖ Charging lead-acid or nickel iron batteries is a process of electrolysis in which oxides created by operation of the battery are reduced to metal and redeposited on the electrode plates. The process results in the rejuvenation of the electrolyte in the battery and the emission of both oxygen and hydrogen gases as well as corrosive fumes. If these gases are allowed to accumulate in an enclosed space, they could eventually reach an ignitable or detonable level. Section 608.6 and the applicable provisions of the *International Mechanical Code*® (IMC)® describe one method of ventilation used to carry off and dilute the concentrations of hazardous gases. See the commentaries to Section 608.6 and its subsections.

**309.4 Fire extinguishers.** Battery-charging areas shall be provided with a fire extinguisher complying with Section 906 having a minimum 4-A:20-B:C rating within 20 feet (6096 mm) of the battery charger.

❖ Because of the electrical hazards associated with the battery-charging operation; the fuel load presented by the plastic battery cases and other area contents; and the potential for the presence of gases in the room, an appropriately sized portable fire extinguisher must be located within the battery-charging area. The extinguisher must be accessible with minimum travel.

**309.5 Refueling.** Powered industrial trucks using liquid fuel, LP-gas or hydrogen shall be refueled outside of buildings or in areas specifically *approved* for that purpose. Fixed fuel-dispensing equipment and associated fueling operations shall be in accordance with Chapter 23. Other fuel-dispensing equipment and operations, including cylinder exchange for LP-gas-fueled vehicles, shall be in accordance with Chapter 57 for flammable and *combustible liquids* or Chapter 61 for LP-gas.

❖ Because of the hazards associated with liquid fuel spills and gaseous fuel discharges, this section requires that powered industrial trucks be refueled outside where the vapors or gas can be readily dissipated. This section also allows the alternative of fueling inside of buildings where safeguards mitigate the hazards of the operation and the location is specifically approved for the use by the fire code official. Where fueling with liquid or gaseous fuel is done from fixed equipment, compliance with Chapter 23 of the code is required for both the fueling equipment and its operation because of the proven safeguards for such operations that are included in that chapter. Similarly, fueling equipment and operations for flammable or combustible liquids or LP-gas utilizing non-fixed equipment must be conducted in accordance with the applicable provisions of the appropriate material-specific chapter.

**309.6 Repairs.** Repairs to fuel systems, electrical systems and repairs utilizing open flame or welding shall be done in *approved* locations outside of buildings or in areas specifically *approved* for that purpose.

❖ Repairs that could create ignition sources or a fuel load for an ignition source must be done in indoor or outdoor locations that are designed specifically for vehicle repairs and that have been approved by the fire code official.

## SECTION 310 SMOKING

**310.1 General.** The smoking or carrying of a lighted pipe, cigar, cigarette or any other type of smoking paraphernalia or material is prohibited in the areas indicated in Sections 310.2 through 310.8.

❖ This section states that smoking is prohibited in those areas designated in Sections 310.2 and 310.8. Before entering an area posted with “No Smoking”

signs, anyone carrying a lighted smoking product or device must extinguish the smoking material and properly dispose of the ashes and other residue. Suitable ashtrays should be available at the entry to “No Smoking” areas for disposal of the prohibited smoking materials.

**310.2 Prohibited areas.** Smoking shall be prohibited where conditions are such as to make smoking a hazard, and in spaces where flammable or combustible materials are stored or handled.

❖ Smoking can be prohibited wherever it would be a hazard in the judgment of the fire code official.

**310.3 “No Smoking” signs.** The *fire code official* is authorized to order the posting of “No Smoking” signs in a conspicuous location in each structure or location in which smoking is prohibited. The content, lettering, size, color and location of required “No Smoking” signs shall be *approved*.

**Exception:** In Group I-2 occupancies where smoking is prohibited, “No Smoking” signs are not required in interior locations of the facility where signs are displayed at all major entrances into the facility.

❖ The fire code official is not only authorized to designate where signs are to be posted, but is also responsible for establishing the specification for all aspects of those signs. A typical sign design is shown in Commentary Figure 310.3.

The exception provides correlation with NFPA 101 on this topic. Since the majority of healthcare facilities already prohibit smoking, where signs are posted at the main entrances, it is redundant and unnecessary to also require the signs to be posted throughout a facility that does not permit smoking, has a staff

trained to monitor and policies in place to quickly stop or prevent the action (see Commentary Figure 310.3.)

**310.4 Removal of signs prohibited.** A posted “No Smoking” sign shall not be obscured, removed, defaced, mutilated or destroyed.

❖ Posted signs must remain in the locations designated by the fire code official and be readable at all times. Many, if not all, jurisdictions establish penalties for removing, obscuring, defacing or mutilating official signs.

**310.5 Compliance with “No Smoking” signs.** Smoking shall not be permitted nor shall a person smoke, throw or deposit any lighted or smoldering substance in any place where “No Smoking” signs are posted.

❖ Penalties are usually imposed for violating “no smoking” prohibitions. Smoking must be confined to approved areas, and discarded smoking materials must be deposited only in approved ashtrays or receptacles. Violation of this provision customarily constitutes a misdemeanor. Prosecution of misdemeanor offenses should be coordinated with the jurisdiction’s legal counsel. Offense and penalty clauses, such as those included in Section 109, are required in order to prosecute infractions (see commentary, Section 109.3).

**310.6 Ash trays.** Where smoking is permitted, suitable non-combustible ash trays or match receivers shall be provided on each table and at other appropriate locations.

❖ Where smoking is permitted, smokers must have available a noncombustible ashtray or other receptacle where smoking materials can be safely deposited. These receptacles must be located on each table and other locations throughout the smoking area so that the smoker does not have to look for a place to discard used materials.

**310.7 Burning objects.** Lighted matches, cigarettes, cigars or other burning object shall not be discarded in such a manner that could cause ignition of other combustible material.

❖ Lighted matches, burning tobacco products and all other burning objects must be deposited in ashtrays or other approved noncombustible containers to separate these ignition sources from any potential fuel loads.

**310.8 Hazardous environmental conditions.** Where the *fire code official* determines that hazardous environmental conditions necessitate controlled use of smoking materials, the ignition or use of such materials in mountainous, brush-covered or forest-covered areas or other designated areas is prohibited except in *approved* designated smoking areas.

❖ This section gives the fire code official the authority to establish “no smoking” areas whenever and wherever environmental conditions are considered hazardous. This can include prohibiting burning dry grasses and leaves when lack of rain has rendered the environment dangerously dry or burning of specific materials when the smoke plume from the fire would endanger

**Figure 310.3  
NO SMOKING SIGN**

## GENERAL REQUIREMENTS

the health or welfare of a population. The possibilities for determination of hazardous conditions are too numerous to itemize. The judgment of the fire code official, with the advice of other officials being sought as needed, is the determining factor. The fire code official can also exercise the discretion of designating areas in which smoking is permitted.

### SECTION 311 VACANT PREMISES

**311.1 General.** Temporarily unoccupied buildings, structures, premises or portions thereof, including tenant spaces, shall be safeguarded and maintained in accordance with Sections 311.1.1 through 311.6.

❖ Vacant buildings or portions of buildings that are open at doors or windows pose fire safety and criminal trespass hazards to a community and are correctly declared to be unsafe buildings in Section 110.1.1. Such premises are often called an “attractive nuisance” to neighborhood children who may enter them to play or to other persons who may enter seeking shelter from the elements or to engage in potential criminal activities.

**311.1.1 Abandoned premises.** Buildings, structures and premises for which an *owner* cannot be identified or located by dispatch of a certificate of mailing to the last known or registered address, which persistently or repeatedly become unprotected or unsecured, which have been occupied by unauthorized persons or for illegal purposes, or which present a danger of structural collapse or fire spread to adjacent properties shall be considered abandoned, declared unsafe and abated by demolition or rehabilitation in accordance with the *International Property Maintenance Code* and the *International Building Code*.

❖ This section establishes the authority to dispose of by demolition or rehabilitation properties that pose a variety of public safety hazards when the owners of the property cannot be located by customary legal means. Because demolition and rehabilitation are regulated by the IBC, *International Property Maintenance Code*® (IPMC®) and applicable state laws, any action taken must be a carefully coordinated effort by all affected code officials in close relationship with the jurisdiction’s legal counsel.

**311.1.2 Tenant spaces.** Storage and lease plans required by this code shall be revised and updated to reflect temporary or partial vacancies.

❖ The intent of this section is to keep storage and lease plans up to date so that the fire service will always have a complete picture of the kinds of hazards they might face in case of a fire, including vacant, unattended spaces.

**311.2 Safeguarding vacant premises.** Temporarily unoccupied buildings, structures, premises or portions thereof shall

be secured and protected in accordance with Sections 311.2.1 through 311.2.3.

❖ This section lists a number of problems that commonly occur when buildings or portions of buildings remain vacant for long periods of time. It covers concerns for security, fire protection and fire separation in vacant spaces.

**311.2.1 Security.** Exterior and interior openings accessible to other tenants or unauthorized persons shall be boarded, locked, blocked or otherwise protected to prevent entry by unauthorized individuals. The *fire code official* is authorized to placard, post signs, erect barrier tape or take similar measures as necessary to secure public safety.

❖ Unauthorized or illegal activities in vacant buildings can lead to the presence of unanticipated fire loads susceptible to ready ignition and rapid fire spread, thus increasing the hazard to adjoining properties or spaces and fire department personnel (see commentary, Section 110.1.1). This section requires securing the openings of vacant buildings or spaces against unauthorized entry by any of the methods listed or by other equally effective means approved by the fire code official and provides that appropriate signage or other readily visible warnings to the public may be posted. For a suggested standard for boarding windows and doors, see IPMC Appendix A.

**311.2.2 Fire protection.** Fire alarm, sprinkler and stand-pipe systems shall be maintained in an operable condition at all times.

#### Exceptions:

1. Where the premises have been cleared of all combustible materials and debris and, in the opinion of the *fire code official*, the type of construction, *fire separation distance* and security of the premises do not create a fire hazard.
2. Where *approved* by the fire chief, buildings that will not be heated and where *fire protection systems* will be exposed to freezing temperatures, fire alarm and sprinkler systems are permitted to be placed out of service and standpipes are permitted to be maintained as dry systems (without an automatic water supply), provided the building has no contents or storage, and windows, doors and other openings are secured to prohibit entry by unauthorized persons.

❖ The basic requirement of this section is clearly stated. The on-site fire protection systems must be maintained whether the property is occupied or vacant. The systems would be subject to the same inspections in either case.

Exception 1 gives the fire code official the authority to determine whether vacant premises pose a significant hazard and lists criteria he or she can use in making that determination.

Exception 2 recognizes that systems located in unheated premises in cold climates could be ren-

dered inoperable by freezing and authorizes permission to disable those systems when the security of the premises and fire separation arrangements meet the code requirements stated in Sections 311.2.1 and 311.2.3. Since an inoperative fire protection system has a direct effect on the tactical approaches and operations of the fire department, this exception is only applicable where the fire chief of the jurisdiction has approved the securing of the system.

**311.2.3 Fire separation.** Fire-resistance-rated partitions, *fire barriers* and *fire walls* separating vacant tenant spaces from the remainder of the building shall be maintained. Openings, joints and penetrations in fire-resistance-rated assemblies shall be protected in accordance with Chapter 7.

❖ Fire-resistance-rated construction separating vacant spaces from the remainder of the building must be maintained to the satisfaction of the fire code official. The requirements for openings, joints and penetrations are covered in Chapter 7.

**311.3 Removal of combustibles.** Persons owning, or in charge or control of, a vacant building or portion thereof, shall remove therefrom all accumulations of combustible materials, flammable or combustible waste or rubbish and shall securely lock or otherwise secure doors, windows and other openings to prevent entry by unauthorized persons. The premises shall be maintained clear of waste or hazardous materials.

**Exceptions:**

1. Buildings or portions of buildings undergoing additions, *alterations*, repairs or change of occupancy in accordance with the *International Building Code*, where waste is controlled and removed as required by Section 304.
2. Seasonally occupied buildings.

❖ Property owners, their agents and persons leasing vacant spaces are responsible for preventing accumulations of flammable or combustible materials as well as for securing the vacant space against entry by unauthorized persons.

Exception 1 covers building situations in which larger amounts of flammable or combustible waste would reasonably be generated and cites code references to cover requirements in those situations.

Exception 2 allows reasonable accumulations of flammable or combustible materials in spaces that are occupied seasonally. For example, this exception would allow unattended off-season storage of stock for sale.

**311.4 Removal of hazardous materials.** Persons owning or having charge or control of a vacant building containing hazardous materials regulated by Chapter 50 shall comply with the facility closure requirements of Section 5001.6.

❖ This section gives the fire code official the authority to require property owners, their agents and their tenants to submit a facility closure plan, and make sure combustible and hazardous materials are removed

from the premises. The requirements for the facility closure plan are given in Section 5001.6 (see Section 407.7).

**311.5 Placards.** Any vacant or abandoned buildings or structures determined to be unsafe pursuant to Section 110 of this code relating to structural or interior hazards shall be marked as required by Sections 311.5.1 through 311.5.5.

❖ Vacant or abandoned buildings are often of questionable structural integrity and have a very high probability of intentionally set fires. When fires occur in these buildings, they present a host of unusual hazards to fire fighters. Since the buildings are uninhabited, fires may develop for significant periods of time before they are detected and reported.

In December 1999, six professional fire fighters died after they became lost in a six-floor, maze-like, cold-storage and warehouse building while searching for two reportedly trapped people and fire extension. In the wake of this tragedy, the National Institute for Occupational Safety and Health (NIOSH) conducted a Fatality Assessment and Control Evaluation (FACE) as part of its Fire Fighter Fatality Investigation and Prevention Program and issued its findings in report FACE-99-F47 in September, 2000. NIOSH investigators concluded that, to reduce the risk of similar occurrences, fire departments should, among other recommendations, implement a program to “identify dangerous vacant buildings by affixing warning placards to entrance doorways or other openings where fire fighters may enter.”

In order to improve fire-fighter safety when responding to incidents in buildings that have structural safety issues and have been declared to be unsafe due to being vacant or abandoned, this section establishes an information placarding system that will assist incident commanders in making personnel and equipment deployment decisions.

**311.5.1 Placard location.** Placards shall be applied on the front of the structure and be visible from the street. Additional placards shall be applied to the side of each entrance to the structure and on penthouses.

❖ Prominent positioning of warning placards where they can be readily seen by first-in fire companies or other emergency responders will assist in the initial incident size-up and resource assignments.

**311.5.2 Placard size and color.** Placards shall be 24 inches by 24 inches (610 mm by 610 mm) minimum in size with a red background, white reflective stripes and a white reflective border. The stripes and border shall have a 2-inch (51 mm) minimum stroke.

❖ In order to be truly effective in conveying the critical information about a building’s structural stability, placards must be fabricated so as to be in bold contrast to their mounting surface. The required reflectivity will enhance placard visibility under low ambient light conditions where flashlights, spotlights or emergency vehicle warning lights may be the only light-emitting source.

## GENERAL REQUIREMENTS

**311.5.3 Placard date.** Placards shall bear the date of their application to the building and the date of the most recent inspection.

❖ Including the date of placard posting and the most recent inspection information on the placard will assist the incident commander in verifying the validity and currency of the building's status.

**311.5.4 Placard symbols.** The design of the placards shall use the following symbols:

1.  This symbol shall mean that the structure had normal structural conditions at the time of marking.
2.  This symbol shall mean that structural or interior hazards exist and interior fire-fighting or rescue operations should be conducted with extreme caution.
3.  This symbol shall mean that structural or interior hazards exist to a degree that consideration should be given to limit fire fighting to exterior operations only, with entry only occurring for known life hazards.
4. Vacant marker hazard identification symbols: The following symbols shall be used to designate known hazards on the vacant building marker. They shall be placed directly above the symbol.
  - 4.1. R/O—Roof open
  - 4.2. S/M—Stairs, steps and landing missing
  - 4.3. F/E—Avoid fire escapes
  - 4.4. H/F—Holes in floor

❖ The placard symbols required by this section are intended to provide clear information regarding the level of structural hazard facing personnel in the conduct of rescue and fire-fighting operations as of the inspection date on the placard. Upon considering the degree of hazards, incident commanders can restrict operations to strictly defensive or cautiously offensive.

**311.5.5 Informational use.** The use of these symbols shall be informational only and shall not in any way limit the discretion of the on-scene incident commander.

❖ This section simply states that the placards are but an operational tool and the scene incident commander is the final authority in applying the information provided by the placards to the situation at hand.

**311.6 Unoccupied tenant spaces in mall buildings.** Unoccupied tenant spaces in covered and open mall buildings shall be:

1. Kept free from the storage of any materials.
2. Separated from the remainder of the building by partitions of not less than 0.5-inch-thick (12.7 mm) gypsum board or an *approved* equivalent to the underside of the ceiling of the adjoining tenant spaces.
3. Without doors or other access openings other than one door that shall be kept key locked in the closed position except during that time when opened for inspection.
4. Kept free from combustible waste and be broomswept clean.

❖ This section (formerly Section 408.11.3) is primarily concerned with the hazards posed by tenant spaces that are not in use or that are not under the supervision of employees. These spaces are more likely to be targets of vandalism and possibly incendiary activity. Generally, a fire can grow unnoticed in such spaces as a result of the lack of supervision or activity in the space. To reduce these risks, this section contains several requirements that focus on reducing the fire ignition, growth and spread potential by limiting combustibles in the space, securing the space through the use of locks and installing fire separations constructed of 1/2-inch-thick (12.7 mm) gypsum or similar materials. Note that mall buildings are required to be sprinklered throughout and that the systems in the tenant spaces must be independent of the mall area.

## SECTION 312 VEHICLE IMPACT PROTECTION

**312.1 General.** Vehicle impact protection required by this code shall be provided by posts that comply with Section 312.2 or by other *approved* physical barriers that comply with Section 312.3.

❖ This section applies to those locations where a moving vehicle could strike a piece of equipment that contains fuel or is fuel fired. These applications include motor fuel-dispensing facilities, above-ground storage tanks and repair garages as well as other locations in which gas- or oil-fired equipment or appliances could be installed where they would be in harm's way. Additional requirements for equipment protection are contained in Chapter 3 of the IMC and Section 305 of the *International Fuel Gas Code*® (IFGC®). Acceptable impact protection is dependent upon location and physical arrangement of the equipment requiring protection and is not limited to guard posts only. As indicated in Section 312.3, protection could consist of walls, barricades, guardrails or elevated locations that provide the requisite level of protection and are approved by the fire code official.

**312.2 Posts.** Guard posts shall comply with all of the following requirements:

1. Constructed of steel not less than 4 inches (102 mm) in diameter and concrete filled.
2. Spaced not more than 4 feet (1219 mm) between posts on center.
3. Set not less than 3 feet (914 mm) deep in a concrete footing of not less than a 15-inch (381 mm) diameter.

- 4. Set with the top of the posts not less than 3 feet (914 mm) above ground.
- 5. Located not less than 3 feet (914 mm) from the protected object.

❖ This section lists five requirements that guard posts must satisfy. Typical installations of posts in service stations and other locations are shown in Commentary Figures 312.2(1) and 312.2(2). These guard posts are designed to resist impact from vehicles moving at low speeds, as they would be when pulling up to a fuel pump at a motor fuel-dispensing facility or into a service area in an indoor service facility or repair garage.

**312.3 Other barriers.** Barriers, other than posts specified in Section 312.2, that are designed to resist, deflect or visually deter vehicular impact commensurate with an anticipated impact scenario shall be permitted where *approved*.

❖ This section provides a true performance option to Section 312.2. The text deliberately establishes a broad set of goals that must be achieved by the designer to fit a site-specific application, and the requirement places the onus on the designer to demonstrate selection of a satisfactory design scenario and a suitable solution to achieve approval of the fire code official. Although it could be argued that Section 312.3 could simply be deleted in favor of relying on Section 104.9 (alternate materials and methods), it made more sense to include the suggested

guidance in Section 312.3 of the code. Previously, the 12,000-pound resistance “force” prescribed by this section was actually a static load (i.e., a load with no associated impact velocity or acceleration) rather than an impact load. Without knowing an intended impact velocity, the kinetic energy resistance for a barrier cannot be accurately calculated. It is more appropriate for a performance requirement to accommodate determination of a suitable vehicle weight and impact speed to provide protection from moving vehicles as a design basis. Barriers other than posts could include walls, barricades or elevated locations for equipment (see Commentary Figure 312.3).

**SECTION 313  
FUELED EQUIPMENT**

**313.1 General.** Fueled equipment including, but not limited to, motorcycles, mopeds, lawn-care equipment, portable generators and portable cooking equipment, shall not be stored, operated or repaired within a building.

**Exceptions:**

- 1. Buildings or rooms constructed for such use in accordance with the *International Building Code*.
- 2. Where allowed by Section 314.
- 3. Storage of equipment utilized for maintenance purposes is allowed in *approved* locations where the aggregate fuel capacity of the stored equipment does

## GENERAL REQUIREMENTS

not exceed 10 gallons (38 L) and the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.

- ❖ The restrictions in this section are similar to those in Section 314.4, but this section also regulates portable liquid- or gas-fueled cooking equipment, certain vehicles, the operation and repair of vehicles and equipment, and as storage (see commentary, Section 314.4). It has been documented that multiple fatalities occurred, related to natural disasters, as the result of the improper use and location of portable generators inside buildings. This section clarifies that portable generators are also not allowed to be used inside buildings except when utilized in accordance with one of the exceptions.

Exception 1 recognizes the increased safety afforded when these uses are isolated from other parts of the building with fire-resistance-rated construction in accordance with the IBC. Exception 2 defers to the other section of the code that also regulates fueled equipment covered by this section. Exception 3 recognizes the enhanced level of protection provided by an approved automatic sprinkler system by allowing fueled equipment to be stored inside in a location approved by the fire code official, up to an aggregate quantity of 10 gallons (38 L) of fuel. This exception provides consistency with Section 5704.3.4.4 of the code and, therefore, is applicable to flammable and combustible liquid fuels only; liquefied

gas fuels are not included. Note also that the fuel quantities allowed by this exception are not to be counted when determining maximum allowable quantities in accordance with Table 5003.1.1(1), as indicated in Note p to that table.

**313.1.1 Removal.** The *fire code official* is authorized to require removal of fueled equipment from locations where the presence of such equipment is determined by the *fire code official* to be hazardous.

❖ This section gives the fire code official the authority to conduct inspections to determine whether vehicle operation, repair and storage in buildings comply with the requirements of this section and, if they do not, the authority to order the removal of fueled equipment from the building as a means of eliminating the hazard.

**313.2 Group R occupancies.** Vehicles powered by flammable liquids, Class II *combustible liquids* or compressed flammable gases shall not be stored within the living space of Group R buildings.

❖ Prohibiting storage of fuel-burning vehicles recognizes the hazards associated with having significant quantities of flammable or combustible liquids or compressed gases in inhabited spaces. Most vehicles that use liquid fuels have tanks that are not pressurized and are not vapor tight. Even a small leak over time can build to dangerous levels in enclosed spaces. For these reasons, this section prohibits the storage of gas- or liquid-fueled vehicles and equipment within the dwelling units or sleeping units of Group R buildings including their associated balconies.

## SECTION 314 INDOOR DISPLAYS

**314.1 General.** Indoor displays constructed within any occupancy shall comply with Sections 314.2 through 314.4.

❖ Indoor displays of merchandise and the display of all manner of vehicles inside of buildings can create a number of hazards to building occupants, including blocked egress and rapid fire buildup. This section describes reasonable measures to reduce the hazards associated with indoor displays without prohibiting them.

**314.2 Fixtures and displays.** Fixtures and displays of goods for sale to the public shall be arranged so as to maintain free, immediate and unobstructed access to exits as required by Chapter 10.

❖ The reason for maintaining free and unobstructed access to exits in public shopping spaces is, of course, personal safety in times of emergency. Chapter 10 contains the requirements, criteria and guidelines for this purpose.

**314.3 Highly combustible goods.** The display of highly combustible goods, including but not limited to fireworks,

flammable or *combustible liquids*, liquefied flammable gases, oxidizing materials, pyroxylin plastics and agricultural goods, in main *exit access aisles, corridors*, covered and open malls, or within 5 feet (1524 mm) of entrances to *exits* and exterior exit doors is prohibited where a fire involving such goods would rapidly prevent or obstruct egress.

❖ As stated in Chapter 10, all elements of the means of egress of any occupancy open to the public must be kept clear of obstructions and other hazards that could prevent the occupants from exiting the premises quickly in an emergency. Displaying the hazardous materials itemized in this section where their involvement in a fire would block exit pathways is prohibited for this reason. The hazards associated with each of the materials mentioned in the section are discussed in the commentary to Chapters 50 through 67.

**314.4 Vehicles.** Liquid- or gas-fueled vehicles, boats or other motorcraft shall not be located indoors except as follows:

1. Batteries are disconnected.
2. Fuel in fuel tanks does not exceed one-quarter tank or 5 gallons (19 L) (whichever is least).
3. Fuel tanks and fill openings are closed and sealed to prevent tampering.
4. Vehicles, boats or other motorcraft equipment are not fueled or defueled within the building.

❖ It has become commonplace for covered malls and larger retail stores to have various types of gas- or liquid-fueled vehicles on inside display, such as for promotional events or fire apparatus displays during Fire Prevention Week (see Commentary Figure 314.4). Because the hazards of such displays in a public building are similar to those in residential buildings, Section 314.4 parallels Section 313.1, Exception 2 (see commentary, Section 313.1).

**Figure 314.4  
INDOOR CAR DISPLAY**

## SECTION 315 GENERAL STORAGE

**315.1 General.** Storage shall be in accordance with Sections 315.2 through 315.5.

❖ This section addresses general safety precautions for the storage of any volume of materials, including those regulated elsewhere in the code. Where a material in storage is specifically regulated by another section of the code, then that section would apply in addition to any applicable provisions in Section 315. For example, if the stored material were baled waste paper awaiting recycling, the material-specific provisions of Section 5205 would apply. However, Section 5205 does not specifically regulate the vertical clearance of the stored baled waste paper to the ceiling or sprinkler heads nor does it regulate clearance from heaters or heating devices. Accordingly, the provisions of Sections 315.3 and 315.3.1 would apply. Also note that if the storage meets the definition of high-piled combustible storage in Section 202, the applicable provisions of Chapter 32 would also apply. Control of combustible waste material is covered in Sections 304.2 and 304.3.

**315.2 Permit required.** A permit for miscellaneous combustible storage shall be required as set forth in Section 105.6.

❖ This section establishes the requirement that an operational permit for storage of certain combustible materials must be obtained from the fire code official. Permit fees, if any, must be paid prior to the issuance of the permit. See Section 105 for additional information on permits. Note that a permit is required only for storage of combustible materials. Even though Section 315.3 regulates storage of both combustible and noncombustible materials, a permit is required only for miscellaneous types of combustible materials and then only when the storage volume exceeds 2,500 cubic feet (70.79 m<sup>3</sup>), as specified in the permit requirements in Section 105.6.30. The storage of such combustible materials can easily fall into disarray, present a fire load out of proportion to the surroundings and be susceptible to ready ignition and rapid, uncontrolled combustion. Conversely, the orderly storage of mercantile stocks and goods, business records, etc., in piles, on shelving or in case-work cabinets, for example, while regulated by Section 315, is not considered to be a hazard requiring a permit.

**315.3 Storage in buildings.** Storage of materials in buildings shall be orderly and stacks shall be stable. Storage of combustible materials shall be separated from heaters or heating devices by distance or shielding so that ignition cannot occur.

❖ The first sentence of this section makes it clear that it applies to all storage and that the stacks of stored materials must be stable in order to prevent pile or stack collapse that could obstruct means of egress aisles and impede fire-fighter access. The second sentence applies only to storage of combustible materials and the need for them to be separated from

ignition sources. Throughout the code, the use of fire-resistance-rated construction and spatial separation distances to minimize fire hazards and fire spread is stated as a requirement for a variety of materials. It is not necessary to separate noncombustible materials from ignition sources because there is no combustible material hazard.

**315.3.1 Ceiling clearance.** Storage shall be maintained 2 feet (610 mm) or more below the ceiling in nonsprinklered areas of buildings or not less than 18 inches (457 mm) below sprinkler head deflectors in sprinklered areas of buildings.

❖ If the space is not equipped with sprinklers, the clearance between the stored materials and the ceiling must be 2 feet (610 mm) to allow manual hose streams to effectively reach the top of a burning pile as well as to project over and beyond adjacent piles to reach burning materials. Where sprinklers are installed, the 18-inch (457 mm) clearance permits timely activation of the sprinklers and allows unobstructed water distribution over the storage pile. Materials stored too close to sprinklers can not only prevent the heat of a fire from reaching the sprinkler fusible link but also inhibit water from reaching the seat of a fire once the sprinklers are activated.

In sprinklered areas of buildings, the question often arises as to whether storage on shelving can be installed on a wall not directly below sprinklers, with the storage extending above the level of a horizontal plane located 18 inches (457 mm) below the ceiling sprinkler deflector. Typically, storage on wall-mounted shelving functions the same as a wall with respect to its relationship to the automatic sprinklers installed at ceiling level and the relative obstruction it poses. As long as the storage is not directly below the sprinklers, the sprinkler clearance provisions of Section 315.2.1 would not apply. This is consistent with NFPA 13 annex notes on this topic.

Certain newer types of automatic sprinklers, because of their design or operating characteristics, may require greater clearance distances than the 18 inch (457 mm) minimum prescribed in this section. NFPA 13 and the sprinkler manufacturer's data should be consulted for specific information on the characteristics of the many different types of sprinklers that may be installed in a given building.

**315.3.2 Means of egress.** Combustible materials shall not be stored in exits or enclosures for stairways and ramps.

❖ As was stated in Section 314.3, all elements of the means of egress must be kept free of obstructions that could block an exit pathway and, thus, jeopardize occupants of the affected space. Chapter 10 offers more guidance on means of egress.

**315.3.3 Equipment rooms.** Combustible material shall not be stored in boiler rooms, mechanical rooms, electrical equipment rooms or in *fire command centers* as specified in Section 508.1.5.

❖ This section is intended is to keep ignition sources inherent in the use of certain indicated rooms (e.g.,

fuel-fired equipment, electrical panels) from coming into contact with combustible materials that might be stored in the rooms, whether the rooms are sprinklered or not. See also the commentary to Section 508.1.5 for storage prohibition in fire command centers and Section 605.3 for electrical equipment room clearance requirements and storage prohibition. Note that the IMC, Chapter 2, defines a “mechanical equipment/appliance room” as one in which nonfuel-fired mechanical equipment is located. Even though the ignition hazard is reduced in the absence of fuel-fired equipment in such rooms, they must be kept free of combustible storage to allow ready access for fire fighters and other authorized personnel to reach easily critical controls, such as power or equipment disconnects, in case of an emergency. Limited supplies of combustible materials related to mechanical room equipment (e.g., air distribution system filters) could be allowed but only in accordance with Section 315 of the code and with the specific approval of the fire code official. For additional discussion of requirements applicable to these and other specific occupancy rooms, see Section 509 of the IBC. Further discussion of the hazards of storage in boiler rooms can be found in Section 304 of the IMC.

**315.3.4 Attic, under-floor and concealed spaces.** Attic, under-floor and concealed spaces used for storage of combustible materials shall be protected on the storage side as required for 1-hour fire-resistance-rated construction. Openings shall be protected by assemblies that are self-closing and are of noncombustible construction or solid wood core not less than  $1\frac{3}{4}$  inches (44.5 mm) in thickness. Storage shall not be placed on exposed joists.

**Exceptions:**

1. Areas protected by *approved automatic sprinkler systems*.
2. Group R-3 and Group U occupancies.

❖ This section recognizes the reality that attics, crawl spaces and similar unoccupied, concealed spaces in buildings are attractive to building occupants for storage of all kinds of combustible materials. Storage in such unattended and out-of-the-way spaces creates a hazardous condition by introducing a higher fire load to spaces that were neither designed nor intended for such a high-intensity use and in which a fire could rapidly develop unobserved until it had gained a considerable hold on the building. Placing stored combustibles on exposed joists also could hasten collapse of the joists in a fire, which could lead to flaming debris being dropped into the building space below the joists and possible collapse of all or part of the building structure.

The code provides alternatives to using such spaces for storage and, if they are used for storage, how they can be constructed to isolate the higher fire loads created. Since the intent is to protect against a fire in the storage area from endangering the other occupied areas of the building, the required 1-hour

fire-resistance rating need only be achieved from the storage side. While any access openings in the 1-hour fire-resistant construction need not be rated, they must be self-closing and of either noncombustible construction or a minimum  $1\frac{3}{4}$ -inch (44 mm) thickness of solid wood core. Consistent with Section 102.4, any construction in connection with the concealed spaces regulated by this section must be in accordance with the IBC, especially Section 509.

Exception 1 recognizes the efficiency and reliability of automatic sprinklers as a trade-off for 1-hour fire-resistance-rated construction. This exception only requires the sprinkler system in the attic, under-floor or concealed space. Complete sprinkler protection throughout the building is not required in order to be in compliance with the exception.

Exception 2 exempts Group R-3 and U occupancies from the requirements of this section. In Group R-3, the level of familiarity and control exercised by the building occupants is recognized as offsetting the hazards of storage in concealed spaces. Because Group U occupancies are generally unoccupied, the hazards of miscellaneous storage are of little or no consequence to the few occupants that might be in such buildings. For further information on Group U occupancies, see Section 312 of the IBC and its commentary.

**315.4 Outside storage.** Outside storage of combustible materials shall not be located within 10 feet (3048 mm) of a lot line.

**Exceptions:**

1. The separation distance is allowed to be reduced to 3 feet (914 mm) for storage not exceeding 6 feet (1829 mm) in height.
2. The separation distance is allowed to be reduced where the *fire code official* determines that no hazard to the adjoining property exists.

❖ Outside storage of combustible materials, such as raw materials for production, idle pallets, dunnage and packaging, must be neat and compact. The requirement for a 10-foot (3048 mm) separation is consistent with storage area aisle width requirements throughout the code, often expressed as “one-half the pile height or 10 feet (3048 mm), whichever is greater.” The requirement of this section is consistent with that concept, as is Section 315.3.2, which limits pile height to 20 feet (6096 mm). The intent of this section is to provide fire suppression access on all sides of storage arrangements and reduce the likelihood of the spread of fire to adjacent properties in the event of a pile collapse. Pile collapses will generally not involve a full-height topple-over of a pile but rather only a partial collapse. Accordingly, Exception 1 allows a reduction in separation distance where the pile height is substantially less than the separation requirement.

Exception 2 allows the fire code official to grant separation reductions when the combustibles are

## GENERAL REQUIREMENTS

judged to be no threat to adjoining property. Examples of such conditions could include storage where the combustible materials are enclosed in noncombustible containers, the presence of an impervious property line barrier or the provision of fixed fire protection equipment, such as deluge monitors, especially designed for rapid fire suppression and exposure protection.

**315.4.1 Storage beneath overhead projections from buildings.** Where buildings are protected by automatic sprinklers, the outdoor storage, display and handling of combustible materials under eaves, canopies or other projections or overhangs are prohibited except where automatic sprinklers are installed under such eaves, canopies or other projections or overhangs.

❖ The storage or display of combustible materials beneath unsprinklered canopies or other building projections attached to an otherwise fully sprinklered building could lead to a rapidly developing fire in the stored material, which could gain sufficient headway beyond the capability of the building sprinkler system to suppress it, should it spread into the building's interior. This section reinforces the requirements of NFPA 13 concerning the use of areas beneath building projections, such as eaves or canopies, for the storage or display of combustible materials where those locations are exempt from sprinkler protection as allowed in Section 8.15 of NFPA 13. NFPA 13 mandates that the scope of required sprinkler protection includes canopies or roofed-over areas attached to sprinklered buildings, unless these projections are constructed of noncombustible materials and the areas are not used for the storage, handling or display of combustible materials. Because NFPA 13 is a design standard and cannot be enforced as a maintenance document, this section essentially restates the NFPA 13 design requirement exception conditions in enforceable terms. Also note that, in the event that Appendix B of the code is adopted by a jurisdiction, areas used for the storage of combustible materials beneath a building's horizontally projecting elements must be included in the building area for purposes of determining the required fire flow.

**315.4.2 Height.** Storage in the open shall not exceed 20 feet (6096 mm) in height.

❖ Storage pile height limitations are a means of controlling the size of potential fires and reducing the tip-over potential as well as a way to facilitate the manual fire suppression process by keeping the top of the pile within reach of conventional fire-fighting and overhaul tools, such as the ground ladders carried by an engine company or the long pike poles carried by ladder companies. The 20-foot (6096 mm) storage pile height limitation also correlates with Section 315.3 and helps reduce the likelihood that a fire would jeopardize adjacent properties in the event of a pile collapse.

**315.5 Storage underneath high-voltage transmission lines.** Storage located underneath high-voltage transmission lines shall be in accordance with Section 316.6.2.

❖ High-voltage transmission lines are a special hazard requiring specific regulations to prevent them from being exposed to fire conditions that could cause them to fail or fall to the ground. This general section directs the code user to the section containing more specific requirements for this topic.

**315.6 Storage in plenums.** Storage shall not be permitted in plenums. Abandoned material in plenums shall be deemed to be storage and shall be removed. Where located in plenums, the accessible portion of abandoned cables that are not identified for future use with a tag shall be deemed storage and shall be removed.

❖ This section introduces a concept that has long been in NFPA 70 and NFPA 90A—that plenums (see Chapter 2 commentary to the definition of "Plenum") are intended specifically to be a part of the air distribution system. Plenums are also legitimately used for stringing communications and data cables as well as utility pipes, sprinkler pipes and similar items. However, such items often are not removed from the plenum when they become obsolete. For example, when an updated data system is installed in a facility (which can occur every 18 to 24 months), it is not unusual for old wires to be cut out of the system but left in place with a new wiring system added on top of them (see Commentary Figure 315.6).

The suspended ceiling tile systems that often enclose plenums are not intended to support any significant weight and can, therefore, easily be overwhelmed by the added weight of storage or abandoned materials such as cables (see commentary to IBC, Section 808.1.1.1). Recently, a plenum space fuel load study showed how the safety of fire fighters is compromised by the weight of these abandoned cables. It pointed out that plenum space fuel

**Figure 315.6**  
**ABANDONED DATA CABLE IN A PLENUM**

loads and wiring issues are serious concerns for fire fighters during interior fire-fighting operations and its key recommendation was that abandoned wiring be removed.

Although the primary reason to require the removal of abandoned materials in plenums is the elimination of unnecessary weight, fire safety considerations should also be taken into account, as should the practical consideration that the HVAC design airflow through the plenum could be adversely affected. Such a requirement was long believed not to be enforceable primarily because fire code inspectors would rarely spend their time looking into plenums in existing buildings. However, the danger presented by the fire load of storage or abandoned materials is well-documented. Thus, there should be no significant difficulty in having inspectors identify the existence of abandoned products—especially abandoned cables—classify them as storage and require their removal. Note that only the “accessible portions” of abandoned cables must be removed because there is no intent to cause potential damage to the building or facility by attempting to remove cables or circuits that are strung through walls, floors or other building elements. Where some cables are left in place because they are intended to be reused at a future date, they must be clearly identified as such by affixing a tag. See also Section 605.12.

**SECTION 316  
HAZARDS TO FIRE FIGHTERS**

**316.1 Trapdoors to be closed.** Trapdoors and scuttle covers, other than those that are within a *dwelling unit* or automatically operated, shall be kept closed at all times except when in use.

❖ Trapdoors and unguarded openings in floors and walkways must remain in the closed position or be designed to automatically close upon activation of the

fire alarm system. Openings in floors or walkways can injure emergency responders, especially if vision is obscured.

**316.2 Shaftway markings.** Vertical shafts shall be identified as required by this section.

❖ This section was developed to prevent fire fighters from falling through shafts when entering buildings off ladders placed on the exterior of the building.

**316.2.1 Exterior access to shaftways.** Outside openings accessible to the fire department and that open directly on a hoistway or shaftway communicating between two or more floors in a building shall be plainly marked with the word **SHAFTWAY** in red letters not less than 6 inches (152 mm) high on a white background. Such warning signs shall be placed so as to be readily discernible from the outside of the building.

❖ Exterior wall openings that are accessible to fire fighters by way of ladders and aerial equipment and open directly into shafts or hoistways communicating between two or more floors must be clearly marked (see Commentary Figure 316.2.1).

**316.2.2 Interior access to shaftways.** Door or window openings to a hoistway or shaftway from the interior of the building shall be plainly marked with the word **SHAFTWAY** in red letters not less than 6 inches (152 mm) high on a white background. Such warning signs shall be placed so as to be readily discernible.

**Exception:** Marking shall not be required on shaftway openings that are readily discernible as openings onto a shaftway by the construction or arrangement.

❖ Openings into shaftways from the interior of the building pose a threat to fire fighters when visibility is poor. Interior shaft openings must be marked so that they are plainly visible from the interior of the building.

If fire fighters can readily identify an opening into a shaft by the way the opening is constructed, the shaft opening need not be marked, keeping in mind that

**Figure 316.2.1  
SHAFTWAY SIGNAGE**

## GENERAL REQUIREMENTS

the fire fighter may be feeling his or her way in heavy smoke or darkness.

**316.3 Pitfalls.** The intentional design or *alteration* of buildings to disable, injure, maim or kill intruders is prohibited. A person shall not install and use firearms, sharp or pointed objects, razor wire, *explosives*, flammable or *combustible liquid* containers, or dispensers containing highly toxic, toxic, irritant or other hazardous materials in a manner that could passively or actively disable, injure, maim or kill a fire fighter who forcibly enters a building for the purpose of controlling or extinguishing a fire, rescuing trapped occupants or rendering other emergency assistance.

❖ This paragraph prohibits the use of “booby-traps” in buildings, for whatever reason, if they could injure or disable the emergency responder during the performance of his or her duties.

**316.4 Obstructions on roofs.** Wires, cables, ropes, antennas, or other suspended obstructions installed on the roof of a building having a roof slope of less than 30 degrees (0.52 rad) shall not create an obstruction that is less than 7 feet (2133 mm) high above the surface of the roof.

### Exceptions:

1. Such obstruction shall be permitted where the wire, cable, rope, antenna or suspended obstruction is encased in a white, 2-inch (51 mm) minimum diameter plastic pipe or an approved equivalent.
  2. Such obstruction shall be permitted where there is a solid obstruction below such that accidentally walking into the wire, cable, rope, antenna or suspended obstruction is not possible.
- ❖ Part of the intent of the code in Section 101.2 is to control conditions that can affect the safety of fire fighters and emergency responders during operations. One of these conditions is obstructions on the roofs of buildings. This section does not prohibit the installation of these items, but it requires that they be identified or protected. The primary concern is poorly identified or unidentified obstructions on building roofs that can become an entanglement hazard or, in the case of equipment such as cellular or wireless communication antennas, a potential pathway for stray current if the electrical ground is somehow compromised and an emergency responder comes into contact with it. These provisions will also help to protect maintenance workers as they are working on a rooftop.

This section addresses obstructions on building roofs and was developed to establish criteria for identifying such obstructions. It is applicable only to roofs with a slope of 30 degrees (0.52 rad) or less. This section requires that a means of identification, a barrier, or some other form of obstruction be provided when a guy wire, cable, or rope is less than 7 feet (2133 mm) above the roof level. The 7-foot (2133 mm) value is based on the potential of a firefighter in a smoke-obscured environment striking the cable or wire, especially in the head, neck or upper torso area. A common fire service slang term for this is “being

clothes lined” and these events have resulted in serious injury from entanglement or falling from a roof, including permanent paralysis of fire fighters and other emergency responders.

Where the obstruction is located in the plane that is 7 feet (2133 mm) or less below the roof surface, Exception 1 allows the use of a protective collar such as a 2-inch (51 mm) diameter plastic pipe that is sleeved over the cable. Other options could include illuminating the cable, or providing reflective marking of the cable, wire or rope with a material similar to that used for marking of fire fighter clothing and gear. Any method that offers equivalency to the prescribed pipe sleeve can be approved by the fire code official upon demonstration of equivalency.

Exception 2 recognizes that solid obstructions such as screen walls or fencing can provide a physical barrier so that walking under the wire is not possible and can eliminate the need for protecting the emergency responders from roof obstructions that are less than 7 feet (2133 mm) above the roof level.

**316.5 Security device.** Any security device or system that emits any medium that could obscure a *means of egress* in any building, structure or premise shall be prohibited.

❖ Security devices that, when activated, emit a medium such as smoke or other aerosols into a building could obscure exits or confuse occupants, thus creating an inherently dangerous situation for the public and responding emergency personnel. In cases of activation of these devices, armed criminal perpetrators could be trapped inside buildings. Law enforcement personnel arriving on the scene could easily believe that a building is on fire and responding fire fighters could enter and be confronted by the perpetrator. Another danger is that false fire alarms could be transmitted automatically or by passers-by because of the appearance of smoke in the building. See also the commentary to Section 1031.2 regarding the reliability of exits.

**316.6 Structures and outdoor storage underneath high-voltage transmission lines.** Structures and outdoor storage underneath high-voltage transmission lines shall comply with Sections 316.6.1 and 316.6.2, respectively.

❖ This section introduces code provisions that address requirements for structure construction and material storage beneath high-voltage transmission lines (see definition in Section 202). The importance of such regulations and their impact on fire-fighter safety cannot be overstated. Among the various hazards fire fighters face in the course of duty are electrical hazards during fire suppression or rescue activities. Performing fire-ground operations near power lines may expose fire fighters to electric shock hazards through the following means, among others:

- Energized electrical lines or equipment obscured by dense smoke.
- Smoke and hot gases from a large fire creating a conductive path for electricity. When a fire is

burning under a high-voltage transmission line, electricity could arc from the conductor to the ground, endangering people and objects near the arc.

- Making accidental contact with power lines that are still energized.
- Overhead power lines falling on and energizing conductive equipment and materials located on the fire ground.
- Electrical currents flowing through the ground and extending several feet (ground gradient).
- Solid-stream water applications on or around energized or downed power lines or equipment.

The regulations in Sections 316.6.1 and 316.6.2 are intended to minimize the noted exposures by prohibiting buildings, structures and storage from being constructed or maintained beneath high-voltage transmission lines except under the strictest of conditions and only with the fire code official's approval.

**316.6.1 Structures.** Structures shall not be constructed within the utility easement beneath high-voltage transmission lines.

**Exception:** Restrooms and unoccupied telecommunication structures of noncombustible construction less than 15 feet (4572 mm) in height.

- ❖ Structure fires underneath high-voltage transmission lines could cause arcing and shock hazard. Fire-fighting operations can involve the use of elevated platforms or aerial ladder apparatus and other emergency equipment, personnel above ground and hose streams that may come in close proximity to high-voltage transmission lines. According to nationally recognized utility companies, manual de-energization of lines may take 20 minutes or longer to accomplish.

The exception recognizes that certain ancillary structures, such as restroom buildings and telecommunications structures, do not generally present a significant exposure threat to overhead power lines.

**316.6.2 Outdoor storage.** Outdoor storage within the utility easement underneath high-voltage transmission lines shall be limited to noncombustible material. Storage of hazardous materials including, but not limited to, flammable and *combustible liquids* is prohibited.

**Exception:** Combustible storage, including vehicles and fuel storage for backup power equipment serving public utility equipment, is allowed, provided that a plan indicating the storage configuration is submitted and *approved*.

- ❖ This section regulates the fire load that can be allowed to exist beneath overhead high-voltage transmission lines by restricting outdoor storage within the easement to only noncombustible materials. The exception recognizes that, in certain instances, combustible materials may need to be stored within the easement, such as for utility work on the power lines. Such materials storage must be strictly regulated

through a plans submittal and review process and approval by the fire code official. This section also makes it clear that under no circumstances are hazardous materials allowed to be stored beneath the power lines.

## SECTION 317 ROOFTOP GARDENS AND LANDSCAPED ROOFS

**317.1 General.** Rooftop gardens and landscaped roofs shall be installed and maintained in accordance with Sections 317.2 through 317.5 and Sections 1505 and 1507.16 of the *International Building Code*.

- ❖ Among the major elements of green building construction are energy conservation and preservation of natural resources such as water. Rooftop vegetation accomplishes both, in the form of gardens or using landscaping to cover part of a building roof. Roof gardens or landscaped roofs offer a number of savings to the building owner. For buildings constructed with a membrane-type roofing system, roof gardens or landscaping can increase the life of the roofing materials by almost 100 percent according to some studies. Depending on the design, roof area and local climate, research has found certain green roofs can reduce summer cooling loads by about 25 percent and in some cases have reduced heat gain by 95 percent. In addition to reduced energy costs, these reductions have the potential to reduce the size of HVAC equipment, which in turn lowers the capital costs for construction. These roofs and gardens can also reduce the sound pressure level inside of the building and are helpful in controlling storm water runoff.

Section 317 addresses rooftop gardens and landscaped roofs. The requirements in this section limit the area of roof gardens, require the use of roof assemblies designed for severe fire exposures, and provide for the installation of a standpipe connection. It also sets forth requirements for establishing a maintenance plan for the vegetation installed on roof gardens or landscaped roofs. This section does not define what constitutes a roof garden or landscaped roof; however, its intent is to deal with the structural and fire safety concerns regarding construction that creates a green space on a building roof rather than the placement of a small roof garden.

This section references the requirements in Chapter 15 of the IBC for roof gardens and landscaped roofs. Section 1507.16 of the IBC requires compliance with the requirements of the code, Chapter 15 of the IBC and specific structural requirements in Chapter 16 of the IBC for special purpose roofs and landscaped roofs. The IBC requires roof gardens and landscaped roofs to be calculated at a minimum 20 pound/square foot (0.958 kN/m<sup>2</sup>) uniform live load and that the weight of landscaping materials be considered as dead loads and computed assuming the rooftop soil is saturated.

In addition to the IBC structural requirements, roof

gardens and landscaped roofs can also require the installation of a Class A roof assembly. Section 317.1 of the code references the provisions in Section 1505 of the IBC, which sets forth the fire exposure ratings for roof assemblies. The IBC fire classification requirements for roof assemblies are based on the building's construction type, not on the classification of the building's occupancy. The minimum roof covering classification prescribed by the IBC is either a Class B or Class C roof assembly. The only time Class A roof assemblies are specified is when the jurisdiction has adopted Appendix D of the IBC and the building is located in a fire district or when required in the IWUIC. Section 1505.2 of the IBC requires Class A assemblies to be listed and identified as such by an approved testing agency, but because the IBC does not normally require the installation of Class A roof assemblies, the number of listed systems available to design professionals will be limited. Additional requirements on the design of green roofs are contained in the *International Green Construction Code*® (IgCC®). Another source of information on "green roofs" is contained in Property Loss Prevention Data Sheet 1-35, *Green Roof Systems*, published by FM Global.

**317.2 Rooftop garden or landscaped roof size.** Rooftop garden or landscaped roof areas shall not exceed 15,625 square feet (1450 m<sup>2</sup>) in size for any single area with a maximum dimension of 125 feet (39 m) in length or width. A minimum 6-foot-wide (1.8 m) clearance consisting of a Class A-rated roof system complying with ASTM E108 or UL 790 shall be provided between adjacent rooftop gardens or landscaped roof areas.

❖ On large roofs, the code does not permit complete coverage of the roof with vegetation. This section limits the area of roof gardens or landscaping to an area not exceeding 15,625 square feet (1,450 m<sup>2</sup>) and its maximum length or width dimension cannot exceed 125 feet (39 m). The 125-foot value is based on the typical amount of hose carried by fire departments for high-rise hose packs. If the area or dimension of a landscaped garden or roof exceeds the prescribed area or dimension limits, this section allows multiple landscaped areas when each is separated by a minimum 6-foot-wide (1.8 m) buffer space constructed as a Class A roof assembly. This buffer space will slow fire spread between multiple landscaped areas and will afford fire-fighter access to each separated segment and provide access to roof surface areas that may be used for fire department ventilation operations. Note that for buildings in which Section 905 requires the installation of a standpipe system, Section 905.3.8 will require the extension of a standpipe hose valve to the roof level serving the landscaped roof or roof garden.

**317.3 Rooftop structure and equipment clearance.** For all vegetated roofing systems abutting combustible vertical surfaces, a Class A-rated roof system complying with ASTM E108 or UL 790 shall be achieved for a minimum 6-foot-

wide (1829 mm) continuous border placed around rooftop structures and all rooftop equipment including, but not limited to, mechanical and machine rooms, penthouses, skylights, roof vents, solar panels, antenna supports and building service equipment.

❖ Where a building utilizes combustible construction for the construction of penthouses, mechanical equipment or rooftop elevator machine rooms, this section requires a minimum 6-foot-wide (1.8 m) border constructed around the combustible construction. The buffer space is also constructed to the IBC requirements for a Class A roof assembly (see the commentary to Section 317.1). The buffer space is not required if the roof garden or landscaped roof is separated by more than 6 feet (1.8 m) from the combustible construction or when noncombustible construction is used. This buffer space will slow fire spread between landscaped areas and combustible construction and will afford fire fighter access.

**317.4 Vegetation.** Vegetation shall be maintained in accordance with Sections 317.4.1 and 317.4.2.

❖ This section introduces requirements for the maintenance of rooftop garden or landscaped roof areas to reduce the fire risk that could otherwise arise for buildings and exposure buildings because of the possible lack of maintenance. Basically, an unmaintained roof garden that catches fire could be likened to a brush fire being conducted on top of a building rather than on the ground, creating an increased exposure hazard since roof covering rating requirements are based on flying embers, not falling ones.

**317.4.1 Irrigation.** Supplemental irrigation shall be provided to maintain levels of hydration necessary to keep green roof plants alive and to keep dry foliage to a minimum.

❖ Care of rooftop vegetation by simple watering provides a basic line of defense against accumulation of dry biomass that can present a significant fire load if ignited. The frequency of watering is not specified due to the diverse moisture needs of the wide variety of planted materials possible on any given roof. The person responsible for the landscaped roof must determine the level of watering needed for this purpose and that information should be included in the maintenance plan authorized by Section 317.4.3.

**317.4.2 Dead foliage.** Excess biomass, such as overgrown vegetation, leaves and other dead and decaying material, shall be removed at regular intervals not less than two times per year.

❖ In order to manage the significant fuel load accumulation and fire hazard associated with dead or unkempt rooftop vegetation, this section sets a basic level of maintenance and regular removal of dead biomass, similar to that found in Section 304.1.2 for the maintenance of vegetation in and around a building (see commentary, Section 304.1.2).

**317.4.3 Maintenance plan.** The *fire code official* is authorized to require a maintenance plan for vegetation placed on

roofs due to the size of a roof garden, materials used or where a fire hazard exists to the building or exposures due to the lack of maintenance.

- ❖ This section authorizes the fire code official to require a maintenance plan that may be used to guide maintenance personnel and inspectors in the care and upkeep of vegetation to reduce the hazard of having highly combustible dead plantings on the roof. This is beneficial to determine if the roof garden will be maintained or is just a bunch of vegetation placed on the roof as a “do-it-yourself” project. The maintenance plan is also beneficial to determine what happens to a building that goes vacant or when the building owner does not keep up with maintenance.

**317.5 Maintenance equipment.** Fueled equipment stored on roofs and used for the care and maintenance of vegetation on roofs shall be stored in accordance with Section 313.

- ❖ This section simply sends the code user to Section 313 for appropriate storage regulations for fueled equipment (see commentary, Section 313).

### SECTION 318 LAUNDRY CARTS

**318.1 Laundry carts with a capacity of 1 cubic yard or more.** Laundry carts with an individual capacity of 1 cubic yard [200 gallons (0.76 m<sup>3</sup>)] or more, used in laundries within Group B, E, F-1, I, M and R-1 occupancies, shall be constructed of noncombustible materials or materials having a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> at a flux of 50 kW/m<sup>2</sup> where tested in a horizontal orientation in accordance with ASTM E1354.

#### Exceptions:

1. Laundry carts in areas protected by an *approved automatic sprinkler system* installed throughout in accordance with Section 903.3.1.1.
  2. Laundry carts in coin-operated laundries.
- ❖ The change from cooking with animal fat to vegetable oil has increased the number of spontaneous ignition fires. These fires occur frequently in laundry operations due to insufficient cool-down time in the laundry drying process and have been known to ignite in freshly folded linen, often contained in polyethylene laundry carts. Medium-density polyethylene laundry carts which have a fuel content of approximately 20,020 Btu per pound [27 ft<sup>3</sup> (0.76 m<sup>3</sup>)] are commonly used in industrial, commercial and institutional laundry operations. This material is essentially equal to the fuel value for gasoline and becomes a burning liquid that spreads and flows when involved in a fire. As such, the cart flammability hazard must be mitigated. This section does that by limiting combustible container heat release rate and heat flux using the test parameters of ASTM E1354. The peak rate of heat release criterion is consistent with the one in Sections 304.3.2, 304.3.4 and 808.1. The efficacy of using

these lesser-hazard carts has been demonstrated in several commercial and institutional fire incidents wherein the burning commercial dryer contents were emptied into an ASTM E1354 container and taken outside and overhauled without evacuation of the building, loss to the structure or damage to the container.

Exception 1 permits the use and storage of ordinary laundry carts in areas protected by an approved sprinkler system. It would be up to the fire code official to determine the maximum number that could be stored under these conditions.

Exception 2 recognizes that the small carts used in neighborhood coin laundries do not present the same hazard as those used in commercial-type operations because the clothes and other laundered items do not remain in the cart for a significant length of time.

# Chapter 4: Emergency Planning and Preparedness

## General Comments

This chapter is an expansion of the provisions found in the legacy fire codes used to develop the code. The overall approach has been to place all similar requirements into general sections. Unique occupancy and use-specific requirements are provided in Section 403.

This chapter first provides general scope and requirements for reporting emergencies and preventing interference with fire department activities in Section 401.

Section 403 provides detailed requirements based on occupancy. These requirements include seating plans for Group A occupancies. This section also establishes requirements for general public safety regarding fire watch personnel, crowd managers and planning requirements for public assemblages.

Section 404 provides detailed requirements for fire safety plans, fire evacuation plans and lockdowns.

The frequency and required documentation related to evacuation drills are addressed in Section 405. The minimum criteria for the training of occupants for emergency situations are found in Section 406. Section 407 provides requirements that apply to occupancies that contain hazardous materials. Some of the key elements are Hazardous Materials Inventory Statements (HMIS) and Hazardous Materials Management Plans (HMMP).

## Purpose

In addition to the requirements found throughout the building and fire codes, this chapter focuses on the actions of occupants. These additional requirements are warranted based on higher levels of care related to the concentration of people; physical and mental capabilities of the occupants; lack of familiarity with a building; or the complexity and size of the building. These requirements are intended to improve the effectiveness of other measures required by the code and the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>).

Basically, this chapter addresses human contributions to life safety in buildings when a fire or other emergency occurs. The requirements for continuous training and scheduled evacuation drills can be as important as the required periodic inspections and maintenance of built-in fire protection features. The level of preparation by the occupants also improves the emergency responders' abilities during an emergency.

The IBC focuses on built-in fire protection features, such as automatic sprinkler systems, fire-resistance-rated construction and properly designed egress systems. The human element is only indirectly addressed in the IBC, whereas this chapter fully addresses the human element. Traditionally, fire codes address the

human element more directly in their role in the long-term maintenance of buildings and systems.

Chapters 3 and 6 through 10 of the code and Chapters 7 through 10 of the IBC set forth provisions for how and when buildings are to be properly equipped and maintained to prevent damage and loss of life in the event of a fire. These requirements are based on two complementary fire safety strategies: managing the fire and managing the occupants. These strategies are discussed in more detail in the commentary for Chapter 1.

## Managing Fire

A fire can be either prevented or managed. This chapter of the code focuses on training and preparedness while also emphasizing prevention. In some cases, moving occupants to minimize their exposure to a hazard is difficult or impractical. In these situations, controlling or eliminating the hazard is preferable, especially while it is still manageable. In fact, this is the concept underlying all fire-suppression requirements. Successful fire control depends on building occupants recognizing the fire threat, deciding to respond, choosing how to respond and, in the case of choosing fire control, identifying, locating and using the correct method. All of these functions must promptly take place in that order. Failure to perform promptly may preclude alternative strategies; therefore, location and identification of fire extinguishers and occupant standpipe hose lines are provided so that incipient fire-fighting equipment is readily accessible to occupants. These appliances, however, are often difficult to operate, and regardless of experience, fighting fire is a difficult and dangerous task. This chapter prescribes training requirements that assist occupants who are expected to respond to incipient fires to be adequately prepared and trained.

## Managing Occupants

The management of occupants is primarily moving them away from the hazard. Verifying that enough exits have ample capacity, are immediately accessible, adequately arranged, appropriately identified and suitably protected are only the first steps toward achieving functional life safety. Occupants must know not only where exits are, but also when and how to use them. For instance, studies have shown that people have a "learned irrelevance" to emergency exits. Learned irrelevance is a psychological phenomenon that occurs when a person is exposed to a stimulus but usually does not need to respond to it. Because of this phenomenon, most occupants are likely to exit the way they have

entered, whether it is the correct way or not; therefore, beyond designing the building with an adequate number of exits, a method of encouraging the use of the best exits must be developed. Identifying dangerous conditions, deciding how to act and responding appropriately and promptly are essential. Various factors and situations can make evacuation not only difficult but potentially impractical. All of these factors involve the interaction between the building, its systems and features, occupants and the fire. The code concentrates on the last two factors while the IBC regulates the first two factors. Planning for life safety requires a response to these factors by defining the life safety strategies that must be implemented, as well as the means to achieve them. Life safety factors, such as buildings, fire and people, are important in managing exposed occupants.

This chapter concentrates on planning and practicing the desired actions of building occupants when a fire occurs. The remainder of the code focuses on the behaviors and procedures that must be practiced or observed to prevent or control a fire. The best way to create a safe building environment is through fire prevention. No system can ensure complete protection of building occupants.

Fires are not the only emergencies necessitating the implementation of life safety strategies; therefore, this chapter describes requirements for preparing and implementing life safety plans and programs in occupancies with special life safety problems. These include occupancies in which the number of occupants or the arrangement or complexity of the building may make evacuation or removal from hazardous conditions difficult or impractical.

A reality of the 21st century in the wake of terrorist attacks and school and business shootings is a need to establish so-called “lockdown” procedures in order to protect and defend building occupants. While the code does not mandate the implementation of lockdown plans and procedures, it does provide some minimum standards such plans must meet when they are prepared.

Not all occupants of each building are equally capable of performing tasks essential to their safety. A growing awareness, not only of people with physical disabilities, but also of what constitutes a disability, has focused life safety on everyone. Federal health care policies and funding criteria have spurred the deinstitutionalization of people who were formerly confined to nursing homes and other traditional health care institutions. This has created a new category of occupancies—board and care homes (institutional, residential care; I-1)—while the number of beds provided in nursing homes and hospitals continues to grow. Similarly, technological advances have promoted the creation of larger and more complex buildings, including high rises, open malls, domed stadiums, mixed-use complexes and convention centers. All of

these situations create special life safety problems that physical features alone cannot remedy. Additionally, these situations require that not only adequate physical accommodations be provided but also building occupants be trained to respond to emergencies in these facilities.

### **Life Safety**

Life safety strategies involve the development of an explicit statement of a desired life safety outcome. This statement, once designed to the capabilities of the building occupants and the physical arrangement of the exits, becomes a life safety strategy. Such approaches stress defining a specific strategy or strategies for protecting occupants. Protection may include moving them (assisting), causing them to move (directing), defending them in place or a combination of these measures. An effective strategy must consider the number and capabilities of building occupants; the type, location and arrangement of building exits; the fire; its effects on the people and building; and the number, training and capability of staff to direct or perform fire evacuation or incipient fire-fighting duties. Each strategy, combined with effective planning and practice, becomes the means for achieving the desired life safety outcome.

The life safety strategies for a health care facility, a high-rise office building and a multiplex theater could vary considerably based on the specific characteristics of the use. First, while the number of occupants will be significant in each case, the actual number occupying the building may be varied. Similarly, the occupant density and location of people in the building will vary, as well as the physical arrangement of the building, which in the first example that follows may be assumed as primarily horizontal and, in the second, as principally vertical. The most profound difference will be the capabilities of the occupants. In high rises and theaters, building occupants will be expected to perform life safety behaviors themselves, while patients in a health care facility may require substantial assistance or need to defend in place. High-rise and theater occupants will differ from each other in their levels of familiarity with the building design. Further, in a theater, lighting conditions may interfere with the occupants’ ability to discern the path of egress travel.

In the first two examples, health care and high rise, removing all occupants from the building in the event of fire is impractical. In a high-rise building, occupants located above a fire are in greater danger than occupants located below the fire, since combustion products naturally rise. In a health care occupancy, the risk to most occupants is compounded by their weakened or disabled condition prior to the fire. In both of these examples, a life safety strategy should first address the needs of those at greatest risk by removing them from harm. Secondly, the life safety strategy

should stress separating endangered occupants and their immediate neighbors from danger until the hazard can be controlled or confined. As seen in each example, life safety strategies should also incorporate both partial relocation and defend-in-place concepts. In the health care facility, however, occupants will be moved horizontally to achieve this objective, while in high-rise buildings, occupants will be expected to move downward or upward to separate themselves from danger. In the case of a multiplex theater, occupants will usually be directed to the nearest exit; however, its location may not be known to all or some of them. Further, because employees in assembly occupancies must be trained in the proper use of portable fire extinguishers, the life safety strategy should include instruction in using these appliances to minimize occupant exposure to fire effects. The resulting life safety strategies for these occupancies may resemble the following:

**Example 1 – Health Care Facility:** Upon notice of fire, direct or assist evacuation and relocate occupants from the area of fire origin to an adjacent smoke compartment through horizontal exits. Remove the most critically ill patients and those with special needs to an area providing the most appropriate level of care.

**Example 2 – High-rise Building:** Direct occupants in the area or floor of fire origin to the nearest exits. Occupants on the fire floor, the floor above and the floor below will relocate sequentially up or down at least two floors. Occupants located two floors above and two floors below the fire floor will be sequentially relocated following movement of fire floor occupants.

**Example 3 – Multiplex Theater:** Announce exit locations and evacuation instructions prior to each movie. Over voice/alarm systems, direct occupants to nearest exit. Employees in the immediate vicinity of an incipient fire may attempt to control or extinguish it using a portable fire extinguisher after activating the fire alarm system.

Once the appropriate strategy has been defined, a plan can be expanded with little additional effort to form the backbone of a comprehensive life safety protocol.

The following statements provide additional instructions for the aforementioned examples:

**Example 1 – Health Care Facility:** Monitor or reinforce fire barriers so that they provide adequate defense against fire until it is controlled and extinguished. Staff will report progress of the fire and relocation operation to the Private Branch Exchange (PBX) operator through the nurse call station in adjacent smoke compartments.

**Example 2 – High-rise Building:** Building fire manager will meet fire department personnel at the central control station located off the main lobby.

**Example 3 – Multiplex Theater:** Projectionist will stop films so that the alarm and evacuation instructions are heard and followed. Upon activation of the alarm, instructions are heard and followed while the on-duty manager telephones the fire department to confirm that the fire was reported. Ushers will follow occupants out of each auditorium as conditions permit, closing exit doors and preventing reentry. Upon completing assigned duties, all staff will report to the manager located in front of the lobby entrance.

These expanded statements certainly do not constitute a fully developed plan; however, with these elements of the life safety plan defined, details can be added to send the plan from preincident preparation through post-incident follow-up. A well-developed plan should include all or most of the following elements:

- Assignment of roles and responsibilities;
- Description of fire protection systems, including operating instructions, if appropriate;
- Building floor plans and sections;
- Seating diagrams and occupant load;
- Number, location and path of travel to exits;
- Emergency notification lists and procedures;
- Post-incident follow-up procedures, including salvage and insurance information; and
- Plan revision and evaluation procedures.

Once a plan is developed, reviewed and approved, it must be distributed, practiced and periodically revised.

## SECTION 401 GENERAL

**401.1 Scope.** Reporting of emergencies, coordination with emergency response forces, emergency plans and procedures for managing or responding to emergencies shall comply with the provisions of this section.

**Exception:** Firms that have *approved* on-premises fire-fighting organizations and that are in compliance with *approved* procedures for fire reporting.

❖ This section describes the overall scope of Chapter 4, which notes that all procedures relating to reporting

and managing fire and other emergencies be in accordance with this chapter. There is one exception recognizing organizations, such as large industrial sites, that have on-site fire brigades. The fire brigades and the associated reporting procedures must be approved by the fire code official.

**401.2 Approval.** Where required by this code, fire safety plans, emergency procedures and employee training programs shall be *approved* by the *fire code official*.

❖ To verify that emergency procedures, training and fire safety plans have taken all essential factors into

## EMERGENCY PLANNING AND PREPAREDNESS

account, the plans and procedures must be approved by the fire code official.

**401.3 Emergency responder notification.** Notification of emergency responders shall be in accordance with Sections 401.3.1 through 401.3.3.

❖ This section simply states that the notification of emergency forces must comply with Section 401.3 and all of its subsections.

**401.3.1 Fire events.** In the event an unwanted fire occurs on a property, the *owner* or occupant shall immediately report such condition to the fire department.

❖ This section requires prompt notification of the fire department in the event of a fire emergency. Employees or other occupants are prohibited from delaying in any way the notification of the fire department.

**401.3.2 Alarm activations.** Upon activation of a fire alarm signal, employees or staff shall immediately notify the fire department.

❖ This section specifically requires immediate notification of the fire department or other emergency response groups when an alarm signal is activated in order to bring emergency forces in the shortest amount of time.

**401.3.3 Delayed notification.** A person shall not, by verbal or written directive, require any delay in the reporting of a fire to the fire department.

❖ Emergency plans and procedures must not include a requirement that employees report an alarm to a supervisor or similar person before calling the fire department. There can be no substitute for immediate notification of emergency forces because a quick response is the key to efficient and effective rescue and fire fighting.

**401.4 Required plan implementation.** In the event an unwanted fire is detected in a building or a fire alarm activates, the emergency plan shall be implemented.

❖ Sections 401.3.1 through 401.3.3 mandate the prompt notification of emergency responders whenever a fire alarm is activated or an actual fire or suspected fire occurs. Since the emergency plan is designed to safely and effectively deal with those circumstances and safeguard the occupants, it must be implemented simultaneously with emergency responder notification as required by this section.

**401.5 Making false report.** A person shall not give, signal or transmit a false alarm.

❖ Chapter 2 of the code defines a false alarm as an intentional activation of an alarm or notification of a fire or other emergency when no emergency exists. This would not include a malfunctioning alarm system. False alarms have the potential for causing confusion or panic among occupants of the affected premises, a situation that could lead to property damage, personal injury or death. False alarms also place fire fighters and other emergency personnel in poten-

tial danger during the unnecessary emergency response. This can jeopardize other lives and property in the community by committing emergency forces to a false situation when they might be needed at an actual emergency elsewhere.

**401.6 Emergency evacuation drills.** The sounding of a fire alarm signal and the carrying out of an emergency evacuation drill in accordance with the provisions of Section 405 shall be allowed.

❖ This section specifically allows fire alarm signals to be utilized as part of emergency evacuation drills. Without this provision, Section 401.3.1 would not allow the activation of the alarm signal during an emergency evacuation drill.

**401.7 Unplanned evacuation.** Evacuations made necessary by the unplanned activation of a fire alarm system or by any other emergency shall not be substituted for a required evacuation drill.

❖ This section makes it clear that unplanned evacuations will not be applied toward fulfillment of the number of drills required. Evacuation drills are intended to provide for an assessment of the adequacy of an emergency action plan and the response of the building occupants. Occupants may or may not be forewarned of a pending drill depending on the circumstances. Responsible staff prepares for and conducts the drills, a key aspect of which is having monitors in place to assess individual and group performance. An unplanned evacuation does not allow for effective monitoring of performance and, therefore, must not be counted as a required drill.

**401.8 Interference with fire department operations.** It shall be unlawful to interfere with, attempt to interfere with, conspire to interfere with, obstruct or restrict the mobility of or block the path of travel of a fire department emergency vehicle in any way, or to interfere with, attempt to interfere with, conspire to interfere with, obstruct or hamper any fire department operation.

❖ A potential hazard when fire departments respond to an emergency is the inability to perform operations because of physical obstructions, restricted mobility or human interference. This section prohibits any type of interference with emergency response operations. The delay of even a few minutes can cause serious property damage, injuries or fatalities.

## SECTION 402 DEFINITIONS

**402.1 Definitions.** The following terms are defined in Chapter 2:

### EMERGENCY EVACUATION DRILL.

### LOCKDOWN.

❖ Definitions of terms can help in the understanding and application of the code requirements. This sec-

tion directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2, in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 403 EMERGENCY PREPAREDNESS REQUIREMENTS

**403.1 General.** In addition to the requirements of Section 401, occupancies, uses and outdoor locations shall comply with the emergency preparedness requirements set forth in Sections 403.2 through 403.12.3.3. Where a fire safety and evacuation plan is required by Sections 403.2 through 403.11.4, evacuation drills shall be in accordance with Section 405 and employee training shall be in accordance with Section 406.

❖ Section 403 contains the occupancy-specific requirements for emergency preparedness. This section primarily notes when a fire safety and evacuation plan is required, but also provides specific requirements as necessary. For instance, seating plans must be provided for Group A occupancies or, in the case of Group I-2 occupancies, specific requirements are provided for staff training. Section 403 also has a section with special requirements to address the need for fire watches and planning for large gatherings (see Section 403.12).

The occupancies addressed by this section were chosen based on the density and location of occupants, the layout of the building or the limitations of the occupants during an emergency. The *Evacuation Planning Guide for Stadiums* published by the U.S. Department of Homeland Security (DHS) provides useful guidance for evacuation planning in large assembly structures. The principles used in that document could also be applied to the other occupancy groups listed in this section. Two additional resources to better understand the evacuation needs of specific types of structures such as tall buildings and airports are the SFPE *Engineering Guide: Fire Safety for Very Tall Buildings* and *Egress Design Solutions*.

**403.2 Group A occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group A *occupancies*, other than those occupancies used exclusively for purposes of religious worship with an occupant load less than 2,000, and for buildings containing both a Group A occupancy and an atrium. Group A occupancies shall comply with Sections 403.2.1 through 403.2.4.

❖ Group A occupancies are a special concern because of the high density and number of occupants. Additionally, occupants in Group A occupancies are generally not very familiar with the building. Due to lack of losses associated with those attending religious wor-

ship services, such occupancies are given an exception to the application of these requirements of less than 2,000 people.

**403.2.1 Seating plan.** In addition to the requirements of Section 404.2, the fire safety and evacuation plans for assembly occupancies shall include a detailed seating plan, *occupant load* and *occupant load* limit. Deviations from the *approved* plans shall be allowed provided the *occupant load* limit for the occupancy is not exceeded and the *aisles* and exit accessways remain unobstructed.

❖ Proper planning for an assembly occupancy must consider the number, capacity and physical arrangement of exits. In turn, these factors will dictate how seating may be arranged to prevent obstruction of aisles and exits. The number of seats provided may not exceed what is permitted by the number, arrangement and capacity of exits. Floor area factors are only one element in determining whether the exit capacity is adequate. Additionally, the egress plan must be approved by the fire code official with a copy of the approved plan maintained on the premises for review by employees and inspectors. Many facilities have several approved plans to accommodate various situations and functions. The seating plan selected for any event should reflect the needs of the group and the requirement to keep aisles and exits clear. Deviations from an approved plan may be permitted only if they do not obstruct the complete egress path, including aisles and exits.

**403.2.2 Announcements.** In theaters, motion picture theaters, auditoriums and similar assembly occupancies in Group A used for noncontinuous programs, an audible announcement shall be made not more than 10 minutes prior to the start of each program to notify the occupants of the location of the exits to be used in the event of a fire or other emergency.

**Exception:** In motion picture theaters, the announcement is allowed to be projected upon the screen in a manner *approved by the fire code official*.

❖ Announcements are intended to familiarize occupants with life safety system features they may need to use if a fire occurs. Information is the most valuable commodity during fires and other emergencies; however, it is often difficult, if not impossible, to override the emotion and confusion caused by a fire or other emergency. Studies have generally shown, however, that occupants do not panic as once thought; therefore, it is imperative that occupants receive information necessary for them to make decisions before an emergency occurs. To convey information and motivate an adaptive response to fires or other emergencies, the message must stimulate interest and speak directly to the topic. Many movie theaters currently use “trailers” or “shorts” to market concession items, as well as fire safety. These messages can be especially effective if they are specific and adequately distinguished from other promotions.

Any message should reflect the life safety strategy and must point out specific features of the occupancy. Occupants in most theaters and auditoriums are usually expected to leave the building immediately upon notification of a fire using the nearest available exit. This is largely a reflection on the building type and arrangement of exits. In these cases, the locations of all exits must be identified. Raising the house lights along the egress path or modulating aisle lighting at appropriate times during the message can reinforce the message.

This section specifically requires an audible announcement, but the exception for motion picture theaters would allow the message to be visually displayed upon the screen as approved. A combination of both an audible and visual message would most likely be the most effective. This section also has a maximum time from the start of the show to provide such announcements. An announcement that comes too early will lose its effectiveness.

**403.2.3 Fire watch personnel.** Fire watch personnel shall be provided where required by Section 403.12.1.

❖ This section links to Section 403.12.1, which establishes the authority of the fire code official to require a fire watch as necessary.

**403.2.4 Crowd managers.** Crowd managers shall be provided where required by Section 403.12.3.

❖ Assembly occupancies contain many occupants potentially unfamiliar with the building. The larger the number of occupants in a single space, the more critical that crowd managers be available to direct people. Section 403.12.3 requires crowd managers when a gathering exceeds 1,000 people.

**403.3 Ambulatory care facilities.** Ambulatory care facilities shall comply with the requirements of Sections 403.3.1 through 403.3.3 as well as 401 and 404 through 406.

❖ Ambulatory care facilities, similar to Group I-1 Condition 2 and Group I-2 occupancies, use a “defend-in-place” method of occupant protection. Defend in place is a widely used approach to protecting occupants who are bedridden, unconscious or otherwise unable to self-preserve in a fire event. The method relies on both active and passive fire protection systems as well as the actions of trained staff and responders. The heavy emphasis on staff action requires a comprehensive fire safety and evacuation plan. Any building containing an ambulatory health-care occupancy will, by definition, contain occupants who may be incapable of self-preservation. The intent of the current IBC requirements for ambulatory care is to create a type of defend-in-place environment. Sections 403.3.1 through 403.3.4 provide requirements for ambulatory care that are more specific than those provided in Sections 404 and 405.

**403.3.1 Fire evacuation plan.** The fire safety and evacuation plan required by Section 404 shall include a description of special staff actions. This shall include procedures for stabi-

lizing patients in a defend-in-place response, staged evacuation, or full evacuation in conjunction with the entire building if part of a multitenant facility.

❖ Fire safety and evacuation plans must be developed, reviewed and approved to support this strategy. The reference to “defend in place” is added in Section 404.2.2 to recognize the defend-in-place method. This is not a new concept. The IBC and legacy codes have been written to support this concept, and fire safety and evacuation plans must acknowledge this strategy. The term “defend in place” is defined in the IBC. Fire safety plans should describe in the life safety strategy the method of notifying occupants, including the use of a private-mode alarm system as allowed by code. Procedures for dealing with occupants in a defend-in-place strategy should also be described so that it is clear what the staff will be trained on and what the first responders should expect to encounter. Fire evacuation plans are required to describe the special actions of staff, especially staff that must stabilize a patient prior to moving. This will be the basis of the staff education and training. This will also help the code official understand the expected performance of the building. It is imperative that the building and fire official know the size and location of the facility as well as the number of patients who are incapable of self-preservation. This information will help the building official determine the proper classification and mitigations required. It will also allow the fire official to preplan the response for a particular building. Any special characteristics of the means of egress, such as path to the adjacent smoke compartment and special locking arrangements, should also be described to aid in verifying code compliance. Practically, these documents will be the basis for staff training as well.

**403.3.2 Fire safety plan.** A copy of the plan shall be maintained at the facility at all times. The plan shall include all of the following in addition to the requirements of Section 404:

1. Locations of patients who are rendered incapable of self-preservation.
2. Maximum number of patients rendered incapable of self-preservation.
3. Area and extent of each ambulatory care facility.
4. Location of adjacent smoke compartments or refuge areas, where required.
5. Path of travel to adjacent smoke compartments.
6. Location of any special locking, delayed egress or access control arrangements.

❖ This section sets out information required for the fire safety plan specific to ambulatory care facilities. Fire safety plans are required to show the location where incapable patients are likely to be. They are required to show the location of smoke compartments, routes of travel, patient movement elevators and any locking constraints that might affect the horizontal evacuation

of patients. All of these will be essential to robust staff training as well as operational planning for first responders.

**403.3.3 Staff training.** Employees shall be periodically instructed and kept informed of their duties and responsibilities under the plan. Records of instruction shall be maintained. Such instruction shall be reviewed by the staff not less than every two months. A copy of the plan shall be readily available at all times within the facility.

❖ In ambulatory care facilities, due to the condition of the occupants, the actions of the staff are critical to the success of the fire evacuation plan. Therefore, staff training on a regular basis is necessary. This section requires that the staff review the fire evacuation plan and fire safety plan regularly. These plans always need to be available for review.

**403.3.4 Emergency evacuation drills.** Emergency evacuation drills shall comply with Section 405. Emergency evacuation drills shall be conducted not less than four times per year.

**Exceptions:** The movement of patients to safe areas or to the exterior of the building is not required.

❖ This section requires not less than four evacuation drills each year. This requirement is more restrictive than what Table 405.2 would require. Therefore, although Table 405.2 requires only annual evacuation drills, they must be done four times a year. This is similar to what is required for Group I-2 occupancies. Such drills are limited to the employees. The exception emphasizes that patient participation is not required.

**403.4 Group B occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for buildings containing a Group B occupancy where the Group B occupancy has an *occupant load* of 500 or more persons or more than 100 persons above or below the lowest *level of exit discharge* and for buildings having an ambulatory care facility.

❖ This section requires a fire and evacuation plan when the number of occupants in a Group B occupancy becomes large. The increased risk when such occupants are not located on the level of exit discharge is also addressed. Generally, Group B occupancies are not used for sleeping and occupants are familiar with their surroundings. This section is for Group B occupancies that are not considered ambulatory care facilities. Ambulatory care facilities are also Group B occupancies but would be addressed more specifically by Section 403.3. Group F and M occupancies have the same occupant load and location trigger for fire safety and evacuation plans (see Sections 403.6 and 403.9).

**403.5 Group E occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group E occupancies and for buildings containing both a Group E occupancy and an atrium.

Group E occupancies shall comply with Sections 403.5.1 through 403.5.3.

❖ Group E occupancies are among the primary occupancies requiring emergency evacuation drills. They are among the few occupancies that require all occupants to participate in evacuation drills. The effectiveness of pre-emergency planning in Group E occupancies has been significant, as evidenced by a remarkable decline in tragic fires in schools over the years. The evacuation skills learned by children in school are often carried with them into adulthood.

**403.5.1 First emergency evacuation drill.** The first emergency evacuation drill of each school year shall be conducted within 10 days of the beginning of classes.

❖ Group E occupants vary from year to year as children enter and leave grade levels. In addition, even though a child may be in the same school for a number of years, location within the building and leaders change. It is important, therefore, that the first evacuation drill occurs within the first 10 days of school. This provides students with nearly immediate training and the school and emergency responders with information about where problems exist. Additionally, in more recent years schools have been immersing students with disabilities into the general classroom. The location and number of these students vary each year. The ability to evacuate them must be assessed early in the school year.

**403.5.2 Time of day.** Emergency evacuation drills shall be conducted at different hours of the day or evening, during the changing of classes, when the school is at assembly, during the recess or gymnastic periods, or during other times to avoid distinction between drills and actual fires.

❖ If evacuation drills are done routinely, they will be easily distinguished as drills and not an actual fire. This is potentially dangerous because the behavior patterns will be different and actual preparedness for emergencies will be lessened. Time of day, therefore, should be varied whether it is convenient or not. A fire will not differentiate between a convenient and an inconvenient time.

**403.5.3 Assembly points.** Outdoor assembly areas shall be designated and shall be located a safe distance from the building being evacuated so as to avoid interference with fire department operations. The assembly areas shall be arranged to keep each class separate to provide accountability of all individuals.

❖ A key element in safe evacuation is the exit discharge portion of the evacuation route. Once occupants are outside the building, they need to be located far enough away to avoid further hazards. Additionally, there is a potential for people at the assembly point to interfere with the emergency operations of the fire department, which may not be present during an evacuation drill. Locations, therefore, need to be des-

ignated such that they avoid hazards and keep the evacuated occupants away from probable paths of emergency response. Also, to simplify accounting for the occupants once outside, the code requires each class to remain together as a group and separate from other classes.

**403.6 Group F occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for buildings containing a Group F occupancy where the Group F occupancy has an *occupant load* of 500 or more persons or more than 100 persons above or below the lowest *level of exit discharge*.

❖ Group F occupancies require a fire safety and evacuation plan under the same occupant load and location conditions as Group B and M occupancies. Essentially, when the occupant load begins to get large or increases on a level other than the level of exit discharge, such plans become more critical (see commentary, Section 403.4).

**403.7 Group H occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group H occupancies.

❖ This section requires that all Group H occupancies have a fire safety and evacuation plan. These occupancies, regardless of size or type, tend to contain significant hazards that make the need for preplanning critical. Semiconductor facilities have more specific requirements found in Section 403.7.1.

**403.7.1 Group H-5 occupancies.** Group H-5 occupancies shall comply with Sections 403.7.1.1 through 403.7.1.4.

❖ Group H-5 occupancies are semiconductor fabrication facilities. These types of facilities are unique in that they have a very large allowable area and house a significant amount of hazardous materials. Essentially, the building is divided into fabrication areas, hazardous production materials (HPM) rooms (which are Group H occupancy storage rooms) and networks of service corridors and spaces. The area of the building needs to be large to incorporate all of the operations needed by the semiconductor industry. To facilitate these operations, a special package of requirements and occupancy classification was created. This package is found within the occupancy requirements in the IBC and Chapter 27 of the code. As part of the package, special emergency preparedness and preparation are also required. Sections 403.7.1.1 through 403.7.1.4 provide specific requirements for emergency preparedness and preparation. These requirements are in addition to others pertaining to hazardous materials found in Section 407.

**403.7.1.1 Plans and diagrams.** In addition to the requirements of Section 404 and Section 407.6, plans and diagrams shall be maintained in *approved* locations indicating the approximate plan for each area, the amount and type of HPM stored, handled and used, locations of shutoff valves for HPM

supply piping, emergency telephone locations and locations of exits.

❖ The requirements for plans and diagrams are in addition to those required in Sections 404 and 407. More specifically, the additional details required include the approximate plan for each area of the building. This includes the amount of HPM stored, handled and used in both the fabrication areas and the HPM rooms. Additionally, since it is typical that such facilities tend to pipe HPM throughout the building for efficiency, all shutoff valves must be identified. Finally, exits must be clearly marked. This is specifically necessary because many service corridors for the transport of materials are not considered part of the means of egress. These details will assist both the occupants and the emergency responders.

**403.7.1.2 Plan updating.** The plans and diagrams required by Sections 404, 403.7.1.1 and 407.6 shall be maintained up to date and the *fire code official* and fire department shall be informed of major changes.

❖ Semiconductor facilities are constantly changing because of the needs of new technology; therefore, the types and amounts of materials and their application are constantly changing. These changes must be accounted for within the plans and diagrams required in Sections 403.7.1.1 and 407; otherwise, the critical information needed by the emergency responders may not be available.

**403.7.1.3 Emergency response team.** Responsible persons shall be designated as an on-site emergency response team and trained to be liaison personnel for the fire department. These persons shall aid the fire department in preplanning emergency responses, identifying locations where HPM is stored, handled and used, and be familiar with the chemical nature of such material. An adequate number of personnel for each work shift shall be designated.

❖ This section is similar to Section 407.4, but has some specific requirements unique to semiconductor facilities. More specifically, liaisons familiar with the location of HPM and hazards related to those materials must be on site. For example, semiconductor facilities make use of silane gas, which is a pyrophoric material—it will instantly ignite when exposed to atmospheric conditions. Knowing the characteristics of the material, where it is located and the quantity used is critical to the responding emergency personnel.

**403.7.1.4 Emergency drills.** Emergency drills of the on-site emergency response team shall be conducted on a regular basis but not less than once every three months. Records of drills conducted shall be maintained.

❖ This section requires employees to conduct drills every 3 months to practice specific emergency procedures for the facilities. Again, this requirement is specific to semiconductor facilities because of their

unique layout and contents. The emergency responders rely heavily on the on-site actions of the employees because of their intimate knowledge of the site and the complexity of these buildings. Records must be maintained.

**403.8 Group I occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group I occupancies. Group I occupancies shall comply with Sections 403.8.1 through 403.8.3.4.

❖ Group I occupancies are those where occupants are often incapable of self-preservation due to their physical condition or they are physically able but under restraint. Therefore, fire safety and evacuation plans are critical and also have some specific needs unique from other occupancies.

**403.8.1 Group I-1 occupancies.** Group I-1 occupancies shall comply with Sections 403.8.1.1 through 403.8.1.7.

❖ A Group I-1 occupancy is one that houses more than 16 individuals who live in a supervised residential care facility on a 24-hour basis. This would include residential board and care homes, congregate care facilities, social rehabilitation facilities, alcohol and drug centers, assisted living facilities and convalescent facilities. Generally, occupants of these facilities are able to respond to an emergency with some assistance from staff. Note that there are two levels of Group I-1 occupancies (Condition 1 and Condition 2). These are further clarified in Section 202 but, essentially, those found in Condition 2 need additional protection due to an increased need for assistance.

**403.8.1.1 Fire safety and evacuation plan.** The fire safety and evacuation plan required by Section 404 shall include special employee actions, including fire protection procedures necessary for residents, and shall be amended or revised upon admission of any resident with unusual needs.

❖ This section is in addition to the general requirements found in Section 404. It specifies that requirements based on the particular needs of residents must be included as part of the plan. These plans must be reviewed each time a new occupant arrives to assess whether there are any special features that need to be included in the plan to address those particular needs. Group R-4 occupancies are being addressed in a similar manner (see Section 403.10.3.1).

**403.8.1.1.1 Fire evacuation plan.** The fire evacuation plan required by Section 404 shall include a description of special staff actions. In addition to the requirements of Section 404, plans in Group I-1 Condition 2 occupancies shall include procedures for evacuation through a refuge area in an adjacent smoke compartment and then to an exterior assembly point.

❖ Similar to ambulatory care facilities, the actions of the staff are critical and must be addressed beyond the requirements of Section 404. This is only applicable to Group I-1 Condition 2 occupancies where the residents depend more on the staff than they do in a

Group I-1 Condition 1 occupancy. Group I-1 Condition 2 occupancies depend on the concept of smoke compartments similar to Group I-2 occupancies (see Section 420.4 of the *International Building Code*).

**403.8.1.1.2 Fire safety plans.** A copy of the fire safety plan shall be maintained at the facility at all times. Plans shall include the following in addition to the requirements of Section 404:

1. Location and number of resident sleeping rooms.
2. Location of special locking or egress control arrangements.

❖ This section requires that Group I-1 occupancies provide the location and number of residents sleeping and any special locking or egress control arrangements. This assists in search and rescue and understanding how the residents may be hampered in their evacuation. This information is critical for preplanning by both staff and the fire department. This applies to conditions of Group I-1 occupancies. The same requirement is provided for Group R-4 occupancies, which are essentially smaller Group I-1 occupancies.

**403.8.1.2 Employee training.** Employees shall be periodically instructed and kept informed of their duties and responsibilities under the plan. Such instruction shall be reviewed by employees at intervals not exceeding two months. A copy of the plan shall be readily available at all times within the facility.

❖ These types of facilities are normally occupied by people who have the ability to evacuate or relocate with a certain level of assistance from the staff; therefore, employee training is critical. Again, residents in Group I-1 Condition 2 occupancies will need more evacuation assistance than in Group I-1 Condition 1 occupancies. Group I-1 Condition 2 occupancies utilize the concept of smoke compartments. Additional training in this regard is necessary for employees. This section requires that training occur every 2 months because the needs of the occupants may change over time as certain physical or mental conditions progress or new occupants arrive.

**403.8.1.3 Resident training.** Residents capable of assisting in their own evacuation shall be trained in the proper actions to take in the event of a fire. In Group I-1 Condition 2 occupancies, training shall include evacuation through an adjacent smoke compartment and then to an exterior assembly point. The training shall include actions to take if the primary escape route is blocked. Where the resident is given rehabilitation or habilitation training, methods of fire prevention and actions to take in the event of a fire shall be a part of the rehabilitation training program. Residents shall be trained to assist each other in case of fire to the extent their physical and mental abilities permit them to do so without additional personal risk.

❖ As noted, Group I-1 occupants are capable of responding to an emergency but will most likely need direction from staff and perhaps physical assistance to ensure the appropriate response. This is more the

case with Group I-1 Condition 2 occupancies. Unlike other Group I occupancies, I-1 occupancies rely on the abilities of residents to take some level of responsibility for their own evacuation or relocation; therefore, training residents in these occupancies is critical. One major element that must be communicated to residents is what to do when the main exit route is blocked.

If residents are receiving rehabilitation or habilitation, fire prevention and appropriate actions to take during a fire should be communicated as part of the sessions. This section also requires the occupants to assist one another as long as a physical or mental condition would not limit their ability to do so.

Since Group I-1 Condition 2 occupancies utilize the concept of smoke compartments, occupants must be trained to evacuate to the adjacent smoke compartment to the refuge area.

**403.8.1.4 Drill frequency.** In addition to the evacuation drills required in Section 405.2, employees shall participate in drills an additional two times a year on each shift. Twelve drills with all occupants shall be conducted in the first year of operation. Drills are not required to comply with the time requirements of Section 405.4.

❖ Occupants of Group I-1 facilities need to be reminded often of evacuation procedures given their sometimes limited abilities to recall procedures, changes in the residents' abilities over time and the introduction of new residents to the facility. Therefore, this section requires more frequent drills than Table 405.2. Employees on each shift are required to participate in additional drills. Each shift potentially has different staff and also different conditions due to the time of day. Another very specific difference from Table 405.2 is that such facilities are required to have, essentially, monthly drills for the first year. Over time the occupants and staff will change, but this sets the tone for how the facility operates. This also increases staff awareness of procedures.

**403.8.1.5 Drill times.** Drill times are not required to comply with Section 405.4.

❖ This provides the flexibility to create an appropriate schedule that works with these facilities. The residents participate, making it slightly more difficult to follow Section 405.4.

**403.8.1.6 Resident participation in drills.** Emergency evacuation drills shall involve the actual evacuation of residents to a selected assembly point and shall provide residents with experience in exiting through all required exits. All required exits shall be used during emergency evacuation drills.

❖ This section clarifies that drills must include all occupants, not just staff. In other institutional occupancies where the occupants are not capable or it is not desirable to evacuate them on their own, inclusion of the residents in drills is not necessary. Since dependence is placed on the residents to react in Group I-1 occupancies, their involvement is critical. This section is designed to promote resident familiarity with all the

exits that are available in the building. This will help residents understand that, during emergencies, there are multiple paths to safety. Note that, in Group I-1 Condition 2 occupancies, smoke compartments are used and occupants will typically need to simply move to the adjoining smoke compartment to defend in place.

**403.8.1.7 Emergency evacuation drill deferral.** In severe climates, the *fire code official* shall have the authority to modify the emergency evacuation drill frequency specified in Section 405.2.

❖ It is not appropriate to send residents of Group I-1 occupancies outside during extreme weather conditions unnecessarily. Generally, the occupants of such facilities have failing health or are more susceptible to illness than the average population. This section provides the authority to the fire code official to make adjustments for these reasons.

**403.8.2 Group I-2 occupancies.** Group I-2 occupancies shall comply with Sections 403.8.2.1 through 403.8.2.3 as well as 401 and 404 through 406.

❖ Group I-2 occupancies as well as ambulatory care facilities and Group I-1 Condition 2 occupancies use a “defend-in-place” method of occupant protection. Defend in place is a widely used approach to protect occupants who are bedridden, unconscious or otherwise unable to self-preserve in a fire event. The method relies on both active and passive fire protection systems as well as the actions of trained staff and responders. The heavy emphasis on staff action requires a comprehensive fire safety and evacuation plan. Any building containing an ambulatory health-care occupancy will, by definition, contain occupants who may be incapable of self-preservation. The intent of the current IBC requirements for Group I-2 occupancies is to create a type of defend-in-place environment. Sections 403.8.2.1 through 403.8.2.3 provide requirements for Group I-2 occupancies that are more specific than what is provided in Sections 404 and 405.

**403.8.2.1 Fire evacuation plans.** The fire safety and evacuation plans required by Section 404 shall include a description of special staff *actions*. Plans shall include all of the following in addition to the requirements of Section 404.

1. Procedures for evacuation for patients with needs for containment or restraint and post-evacuation containment, where present.
2. A written plan for maintenance of the means of egress.
3. Procedure for a defend-in-place strategy.
4. Procedures for a full-floor or building evacuation, where necessary.

❖ Staff actions are critical to the success of a fire evacuation plan for Group I-2 occupancies; therefore, procedures need to be documented. In addition to the requirements of Section 404, this section provides four more-specific requirements for the fire evacua-

tion plan. These requirements include how patients are to be evacuated and documentation of maintenance plans for means of egress in such facilities. Procedures for defend-in-place strategy must be documented so that each shift is familiar with those strategies. Defend-in-place procedures depend upon the use of refuge areas that need to be maintained. In some cases, the defend-in-place evacuation may need to escalate to full-floor or building evacuation. Such evacuations need to be documented, as well.

**403.8.2.2 Fire safety plans.** A copy of the plan shall be maintained at the facility at all times. Plans shall include all of the following in addition to the requirements of Section 404:

1. Location and number of patient sleeping rooms and operating rooms.
2. Location of adjacent smoke compartments or refuge areas.
3. Path of travel to adjacent smoke compartments.
4. Location of special locking, delayed egress or access control arrangements.
5. Location of elevators utilized for patient movement in accordance with the fire safety plan, where provided.

❖ Fire safety plans should describe the method of notifying occupants, including the use of a private-mode alarm system as allowed by code. Procedures for dealing with occupants in a defend-in-place strategy should also be described so that it is clear what the staff will be trained on and what the first responders should expect to encounter. It is imperative that the building and fire code officials know the size and location of the facility as well as the number of patients who are incapable of self-preservation. This information will help the building official determine the proper classification and mitigations required. It will also allow the fire official to preplan the response for a particular building. Any special characteristics of the means of egress, such as path to the adjacent smoke compartment and special locking arrangements, should also be described to aid in verifying code compliance. Practically, these documents will be the basis for staff training as well.

**403.8.2.3 Emergency evacuation drills.** Emergency evacuation drills shall comply with Section 405.

**Exceptions:**

1. The movement of patients to safe areas or to the exterior of the building is not required.
  2. Where emergency evacuation drills are conducted after visiting hours or where patients or residents are expected to be asleep, a coded announcement shall be an acceptable alternative to audible alarms.
- ❖ Group I-2 occupancies are required to comply with the evacuation drill frequency established in Section 405. However, Group I-2 occupancies do not evacuate occupants from the building but instead utilize a

defend-in-place strategy. This is related to the conditions of the patients found in such facilities. Therefore, Exception 1 clarifies that evacuation to the exterior is not required. Exception 2 allows the use of coded signals for staff evacuation drills. This avoids disturbing patients or alarming visitors. The drills in such facilities do not involve the patients.

**403.8.3 Group I-3 occupancies.** Group I-3 occupancies shall comply with Sections 403.8.3.1 through 403.8.3.4.

❖ Group I-3 occupancies are institutional occupancies where the occupants are under restraint. Typically, the occupants are physically able but are restrained from moving freely. Several levels of restraint in such occupancies are described in more detail in Chapter 2 under the definition of “Group I-3 occupancies.” As in Group I-2 occupancies, the only participants in drills will be staff. These requirements are in addition to the requirements of Sections 404 and 405.

**403.8.3.1 Employee training.** Employees shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment. Training of new employees shall be provided promptly upon entrance to duty. Refresher training shall be provided not less than annually.

❖ Group I-3 facilities are more likely to have incendiary activity; therefore, staff must be trained in the use of various fire protection equipment, including fire extinguishers. Additionally, any new employees must be immediately trained in the use of this equipment. Because of difficulties presented by relocating or evacuating confinees, fires should be managed, when practical, to minimize the threat to occupants. Since combustibles are strictly limited in most of these occupancies, accidental fires generally remain small—at least long enough to be manageable. Incendiary fires often pose greater challenges and generally reflect a breakdown in security discipline. Notwithstanding this problem, fire extinguisher training, and even incipient fire brigades, may be especially effective elements of a fire safety plan in restrained-care occupancies. This training is required of new employees before they can begin their official duties. This training must then be refreshed once a year.

**403.8.3.2 Employee staffing.** Group I-3 occupancies shall be provided with 24-hour staffing. An employee shall be within three floors or 300 feet (91 440 mm) horizontal distance of the access door of each resident housing area. In Group I-3 Conditions 3, 4 and 5, as defined in Chapter 2, the arrangement shall be such that the employee involved can start release of locks necessary for emergency evacuation or rescue and initiate other necessary emergency actions within 2 minutes of an alarm.

**Exception:** An employee shall not be required to be within three floors or 300 feet (91 440 mm) horizontal distance of the access door of each resident housing area in areas in which all locks are unlocked remotely and auto-

## EMERGENCY PLANNING AND PREPAREDNESS

matically in accordance with Section 408.4 of the *International Building Code*.

- ❖ Group I-3 occupancies place a lot of importance on the actions of staff in emergencies. This section provides specific direction regarding the staff's locations and actions in an emergency. Staff members responsible for initiating the relocation or evacuation of confinees must be constantly alert to potential fire hazards and incipient fires. If a fire occurs, 2 minutes will seem like a long time to confined people. When a remote-release locking system is neither required nor provided, the number of locks requiring manual unlocking should be limited with due regard to staff and confinee safety. This may require additional staff to accomplish the unlocking procedure in a timely manner. This section does have a specific exception for systems that utilize a remote locking and unlocking system.

**403.8.3.3 Notification.** Provisions shall be made for residents in Group I-3 Conditions 3, 4 and 5, as defined in Chapter 2, to readily notify an employee of an emergency.

- ❖ Group I-3 occupancies under Use Conditions 3, 4 and 5 where the occupants are very limited in their freedom would be considered moderate- and high-security facilities. Because the occupants are so limited and could be located remotely from guards or other staff members as a result of confinement within a compartment, a method is necessary for staff notification of a fire. In open cell blocks, staff members may be within earshot of occupants but generally this requirement necessitates monitors, intercoms or other communication appliances.

**403.8.3.4 Keys.** Keys necessary for unlocking doors installed in a *means of egress* shall be individually identifiable by both touch and sight.

- ❖ Keys must be distinctive from one another so they may be promptly and reliably identified under emergency conditions. Fumbling for the right key can cost valuable seconds, and possibly lives, in the event of a fire (see Commentary Figure 403.8.3.4).

**403.9 Group M occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for buildings containing a Group M occupancy where the Group M occupancy has an *occupant load* of 500 or more persons or more than 100 persons above or below the lowest level of *exit discharge* and for buildings containing both a Group M occupancy and an atrium.

- ❖ This section requires a fire and evacuation plan when the number of occupants in a Group M occupancy becomes large. An increased risk is also addressed when such occupants are not located on the level of exit discharge. This is the same requirement as that provided for Group B and F occupancies. However, Group M occupants may not be quite as familiar with their surroundings but the staff in such facilities are available to direct occupants during an emergency. Also, this is an occupancy where people do not sleep (see Sections 403.4 and 403.6).

**403.10 Group R occupancies.** Group R occupancies shall comply with Sections 403.10.1 through 403.10.3.6.

- ❖ This section provides fire safety and evacuation plans specific to Group R-1, R-2 and R-4 occupancies. These are occupancies where people sleep, thus the need for fire safety and evacuation plans is more critical.

**403.10.1 Group R-1 occupancies.** An approved fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group R-1 occupancies. Group R-1 occupancies shall comply with Sections 403.10.1.1 through 403.10.1.3.

- ❖ Group R-1 occupancies are residential occupancies that include hotels and boarding houses. These occupancies contain residents that are temporary in nature; therefore, they are more unfamiliar with their surroundings than Group R-2 and R-3 occupants. Sections 403.10.1.1 through 403.10.1.3 provide specific requirements that take into account characteristics of Group R-1 occupancies.

**403.10.1.1 Evacuation diagrams.** A diagram depicting two evacuation routes shall be posted on or immediately adjacent to every required egress door from each hotel or motel sleeping unit.

- ❖ This section requires an evacuation plan diagram to be posted in each hotel or motel sleeping unit. Both the format of the diagram and its location must be approved by the fire code official. This diagram is to display both a primary and a secondary exit route in case a fire or other obstacle blocks the primary route. The plan should be prepared so that the orientation of rooms in relation to the exits is accurately portrayed and easily discernible to the occupant. Often, additional safety information is included on the plan diagram, such as fire alarm box and fire extinguisher locations; however, those added items should not clutter the diagram to the extent that they detract from

the clarity of its primary purpose of showing exit routes and exit locations.

**403.10.1.2 Emergency duties.** Upon discovery of a fire or suspected fire, hotel and motel employees shall perform the following duties:

1. Activate the fire alarm system, where provided.
2. Notify the public fire department.
3. Take other action as previously instructed.

❖ This section contains specific actions employees are to take if a fire occurs. The requirement that they first activate the fire alarm and then call the fire department is intended to avoid a situation in which the employee first investigates or calls security. Immediate notification of the occupants facilitates evacuation or relocation as necessary. Notifying the fire department as early as possible will enable fire fighters to reach the building at an earlier stage in the fire.

**403.10.1.3 Fire safety and evacuation instructions.** Information shall be provided in the fire safety and evacuation plan required by Section 404 to allow guests to decide whether to evacuate to the outside, evacuate to an *area of refuge*, remain in place, or any combination of the three.

❖ The procedures for isolating occupants from a fire depend on the layout and overall fire protection design of a building. For example, a hotel in a high-rise building may be specifically designed to evacuate in phases; therefore, the occupants need to know the procedures to facilitate a smooth and organized reaction to a fire. The appropriate actions that are available should be communicated. Options may include occupants remaining in their rooms, evacuating or relocating.

**403.10.2 Group R-2 occupancies.** Group R-2 occupancies shall comply with Sections 403.10.2.1 through 403.10.2.3.

❖ Group R-2 occupancies are permanent residential occupancies that house multiple occupants in multiple dwelling units. Typically, this includes apartment buildings, dormitories and other related residential occupancies. Generally, the occupants tend to be familiar with their surroundings but may be sleeping when an emergency occurs. Sections 403.10.2.1 through 403.10.2.3 provide specific requirements in addition to the general requirements of Chapter 4. This section deals with Group R-2 occupancies generally and, more specifically, with Group R-2 college and university buildings.

**403.10.2.1 College and university buildings.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group R-2 college and university buildings. Group R-2 college and university buildings shall comply with Sections 403.10.2.1.1 and 403.10.2.1.2.

❖ This section establishes the applicability of certain provisions to college and university residence halls and dormitories classified in Group R-2. Fire rep-

resents a significant risk to life and property in dormitory occupancies, particularly at colleges and universities. The large number of young people living in close proximity to one another creates the potential for a relatively small fire to have serious and possibly fatal consequences. Applying these requirements in conjunction with the drills required by Table 405.2 will enhance the likelihood of occupants being familiar with exiting buildings under emergency conditions at varying times throughout the day.

**403.10.2.1.1 First emergency evacuation drill.** The first emergency evacuation drill of each school year shall be conducted within 10 days of the beginning of classes.

❖ The residents of Group R-2 college and dormitory occupancies typically change each year. It is important, therefore, that the first evacuation drill occurs within the first 10 days of school.

**403.10.2.1.2 Time of day.** Emergency evacuation drills shall be conducted at different hours of the day or evening, during the changing of classes, when school is at assembly, during recess or gymnastic periods or during other times to avoid distinction between drills and actual fires. One required drill shall be held during hours after sunset or before sunrise.

❖ If evacuation drills are done routinely, they will become easily distinguishable as drills and not an actual fire. This is potentially dangerous because the behavior patterns will be different and actual preparedness for an emergency will be lessened. Time of day, therefore, should be varied whether or not it is convenient. A fire will not differentiate between a convenient and an inconvenient time. At least one of the drills required by Table 405.2 must be conducted between sunset and sunrise so that residents can experience nighttime evacuation.

**403.10.2.2 Emergency guide.** Fire emergency guides shall be provided for Group R-2 occupancies. Guide contents, maintenance and distribution shall comply with Sections 403.10.2.2.1 through 403.10.2.2.3.

❖ The next few sections lay out the requirements for emergency guides for Group R-2 occupancies. This includes what is to be in the guide, obtaining approval from the fire code official and distribution requirements. The guide in general will better inform the residents and provide preplanning tools for the fire department.

**403.10.2.2.1 Guide contents.** A fire emergency guide shall describe the location, function and use of fire protection equipment and appliances accessible to residents, including fire alarm systems, smoke alarms and portable fire extinguishers. Guides shall include an emergency evacuation plan for each *dwelling unit*.

❖ The guide must contain the intended evacuation plan for each unit and information about the various fire protection features provided to occupants. Providing this information to residents increases the likelihood of a proper response, which in turn increases resident

safety and makes the fire department's job a little easier when responding to a scene.

**403.10.2.2.2 Emergency guide maintenance.** Emergency guides shall be reviewed and approved by the *fire code official*.

❖ This section makes it clear that the fire code official must sign off on the emergency guide contents. This will make fire department response consistent with the features of the building.

**403.10.2.2.3 Emergency guide distribution.** A copy of the emergency guide shall be given to each tenant prior to initial occupancy.

❖ This section requires that a guide illustrating the fire safety features of the building be provided to each dwelling unit. There is no purpose in having a guide to assist residents if there is no requirement that it be distributed. This must occur before they become occupants.

**403.10.2.3 Evacuation diagrams for dormitories.** A diagram depicting two evacuation routes shall be posted on or immediately adjacent to every required egress door from each dormitory *sleeping unit*. Evacuation diagrams shall be reviewed and updated as needed to maintain accuracy.

❖ The same concept is used for Group R-1 occupancies; this simply increases the information available to occupants. Group R-2 dormitory occupants are typically more transient than most occupants of Group R-2 occupancies (see commentary for Section 403.10.1.1).

**403.10.3 Group R-4 occupancies.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for Group R-4 occupancies. Group R-4 occupancies shall comply with Sections 403.10.3.1 through 403.10.3.6.

❖ A Group R-4 occupancy is a residential care/assisted living facility for more than five but not more than 16 residents. The occupants are similar to those found in a Group I-1 occupancy; therefore, they are capable of self-preservation but, may have mental or physical conditions that could impede their reactions.

**403.10.3.1 Fire safety and evacuation plan.** The fire safety and evacuation plan required by Section 404 shall include special employee actions, including fire protection procedures necessary for residents, and shall be amended or revised upon admission of a resident with unusual needs.

❖ This section is in addition to the general requirements found in Section 404. It specifies that requirements based on the particular needs of residents must be included as part of the plan. These plans must be reviewed each time a new occupant arrives to assess any special features that need to be included in the plan to address those particular needs. This is the same requirement as provided for Group I-1 occupancies.

**403.10.3.1.1 Fire safety plans.** A copy of the plan shall be maintained at the facility at all times. Plans shall include the following in addition to the requirements of Section 404:

1. Location and number of resident sleeping rooms.
2. Location of special locking or egress control arrangements.

❖ This section requires that fire safety plans in Group R-4 occupancies provide the location and number of residents sleeping and any special locking or egress control arrangements. This assists in search and rescue and understanding how the residents may be hampered in their evacuation. This information is critical for preplanning by both staff and the fire department. This is the same requirement as provided for Group I-1 occupancies (see Section 403.8.1.1.2).

**403.10.3.2 Employee training.** Employees shall be periodically instructed and kept informed of their duties and responsibilities under the plan. Records of instruction shall be maintained. Such instruction shall be reviewed by employees at intervals not exceeding two months. A copy of the plan shall be readily available at all times within the facility.

❖ These types of facilities are normally occupied by people who have the ability to evacuate or relocate with a certain level of assistance from the staff; therefore, employee training is critical. Residents of Group R-4 Condition 2 occupancies will need more assistance in evacuation than in Group R-4 Condition 1. This section requires that training occur every 2 months because the needs of the occupants may change over time as certain physical or mental conditions progress or new occupants arrive.

**403.10.3.3 Resident training.** Residents capable of assisting in their own evacuation shall be trained in the proper actions to take in the event of a fire. The training shall include actions to take if the primary escape route is blocked. Where the resident is given rehabilitation or habilitation training, methods of fire prevention and actions to take in the event of a fire shall be a part of the rehabilitation training program. Residents shall be trained to assist each other in case of fire to the extent their physical and mental abilities permit them to do so without additional personal risk.

❖ As noted, Group R-4 occupants are capable of responding to an emergency, but most likely will need direction from staff and perhaps physical assistance. This is more the case with Group R-4 Condition 2 occupancies. Group R-4 occupancies, similar to Group I-1 occupancies, rely on the abilities of residents to take some level of responsibility for their own evacuation or relocation; therefore, training residents in these occupancies is critical. One major element that must be communicated to residents is what to do when the main exit route is blocked.

If residents are receiving rehabilitation or habilitation, fire prevention and appropriate actions to take during a fire should be communicated as part of the sessions. This section also requires the occupants to

assist one another as long as a physical or mental condition would not limit their ability to do so.

Since Group I-1 Condition 2 occupancies utilize the concept of smoke compartments, occupants must be trained how to evacuate to the adjacent smoke compartment to the refuge area.

**403.10.3.4 Drill frequency.** In addition to the evacuation drills required in Section 405.2, employees shall participate in drills an additional two times a year on each shift. Twelve drills with all occupants shall be conducted in the first year of operation.

❖ Occupants of Group R-4 facilities need to be reminded often of evacuation procedures given their sometimes limited capabilities to recall procedures, changes in their abilities over time and the introduction of new residents to the facility. Therefore, this section requires more frequent drills than Table 405.2. Employees on each shift are required to participate in additional drills. Each shift potentially has different staff and also different conditions due to the time of day. Another very specific difference from Table 405.2 is that such facilities are required to have, essentially, monthly drills for the first year. Over time the occupants and staff will change, but this sets the tone for how the facility operates. This also increases staff awareness of procedures.

**403.10.3.5 Drill times.** Drill times are not required to comply with Section 405.4.

❖ This provides the flexibility to create an appropriate schedule that works with Group R-4 facilities. The residents participate, making it slightly more difficult to follow Section 405.4.

**403.10.3.6 Resident participation in drills.** Emergency evacuation drills shall involve the actual evacuation of residents to a selected assembly point and shall provide residents with experience in exiting through all required exits. All required exits shall be used during emergency evacuation drills.

**Exception:** Actual exiting from emergency escape and rescue windows shall not be required. Opening the emergency escape and rescue window and signaling for help shall be an acceptable alternative.

❖ This section clarifies that drills must include all occupants, not just the staff. Since dependence is placed on the residents to react in Group R-4 occupancies, their involvement is critical. This section is designed to promote resident familiarity with all the exits that are available in the building. This will help residents understand that, during emergencies, there are multiple paths to safety.

**403.11 Special uses.** Special uses shall be in accordance with Sections 403.11.1 through 403.11.4.

❖ The next several sections are focused on special uses that require fire safety and evacuation plans, including:

- Malls and mall buildings.

- High-rise buildings.
- Underground buildings.
- Occupant evacuation elevators.

**403.11.1 Covered and open mall buildings.** Covered and open mall buildings shall comply with the requirements of Sections 403.11.1.1 through 403.11.1.6.

❖ A covered mall building is a special use as described in Section 402 of the IBC and as defined in Chapter 2 of the code. Generally, a covered mall building is a single building housing multiple occupancies including, but not limited to, retail, assembly, drinking, dining and entertainment in which two or more tenants have a main entrance into a mall area. A mall area is also defined in Chapter 2 of the IBC as “a roofed or covered mall building that serves as access for two or more tenants and does not exceed three levels that are open to each other”; therefore, it presents some unique issues concerning fire department response to an emergency.

An open mall is an uncovered common pedestrian walk that is open to the sky above and to tenant spaces within the open mall building, and typically connects to the anchor buildings. Unless noted otherwise, open malls must comply with all IBC provisions. The open mall building includes all of the buildings wherein two or more tenants have a main entrance into one or more open malls. Because open malls are characterized by there not being a roof connecting one side of the pedestrian mall to the other, the open mall “building” may actually be a collection of separate buildings that all rely on a shared pedestrian concourse for egress. Similar to the covered mall building, the open mall “building” does not include the anchor buildings. Unless noted otherwise, open mall buildings have to comply with all provisions for covered mall buildings.

The requirements of Sections 403.11.1.1 through 403.11.1.6 are related primarily to the complexity of the building and provide appropriate information to emergency responders so they can more effectively respond to a fire or other emergency.

**403.11.1.1 Malls and mall buildings exceeding 50,000 square feet.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for covered malls exceeding 50,000 square feet (4645 m<sup>2</sup>) in aggregate floor area and for open mall buildings exceeding 50,000 square feet (4645 m<sup>2</sup>) in aggregate area within the perimeter line.

❖ The requirement for fire safety and evacuation plans for both covered malls and open malls is only applicable when such malls become larger. Smaller malls simplify the evacuation process and detailed information such as a lease plan is not required.

**403.11.1.2 Lease plan.** In addition to the requirements of Section 404.2.2, a lease plan that includes the following information shall be prepared for each covered and open mall building:

1. Each occupancy, including identification of tenant.

2. Exits from each tenant space.
3. Fire protection features, including the following:
  - 3.1. Fire department connections.
  - 3.2. Fire command center.
  - 3.3. Smoke management system controls.
  - 3.4. Elevators, elevator machine rooms and controls.
  - 3.5. Hose valve outlets.
  - 3.6. Sprinkler and standpipe control valves.
  - 3.7. Automatic fire-extinguishing system areas.
  - 3.8. Automatic fire detector zones.
  - 3.9. Fire barriers.

❖ Item 1 assists the emergency responders by requiring detailed documentation regarding the identification of each tenant, location and occupancy. This will let them locate the highest density of occupants and the types of hazards that may be anticipated.

Item 2 is the identification of exits. This will assist emergency responders in the identification of necessary access routes and how they may interact with the exits.

Item 3 is a report of the available fire protection features. These features, such as identification of the fire detector zones, will help responders quickly assess where a fire is located. If the mall has a smoke control system, access to the controls may be necessary; therefore, the location of those controls is critical. This information gives the fire department a general feel for how the building is intended to perform during a fire. This information is valuable in the sense that they will have more information to promote effective use of the fire protection features installed. If little information is provided, the fire department could actually disrupt the essential activation of a system, such as smoke control.

**403.11.1.3 Lease plan approval.** The lease plan shall be submitted to the *fire code official* for approval, and shall be maintained on site for immediate reference by responding fire service personnel.

❖ The lease plan must be approved. This allows the fire department to determine whether all necessary information, from the perspective of the responders, is addressed. Also, this section requires that the lease plan is available on site for use by the emergency responders.

**403.11.1.4 Lease plan revisions.** The lease plans shall be revised annually or as often as necessary to keep them current. Modifications or changes in tenants or occupancies shall not be made without prior approval of the *fire code official* and building official.

❖ This section provides the authority to require a review of the lease plan at least once each year. In addition, the fire code official has the authority to ask for more frequent reviews of the plan.

If a change occurs in the building, the lease plan may no longer be valid; therefore, this section

requires that no changes to any tenant space be made without approval and review by the fire code official. These changes would have to be documented in the lease plan.

**403.11.1.5 Tenant identification.** Tenant identification shall be provided for secondary *exits* from occupied tenant spaces that lead to an *exit corridor* or directly to the exterior of the building. Tenant identification shall be posted on the exterior side of the *exit* or exit access door and shall identify the business name and address using plainly legible letters and numbers that contrast with their background.

**Exception:** Tenant identification is not required for anchor stores.

❖ Identifying secondary exits from tenant spaces that enter into an exit passageway or lead directly outside is a critical need for emergency responders. This identification needs to contain the business name and address. Having multiple tenants within a building makes this identification necessary. Anchor stores do not need these labels, since they are fairly recognizable without them.

**403.11.1.6 Unoccupied tenant spaces.** The fire safety and evacuation plan shall provide for compliance with the requirements for unoccupied tenant spaces in Section 311.

❖ This section addresses the hazards posed by a tenant space that is not in use or that is not under the supervision of employees. These spaces are more likely to be targeted by vandalism and possibly incendiary activity. Generally, a fire can grow unnoticed in such spaces as a result of the lack of supervision or activity in the space. This section simply references Section 311.6, where requirements dealing with vacant premises are found. To reduce the risks in unsupervised tenant spaces, several requirements in Section 311.6 focus on reducing the fire ignition, growth and spread potential by limiting combustibles in the space, securing the space through the use of locks and installing fire separations constructed of  $\frac{1}{2}$ -inch-thick (12.7 mm) gypsum or similar materials. Note that mall buildings are required to be sprinklered throughout and that the systems in the tenant spaces must be independent of the mall area.

**403.11.2 High-rise buildings.** An *approved* fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for high-rise buildings.

❖ High-rise buildings can involve many different uses, such as business, assembly and residential. The types of occupancies on their own may or may not have specific requirements for fire safety and evacuation plans, but due to the fact that the building is tall, evacuation and fire safety become more complex. Such buildings tend to use phased evacuation, but may have other unique evacuation requirements such as the need for full-building evacuation or assisting those who cannot use stairways. The types of evacuation strategies for high rises vary. More detailed discussion on these strategies can be found in the SFPE *Engineering Guide: Fire Safety for Very*

*Tall Buildings* (ICC and SFPE 2013) and *Egress Design Solutions* (Tubbs and Meacham 2005).

**403.11.3 Underground buildings.** An approved fire safety and evacuation plan in accordance with Section 404 shall be prepared and maintained for underground buildings.

❖ Like high-rise buildings, underground buildings can contain a variety of uses. Those uses may not, on their own, require unique fire safety and evacuation plans, but since the building is located below grade, evacuation and fire fighting become more complex. Therefore, it is important that a fire safety and evacuation plan be required in accordance with Section 404. Note that Item 4 in Section 404.2.1 specifically addresses those unable to use the stairways.

**403.11.4 Buildings using occupant evacuation elevators.** In buildings using occupant evacuation elevators in accordance with Section 3008 of the *International Building Code*, the fire safety and evacuation plan and the training required by Sections 404 and 406, respectively, shall incorporate specific procedures for the occupants using such elevators.

❖ This is not a specific use but instead is an evacuation strategy that is very different than what the general public has been taught about the use of elevators during fires. The successful use of such elevators depends greatly on preplanning and training as to how they are to be used by building occupants. This section requires that when these elevators are used, specific procedures be worked into the fire safety and evacuation plans and into employee training. Note that Item 3 in Section 404.2.1 specifically requires these procedures to be included in the fire evacuation plans. It should be noted that this ties in with the requirements for high-rise buildings and how they are intended to be evacuated. As with high-rise buildings, a good resource for extensive discussion on occupant evacuation and evacuation using elevators can be found in the SFPE *Engineering Guide: Fire Safety for Very Tall Buildings* and *Egress Design Solutions* (Tubbs and Meacham 2005).

**403.12 Special requirements for public safety.** Special requirements for public safety shall be in accordance with Sections 403.12.1 through 403.12.3.3.

❖ The following requirements authorize a jurisdiction to require fire watches, address large public assemblies and provide specific requirements for crowd managers.

**403.12.1 Fire watch personnel.** Where, in the opinion of the *fire code official*, it is essential for public safety in a place of assembly or any other place where people congregate, because of the number of persons, or the nature of the performance, exhibition, display, contest or activity, the *owner*, agent or lessee shall provide one or more fire watch personnel, as required and *approved*. Fire watch personnel shall comply with Sections 403.12.1.1 and 403.12.1.2.

❖ Even though Chapter 31 requires standby personnel in tents and membrane structures because of the inherently higher life safety risks associated with such

occupancies, this section gives the fire code official the authority to require fire watch personnel in indoor or outdoor venues where people congregate where the number of persons or the nature of the performance, exhibition, display, contest or activity is such that the presence of fire watch personnel are essential to public safety (see commentary, Section 202, definition of “Fire watch”).

**403.12.1.1 Duty times.** Fire watch personnel shall remain on duty while places requiring a fire watch are open to the public, or when an activity requiring a fire watch is being conducted.

❖ This section establishes the key times a fire watch should be conducted. Once it is established that a fire watch is necessary, it is critical that it be conducted while the public is present. Also, it may be necessary for the fire watch to occur based upon a specific hazard or activity even while not open to the public.

**403.12.1.2 Duties.** On-duty fire watch personnel shall have the following responsibilities:

1. Keep diligent watch for fires, obstructions to *means of egress* and other hazards.
2. Take prompt measures for remediation of hazards and extinguishment of fires that occur.
3. Take prompt measures to assist in the evacuation of the public from the structures.

❖ Fire watch personnel provide temporary fire safety where there are potential fire and life safety hazards that could affect large numbers of assembled people. Such personnel does not simply watch for a fire but is also present to prevent fire by identifying and controlling fire hazards; monitoring and maintaining the availability of the means of egress; and taking initial action to suppress a fire should one occur. Fire watch personnel also provide a method of notifying the fire department if a fire should occur.

**403.12.2 Public safety plan for gatherings.** Where the *fire code official* determines that an indoor or outdoor gathering of persons has an adverse impact on public safety through diminished access to buildings, structures, fire hydrants and fire apparatus access roads or where such gatherings adversely affect public safety services of any kind, the *fire code official* shall have the authority to order the development of or prescribe a public safety plan that provides an *approved* level of public safety and addresses the following items:

1. Emergency vehicle ingress and egress.
2. Fire protection.
3. Emergency egress or escape routes.
4. Emergency medical services.
5. Public assembly areas.
6. The directing of both attendees and vehicles, including the parking of vehicles.
7. Vendor and food concession distribution.

8. The need for the presence of law enforcement.
9. The need for fire and emergency medical services personnel.

❖ This section is important because it grants the fire code official the authority to require the development of or to prescribe a specific plan for large gatherings. Such gatherings could include outdoor festivals, demonstrations or receptions. If such assemblies include the use of tents and canopies, Chapter 31 would also apply.

Again, the primary aim of this section is to address the fact that these large gatherings may hamper the ability of the fire department and other emergency responders to access and protect buildings and building occupants.

Further, this section provides some specific issues to be addressed, including: the direction of traffic; vendor and food concession distributors; and the need for law enforcement and medical services.

**403.12.3 Crowd managers for gatherings exceeding 1,000 people.** Where facilities or events involve a gathering of more than 1,000 people, crowd managers shall be provided in accordance with Sections 403.12.3.1 through 403.12.3.3.

❖ This section is similar to the requirement for standby personnel for tents in Section 3104.20. Large assemblies of people create the need for crowd management due to the increased potential for panic and fear in emergency situations. It is the intent of this section that crowd managers can be personnel already assigned and employed by the facility, provided that they are trained as crowd managers to fulfill this requirement. At the time of an emergency, the trained crowd managers would take on additional responsibilities to control and direct the audience or attendees in a safe manner.

**403.12.3.1 Number of crowd managers.** The minimum number of crowd managers shall be established at a ratio of one crowd manager for every 250 persons.

**Exception:** Where approved by the *fire code official*, the number of crowd managers shall be permitted to be reduced where the facility is equipped throughout with an *approved automatic sprinkler system* or based upon the nature of the event.

❖ The minimum number of crowd managers would be four, based on the minimum requirements of Section 403.12.3. Since the fire and life safety profile of a facility is improved where an automatic sprinkler system is installed throughout, the fire code official is authorized by this section to reduce the crowd manager-to-occupant ratio for events on a case-by-case basis (see commentary, Section 3104.20).

**403.12.3.2 Training.** Training for crowd managers shall be *approved*.

❖ Training is critical for crowd managers to be effective. This section provides the mechanism to ensure such training occurs. There are various crowd manager training courses available.

**403.12.3.3 Duties.** The duties of crowd managers shall include, but not be limited to:

1. Conduct an inspection of the area of responsibility and identify and address any egress barriers.
2. Conduct an inspection of the area of responsibility to identify and mitigate any fire hazards.
3. Verify compliance with all permit conditions, including those governing pyrotechnics and other special effects.
4. Direct and assist the event attendees in evacuation during an emergency.
5. Assist emergency response personnel where requested.
6. Other duties required by the *fire code official*.
7. Other duties as specified in the fire safety plan.

❖ The exact duties and responsibilities of individuals employed as crowd managers are not defined here other than the requirement that they be trained and present. They could serve as ushers, tour guides, service supervisors for table seating or in some other capacity related to making sure occupants are moved to or from assigned places in an orderly way. The key to the success of this section is that crowd managers must be trained in crowd management procedures appropriate to the activity being carried on in the facility and they must be present in the required numbers. Training of personnel and the duties assigned to them would have to be approved by the fire code official. See also the commentary to Section 3104.20 for further information on crowd managers.

## SECTION 404 FIRE SAFETY, EVACUATION AND LOCKDOWN PLANS

**404.1 General.** Where required by Section 403, fire safety, evacuation and lockdown plans shall comply with Sections 404.2 through 404.4.1.

❖ This section simply states that all fire safety, evacuation and lockdown plans must comply with Section 404. Section 403 outlines, for many different occupancies and uses, when this section would apply. In addition, Section 403 provides specific requirements that are intended to be addressed along with the requirements in Section 404.

**404.2 Contents.** Fire safety and evacuation plan contents shall be in accordance with Sections 404.2.1 and 404.2.2.

❖ The two primary plans required by Section 404.3 are a fire evacuation plan and a fire safety plan. The fire evacuation plan focuses primarily on the procedures for the evacuation of the occupants in an emergency. The fire safety plan focuses on the overall understanding of the fire protection package of the building as it pertains to the layout of the building, the contents of the building, the means of egress system, the fire hazards and the identification of key contacts during an emergency.

**404.2.1 Fire evacuation plans.** Fire evacuation plans shall include the following:

1. Emergency egress or escape routes and whether evacuation of the building is to be complete by selected floors or areas only or with a defend-in-place response.
  2. Procedures for employees who must remain to operate critical equipment before evacuating.
  3. Procedures for the use of elevators to evacuate the building where occupant evacuation elevators complying with Section 3008 of the *International Building Code* are provided.
  4. Procedures for assisted rescue for persons unable to use the general *means of egress* unassisted.
  5. Procedures for accounting for employees and occupants after evacuation has been completed.
  6. Identification and assignment of personnel responsible for rescue or emergency medical aid.
  7. The preferred and any alternative means of notifying occupants of a fire or emergency.
  8. The preferred and any alternative means of reporting fires and other emergencies to the fire department or designated emergency response organization.
  9. Identification and assignment of personnel who can be contacted for further information or explanation of duties under the plan.
  10. A description of the emergency voice/alarm communication system alert tone and preprogrammed voice messages, where provided.
- ❖ The primary focus of evacuation plans is to prepare for and define roles for evacuation and relocation of occupants during an emergency. The fire evacuation plan is important for both emergency responders and building or facility occupants. It focuses the occupants' activities on facilitating a smoother evacuation or relocation process and provides the fire department with critical information on the building and the location of the occupants. Keep in mind that these requirements apply to all occupancies listed in Section 404.2. The occupancy- and use-specific requirements are located within Section 403; therefore, the requirements listed here are general and will vary based on many factors, such as the occupants' mobility and familiarity with the building.

Item 1 requires that specific escape routes be defined. This is important because the building is generally designed to facilitate a particular pattern of evacuation or relocation in an emergency. For instance, as noted earlier, a high-rise building will most likely be evacuated in phases. If floors begin evacuating before intended, the evacuation of the occupants in the fire area may be delayed. Also, if everyone tries to use the same exits in a facility, such as a multiplex theater, evacuation of the building will be delayed. As stated earlier, studies have shown that people tend to exit the way they enter a building.

Note that the code sometimes requires a certain level of redundancy to account for occupants using the same exits. For example, the IBC requires that the main exit of multiplex theaters be sized for at least half of the occupants even though plenty of egress width may be available elsewhere in the building. The more coordinated the plan, the more evenly the exits will be used.

Item 2 requires that specific procedures for evacuation be provided to those employees who must operate critical equipment before evacuation. These procedures are necessary to ensure a clear understanding to the occupant when evacuation is critical and the operation should be abandoned.

Item 3 requires that specific procedures be provided when occupant evacuation elevators are used. This is critical as each building may have unique aspects regarding the use of such elevators and the types of evacuations they may undertake.

Item 4 provides for the inclusion of procedures relative to those occupants unable to evacuate using the general egress features who, therefore, may need assisted rescue. It is important that there be adequate information and procedures established and available to staff and fire fighters so that assistance can be offered to anyone who needs help using the general means of egress as quickly as possible.

Item 5 simply states that a plan be developed to account for all occupants after evacuation or relocation. This is important not only to the occupants but also to the emergency responders to assess their actions when arriving at the scene.

Item 6 has two roles. First, it provides a designated person for occupants to look to for assistance in an emergency. This will reduce the stress of the situation. Second, when the emergency responders arrive they will have a specific contact to help them assess the situation. These contacts can also be beneficial to emergency responders when preplanning their response to that specific facility.

Item 7 requires that the notification to the occupants of the emergency be standardized. The approach will vary based on occupancy and use. For instance, all occupants in a multiplex theater would be notified, whereas in a correctional facility or hospital only staff will be notified. Also, if the method is standardized, it is easier to differentiate between emergency and nonemergency signals, which facilitates a smoother reaction when an emergency does occur.

Item 8 is focused on the notification of emergency responders. They are more likely to get the notification of an emergency if a standard protocol exists. This can vary from one occupancy or use to another, but as long as a straightforward, consistent method is used, it will facilitate a quicker response. Note that Section 401.3.2 requires direct contact with the fire department once the fire alarm signal is activated; therefore, no intermediate steps, such as an investigation, are allowed.

As with Item 6, Item 9 requires a specific contact who is familiar with the plan and how the building operates. This information is helpful for the emergency responders in their preplanning activities. Without a specific contact, the process of getting vital information can become much more difficult for the fire department. In a large building or facility, the safety officer or similar person is most appropriate for such a role.

Item 10 requires documentation of the voice/alarm communications system alert tone and preprogrammed voice messages. This provides emergency responders with a better understanding of the information provided to occupants to better assess the appropriate response. Additionally, if conditions in that building change, the plan can be evaluated to see whether this aspect of the notification system needs to be revised. For instance, if the procedures for evacuation have changed, the voice announcement may need to be revised.

**404.2.2 Fire safety plans.** Fire safety plans shall include the following:

1. The procedure for reporting a fire or other emergency.
2. The life safety strategy including the following:
  - 2.1. Procedures for notifying occupants, including areas with a private mode alarm system.
  - 2.2. Procedures for occupants under a defend-in-place response.
  - 2.3. Procedures for evacuating occupants, including those who need evacuation assistance.
3. Site plans indicating the following:
  - 3.1. The occupancy assembly point.
  - 3.2. The locations of fire hydrants.
  - 3.3. The normal routes of fire department vehicle access.
4. Floor plans identifying the locations of the following:
  - 4.1. Exits.
  - 4.2. Primary evacuation routes.
  - 4.3. Secondary evacuation routes.
  - 4.4. Accessible egress routes.
    - 4.4.1. Areas of refuge.
    - 4.4.2. Exterior areas for assisted rescue.
  - 4.5. Refuge areas associated with *smoke barriers* and *horizontal exits*.
  - 4.6. Manual fire alarm boxes.
  - 4.7. Portable fire extinguishers.
  - 4.8. Occupant-use hose stations.
  - 4.9. Fire alarm annunciators and controls.
5. A list of major fire hazards associated with the normal use and occupancy of the premises, including maintenance and housekeeping procedures.
6. Identification and assignment of personnel responsible for maintenance of systems and equipment installed to prevent or control fires.
7. Identification and assignment of personnel responsible for maintenance, housekeeping and controlling fuel hazard sources.

❖ This section requires an overall fire safety plan with emphasis on the building and building site layout and hazards. More specifically, information, such as the evacuation and relocation aspects of the building layout, needs to be clarified; the list of specific hazards associated with normal use of the building needs to be noted and fire department access road locations need to be provided.

This plan also includes identification of specific personnel charged with managing fire protection systems and equipment and with fire prevention duties, such as controlling combustibles on site. Having specific personnel assigned to perform this duty will work to increase the likelihood of these actions occurring.

The requirements of this plan provide the building owner and occupants a better understanding of how to react in an emergency and how to decrease the likelihood of an emergency occurring. Additionally, this report assists emergency responders during periodic inspections and evaluations of the plans and, more importantly, when responding to an emergency. Generally, buildings that have fairly rigid and well-maintained plans and procedures in place reduce not only the likelihood and magnitude of an incident within the jurisdiction but also the burden to emergency responders.

**404.2.3 Lockdown plans.** Where facilities develop a lockdown plan, it shall be in accordance with Sections 404.2.3.1 through 404.2.3.3.

❖ The provisions of this section introduce the requirements for plans and procedures for lockdowns (see commentary to the definition in Section 202). Note that the code does not require a lockdown plan; however, if a lockdown plan is developed, it must be strictly supervised in order to maintain occupant safety at an acceptable level. Many facilities are adopting procedures that can significantly affect fire and life safety, such as using the fire alarm system to signal a security emergency, locking doors with devices that prevent egress in violation of the provisions of Chapter 10 of the code, and chaining exit discharge doors from the inside to prevent occupants from leaving the building. It is important that plans for security threats do not include procedures that result in violations of life safety and actually increase the

hazard to the occupants. The sections that follow intend to establish the conditions for lockdown plans so that they will not decrease the level of life safety in the event of fire.

**404.2.3.1 Lockdown plan contents.** Lockdown plans shall be *approved* by the *fire code official* and shall include the following:

1. Initiation. The plan shall include instructions for reporting an emergency that requires a lockdown.
  2. Accountability. The plan shall include accountability procedures for staff to report the presence or absence of occupants.
  3. Recall. The plan shall include a prearranged signal for returning to normal activity.
  4. Communication and coordination. The plan shall include an *approved* means of two-way communication between a central location and each secured area.
- ❖ Lockdown plans often include procedures for locking occupants into individual rooms within the building. If the lockdown plan is not reviewed for life safety precautions, it could have a negative impact on fire and life safety. To reduce the likelihood of an inadequate or substandard plan, approval of the plan by the fire code official is required.

In accordance with Item 1, the plan must include a well thought out list of exactly what types of situations will warrant the implementation of a lockdown and how and to whom those “trigger” situations will be reported. Key to the success of a lockdown is the ability to account for all building occupants. To increase the likelihood that everyone will be properly accounted for, Item 2 requires that specific accountability procedures to be followed by lockdown supervisors be included in the plan. When the reason for a lockdown has been mitigated and it is safe to again move about within or reenter a building, Item 3 requires that an “all-clear” signal must be done by an authorized person by a means used only for that purpose and readily recognizable as such. Item 4 requires that a central “command” location be pre-planned and that a reliable means of two-way communication be provided in order to keep locked-down occupants apprised of the status of the situation, thus reducing their level of anxiety and the likelihood of panic.

Note that although the code does not assume simultaneous events, it would be advisable for the lockdown plan to include procedures to be followed if a fire alarm occurs during a lockdown.

**404.2.3.2 Training frequency.** The training frequency shall be included in the lockdown plan. The lockdown drills shall not substitute for any of the fire and evacuation drills required in Section 405.2.

- ❖ To utilize lockdown training and the lessons learned from it to the best advantage, training should be conducted on a regular basis to familiarize staff and occupants with the lockdown plan. Training should be

designed and practiced to reinforce lockdown procedures as adaptive planned responses to stressful and potentially dangerous situations. It is important to note that lockdown training and drills may not be counted toward the required number of fire and evacuation drills so as not to diminish the impact of either (see also commentary, Section 406.3.3).

**404.2.3.3 Lockdown notification.** The method of notifying building occupants of a lockdown shall be included in the plan. The method of notification shall be separate and distinct from the fire alarm signal.

- ❖ Area-wide notification systems, ranging from low-tech sirens to text-message alerts on cell phones, are among several means of notification available for lockdown announcements. Whatever the method chosen for a particular occupancy, it must be separate and distinct from the building fire alarm system to avoid a miscue that could trigger an inappropriate response to a threatening situation unrelated to a fire.

**404.3 Maintenance.** Fire safety and evacuation plans shall be reviewed or updated annually or as necessitated by changes in staff assignments, occupancy or the physical arrangement of the building.

- ❖ In order to be of optimum value to a facility, plans must accurately reflect building conditions. Plans must be reviewed annually or when building changes affecting the instructions or procedures in the fire safety or emergency evacuation plan occur. Such a review should prompt an immediate revision and redistribution of the plan to all concerned parties, including emergency response personnel.

**404.4 Availability.** Fire safety and evacuation plans shall be available in the workplace for reference and review by employees, and copies shall be furnished to the *fire code official* for review upon request.

- ❖ This essentially requires that these plans be easily accessible to building occupants and the fire code official. If the plans are difficult to access, they are less likely to be updated when necessary and are more likely to be lost or forgotten. This places a burden on the emergency responders when planning methods of response, and puts the occupants of the building at a higher risk during an emergency. Having the documents readily available makes review and use for training occupants more likely.

**404.4.1 Distribution.** The fire safety and evacuation plans shall be distributed to the tenants and building service employees by the *owner* or *owner’s* agent. Tenants shall distribute to their employees applicable parts of the fire safety plan affecting the employees’ actions in the event of a fire or other emergency.

- ❖ Fire safety and evacuation plans are only effective when all building occupants have been informed of the contents of the plan. In the case of a multiple-tenant building, the plan must address individual tenant spaces. Distribution to all affected occupants is important for a coordinated response to an emergency.

This section requires that the building owner or the owner's agent distribute the plan to all tenants and building service employees. Since the owner or agent of the owner usually does not have direct access to the tenants' employees, the individual tenants would then have the responsibility to distribute the applicable portion of the plan to their employees. This provides for a wider distribution of the responsibility to plan for emergencies and to follow the requirements of the plan.

## SECTION 405 EMERGENCY EVACUATION DRILLS

**405.1 General.** Emergency evacuation drills complying with Sections 405.2 through 405.9 shall be conducted not less than annually where fire safety and evacuation plans are required by Section 403 or where required by the *fire code official*. Drills shall be designed in cooperation with the local authorities.

❖ The fire safety and evacuation plans required by Sections 403 and 404 are critical components of life safety strategies in high-density occupancies and extraordinary buildings, such as high-rise buildings. Many times such plans are developed with the best of intentions and available expertise, but fail to adequately consider certain site- or area-specific conditions. Just as emergency operations and hazardous material response plans require operational drills to verify their continued viability and effectiveness, so too do evacuation plans require periodic implementation to gauge effectiveness in achieving their objectives. Since not all of the occupancies that are required to prepare and maintain fire safety and evacuation plans by Section 403 are required to conduct drills by Table 405.2, this section requires at least an annual drill to exercise the required plan.

An additional benefit of an annual drill is the enhanced recognition by occupants, particularly in the case of a high-rise structure, of the possibility of selected-floor evacuation. Given the generally heightened awareness following the events of September 11, 2001, building occupants understandably exhibit a greater reluctance to remain inside a building in the event of an emergency. A complete building evacuation may be unnecessary in a large number of cases and may actually work counter to effective fire-ground operations if uncontrolled. An annual drill in these instances would serve to reinforce the local jurisdiction's preferences regarding evacuation, as well as provide a verification tool that the plan, as developed, is functional and presents opportunities for critique and improvement. The use of an annual drill could easily be incorporated with specific additional training to satisfy the requirements in Section 406 as well.

**405.2 Frequency.** Required emergency evacuation drills shall be held at the intervals specified in Table 405.2 or more

frequently where necessary to familiarize all occupants with the drill procedure.

❖ To utilize fire drills and the lessons that they teach to the best of their advantage, drills should be conducted on a regular basis to familiarize both staff and residents with the evacuation plan. The element of surprise is not necessarily of significant benefit in those occupancies where residents may be prone to maladaptive behavior. Drills should be designed and practiced to reinforce relocation or evacuation behaviors as adaptive planned responses to stressful and potentially dangerous situations. Drills should be scheduled so that all staff members on all shifts have an opportunity to participate in them. Practice makes perfect, and when it comes to effective egress, there is no substitute for fire drills at regular intervals so that all occupants are familiar with the plan's details and their particular responsibilities in implementing them. Truly effective drills test the plan by varying conditions and force occupants to adapt. Many conditions can combine to affect available safe egress time, and drills should incorporate some allowance for unanticipated conditions, such as delayed detection, rapid fire growth, reduced staffing or poor weather conditions, as may be appropriate for the occupancy. Discovering deficiencies in the evacuation plan should be encouraged, and every opportunity should be taken to improve the plans.

**TABLE 405.2.** See page 4-23.

❖ Table 405.2 provides varying evacuation drill frequencies based on building occupancy. The table also prescribes who should be involved in these drills. The level of participation is based on the type of occupancy. In some cases, this is further qualified by the number or location of such occupants with respect to the lowest level of fire department vehicle access. It is unreasonable, for example, in a Group A occupancy such as a hospital or correctional facility, to require the general public to participate in an evacuation drill. It is potentially dangerous to involve anyone but the employees in such drills.

The overall strategy for these occupancies is to provide a package of relevant information before an emergency and to have the employees facilitate and direct occupants during an emergency. The necessary participants in the drills are related to the overall emergency strategies for those buildings. Note that Group B, E, I-1 assisted living, I-4, R-2 and R-4 occupancies require that everyone be involved. This is related to the fact that occupants are generally able to evacuate. In the case of educational occupancies, drills serve as a learning tool for children to carry through their lives. Schools have generally stressed these drills because of large losses in fires, such as in 1958 at Our Lady of Angels School in Chicago. In terms of Group I-1, I-4 and R-4 facilities, the occupants generally are able to evacuate with some assis-

tance. In Group R-2 occupancies, the occupants are usually able-bodied and it is in their best interest to be familiar with the egress routes. More occupancy-specific discussion is provided in the commentary for

**TABLE 405.2  
FIRE AND EVACUATION DRILL  
FREQUENCY AND PARTICIPATION**

GROUP OR OCCUPANCY	FREQUENCY	PARTICIPATION
Group A	Quarterly	Employees
Group B <sup>b</sup>	Annually	All occupants
Group B <sup>b, c</sup> (Ambulatory care facilities)	Annually	Employees
Group B <sup>b</sup> (Clinic, outpatient)	Annually	Employees
Group E	Monthly <sup>a</sup>	All occupants
Group F	Annually	Employees
Group I-1	Semiannually on each shift	All occupants
Group I-2	Quarterly on each shift <sup>a</sup>	Employees
Group I-3	Quarterly on each shift <sup>a</sup>	Employees
Group I-4	Monthly on each shift <sup>a</sup>	All occupants
Group R-1	Quarterly on each shift	Employees
Group R-2 <sup>d</sup>	Four annually	All occupants
Group R-4	Semiannually on each shift <sup>a</sup>	All occupants

- a. In severe climates, the *fire code official* shall have the authority to modify the emergency evacuation drill frequency.
- b. Emergency evacuation drills are required in Group B buildings having an *occupant load* of 500 or more persons or more than 100 persons above or below the lowest level of exit discharge.
- c. Emergency evacuation drills are required in ambulatory care facilities in accordance with Section 403.3.
- d. Emergency evacuation drills in Group R-2 college and university buildings shall be in accordance with Section 403.10.2.1. Other Group R-2 occupancies shall be in accordance with Section 403.10.2.2.

### Section 403.

**405.3 Leadership.** Responsibility for the planning and conduct of drills shall be assigned to competent persons designated to exercise leadership.

- ❖ This section requires a focal point in the planning and execution of evacuation drills. Having a single point of contact streamlines the process and provides a necessary leadership role.

**405.4 Time.** Drills shall be held at unexpected times and under varying conditions to simulate the unusual conditions that occur in case of fire.

- ❖ If fire and emergency drills are a routine planned occurrence, they will not simulate actual reaction to an emergency but will provide an inaccurate and most likely optimistic outcome; therefore, the drills need to occur at random.

**405.5 Record keeping.** Records shall be maintained of required emergency evacuation drills and include the following information:

1. Identity of the person conducting the drill.
2. Date and time of the drill.
3. Notification method used.
4. Employees on duty and participating.
5. Number of occupants evacuated.
6. Special conditions simulated.
7. Problems encountered.
8. Weather conditions when occupants were evacuated.
9. Time required to accomplish complete evacuation.

- ❖ Documenting the frequency and efficiency of emergency evacuation drills not only aids the fire code official in verifying that drills complying with these provisions have been performed but may also help administrators identify trends in emergency evacuation drill performance. Accurate records help life safety planners determine the adequacy of their plans. Identifying issues such as problems encountered and weather conditions helps to further determine which elements create the largest delays and why.

**405.6 Notification.** Where required by the *fire code official*, prior notification of emergency evacuation drills shall be given to the *fire code official*.

- ❖ In some cases, the fire code official will want prior notification of evacuation drills because he or she may need to prepare for such an event. This section provides the fire code official with the authority to require such notification.

**405.7 Initiation.** Where a fire alarm system is provided, emergency evacuation drills shall be initiated by activating the fire alarm system.

- ❖ To simulate conditions normally experienced during an emergency, the emergency notification procedures, which would include a fire alarm system in many cases, must be used.

**405.8 Accountability.** As building occupants arrive at the assembly point, efforts shall be made to determine if all occupants have been successfully evacuated or have been accounted for.

- ❖ This requirement is key to the success of evacuation plans. If a method is not available to account for the occupants once evacuation or relocation is complete, search and rescue activities will be more difficult for the emergency responders. Also, it would be difficult to measure the success of the plan.

**405.9 Recall and reentry.** An electrically or mechanically operated signal used to recall occupants after an evacuation shall be separate and distinct from the signal used to initiate the evacuation. The recall signal initiation means shall be manually operated and under the control of the person in charge of the premises or the official in charge of the inci-

dent. Persons shall not reenter the premises until authorized to do so by the official in charge.

- ❖ This section is primarily aimed at the concern that occupants will be confused if similar signals are used to notify them of an alarm and for reentry. This confusion has the consequences of slowing or even halting evacuation during an actual emergency. Additionally, to make sure that occupants do not go back into the building prematurely, any reentry signal must be operated manually to avoid a situation where it automatically sounds. Finally, this section specifically prohibits reentry until authorization is provided by the official in charge at the scene.

### SECTION 406 EMPLOYEE TRAINING AND RESPONSE PROCEDURES

**406.1 General.** Where fire safety and evacuation plans are required by Section 403, employees shall be trained in fire emergency procedures based on plans prepared in accordance with Section 404.

- ❖ In most cases, the success of an evacuation and fire safety plan hinges on the appropriate reactions of the building occupants. The main activity that building occupants must undertake is removing themselves from the hazards. In some cases, fire safety and evacuation plans involve additional actions by the employees of the facility. For instance, in the case of hospitals, the nurses and other hospital staff must relocate care recipients; therefore, specific training is required for those activities.

Additionally, employees must be trained based on the specific fire safety and fire evacuation plans.

**406.2 Frequency.** Employees shall receive training in the contents of fire safety and evacuation plans and their duties as part of new employee orientation and not less than annually thereafter. Records of training shall be maintained.

- ❖ This section requires that employee training occur during new employee indoctrination and annually thereafter. A record of this training must be provided to the fire code official when requested. This section provides a minimum criterion for the training frequency for all occupancies addressed by Chapter 4. Section 403 may require more restrictive training frequencies.

**406.3 Employee training program.** Employees shall be trained in fire prevention, evacuation and fire safety in accordance with Sections 406.3.1 through 406.3.4.

- ❖ This is a general section that requires all employees to be trained in fire prevention, evacuation and fire safety in accordance with the subsections that follow. These provisions are primarily intended as a mechanism to ensure that training occurs, not as a requirement for establishing training criteria.

**406.3.1 Fire prevention training.** Employees shall be apprised of the fire hazards of the materials and processes to

which they are exposed. Each employee shall be instructed in the proper procedures for preventing fires in the conduct of their assigned duties.

- ❖ If a fire can be prevented, evacuation and relocation of the occupants will also be avoided. Employees must be made aware of the potential hazards related to their particular area of the facility and what can be done to avoid a hazardous situation. Having specific procedures increases the likelihood that proper fire prevention techniques will be followed. Generally, people tend to be unaware of many hazards unless they are alerted to them. An example is the use of space heaters.

**406.3.2 Evacuation training.** Employees shall be familiarized with the fire alarm and evacuation signals, their assigned duties in the event of an alarm or emergency, evacuation routes, areas of refuge, exterior assembly areas and procedures for evacuation.

- ❖ In the event that an emergency does occur, employees must be prepared to assist in the evacuation or relocation of occupants. This training will vary widely from one occupancy type to another. In a high-rise building only some of the occupants will be evacuated at a time, whereas a school will evacuate all occupants at once. This section requires that the training occurs.

**406.3.3 Fire safety training.** Employees assigned fire-fighting duties shall be trained to know the locations and proper use of portable fire extinguishers or other manual fire-fighting equipment and the protective clothing or equipment required for its safe and proper use.

- ❖ Any time employees are to take specific action during a fire event, proper training is required. This section holds the building owner or operator responsible for making sure the training occurs.

**406.4 Emergency lockdown training.** Where a facility has a lockdown plan, employees shall be trained on their assigned duties and procedures in the event of an emergency lockdown.

- ❖ If a facility goes to the trouble of creating a lockdown plan, it stands to reason that it would want its staff to be versed in the plan's contents. Training should be scheduled so that all staff members on all shifts or occupants, as applicable, have an opportunity to participate. Practice makes perfect, and when it comes to effective lockdowns, there is no substitute for training at regular intervals so that all staff and occupants are familiar with the plan's details and their particular responsibilities in implementing it. Drills should be scheduled to test the plan by varying conditions, forcing occupants to adapt and respond instinctively to emergencies without panicking and allowing the staff to identify weaknesses in the preparations.

Many conditions can conspire to affect lockdown success and drills should incorporate some allowance for unanticipated conditions as may be appropriate for the occupancy. Discovering deficiencies in

the plan should be encouraged, and every opportunity should be taken to improve the plans (see also commentary, Section 404.2.3.2).

## SECTION 407 HAZARD COMMUNICATION

**407.1 General.** The provisions of Sections 407.2 through 407.7 shall be applicable where hazardous materials subject to permits under Section 5001.5 are located on the premises or where required by the *fire code official*.

❖ This section is specific to buildings and facilities that contain hazardous materials over the permitted amounts listed in Section 105.6. Knowledge related to which hazardous materials are on site is critical for several reasons. First, it assists emergency responders in knowing what to expect when responding to a scene. Second, it provides emergency responders with an idea of incidents that may occur at a building or facility. Lastly, it provides a better understanding to the occupants of the potential hazards present and how to avoid emergencies.

Facilities that store, use or handle hazardous materials on a large scale generally depend heavily on the actions of the employees to prevent or minimize hazardous materials incidents. Therefore, the occupants play a strong role in the overall protection of the building. These types of requirements would, in the past, have been found only within the hazardous materials section of the code. These provisions have also been located within this chapter because of the nature of the information. These requirements are aimed at preparing both the occupants and the emergency responders. Hazardous materials present a wide range of problems because of the significant variation of properties and reactions; therefore, a reference to these requirements has been included in Chapter 4. These specific provisions are found in Section 5001.

This section states that when subject to permit requirements, hazardous materials must also be addressed. This section has requirements for the submittal of Material Safety Data Sheets (MSDS); the labeling or marking of hazardous materials through placarding and related identification; training; the compilation, when required, of both HMIS and HMMP; and finally, the submittal of a closure plan when a facility is being shut down.

**407.2 Material Safety Data Sheets.** Material Safety Data Sheets (MSDS) for all hazardous materials shall be either readily available on the premises as a paper copy, or where *approved*, shall be permitted to be readily retrievable by electronic access.

❖ MSDS provide critical information about individual chemicals and their related hazards. This section requires that these data sheets be readily available on the premises or, where equivalent access can be achieved, as approved by the *fire code official*, they may be retrievable by electronic means. This allows availability for review by both employees and emer-

gency responders. An appropriate location may be the security room at a facility or perhaps the main office. These sheets can potentially play a role in the response to an emergency. For example, if a chemical is noted as being water reactive on the MSDS, depending on the level of water reactivity, applying water to that spill may not be an appropriate response.

**407.3 Identification.** Individual containers of hazardous materials, cartons or packages shall be marked or labeled in accordance with applicable federal regulations. Buildings, rooms and spaces containing hazardous materials shall be identified by hazard warning signs in accordance with Section 5003.5.

❖ This section requires two activities related to the identification of hazardous materials. First, chemicals must be specifically labeled. Second, rooms or areas where the materials are located must be specifically labeled. In this case, the code essentially requires placarding as defined in Section 5003.5, which references NFPA 704.

**407.4 Training.** Persons responsible for the operation of areas in which hazardous materials are stored, dispensed, handled or used shall be familiar with the chemical nature of the materials and the appropriate mitigating actions necessary in the event of a fire, leak or spill. Responsible persons shall be designated and trained to be liaison personnel for the fire department. These persons shall aid the fire department in preplanning emergency responses and identification of where hazardous materials are located, and shall have access to Material Safety Data Sheets and be knowledgeable in the site emergency response procedures.

❖ This section requires training specific to the hazards of the materials located and used at a particular building or facility. As noted, the actions taken will vary based on the hazards associated with the materials. Additionally, this section requires a specific group of persons to be designated as points of contact for the fire department. Having specific points of contact is critical because it eases planning and response procedures. These contacts also provide the fire department with specific persons who are more familiar with the hazards of the building or facility. The fire department is charged with responding to many different businesses within a community. Having specified contacts at facilities containing hazardous materials helps them prepare and respond.

**407.5 Hazardous Materials Inventory Statement.** Where required by the *fire code official*, each application for a permit shall include a Hazardous Materials Inventory Statement (HMIS) in accordance with Section 5001.5.2.

❖ An HMIS is further described in Chapter 50 but is essentially a document listing all the hazardous materials found on site. This documentation includes information such as the type and amount of specific hazards associated with the material and how it is used. All of this information can be very important for emergency planning and preparedness. An HMIS is

## EMERGENCY PLANNING AND PREPAREDNESS

required only if the fire code official specifically requires one. See Appendix H for further information on HMIS and HMMP preparation.

**407.6 Hazardous Materials Management Plan.** Where required by the *fire code official*, each application for a permit shall include a Hazardous Materials Management Plan (HMMP) in accordance with Section 5001.5.1. The *fire code official* is authorized to accept a similar plan required by other regulations.

❖ As with the HMIS, an HMMP is necessary only when the fire code official specifically requires one. This document is somewhat different from the HMIS in that it is geared to the layout of the building and the location and use of the hazardous materials. This document provides a better understanding of how the facility operates. This information in turn provides more detailed information to the emergency responders. This plan will also include such information as the location of aisles; the type and location of emergency equipment available; and location of specific shutoff valves and other operating equipment. The detailed requirements for HMMPs are located in Chapter 50. See Appendix H for further information on HMIS and HMMP preparation.

**407.7 Facility closure plans.** The permit holder or applicant shall submit to the *fire code official* a facility closure plan in accordance with Section 5001.6.3 to terminate storage, dispensing, handling or use of hazardous materials.

❖ It is important for emergency responders to be made aware of the closure of a plant that uses or stores hazardous materials. First, closure means a readjustment in their planning. Second, the extent of the closure must be communicated so that the emergency responders are made aware of hazards that may still be present. Any hazards that are still present may potentially be more dangerous since the facility is now unattended; therefore, the building owner must develop a plan that is acceptable to the fire code official. In some cases, a facility will be only temporarily closed, which would mean maintaining a permit and continuing inspections.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Evacuation Planning Guide for Stadiums.* Washington, DC: U.S. Department of Homeland Security, 2008.

*SFPE Engineering Guide: Fire Safety for Very Tall Buildings* (ICC and SFPE 2013)

*Egress Design Solutions* (Tubbs and Meacham 2005).

## Part III—Building and Equipment Design Features

# Chapter 5: Fire Service Features

### General Comments

The requirements of this chapter apply to all occupancies and pertain to access roads; access to building openings and roofs; premises identification; key boxes; hazards to fire fighters; fire protection water supplies; fire command centers; and fire department access to equipment.

### Purpose

This chapter contains the requirements for fire service access to the property that is to be protected, including access roads, security devices and access through openings in the building.

The chapter also addresses fire-fighter hazards, the requirements for a fire department command center and fire-fighter access to equipment, such as fire suppression equipment, air-handling equipment, emergency power equipment and access to the roof. In addition, this chapter addresses the fire protection water supply.

### SECTION 501 GENERAL

**501.1 Scope.** Fire service features for buildings, structures and premises shall comply with this chapter.

❖ This chapter contains requirements that will enable the fire service to respond to an emergency on the premises of a building or structure.

**501.2 Permits.** A permit shall be required as set forth in Sections 105.6 and 105.7.

❖ Permits must be obtained from the fire code official. Permit fees, if any, must be paid prior to the issuance of the permit. There are two types of permits: operational and construction. The operational permits required by this section are for the use or operation of fire protection valves and fire hydrants (see Section 105.6.16) or the use or removal from service of a private fire hydrant (see Section 105.6.37). The construction permit (see Section 105.7.13) allows the applicant to install or modify private fire hydrants. See Section 105 for additional information on permits.

**501.3 Construction documents.** *Construction documents* for proposed fire apparatus access, location of *fire lanes*, security gates across fire apparatus access roads and *construction documents* and hydraulic calculations for fire hydrant systems shall be submitted to the fire department for review and approval prior to construction.

❖ The integrity of the design of fire apparatus access roads and private fire hydrant systems is critical to successful fire department operations in protecting

lives and property. Construction documents must be drawn to scale and clearly show the details of the indicated features in order for the fire department to properly evaluate fire service features and issue approvals. While this section is primarily for new installations, if a security gate was not on the original construction plans for fire apparatus access, this section reinforces that a security gate installed at a later time requires a construction plan to be submitted and approved prior to construction.

**501.4 Timing of installation.** Where fire apparatus access roads or a water supply for fire protection are required to be installed, such protection shall be installed and made serviceable prior to and during the time of construction except when *approved* alternative methods of protection are provided. Temporary street signs shall be installed at each street intersection where construction of new roadways allows passage by vehicles in accordance with Section 505.2.

❖ Buildings under construction are quite vulnerable to fire and other types of construction incidents, such as injuries from falling objects. Access roads and water for fire protection are essential for fire-fighting purposes. Temporary street signs are also valuable to emergency responders because the streets in new developments will most likely not be familiar to them or be on their maps.

Marked access roads and an emergency water supply should be in place before any large amount of combustible building materials is placed on site and before any construction is initiated.

**SECTION 502  
DEFINITIONS**

**502.1 Definitions.** The following terms are defined in Chapter 2:

**AGENCY.**

**FIRE APPARATUS ACCESS ROAD.**

**FIRE COMMAND CENTER.**

**FIRE DEPARTMENT MASTER KEY.**

**FIRE LANE.**

**KEY BOX.**

**TRAFFIC CALMING DEVICES.**

❖ Definitions of terms can help in the understanding and application of code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2, or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (also see the commentary to Sections 201 through 201.4).

**SECTION 503  
FIRE APPARATUS ACCESS ROADS**

**503.1 Where required.** Fire apparatus access roads shall be provided and maintained in accordance with Sections 503.1.1 through 503.1.3.

❖ This section introduces the requirements for dedicated fire apparatus access roads serving new and relocated buildings in the jurisdiction. The requirements are to be established in coordination with the local fire service to accommodate the jurisdiction's fire apparatus and equipment. The intent of the requirements is to provide the fire department with sufficient access to buildings to enable efficient fire suppression and rescue operations.

**503.1.1 Buildings and facilities.** *Approved* fire apparatus access roads shall be provided for every facility, building or portion of a building hereafter constructed or moved into or within the jurisdiction. The fire apparatus access road shall comply with the requirements of this section and shall extend to within 150 feet (45 720 mm) of all portions of the facility and all portions of the *exterior walls* of the first story of the building as measured by an *approved* route around the exterior of the building or facility.

**Exceptions:**

1. The *fire code official* is authorized to increase the dimension of 150 feet (45 720 mm) where any of the following conditions occur:
  - 1.1. The building is equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, 903.3.1.2 or 903.3.1.3.
  - 1.2. Fire apparatus access roads cannot be installed because of location on property,

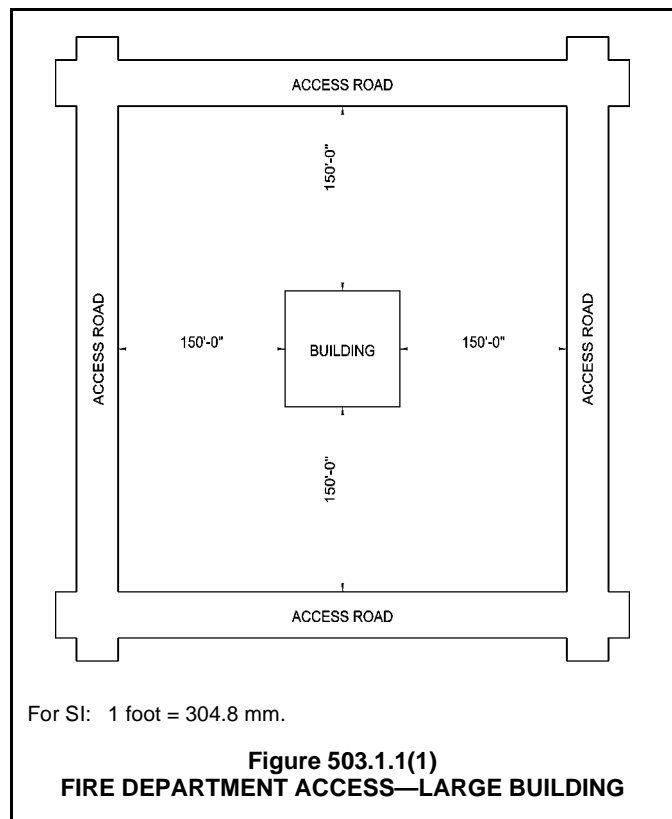

topography, waterways, nonnegotiable grades or other similar conditions, and an *approved* alternative means of fire protection is provided.

1.3. There are not more than two Group R-3 or Group U occupancies.

2. Where approved by the *fire code official*, fire apparatus access roads shall be permitted to be exempted or modified for solar photovoltaic power generation facilities.

❖ This section establishes a requirement for a fire apparatus access road and the maximum distance from buildings or facilities to fire apparatus access roads. The provisions are intended to limit the maximum length of hose needed to reach any point along the exterior of a building or facility from a fire department vehicle. Large-area buildings may require a fire apparatus access road on all four sides. An access road is required to extend to within 150 feet (45 720 mm) of all portions along the exterior wall of the grade level story of each new or relocated building [see Commentary Figure 503.1.1(1)]. The 150-foot (45 720 mm) distance is based on the standard length of preconnected hoses carried on fire apparatus and is not intended to be measured to any point within the building.

A long, narrow building may require fire department access roads on two sides only, if all portions of the exterior of the grade level story are within 150 feet (45 720 mm) of the access road [see Commentary Figure 503.1.1(2)].

Small buildings may require an access road on one side only, if the access road is within 150 feet (45 720 mm) of all portions of the grade level floor [see Commentary Figure 503.1.1(3)].

In a case where new construction creates an addition (“...portion of a building hereafter constructed...”) to an existing building, the new building as completed should be evaluated as it relates to compliance with this section because the new addition increases the fuel load and potential fire-fighting complications. An addition to a building may require the construction of a new fire apparatus access road or the reconfiguration of an existing fire apparatus access road. This is consistent with the prescriptive compliance method provisions of Section 402.1 of the *International Existing Building Code*® (IEBC®) [formerly Section 3403.1 of the *International Building Code*® (IBC®)] which require that the “...existing building together with the addition are no less conforming...than the existing building...was prior to the addition.” This is also consistent with Section 1101.2 of the IEBC, which states, “An addition shall not create or extend any nonconformity in the existing building to which the addition is being made with regard to fire safety, means of egress, or the capacity of mechanical, plumbing, or electrical systems.” In other words, an existing, non-conforming condition should not be made more non-conforming by construction of the addition. Note also that, since an addition is an increase in the area or height of an existing building, when a new building is erected immediately adjacent to an existing building, and they are separated by a fire wall constructed in accordance with Section 706 of the IBC, they are considered a separate building, not an addition to the existing structure. In that scenario, only the new building would be subject to this section. In any event, each case must be evaluated independently, especially if site topography or other conditions can slow or limit the response.

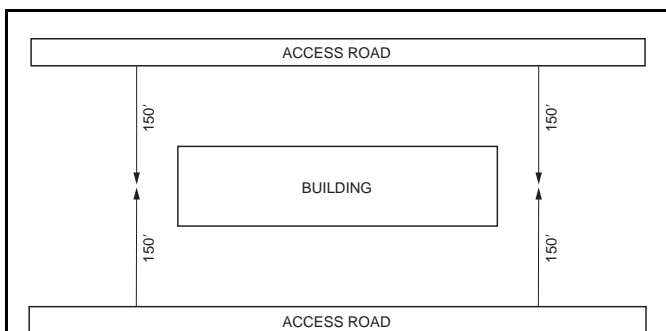

Condition 1.1 of Exception 1 states that the 150-foot (45 720 mm) distance may be increased, with the approval of the fire code official, when the building is

equipped throughout with an NFPA 13, 13R or 13D automatic sprinkler system, as applicable. The code does not give the fire code official guidance on how much of an increase over 150 feet (45 720 mm) is reasonable. The fire code official must make the determination based on the response capabilities of his or her emergency response units and the anticipated magnitude of the incident.

The “alternative means” in Condition 1.2 of Exception 1 may include standpipes, automatic sprinklers, remote fire department connections or additional fire hydrants.

The Group R-3 facilities noted in Condition 1.3 of Exception 1 include one- and two-family dwellings and townhouses not falling within the scope of the *International Residential Code*® (IRC®); care facilities that accommodate five or fewer people; and congregate living facilities (nontransient) with 16 or fewer persons or congregate living facilities (transient) with 10 or fewer persons, among others. Group U occupancies are utility and miscellaneous accessory buildings or structures. Note that, since Section 903.2.8.1 requires that Group R-3 buildings be equipped throughout with automatic sprinkler systems, this condition is redundant with Condition 1.1. Note also that there is no exception for nonsprinklered buildings built under the IRC. See “Occupancy Classification” for the definitions of “Residential Group R” and “Miscellaneous Group U” in Section 202; the IRC Commentary, Section R101.2; and the IBC Commentary, Section 310.1.

Exception 2 addresses photovoltaic panel system/array power generation facilities and provides guid-

For SI: 1 foot = 304.8 mm.

**Figure 503.1.1(2)**  
**FIRE DEPARTMENT ACCESS ON TWO SIDES**

For SI: 1 foot = 304.8 mm.

**Figure 503.1.1(3)**  
**SMALL BUILDING ACCESS**

ance to jurisdictions in determining if a fire apparatus road is needed for hazard mitigation or if it can be exempted. Consideration must be given to the purpose of fire apparatus access roads within these facilities and how the provisions would be applied. Several issues arise when applying Section 503 of the code to ground-mounted photovoltaic systems/arrays. When considering the issues listed below, the fire code official should also consider other available code requirements that provide for appropriate hazard mitigation and risk reduction. Issues for consideration include:

1. Risk/hazard to be mitigated.
2. Risk/hazard to fire fighters or other emergency responders.
3. Interest of public safety and welfare.
4. Economics.
5. Intended access use.
6. Fuel load of the facility and adjacent areas that impact the facility.
7. Array configuration (tightly spaced, access aisles, height).
8. Actual hazard to public safety and welfare.

A question that often arises is whether code requirements pertaining to fire apparatus access roads are intended to be applicable to residential development sites upon which buildings are constructed under the provisions of the IRC. For information on this topic, see the commentary to Section 102.5.

Another question that arises is whether this section is intended to preclude locating a new building directly on a lot line, often referred to as a “zero lot line building.” While it is true that some very large area buildings may require a fire apparatus access road on all four sides, this section does not specifically deal with exterior walls that may be located on the lot line in such buildings where the distance to a portion of that wall exceeds 150 feet (45 720 mm) from a fire apparatus access road. As such, the fire code official must determine the code’s application in accordance with Section 102.9 and in consideration of the exception to this section.

In determining the application, however, it should be considered that, in order for the fire department access contemplated by this section to be effective, an exterior wall would need to have openings in it through which access to the interior of the building could be achieved by hose streams or personnel. In the case of an exterior wall constructed on a property line with a zero-foot fire separation distance, Table 602 of the IBC requires that such walls have a fire-resistance rating of between 1 and 3 hours (depending on the occupancy group assigned to the building) and IBC Section and Table 705.8 require that such walls be without any openings. As such, access to the first (or any) floor level of that exterior wall would appear to provide little or no tactical usefulness to the fire department, especially if code-

complying access is provided to other sides of the building.

**503.1.2 Additional access.** The *fire code official* is authorized to require more than one fire apparatus access road based on the potential for impairment of a single road by vehicle congestion, condition of terrain, climatic conditions or other factors that could limit access.

❖ Additional access roads may be required by the fire code official based on his or her knowledge of traffic patterns, local weather conditions, terrain or the anticipated magnitude of a potential incident.

**503.1.3 High-piled storage.** Fire department vehicle access to buildings used for *high-piled combustible storage* shall comply with the applicable provisions of Chapter 32.

❖ Chapter 32 has special requirements for building access in occupancies with high-piled storage, but the requirements for fire apparatus access roads are the same as those required in this chapter.

**503.2 Specifications.** Fire apparatus access roads shall be installed and arranged in accordance with Sections 503.2.1 through 503.2.8.

❖ The dimensions of fire department access roads are based on the size, height and turning radius of emergency vehicles and the fact that emergency vehicles may be required to pass each other on the access road.

**503.2.1 Dimensions.** Fire apparatus access roads shall have an unobstructed width of not less than 20 feet (6096 mm), exclusive of shoulders, except for *approved* security gates in accordance with Section 503.6, and an unobstructed vertical clearance of not less than 13 feet 6 inches (4115 mm).

❖ The dimensions in this section are established to give fire apparatus continuous and unobstructed access to buildings and facilities.

This section requires that the unobstructed width of a fire apparatus access road must not be less than 20 feet (6096 mm). The intent of the minimum 20-foot (6096 mm) width is to provide space for fire apparatus to pass one another during fire-ground operations. The need to pass may occur when engines are parked for hydrant hook-up, laying hose or when trucks are performing aerial ladder operations. When an engine company is connected to a fire hydrant parallel to the curb using a front suction connection and using a side-discharge port on the pump, the horizontal distance that is needed to make a no-kink bend in the discharge fire hose can be considerable, especially when a large-diameter hose (LDH) is being used. The roadway width needed to accommodate such a common operational scenario would be the width of the apparatus plus the no-kink bending radius of the discharge hose, leaving minimal roadway width for other apparatus to squeeze by, if needed. Including adjacent road shoulders in the 20-foot (6096 mm) width measurement could yield sub-standard and inadequate driving surfaces for appa-

tus and, as such, shoulders are not to be included in the minimum width.

The minimum vertical clearance of 13 feet, 6 inches (4115 mm) is the standard clearance used for highway bridges and underpasses. The vertical clearance requirement would apply in cases where a building or portion of a building, such as a canopy or porte-cochere, projects over all or a portion of the required width of the fire apparatus access road. Conversely, if the full required width of the fire apparatus access road is provided outside of the footprint of the projecting building element, the vertical clearance requirement would not apply. It is not the intent of this section that all projecting elements be constructed with a 13-foot, 6-inch (4115 mm) vertical clearance, regardless of whether they encroach upon the required width of a fire apparatus access road. Appendix D contains additional guidance on fire apparatus access road dimensions. It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code).

**503.2.2 Authority.** The *fire code official* shall have the authority to require or permit modifications to the required access widths where they are inadequate for fire or rescue operations or where necessary to meet the public safety objectives of the jurisdiction.

❖ Fire departments respond to many types of emergency situations and the jurisdictions they serve may have traffic safety criteria that impact the design of access roadways used by emergency response vehicles. This section authorizes the fire code official to require greater, or to allow lesser, access-width dimensions based on the size and maneuverability of the anticipated emergency response apparatus, including mutual-aid apparatus from neighboring communities or agencies, among other considerations.

**503.2.3 Surface.** Fire apparatus access roads shall be designed and maintained to support the imposed loads of fire apparatus and shall be surfaced so as to provide all-weather driving capabilities.

❖ This provision does not specify a particular type of surface. It is written in performance language; therefore, the surface must carry the load of the anticipated emergency response vehicles and be driveable in all kinds of weather.

The term “all-weather driving capabilities” would typically require some type of paved or hard surface. Gravel would be prone to problems in areas subject to heavy rain or in snowy climates where plowing could reduce the gravel roadbed to mud very quickly. Alternatives to concrete or asphalt, such as interlocking pavers, may be used when approved by the fire code official. Jurisdictions may benefit from developing a local policy outlining specific design require-

ments for fire apparatus access roads to clarify local interpretations of the section. The policy should include local requirements for surfacing and include acceptable surfacing materials.

**503.2.4 Turning radius.** The required turning radius of a fire apparatus access road shall be determined by the *fire code official*.

❖ The turning radius of an access road should be based on the turning radius of the anticipated responding emergency vehicles and must be approved by the fire code official.

**503.2.5 Dead ends.** Dead-end fire apparatus access roads in excess of 150 feet (45 720 mm) in length shall be provided with an *approved* area for turning around fire apparatus.

❖ In consideration of the hazards inherent in attempting to back emergency vehicles, especially larger ones such as tower ladders, out of a long dead-end roadway, this section is intended to create a safer situation by requiring that dead-end access roads over 150 feet long (45 720 mm) be equipped with an approved turnaround designed for the largest anticipated emergency-response vehicles. Appendix D contains examples of dead-end turnaround configurations. It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code).

**503.2.6 Bridges and elevated surfaces.** Where a bridge or an elevated surface is part of a fire apparatus access road, the bridge shall be constructed and maintained in accordance with AASHTO HB-17. Bridges and elevated surfaces shall be designed for a live load sufficient to carry the imposed loads of fire apparatus. Vehicle load limits shall be posted at both entrances to bridges where required by the *fire code official*. Where elevated surfaces designed for emergency vehicle use are adjacent to surfaces that are not designed for such use, *approved* barriers, *approved* signs or both shall be installed and maintained where required by the *fire code official*.

❖ Bridges and elevated surfaces must be capable of carrying the weight of emergency response apparatus and must be marked with signage posting the weight limit of the bridge or elevated surface. Evaluation of bridges should be done in cooperation with the appropriate local or state agency having jurisdiction over private or public roadway bridges.

**503.2.7 Grade.** The grade of the fire apparatus access road shall be within the limits established by the *fire code official* based on the fire department’s apparatus.

❖ Generally, any grade exceeding 10 percent [e.g., greater than a 10-foot (3048 mm) rise in a 100-foot (30 480 mm) length] is required to have the approval of the fire code official. See Appendix D for additional guidance on fire apparatus access roads. Note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code).

**503.2.8 Angles of approach and departure.** The angles of approach and departure for fire apparatus access roads shall be within the limits established by the *fire code official* based on the fire department’s apparatus.

❖ The angle of approach is the angle between the ground and a line running from the bottom of the front tire to the lowest-hanging point directly in front of it, which is usually the front bumper of the apparatus. This angle gives an indication of how steep an incline the vehicle can clear when approaching that angle.

The angle of departure is the angle between the ground and a line running from the bottom of the rear tire to the lowest-hanging point directly behind it, which is usually the rear step/tailboard of the apparatus. Similar to the approach angle, this angle indicates how steep an incline the vehicle can clear when departing from that angle.

These design aspects of a fire apparatus access road are crucial to successful navigation by apparatus and must be tailored to accommodate each piece of fire apparatus of the jurisdiction. See Commentary Figure 503.2.8.

**503.3 Marking.** Where required by the *fire code official*, approved signs or other approved notices or markings that include the words NO PARKING—FIRE LANE shall be provided for fire apparatus access roads to identify such roads or prohibit the obstruction thereof. The means by which *fire lanes* are designated shall be maintained in a clean and legible condition at all times and be replaced or repaired when necessary to provide adequate visibility.

❖ Fire department access roads are normally designated on private property to provide fire service access; therefore, maintenance of the access roads, signage and any supplementary markings (pavement marking, curbs markings, etc.) are the responsibility of the owner of the property on which the fire apparatus road is located. Signage and supplemental markings should be in accordance with applicable local or state motor vehicle laws and should be enforced with the cooperation of the local police agency. Appendix D contains examples of signage. It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code.

**503.4 Obstruction of fire apparatus access roads.** Fire apparatus access roads shall not be obstructed in any manner, including the parking of vehicles. The minimum widths and clearances established in Sections 503.2.1 and 503.2.2 shall be maintained at all times.

❖ To enforce “no parking” in fire apparatus access roads (fire lanes), the roads must be clearly marked. Some jurisdictions cite the building owner if the fire apparatus road is not properly marked and posted, and cite the vehicle for parking or blocking the access road if the access road is clearly marked. Other jurisdictions place the responsibility for marking the access roads, as well as the policing of “no parking” zones, on the building owner. In some states, motor vehicle laws may stipulate that fire apparatus access roads/fire lanes posted on private property may only be enforced by a traffic citation where an enforcement contract has been executed between the property owner and the local jurisdiction, that all markings be in accordance with the motor vehicle code and that the designated roadways be described in detail in the local “no parking” ordinances of the jurisdiction.

**503.4.1. Traffic calming devices.** Traffic calming devices shall be prohibited unless approved by the *fire code official*.

❖ This section prohibits the installation of traffic calming devices on fire apparatus access roads unless the devices are approved by the fire code official. What it doesn’t do is detail how that approval is to be made within various jurisdictions. Each jurisdiction has its own traffic pattern emergency response challenges. The purpose of this requirement is to ensure that the fire department is part of this decision-making process. In most jurisdictions, the design and construction or review and approval of traffic calming devices is the responsibility of the municipal public works, transportation or engineering department. As a result, the fire code official and the appropriate engineering staff will need to work closely with one another to ensure that traffic calming devices, when approved, not only meet traffic engineering needs but also have the least impact on response time to emergencies. Traffic officials and fire code officials both have the responsibility to ensure that all public interests are properly considered in their decision-making process since both sets of officials have detailed regulations

**Figure 503.2.8**  
**EXAMPLE OF ANGLES OF APPROACH AND DEPARTURE**

to provide for those interests. See the commentary to the Section 202 definition of “Traffic calming device” for further discussion.

**503.5 Required gates or barricades.** The *fire code official* is authorized to require the installation and maintenance of gates or other *approved* barricades across fire apparatus access roads, trails or other accessways, not including public streets, alleys or highways. Electric gate operators, where provided, shall be *listed* in accordance with UL 325. Gates intended for automatic operation shall be designed, constructed and installed to comply with the requirements of ASTM F2200.

❖ The fire code official may require the installation and maintenance of gates or barricades across fire apparatus roads to prevent unauthorized vehicles from blocking or parking in the access road. The design and dimensions of the gates or barricades must be approved by the fire code official. Additionally, the gate or barricade must be operable or removable by the responding emergency units to provide them with quick access.

This section also addresses an important public safety issue regarding automatic operation of vehicular gates. Protection is needed from potential entrapment of individuals between an automatically moving gate and a stationary object or surface in close proximity to such gate. Gates intended for automation require specific design, construction and installation to accommodate entrapment protection to minimize or eliminate excessive gate gaps, openings and protrusions identified as contributing to the hazard of entrapments that have historically caused numerous serious injuries and deaths.

This section references two appropriate standards that deal with automatic gate safety: UL 325 and ASTM F2200. UL 325 is an ANSI-recognized safety standard containing provisions governing gate openers. Gate openers listed to the requirements of UL 325 provide an improved level of assurance that safety requirements have been met for such openers. ASTM F2200 is a consensus document containing provisions governing the construction of vehicular gates intended for automation, and has been harmonized with the applicable provisions of UL 325.

**503.5.1 Secured gates and barricades.** Where required, gates and barricades shall be secured in an *approved* manner. Roads, trails and other accessways that have been closed and obstructed in the manner prescribed by Section 503.5 shall not be trespassed on or used unless authorized by the *owner* and the *fire code official*.

**Exception:** The restriction on use shall not apply to public officers acting within the scope of duty.

❖ The owner may secure the fire apparatus access road and restrict its use to emergency vehicles only, if warranted. If there is a need to secure gates or barricades, jurisdictions may require a padlock or key switch (on electrically operated gates) designed for the same key as key boxes provided in accordance

with Section 506. Occasionally, electronically operated gates are required to be provided with a backup mechanism or breakaway feature in case the primary operating means fails.

The exception makes it clear that the securing of fire apparatus access roads is not intended to impede the legitimate and necessary use of the road by duly authorized public officers, such as police officers or other municipal personnel.

**503.6 Security gates.** The installation of security gates across a fire apparatus access road shall be *approved* by the fire chief. Where security gates are installed, they shall have an *approved* means of emergency operation. The security gates and the emergency operation shall be maintained operational at all times. Electric gate operators, where provided, shall be *listed* in accordance with UL 325. Gates intended for automatic operation shall be designed, constructed and installed to comply with the requirements of ASTM F2200.

❖ This section does not require that security gates be installed, but since they can affect fire department operations, their installation must be approved by the fire chief. Where installed, security gates must be operable in an emergency by the emergency response units and the means of operation must be acceptable to the fire chief. Electrically operated gates should also include a manual method of operation (also see commentary, Section 503.5.1).

This section requires ongoing maintenance of security gates so that ready access to the roadway may be accomplished. If gates are not maintained in a manner that prevents appreciable delay of emergency response, the fire code official has the authority to have gates removed because they would be considered an obstruction of the required roadway width as regulated in Section 503.4.

This section also addresses an important public safety issue regarding automatic operation of vehicular gates. Protection is needed from potential entrapment of individuals between an automatically moving gate and a stationary object or surface in close proximity to such gate. Gates intended for automation require specific design, construction and installation to accommodate entrapment protection to minimize or eliminate excessive gate gaps, openings and protrusions identified as contributing to the hazard of entrapments that have historically caused numerous serious injuries and deaths.

This section references two appropriate standards that deal with automatic gate safety: UL 325 and ASTM F2200. UL 325 is an ANSI-recognized safety standard containing provisions governing gate openers. Gate openers listed to the requirements of UL 325 provide an improved level of assurance that safety requirements have been met for such openers. ASTM F2200 is a consensus document containing provisions governing the construction of vehicular gates intended for automation, and has been harmonized with the applicable provisions of UL 325.

## SECTION 504 ACCESS TO BUILDING OPENINGS AND ROOFS

**504.1 Required access.** Exterior doors and openings required by this code or the *International Building Code* shall be maintained readily accessible for emergency access by the fire department. An *approved* access walkway leading from fire apparatus access roads to exterior openings shall be provided when required by the *fire code official*.

❖ The exterior openings referred to in this section are typically exit discharge doors, since such openings provide fire department access directly into the building or to a fire-resistance-rated enclosure from which to operate in multiple-story buildings. This section also includes access openings for rack or high-piled storage buildings required by Section 3206.6. Under certain circumstances, in order for emergency response personnel to get equipment from the emergency apparatus to the building, the fire code official is authorized to require approved walkways from the apparatus access road to the building openings on grade level.

**504.2 Maintenance of exterior doors and openings.** Exterior doors and their function shall not be eliminated without prior approval. Exterior doors that have been rendered non-functional and that retain a functional door exterior appearance shall have a sign affixed to the exterior side of the door with the words THIS DOOR BLOCKED. The sign shall consist of letters having a principal stroke of not less than  $\frac{3}{4}$  inch (19.1 mm) wide and not less than 6 inches (152 mm) high on a contrasting background. Required fire department access doors shall not be obstructed or eliminated. Exit and *exit access* doors shall comply with Chapter 10. Access doors for *high-piled combustible storage* shall comply with Section 3206.6.1.

❖ This section pertains to emergency access openings and to all exterior doors that have a functional appearance from the outside but are not operable. Doors that are part of the required means of egress or that are required by Section 3206.6 must not be rendered unusable or blocked. Only doors not required by the code or the IBC for means of egress may be blocked or made unusable. Even then, they must be marked from the outside so that emergency personnel will not attempt to use them.

**504.3 Stairway access to roof.** New buildings four or more stories above grade plane, except those with a roof slope greater than four units vertical in 12 units horizontal (33.3-percent slope), shall be provided with a *stairway* to the roof. *Stairway* access to the roof shall be in accordance with Section 1011.12. Such *stairway* shall be marked at street and floor levels with a sign indicating that the *stairway* continues to the roof. Where roofs are used for roof gardens or for other purposes, *stairways* shall be provided as required for such occupancy classification.

❖ The stairway to the roof, required by this section, must comply with Sections 1011.12 through 1011.12.2. If the stairway to the roof serves as a

means of egress from an occupied roof, then the stairway must be equipped with all the components of an exit stairway, such as the required riser and tread dimensions, handrails, etc. If the stairway to the roof is not required for roof egress, Section 1011.14 allows the stairway segment from the top floor to the roof to be an alternating tread device. The access to the roof is required for fire-fighter use and not the general public; therefore, the door leading to the roof may be secured in a manner approved by the fire code official with due consideration given to whether the door is an egress element for the roof. These provisions apply only to new buildings four or more stories in height (see commentary, Sections 1011.12 and 1023.9).

## SECTION 505 PREMISES IDENTIFICATION

**505.1 Address identification.** New and existing buildings shall be provided with *approved* address identification. The address identification shall be legible and placed in a position that is visible from the street or road fronting the property. Address identification characters shall contrast with their background. Address numbers shall be Arabic numbers or alphabetical letters. Numbers shall not be spelled out. Each character shall be not less than 4 inches (102 mm) high with a minimum stroke width of  $\frac{1}{2}$  inch (12.7 mm). Where required by the *fire code official*, address identification shall be provided in additional *approved* locations to facilitate emergency response. Where access is by means of a private road and the building cannot be viewed from the *public way*, a monument, pole or other sign or means shall be used to identify the structure. Address identification shall be maintained.

❖ Buildings must be provided and maintained with address identification that is easily identifiable by emergency responders from the emergency response vehicle. This should include the backs of buildings that face alleys or roads, since the emergency response unit may often be directed to the back entrance to a building, such as in a strip shopping center. The back door of each tenant space should have the numerical address and store name on or above the door.

This section also provides the fire code official with the authority to require additional address locations for facilities with unusual or problematic configurations, such as college or hospital campuses, strip malls, business parks, apartment complexes and other complex properties where identification of buildings is essential to emergency responders. The additional requirements proposed by the added language will assist various emergency responders in identifying specific addresses when an emergency response from locations other than the primary access point is required.

There are also situations where a building's setback from the street is so large that the building itself may not even be visible to emergency responders. In

such circumstances, this section requires that the road or driveway giving access to the building be marked to assist emergency responders in promptly identifying their access. It is important that such remote markings be reviewed and approved by the fire code official prior to installation.

**505.2 Street or road signs.** Streets and roads shall be identified with *approved* signs. Temporary signs shall be installed at each street intersection when construction of new roadways allows passage by vehicles. Signs shall be of an *approved* size, weather resistant and be maintained until replaced by permanent signs.

❖ The names of streets in new developments may not be on maps, making them hard for emergency responders to find. Temporary street signs must be installed before construction begins and replaced later with permanent signs.

**SECTION 506  
KEY BOXES**

**506.1 Where required.** Where access to or within a structure or an area is restricted because of secured openings or where immediate access is necessary for life-saving or fire-fighting purposes, the *fire code official* is authorized to require a key box to be installed in an *approved* location. The key box shall be of an *approved* type listed in accordance with UL 1037, and shall contain keys to gain necessary access as required by the *fire code official*.

❖ The fire code official has the authority to require special key vaults when, in his or her opinion, the need for rapid entry into facilities warrants it. The key boxes or vaults are located on the exterior of the building for ready access, and are openable with a special master key in the possession of the emergency responders. See Commentary Figures 506.1(1) and 506.1(2) and the commentary to the definitions of “Key box” and “Fire department master key” in Section 202.

The section also specifies a level of security for key boxes. Where a rapid-entry key box is required, there is an obligation to make sure that the key box required or approved by the fire code official is secure to prevent the key box from becoming a security threat. This section addresses the issue of security by requiring an approved key box to be listed in accordance with UL 1037. The major key box manufacturers have their rapid entry devices listed under this standard.

Section 506.1 is a discretionary provision based on the jurisdiction’s determination that the use of a key box is safer for fire fighters than performing manual forcible entry into a structure. If properly maintained in accordance with Section 506.2, a key box can also lower property losses because it expedites the entry of fire fighters into a structure without necessitating the damage associated with forcing entry. The decision for the use of key boxes rests solely with the fire code official.

**506.1.1 Locks.** An *approved* lock shall be installed on gates or similar barriers where required by the *fire code official*.

❖ The key box suppliers also have special padlocks and electronic key-operated switches that are controlled by the same fire department master key that opens the key vaults. These padlocks can be required by the fire code official for security gates (also see commentary, Sections 503.5, 503.5.1 and 503.6). The key-activated electronic switches may also be required for the control of certain equipment in the building, such as smoke control equipment, or to shut down a dangerous process.

**Figure 506.1(1)  
SURFACE-MOUNTED KEY BOX  
(Photo courtesy of Knox Company)**

**Figure 506.1(2)  
RECESSED-MOUNTED KEY BOX  
(Photo courtesy of Knox Company)**

**506.1.2 Key boxes for nonstandardized fire service elevator keys.** Key boxes provided for nonstandardized fire service elevator keys shall comply with Section 506.1 and all of the following:

1. The key box shall be compatible with an existing rapid entry key box system in use in the jurisdiction and *approved* by the *fire code official*.
2. The front cover shall be permanently labeled with the words “Fire Department Use Only—Elevator Keys.”
3. The key box shall be mounted at each elevator bank at the lobby nearest to the lowest level of fire department access.
4. The key box shall be mounted 5 feet 6 inches (1676 mm) above the finished floor to the right side of the elevator bank.
5. Contents of the key box are limited to fire service elevator keys. Additional elevator access tools, keys and information pertinent to emergency planning or elevator access shall be permitted where authorized by the *fire code official*.
6. In buildings with two or more elevator banks, a single key box shall be permitted to be used where such elevator banks are separated by not more than 30 feet (9144 mm). Additional key boxes shall be provided for each individual elevator or elevator bank separated by more than 30 feet (9144 mm).

**Exception:** A single key box shall be permitted to be located adjacent to a *fire command center* or the non-standard fire service elevator key shall be permitted to be secured in a key box used for other purposes and located in accordance with Section 506.1.

❖ Many jurisdictions have elevators built prior to the introduction of a standardized elevator key and, as a result, each building with an elevator requires its own elevator key. The key is most likely to be based on the model of the elevator and the year it was manufactured. This section sets forth requirements to assist jurisdictions in managing the issue of having different elevator keys in different buildings. These provisions specify where the key box is to be located inside the building and require it to be compatible with the rapid-entry existing key boxes that may already be in use in the jurisdiction. The exception allows key box installation adjacent to a fire command center or in other locations where approved by the fire code official. See the commentary to Sections 607.8 through 607.8.4 for a discussion of standardized fire service elevator keys.

**506.2 Key box maintenance.** The operator of the building shall immediately notify the *fire code official* and provide the new key where a lock is changed or rekeyed. The key to such lock shall be secured in the key box.

❖ In most cases, the owner of a building cannot open the key vault or box and must call the fire code official

to have someone open it to replace keys that have been changed. The building owner is responsible for maintaining the key box, as well as keeping the keys inside the box current.

## SECTION 507 FIRE PROTECTION WATER SUPPLIES

**507.1 Required water supply.** An *approved* water supply capable of supplying the required fire flow for fire protection shall be provided to premises upon which facilities, buildings or portions of buildings are hereafter constructed or moved into or within the jurisdiction.

❖ This section requires that adequate fire protection water be provided to premises upon which new buildings are constructed or onto which a building is moved, from either outside of the jurisdiction or another location within the jurisdiction. Note that this section states that the water supply must be capable of supplying the required fire flow to the premises; however, the means by which the fire flow is supplied is determined by the policies of the jurisdiction, such as a pumper taking suction from a hydrant, tanker or lake (also see Appendices B and C for further information on fire flows and fire hydrants). It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code). The phrase “... hereafter constructed or moved ...” used in this section (and in Appendices B and C, if duly adopted) limits the application of water supply provisions to only newly erected or relocated buildings, as opposed to existing buildings or existing remodeled buildings.

A question that often arises is whether the code’s regulations pertaining to fire protection water supply are intended to be applicable to one- and two-family residential development sites upon which buildings are constructed under the provisions of the IRC. The IRC is intended to be a stand-alone code for the construction of detached one- and two-family dwellings and townhouses not more than three stories in height. As such, all of the provisions for the construction of buildings of those descriptions are to be regulated exclusively by the IRC and not by another I-Code. However, the IRC applies only to the construction of the structures of those buildings and not to the development of the site upon which such structures are built. Accordingly, where the code is adopted, its fire protection water supply provisions (including specifically adopted related appendices) apply. The code’s requirements address only land development requirements for providing fire protection water supply to residential sites on the same basis as to the rest of the community (also see commentary, Sections 102.5 and 503.1.1).

**507.2 Type of water supply.** A water supply shall consist of reservoirs, pressure tanks, elevated tanks, water mains or

other fixed systems capable of providing the required fire flow.

- ❖ A good water supply consists of an adequate source of water, distribution system and proper pressure for delivery. If the water source is not reliable, it should not be considered as an acceptable water supply.

**507.2.1 Private fire service mains.** Private fire service mains and appurtenances shall be installed in accordance with NFPA 24.

- ❖ Private fire service mains are often installed on private property where facilities are located well away from municipal water distribution systems. Private hydrants may not be installed on mains less than 6 inches (152 mm) in diameter (see Section 5.2.1 of NFPA 24). Where installed, private fire service mains, private hydrants, control valves, hose houses and related equipment must be installed and maintained in accordance with NFPA 24. Private (yard) hydrants may be tested, painted and marked in accordance with NFPA 291 where approved by the fire code official and the fire department.

**507.2.2 Water tanks.** Water tanks for private fire protection shall be installed in accordance with NFPA 22.

- ❖ Water tanks for private fire protection may be required where municipal water systems do not exist or are incapable of supplying sprinkler or standpipe demand, or where Section 403.2 of the IBC or Section 903.3.5.2 of the code requires a secondary water supply for high-rise buildings in Seismic Design Category C, D, E or F. NFPA 22 and Section 1509.3 of the IBC govern the installation of water tanks on buildings. Pressure tanks must bear the label of an approved agency and be installed in accordance with the manufacturer's instructions.

**507.3 Fire flow.** Fire requirements for buildings or portions of buildings and facilities shall be determined by an *approved* method.

- ❖ Appendix B of the code, which sets forth minimum fire flow requirements for one- and two-family dwellings and commercial buildings, offers one method for determining fire flow and its duration that could be approved by the fire code official. In areas that do not have a water supply, such as rural areas with no conventional water storage and distribution system, the jurisdiction may choose to utilize the methods contained in NFPA 1142, *Standard on Water Supplies for Suburban and Rural Firefighting*, the *International Wildland-Urban Interface Code*® (IWUIC®), or the Insurance Services Office's *Guide for Determination of Needed Fire Flow*. Appendix Table B105.1 bases fire flow on the type of construction and the square footage of the fire flow calculation area. All calculations in the table are based on a 20-pounds-per-square-inch (psi) (138 kPa) residual pressure. Note that the provisions of Section B103 provide for increases, reductions and specific alternative methods for determining flows. In addition to Section

B103, Sections 104.8 and 104.9 also provide the fire code official with authority concerning modifications and alternative methods. See the commentary to Appendix B for discussion of the fire flow requirements. It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code).

**507.4 Water supply test.** The *fire code official* shall be notified prior to the water supply test. Water supply tests shall be witnessed by the *fire code official* or *approved* documentation of the test shall be provided to the *fire code official* prior to final approval of the water supply system.

- ❖ Whatever type of water supply is proposed in order to comply with Section 507.1, it must be tested in a manner that will verify it is capable of providing the required fire flow. The water supply system must be tested and the contractor is required to notify the fire code official prior to performing the test on the system. The fire code official will make the final approval by either witnessing the test or accepting the certification documentation. NFPA 291 contains recommended test methodology.

If the water supply system includes private fire service mains, NFPA 24, referenced in Section 507.2.1, contains the testing requirements for private fire service mains, as well as a test certificate form. It should be noted that the test certificate form has signature blocks only for the building owner's representative and the installing contractor's representative. There is no place on the form for the fire code official's signature, nor should he or she expose him or herself to liability of any kind for the installation by signing the form.

**507.5 Fire hydrant systems.** Fire hydrant systems shall comply with Sections 507.5.1 through 507.5.6.

- ❖ When fire hydrant systems are part of the approved water supply, the system must comply with this section.

**507.5.1 Where required.** Where a portion of the facility or building hereafter constructed or moved into or within the jurisdiction is more than 400 feet (122 m) from a hydrant on a fire apparatus access road, as measured by an *approved* route around the exterior of the facility or building, on-site fire hydrants and mains shall be provided where required by the *fire code official*.

**Exceptions:**

1. For Group R-3 and Group U occupancies, the distance requirement shall be 600 feet (183 m).
  2. For buildings equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, the distance requirement shall be 600 feet (183 m).
- ❖ The intent of this section is that not more than 400 feet (122 m) of hose will have to be laid out to reach all portions of the exterior grade level of the building.

**FIRE SERVICE FEATURES**

Each hydrant must be accessible to fire apparatus and the 400-foot (122 m) distance should be measured from the hydrant(s) to all portions of the exterior at ground level [see Commentary Figure 507.5.1(1)]. When on-site hydrants and mains are required to achieve compliance with the distance requirement, this section gives the fire code official the authority to determine and approve hydrant locations on the site.

This paragraph is not intended to prevent development in rural areas where fire hydrants are not available, as long as the fire code official has approved an alternative water supply. The alternative water supply could be a fire department water tanker or a static, all-weather water supply that is approved by the fire code official.

In recognition of the smaller relative size and fire hazard characteristics of one- and two-family dwellings and utility buildings, Exception 1 increases the 400-foot (122 m) distance to 600 feet (183 m) [see Commentary Figure 507.5.1(2)]. Note that the one- and two-family dwellings classified in Group R-3 are those that are not within the scope of the IRC. See Section 102.5.

In recognition of the proven efficiency of sprinklers in applying water directly on the seat of the fire for buildings equipped throughout with automatic sprinklers in accordance with NFPA 13 or NFPA 13R, as applicable, Exception 2 increases the 400-foot (122 m) distance to 600 feet (183 m) [see Commentary Figure 507.5.1(3)].

**507.5.1.1 Hydrant for standpipe systems.** Buildings equipped with a standpipe system installed in accordance

with Section 905 shall have a fire hydrant within 100 feet (30 480 mm) of the fire department connections.

**Exception:** The distance shall be permitted to exceed 100 feet (30 480 mm) where *approved by the fire code official*.

❖ This section provides correlation with NFPA 14, Section 6.4.5.4, which requires that standpipe fire depart-

ment connections be placed within 100 feet (30 m) of a fire hydrant, unless otherwise approved by the authority having jurisdiction. However, that requirement is frequently missed where site work and approval has been based only on the fire apparatus access road and fire protection water supply requirements in this chapter. With the requirement now included in this section, the code user is directed to this requirement during the site design review stage and not as an afterthought as has often happened during the building permit site plan review. The exception provides design flexibility but protects operational needs of the fire department by requiring the fire code official to approve any increase in distance between the fire department connection (FDC) and the hydrant. Note that this requirement is not applicable to sprinkler connections since NFPA 13 does not have a distance requirement to a fire hydrant for connections serving only sprinkler systems.

**507.5.2 Inspection, testing and maintenance.** Fire hydrant systems shall be subject to periodic tests as required by the *fire code official*. Fire hydrant systems shall be maintained in an operative condition at all times and shall be repaired where defective. Additions, repairs, *alterations* and servicing shall comply with *approved* standards. Records of tests and required maintenance shall be maintained.

- ❖ The fire code official has the authority to require periodic tests and to specify the frequency of such tests. The generally accepted procedure is to inspect hydrants annually for proper operation and drainage by opening and closing the hydrants and lubricating all threads. This section also requires that written inspection and maintenance records be kept. Such records should indicate the date and time and the name of the person conducting the inspection or maintenance. These records must be maintained by the owner and should be made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

**507.5.3 Private fire service mains and water tanks.** Private fire service mains and water tanks shall be periodically inspected, tested and maintained in accordance with NFPA 25 at the following intervals:

1. Private fire hydrants of all types: Inspection annually and after each operation; flow test and maintenance annually.
2. Fire service main piping: Inspection of exposed, annually; flow test every 5 years.
3. Fire service main piping strainers: Inspection and maintenance after each use.

Records of inspections, testing and maintenance shall be maintained.

- ❖ NFPA 25 is the Standard for the Inspection, Testing and Maintenance of Water-based Fire Protection Systems. Chapter 7 of that standard covers private fire service mains and Chapter 9 covers water stor-

age tanks. This section also requires that written inspection and maintenance records be kept. Such records should indicate the date and time and the name of the person conducting the inspection or maintenance. These records must be maintained by the owner and should be made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

**507.5.4 Obstruction.** Unobstructed access to fire hydrants shall be maintained at all times. The fire department shall not be deterred or hindered from gaining immediate access to fire protection equipment or fire hydrants.

- ❖ Nothing can be allowed to be placed near a fire hydrant, FDC or control valve that would prevent responding fire fighters from immediately recognizing the device and gaining access to it. Plants and shrubs on public or private property are probably the most common object that can make fire hydrants, FDCs or fire protection system valves virtually invisible to responding fire apparatus engineers. In residential areas especially, some homeowners do not like “that ugly piece of iron” (i.e., a fire hydrant) in their yard, so they plant all manner of vegetation around it in an effort to hide it—a clear violation of this section. On construction sites, fire hydrants or FDCs are often hidden from view and access by deliveries of construction materials randomly dumped at the most convenient spot on the site without regard for the need of the fire department to gain immediate access to hydrants or FDCs.

**507.5.5 Clear space around hydrants.** A 3-foot (914 mm) clear space shall be maintained around the circumference of fire hydrants, except as otherwise required or *approved*.

- ❖ Care must be taken so that fences, utility poles, barricades and other obstructions do not prevent access to and operation of fire hydrants. A clear space of 3 feet (914 mm) must be maintained around hydrants (see Commentary Figure 507.5.5) to allow easy hose connections to the hydrant and the efficient use of hydrant wrenches, spanner wrenches and other tools needed by the apparatus engineer. It is not the intent of this section to allow any of the obstructions described in Section 507.5.4 to exist as long as they are kept 3 feet (914 mm) from the hydrant, FDC or valve.

Though not specifically mentioned in this section, it is also important that hydrants be installed with the center of the outlet cap nuts at least 18 inches (457 mm) above adjoining grade to accommodate the free turning of a hydrant wrench when removing the caps (see NFPA 24, Chapter 7, for further information).

**507.5.6 Physical protection.** Where fire hydrants are subject to impact by a motor vehicle, guard posts or other *approved* means shall comply with Section 312.

- ❖ Section 312 requires vehicle impact protection by placing steel posts filled with concrete around the hydrant (see Commentary Figure 507.5.6). Section

312 gives the specifications for the posts. Note that the provisions of Section 507.5.5 apply to the installation of posts or other protective features.

**SECTION 508  
FIRE COMMAND CENTER**

**508.1 General.** Where required by other sections of this code and in all buildings classified as high-rise buildings by the *International Building Code*, a *fire command center* for fire department operations shall be provided and shall comply with Sections 508.1.1 through 508.1.6.

❖ Fire-ground operations usually involve establishing an incident command post where the incident command officer can observe what is happening; control arriving personnel and equipment; and direct the resources and fire-fighting operations effectively. Because of the difficulties in controlling a fire in a high-rise building, an adequately sized, protected,

readily accessible, separate room for this purpose within the building must be established to assist the incident command officer (see also the commentary to Section 202 for the definition of “Fire command center”).

A fire command center is also required by Section 909.16 in buildings containing smoke-protected assembly seating to house the fire fighter’s smoke control panel. Facilities with smoke-protected seating tend to be larger facilities that, at the very least, would already have a central security center that could also function as a fire command center where approved by the jurisdiction (see commentary, Section 909.16).

**508.1.1 Location and access.** The location and accessibility of the *fire command center* shall be *approved* by the fire chief.

❖ Because of its importance to fire suppression and rescue operations, the fire command center must be provided at a location that is acceptable to the fire department, usually near the front of the building near the main entrance, so that the first arriving command officer can access it quickly and undertake operations. Since fire-ground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have approval authority over the location of and access to the fire command center.

**508.1.2 Separation.** The *fire command center* shall be separated from the remainder of the building by not less than a 1-hour *fire barrier* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assembly* constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ Because of its importance to fire suppression and rescue operations, the fire command center must be separated from the remainder of the building by 1-hour fire barriers and horizontal assemblies, including opening protectives, to protect the room, its contents and occupants from an incident in adjacent areas of the building, and to limit noise and distractions during command operations within the room.

**508.1.3 Size.** The *fire command center* shall be not less than 200 square feet (19 m<sup>2</sup>) in area with a minimum dimension of 10 feet (3048 mm).

❖ This section is intended to provide a minimum size and configuration of the fire command center that allows sufficient space for the necessary command personnel to effectively perform required tasks associated with a fire command center without interfering with each other. Fire command centers must be designed to accommodate several emergency response commanders wearing full protective equipment, provide space to review building emergency plans during incidents, collocate decision-makers within the incident command system (ICS), and interpret fire protection system and building system information generated by the features required by Section 508.1.5. Given the multiple uses of the fire command

center, a room any smaller would serve to compromise the effectiveness of incident management.

**508.1.4 Layout approval.** A layout of the *fire command center* and all features required by this section to be contained therein shall be submitted for approval prior to installation.

❖ The flow of critical tactical information into, within and out of a fire command center is, by its very nature, both high in volume and intense in nature, and has a direct bearing on the safety of building occupants and emergency response personnel at work at an incident. For that reason, the layout and arrangement of the fire command center must comport with the operational procedures of the local fire department to optimize the receipt, processing and dissemination of operational information and orders. Accordingly, the fire code official must review and approve the arrangement of the fire command center prior to the installation of any of the controls and features required by Section 508.1.5. Consistent with Section 508.1.1, given the operational importance of the fire command center, the fire code official should work closely with the jurisdiction's fire chief to make sure that all operational needs are identified and met during the design stages.

**508.1.5 Storage.** Storage unrelated to operation of the *fire command center* shall be prohibited.

❖ Fire command centers are unique rooms in unique buildings and are strictly reserved for emergency management operations. As such, they must be neat and orderly at all times so as not to obstruct or limit access to all of the system controls they contain. This section supports that need by prohibiting the storage within a fire command center of anything not directly related to the function of fire command.

**508.1.6 Required features.** The *fire command center* shall comply with NFPA 72 and shall contain the following features:

1. The emergency voice/alarm communication system control unit.
2. The fire department communications system.
3. Fire detection and alarm system annunciator.
4. Annunciator unit visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air distribution systems.
6. The fire fighter's control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking *stairway* doors simultaneously.
8. Sprinkler valve and water-flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.

11. Fire pump status indicators.
12. Schematic building plans indicating the typical floor plan and detailing the building core, *means of egress*, *fire protection systems*, fire-fighter air-replenishment systems, fire-fighting equipment and fire department access, and the location of *fire walls*, *fire barriers*, *fire partitions*, *smoke barriers* and smoke partitions.
13. An *approved* Building Information Card that includes, but is not limited to, all of the following information:
  - 13.1. General building information that includes: property name, address, the number of floors in the building above and below grade, use and occupancy classification (for mixed uses, identify the different types of occupancies on each floor) and the estimated building population during the day, night and weekend;
  - 13.2. Building emergency contact information that includes: a list of the building's emergency contacts including but not limited to building manager, building engineer and their respective work phone number, cell phone number and e-mail address;
  - 13.3. Building construction information that includes: the type of building construction including but not limited to floors, walls, columns and roof assembly;
  - 13.4. *Exit access stairway* and *exit stairway* information that includes: number of *exit access stairways* and *exit stairways* in building; each *exit access stairway* and *exit stairway* designation and floors served; location where each *exit access stairway* and *exit stairway* discharges, *interior exit stairways* that are pressurized; *exit stairways* provided with emergency lighting; each *exit stairway* that allows reentry; *exit stairways* providing roof access; elevator information that includes: number of elevator banks, elevator bank designation, elevator car numbers and respective floors that they serve; location of elevator machine rooms, control rooms and control spaces; location of sky lobby; and location of freight elevator banks;
  - 13.5. Building services and system information that includes: location of mechanical rooms, location of building management system, location and capacity of all fuel oil tanks, location of emergency generator and location of natural gas service;
  - 13.6. *Fire protection system* information that includes: location of standpipes, location of fire pump room, location of fire department connections, floors protected by automatic sprinklers and location of different types of *automatic sprinkler systems* installed including but not limited to dry, wet and pre-action;

## FIRE SERVICE FEATURES

- 13.7. Hazardous material information that includes: location and quantity of hazardous material.
  14. Work table.
  15. Generator supervision devices, manual start and transfer features.
  16. Public address system, where specifically required by other sections of this code.
  17. Elevator fire recall switch in accordance with ASME A17.1.
  18. Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.
- ❖ The fire command center must contain all equipment necessary to enable the incident commander to monitor or control fire protection and other building service systems as listed in this section (also see commentary, Section 909.16). This room houses fire protection, smoke control and building system controls, as well as a work space for emergency responders. The room also contains schematic plans and a work table so that responders have the basic layout and geometry of the building and can identify locations of utility controls, standby or emergency power systems, and where hazardous materials are stored or used. Providing concise information in a uniform format is essential to fire fighters and emergency responders and improves their ability to utilize building systems to their advantage. This was confirmed during the National Institute of Science and Technology (NIST) investigations of the World Trade Center attacks on September 11, 2001. The Final Report on the collapse of the World Trade Center contained 30 key recommendations compiled by NIST designed to address the building vulnerabilities learned in that tragedy. Three of those 30 recommendations embrace increasing situational awareness and emergency communications of first responders in large-scale emergencies. As a result of that investigation, this section includes an Item 13 that prescribes requirements for the Building Information Card (BIC).

The BIC is divided into multiple information areas and is intended to be formatted as a single form to provide a quick, concise source of information about the building. The code does not prescribe any particular format or layout for the BIC and does not have any limits on the level of information required to satisfy the requirements. It should be recognized that the intent of the BIC is to provide an easily understood and consistent tool to emergency responders who are taking control of systems in high-rise and smoke-protected assembly buildings. Jurisdictions should develop a policy to ensure that BICs are prepared in a standard, consistent format to avoid confusing the responders, and yet provide the minimum information required so they can correctly and efficiently utilize all of the building features. The number and types of features required by this section can create a large vol-

ume of data, thus reinforcing the need for an approved layout as required by Section 508.1.4.

## SECTION 509 FIRE PROTECTION AND UTILITY EQUIPMENT IDENTIFICATION AND ACCESS

**509.1 Identification.** Fire protection equipment shall be identified in an *approved* manner. Rooms containing controls for air-conditioning systems, sprinkler risers and valves, or other fire detection, suppression or control elements shall be identified for the use of the fire department. *Approved* signs required to identify fire protection equipment and equipment location shall be constructed of durable materials, permanently installed and readily visible.

❖ In an emergency, it is vitally important that the fire department and other emergency responders be able to quickly locate and access critical controls for fire protection systems. Obstructed or poorly marked equipment can cause delays in fire-fighting operations while fire fighters locate other hose stations and stretch additional hose, for example. Valves and other controls are often located in rooms or other enclosures. Their location must be clearly identified with written or pictographic signs, which must be clearly visible and legible. Signs using the NFPA 170 symbols for fire protection equipment can provide standardized markings throughout a jurisdiction. White reflective symbols on a red reflective background are effective. For exterior signs, heavy-gage, sign-grade aluminum is recommended. Interior signs may be constructed of plastic, light-gage aluminum or other approved, durable, water-resistant material. As a general rule, fire protection piping, cabinets, enclosures, wiring, equipment and accessories are red or are identified by red or red/white markings. The manner of identification is subject to the approval of the fire code official.

**509.1.1 Utility identification.** Where required by the *fire code official*, gas shutoff valves, electric meters, service switches and other utility equipment shall be clearly and legibly marked to identify the unit or space that it serves. Identification shall be made in an *approved* manner, readily visible and shall be maintained.

❖ This section provides the fire code official with the authority to require utility identification for services serving multiunit/multibuilding properties, including facilities, campuses, strip malls, business parks, residential properties and similar locations where identification of utilities is considered essential to emergency responders. Note that this section does not prescribe any particular design requirements for utility identification markings. It should be recognized that the intent of the markings is to provide an easily understood and consistent tool to emergency responders who must secure utilities during emergency operations. Jurisdictions should develop a policy to ensure that utility identification markings are prepared in a standard, consistent format to avoid

confusing the responders, and yet provide the minimum information required so they can correctly and efficiently utilize them.

**509.2 Equipment access.** *Approved* access shall be provided and maintained for all fire protection equipment to permit immediate safe operation and maintenance of such equipment. Storage, trash and other materials or objects shall not be placed or kept in such a manner that would prevent such equipment from being readily accessible.

- ❖ This section requires immediate access to and working space around all fire suppression, protection, and detection system devices and control elements necessary for fire department use. It further prohibits obstruction of such equipment by materials or objects that may prevent such equipment from being immediately accessed by emergency responders.

## SECTION 510 EMERGENCY RESPONDER RADIO COVERAGE

**510.1 Emergency responder radio coverage in new buildings.** All new buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

### Exceptions:

1. Where *approved* by the building official and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained instead of an *approved* radio coverage system.
  2. Where it is determined by the *fire code official* that the radio coverage system is not needed.
  3. In facilities where emergency responder radio coverage is required and such systems, components or equipment required could have a negative impact on the normal operations of that facility, the *fire code official* shall have the authority to accept an automatically activated emergency responder radio coverage system.
- ❖ The provisions of Section 510 are concerned with the reliability of portable radios used by emergency responders inside buildings. This is in keeping with the philosophy inherent in the I-Codes that, when a facility grows too large or complex for effective fire response, fire protection features must be provided within the building. While modeling and other techniques may provide a good prediction as to whether a building will interfere with radio communications, the reality is that it is unknown if a building will need to install any type of radio system enhancements until after the building is constructed. Determining factors may include construction type, shadows of other buildings, size of the structure, etc. Though this section does not offer specific types of buildings that

should be targeted, discussions with public safety radio professionals found that, based on current radio technologies, these requirements should be applied in any building with one or more basements or below-grade building levels, underground buildings or buildings more than five stories in height.

Emergency responders use portable radios to communicate with other emergency responders, the incident commander and the public safety communications center. Building construction features and materials can absorb or block the radio frequency energy used to carry the signals inside or outside the building. Blockage or absorption of the radio frequency signal can prevent a critical message from an emergency responder from being received and acknowledged. Depending on the incident, this loss of information can place other emergency responders in greater danger, or may prevent an injured or disoriented emergency responder from communicating for assistance. The requirements apply to analog or digital radio systems and are applicable to all buildings.

This section requires that all buildings have approved radio coverage for emergency responders within the building. Approved radio coverage is based on the ability of the existing public safety communications system to transmit a signal inside and outside the building.

Where testing using the existing public safety communications system finds that the signal strengths are not satisfactory, Exception 1 allows for the alternative installation of a wired communication system in accordance with Section 907.2.13.2, which requires that such a system be designed in accordance with NFPA 72. When applying this exception, the concurrent approval of fire and building code officials is required.

Where testing using the existing public safety communications system finds that the signal strengths are satisfactory, Exception 2 allows the fire code official to waive the requirements when it is determined that emergency responder radio coverage is not needed. This exception does not give any criteria as to buildings that can be exempted. However, discussions with public safety radio professionals found that, based on current radio technologies, most wood frame or mixed construction Group R-1 and R-2 occupancies, single-family dwellings, townhomes and buildings with an area less than 50,000 square feet (4645 m<sup>2</sup>) without basements, should engender little concern for loss of radio signal strength inside the building or an inability to transmit to an outdoor receiver.

Exception 3 provides a means for the fire code official to allow the installation of a manual or automatic switch that turns on the emergency responder radio coverage system (ERRCS) when it is needed. These systems allow emergency responders to operate their radios inside telephone central offices (COs) or similar occupancies without disrupting telephone network

operations, including calls for service to a jurisdiction's public safety answering point via 9-1-1. Exception 3 also recognizes that operating public safety radio systems in certain buildings with electronic equipment sensitive to radio frequency (RF) energy can cause damage to the equipment, or worse, impact the operations of a local or regional computer network. One such occupancy is a telephone CO, which is where landline and cellular telephone signals are received and dispatched to the recipient caller. It is not uncommon for a telephone CO to be capable of receiving and processing over  $\frac{1}{4}$  million telephone calls within a 1-minute period. Telephone COs serve an important public safety function because they process emergency or information calls routed via 9-1-1 to a jurisdiction's public safety answering point.

Exception 3 was written to address testing sponsored by the major telecommunications companies and performed at Underwriters Laboratories (UL). The purpose of the tests was to determine the impact of operating handheld radios within a telephone CO. Telephone COs contain an array of digital and analog equipment that receives and routes telephone calls. Some of the equipment, such as digital switches that receive and route calls over landline and cellular circuits, is sensitive to the RF energy generated by handheld radios. Testing by UL confirmed that portable radios programmed to operate in many of the public safety frequency ranges can cause severe service interruptions to equipment in telephone COs. The level of impact to the telephone CO equipment is dependent on the radio's wattage and its sphere of radiation at the antenna. Conversely, the impact of the telephone CO equipment and radio operation inside the building is also dependent on whether the equipment is electrically shielded or unshielded from stray RF energy.

**510.2 Emergency responder radio coverage in existing buildings.** Existing buildings shall be provided with *approved* radio coverage for emergency responders as required in Chapter 11.

❖ See the commentary to Section 1103.2.

**510.3 Permit required.** A construction permit for the installation of or modification to emergency responder radio coverage systems and related equipment is required as specified in Section 105.7.5. Maintenance performed in accordance with this code is not considered a modification and does not require a permit.

❖ A construction permit must be obtained in accordance with Section 105.7.5 prior to the installation of the ERRCS system and for any modification or alteration to the system to ensure that the work is done correctly and any parts replacement will be compatible with the existing system components. Note that normal maintenance required for the system would not require a permit.

**510.4 Technical requirements.** Systems, components and equipment required to provide the emergency responder radio

coverage system shall comply with Sections 510.4.1 through 510.4.2.5.

❖ This section simply introduces Sections 510.4.1 through 510.4.2.5, which are the technical requirements for the ERRCS.

**510.4.1 Radio signal strength.** The building shall be considered to have acceptable emergency responder radio coverage when signal strength measurements in 95 percent of all areas on each floor of the building meet the signal strength requirements in Sections 510.4.1.1 and 510.4.1.2.

❖ This section introduces the minimum acceptable signal criteria that must be achieved and maintained throughout 95 percent of all areas on each floor of a building, as indicated in Sections 510.4.1.1 and 510.4.1.2.

**510.4.1.1 Minimum signal strength into the building.** A minimum signal strength of -95 dBm shall be receivable within the building.

❖ This section requires that a minimum signal strength of -95 dBm be received by radios inside the building. The "dBm" abbreviation represents a measured power level stated in decibels relative to 1 milliwatt (mW) and indicates the strength of the signal as compared to 1 mW.

**510.4.1.2 Minimum signal strength out of the building.** A minimum signal strength of -95 dBm shall be received by the agency's radio system when transmitted from within the building.

❖ This section requires that a minimum signal strength of -100 dBm to the outside of the building be receivable by the local public safety communications system. The "dBm" abbreviation represents a measured power level stated in decibels relative to 1 milliwatt (mW) and indicates the strength of the signal as compared to 1mW.

**510.4.2 System design.** The emergency responder radio coverage system shall be designed in accordance with Sections 510.4.2.1 through 510.4.2.5.

❖ This section simply introduces Sections 510.4.2.1 through 510.4.2.5 as the system design criteria for the ERRCS.

**510.4.2.1 Amplification systems allowed.** Buildings and structures that cannot support the required level of radio coverage shall be equipped with a radiating cable system, a distributed antenna system with Federal Communications Commission (FCC)-certified signal boosters, or other system approved by the *fire code official* in order to achieve the required adequate radio coverage.

❖ There are several methods to provide the amplification needed by fire departments in structures identified as needing ERRCS. Any of the indicated methods is acceptable. The code allows for new technologies that will provide the required radio coverage if approved by the fire code official.

**510.4.2.2 Technical criteria.** The *fire code official* shall maintain a document providing the specific technical infor-

mation and requirements for the emergency responder radio coverage system. This document shall contain, but not be limited to, the various frequencies required, the location of radio sites, effective radiated power of radio sites, and other supporting technical information.

❖ In order to effectively install such systems, the fire code official must provide basic information such as the frequency range to be supported. For example, a fire department may provide a requirement such as “the frequency range which must be supported shall be 806 MHz to 824 MHz and 851 MHz TO 869 MHz.” The fire code official will likely need to provide a reference to the local communications center or provide details on radio sites in the jurisdiction.

**510.4.2.3 Standby power.** Emergency responder radio coverage systems shall be provided with standby power in accordance with Section 604. The standby power supply shall be capable of operating the emergency responder radio coverage system for a duration of not less than 24 hours.

❖ This section requires secondary power to operate the equipment in the case where the primary building power must be shutdown or is lost. The secondary power source, traditionally an engine-driven emergency generator or a backup battery system, must be capable of operating the in-building radio amplification system for a minimum 24-hour duration, which is significantly more than that of most life safety systems in the structure. The 24-hour value was selected to ensure the reliability of the signal boosters during long-term emergency operations such as response to natural disasters where utility-supplied electrical power is disabled. See also Section 604 of the code for secondary power system specifics and standards.

**510.4.2.4 Signal booster requirements.** If used, signal boosters shall meet the following requirements:

1. All signal booster components shall be contained in a National Electrical Manufacturer’s Association (NEMA) 4-type waterproof cabinet.
  2. Battery systems used for the emergency power source shall be contained in a NEMA 4-type waterproof cabinet.
  3. The signal booster system and battery system shall be electrically supervised and monitored by a supervisory service, or when *approved by the fire code official*, shall sound an audible signal at a constantly attended location
  4. Equipment shall have FCC certification prior to installation.
- ❖ If a building is equipped with a signal booster, this section requires that the amplifiers and the standby power source be located in a National Electrical Manufacturers Association (NEMA) Type 4 waterproof cabinet. A NEMA 4 cabinet is designed to protect personnel having incidental contact with the equipment and to protect the equipment from falling dirt, rain,

snow and windblown dust, and both splashing and hose-directed water. This section also requires that a malfunction of the signal booster or its standby power source transmit a trouble signal to an approved central or proprietary station. The code official is authorized to allow the trouble signal to be transmitted to a constantly attended location. The system is also required to be certified by the Federal Communication Commission (FCC) prior to installation.

**510.4.2.5 Additional frequencies and change of frequencies.** The emergency responder radio coverage system shall be capable of modification or expansion in the event frequency changes are required by the FCC or additional frequencies are made available by the FCC.

❖ Because of potential changes in public safety radio frequency bands, the code requires the capability for changing the frequency in the future.

**510.5 Installation requirements.** The installation of the public safety radio coverage system shall be in accordance with Sections 510.5.1 through 510.5.4.

❖ This section simply introduces the installation requirement sections of the appendix.

**510.5.1 Approval prior to installation.** Amplification systems capable of operating on frequencies licensed to any public safety agency by the FCC shall not be installed without prior coordination and approval of the *fire code official*.

❖ The installation of ERRCS in a building is similar to other building features where review of the plans and installation is required and covered under a permit. Part of the approval process for amplification systems operating on frequencies licensed to a public safety agency requires approval of the local fire code official.

**510.5.2 Minimum qualifications of personnel.** The minimum qualifications of the system designer and lead installation personnel shall include both of the following:

1. A valid FCC-issued general radio operators license.
2. Certification of in-building system training issued by a nationally recognized organization, school or a certificate issued by the manufacturer of the equipment being installed.

These qualifications shall not be required where demonstration of adequate skills and experience satisfactory to the *fire code official* is provided.

❖ This section is to ensure that a qualified person designs and installs the ERRCS in the building. The qualification may be from a school program in communications or a manufacturer’s training program. This section also allows the jurisdiction to accept a person or business upon adequate demonstration of skills and experience to the fire code official.

**510.5.3 Acceptance test procedure.** Where an emergency responder radio coverage system is required, and upon completion of installation, the building *owner* shall have the radio

## FIRE SERVICE FEATURES

system tested to verify that two-way coverage on each floor of the building is not less than 90 percent. The test procedure shall be conducted as follows:

1. Each floor of the building shall be divided into a grid of 20 approximately equal test areas.
  2. The test shall be conducted using a calibrated portable radio of the latest brand and model used by the agency talking through the agency's radio communications system.
  3. Failure of not more than two nonadjacent test areas shall not result in failure of the test.
  4. In the event that three of the test areas fail the test, in order to be more statistically accurate, the floor shall be permitted to be divided into 40 equal test areas. Failure of not more than four nonadjacent test areas shall not result in failure of the test. If the system fails the 40-area test, the system shall be altered to meet the 90-percent coverage requirement.
  5. A test location approximately in the center of each test area shall be selected for the test, with the radio enabled to verify two-way communications to and from the outside of the building through the public agency's radio communications system. Once the test location has been selected, that location shall represent the entire test area. Failure in the selected test location shall be considered failure of that test area. Additional test locations shall not be permitted.
  6. The gain values of all amplifiers shall be measured and the test measurement results shall be kept on file with the building *owner* so that the measurements can be verified during annual tests. In the event that the measurement results become lost, the building *owner* shall be required to rerun the acceptance test to reestablish the gain values.
  7. As part of the installation a spectrum analyzer or other suitable test equipment shall be utilized to ensure spurious oscillations are not being generated by the subject signal booster. This test shall be conducted at the time of installation and subsequent annual inspections.
- ❖ This section provides a testing procedure to be followed upon completion of system installation and prior to acceptance of the system by the jurisdiction. The building owner or agent is responsible to see that the ERRCS is functioning properly prior to the building being occupied. Note that if there are problems as a result of the testing, the test area is to be altered to provide more specific data on the strength of the signal-boosting capability of the system. Testing results are to be kept on file by the building owner for annual testing verification. If the testing results are lost, a retest of the building shall be required to determine compliance levels.

**510.5.4 FCC compliance.** The emergency responder radio coverage system installation and components shall also com-

ply with all applicable federal regulations including, but not limited to, FCC 47 CFR Part 90.219.

- ❖ As with all radio systems, the ERRCS and its components must comply with all applicable FCC regulations.

**510.6 Maintenance.** The emergency responder radio coverage system shall be maintained operational at all times in accordance with Sections 510.6.1 through 510.6.3.

- ❖ This section simply introduces the installation requirements for the ERRCS.

**510.6.1 Testing and proof of compliance.** The emergency responder radio coverage system shall be inspected and tested annually or where structural changes occur including additions or remodels that could materially change the original field performance tests. Testing shall consist of the following:

1. In-building coverage test as described in Section 510.5.3.
2. Signal boosters shall be tested to verify that the gain is the same as it was upon initial installation and acceptance.
3. Backup batteries and power supplies shall be tested under load of a period of 1 hour to verify that they will properly operate during an actual power outage. If within the 1-hour test period the battery exhibits symptoms of failure, the test shall be extended for additional 1-hour periods until the integrity of the battery can be determined.
4. Other active components shall be checked to verify operation within the manufacturer's specifications.
5. At the conclusion of the testing, a report, which shall verify compliance with Section 510.5.3, shall be submitted to the *fire code official*.

- ❖ The testing of the signal boosters is to verify that the gain is equal to that produced during the initial acceptance, functional tests of the secondary power supply, and an inspection of any other components connected to the in-building amplification system. The inspection report must be submitted to the fire code official and requires documentation that the amplification system complies with the requirements in Section 510.5.3. This section authorizes the fire code official to require additional tests when structural changes or modifications occur that could materially change the performance of the signal boosting system.

**510.6.2 Additional frequencies.** The building *owner* shall modify or expand the emergency responder radio coverage system at his or her expense in the event frequency changes are required by the FCC or additional frequencies are made available by the FCC. Prior approval of a public safety radio coverage system on previous frequencies does not exempt this section.

- ❖ When additional frequencies are needed to change or expand the coverage of the ERRCS, the building

owner is the responsible person to ensure that the work is performed. Previous approvals of the system do not apply when changes are needed. Changes to the system are not exempt because of prior approval. If the change is needed, the work must be done.

**510.6.3 Field testing.** Agency personnel shall have the right to enter onto the property at any reasonable time to conduct field testing to verify the required level of radio coverage.

- ❖ Like all systems, ERRCS need to be tested to verify their continued sufficiency. Whether the test is an annual review of the system or an in-service familiarization test by an engine, truck or squad company, this section provides the ability of the personnel to enter the building at reasonable hours to test and operate the system. As with any inspection, the right of entry for testing the system is limited by constitutional constraints. See the commentary to Section 104.3 for further discussion on the right of entry.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Final Report of the National Construction Safety Team on the Collapses of the World Trade Center Towers*. Washington, DC: National Institute of Standards & Technology, United States Government Printing Office, 2005.

# Chapter 6: Building Services and Systems

## General Comments

This chapter focuses on building systems and services as they relate to potential safety hazards and when and how they should be installed. In some cases, many of the provisions are located in other portions of the code. This chapter brings together all building system- and service-related issues for convenience and provides a more systematic view of buildings. The following building services and systems are addressed:

- Fuel-fired appliances (Section 603).
- Emergency and standby power systems (Section 604).
- Electrical equipment, wiring and hazards, including solar photovoltaic power systems (Section 605).
- Mechanical refrigeration (Section 606).
- Elevator recall and maintenance (Section 607).
- Stationary storage battery systems (Section 608).
- Commercial kitchen hoods (Section 609).
- Commercial kitchen cooking oil storage tank systems (Section 610).
- Hyperbaric facilities (Section 611).

Some of the sections specifically deal with installation while others deal with reducing the hazards from the use of the services or systems. For example, Section 605 notes that using too many extension cords on the building electrical system may present a fire hazard. On the other hand, the discussion of elevator recall and maintenance in Section 607 simply states when and how recall is required.

## Purpose

As technology progresses and societal expectations increase, building systems and services become more complex and numerous. The use of computers has resulted in a more frequent use of uninterruptible power supplies and emergency power, which are often powered through the use of lead-acid battery systems. In the past, these provisions were simply scattered throughout the code. These various building services and system requirements have been brought together in this chapter to simplify the code requirements and increase the likelihood that these elements are properly addressed.

---

## SECTION 601 GENERAL

**601.1 Scope.** The provisions of this chapter shall apply to the installation, operation and maintenance of fuel-fired appliances and heating systems, emergency and standby power systems, electrical systems and equipment, mechanical refrigeration systems, elevator recall, stationary storage battery systems and commercial kitchen equipment.

❖ This section establishes the applicability of the chapter to a variety of building systems and services when they are being installed, during their operation and for long-term maintenance.

**601.2 Permits.** Permits shall be obtained for refrigeration systems, battery systems and solar photovoltaic power systems as set forth in Sections 105.6 and 105.7.

❖ Only three systems discussed in Chapter 6 require permits: the operation of refrigeration systems, the installation of storage battery systems and the installation of solar photovoltaic power systems. The permit for operation of refrigeration systems is intended to warn emergency responders that a potential haz-

ard exists. This information will better equip them to respond to such a call. The permit for installation of a storage battery system or a solar photovoltaic power system ensures the proper safety requirements and features are installed (see commentary, Section 105).

## SECTION 602 DEFINITIONS

**602.1 Definitions.** The following terms are defined in Chapter 2:

**BATTERY SYSTEM, STATIONARY LEAD-ACID.**

**BATTERY TYPES.**

**COMMERCIAL COOKING APPLIANCES.**

**CRITICAL CIRCUIT.**

**EMERGENCY POWER SYSTEM.**

**HOOD.**

**Type I.**

**Type II.**

**REFRIGERANT.****REFRIGERATION SYSTEM.****STANDBY POWER SYSTEM.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2, in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### **SECTION 603 FUEL-FIRED APPLIANCES**

**603.1 Installation.** The installation of nonportable fuel gas appliances and systems shall comply with the *International Fuel Gas Code*. The installation of all other fuel-fired appliances, other than internal combustion engines, oil lamps and portable devices such as blow torches, melting pots and weed burners, shall comply with this section and the *International Mechanical Code*.

❖ The code regulates the installation of portable gas-fired appliances and portable appliances fueled by methods other than gaseous fuels. The *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>) and the *International Fuel Gas Code*<sup>®</sup> (IFGC<sup>®</sup>) do not cover portable appliances. The code also has provisions that apply to appliances that are not portable and use fuels other than gas.

**603.1.1 Manufacturer's instructions.** The installation shall be made in accordance with the manufacturer's instructions and applicable federal, state and local rules and regulations. Where it becomes necessary to change, modify or alter a manufacturer's instructions in any way, written approval shall first be obtained from the manufacturer.

❖ Compliance with the appliance manufacturer's installation instructions is a fundamental requirement of all I-Codes and those instructions are an enforceable extension of the code. Federal, state, county or municipal laws might supercede part of the installation instructions or could be applied in addition to the requirements in the instructions.

**603.1.2 Approval.** The design, construction and installation of fuel-fired appliances shall be in accordance with the *International Fuel Gas Code* and the *International Mechanical Code*.

❖ The code relies on the IMC and the IFGC for the coverage of appliance installations and contains only a limited number of requirements that apply in addition to those of the IMC and IFGC.

**603.1.3 Electrical wiring and equipment.** Electrical wiring and equipment used in connection with oil-burning equip-

ment shall be installed and maintained in accordance with Section 605 and NFPA 70.

❖ Section 605 contains provisions intended to mitigate fire hazards and shock hazards associated with the use of existing appliances. NFPA 70 covers the installation of electrical appliances.

**603.1.4 Fuel oil.** The grade of fuel oil used in a burner shall be that for which the burner is *approved* and as stipulated by the burner manufacturer. Oil containing gasoline shall not be used. Waste crankcase oil shall be an acceptable fuel in Group F, M and S occupancies where utilized in equipment *listed* for use with waste oil and where such equipment is installed in accordance with the manufacturer's instructions and the terms of its listing.

❖ Different grades of fuel oil have different viscosities and chemical makeup. A burner and fuel mismatch could result in poor combustion, sooting and burner component failure. Oil burners are not designed to burn oil contaminated with chemicals of higher volatility. Appliances that consume used engine oil are allowed only in occupancies of low-occupant density (those without sleeping rooms) and where such appliances will likely be monitored and maintained by facility personnel. Used engine oil appliances use a specialized type of atomizing oil burner designed to burn dirty waste oil collected from internal combustion engine maintenance operations.

**603.1.5 Access.** The installation shall be readily accessible for cleaning hot surfaces; removing burners; replacing motors, controls, air filters, chimney connectors, draft regulators and other working parts; and for adjusting, cleaning and lubricating parts.

❖ The IMC and the IFGC require access for the initial installation as well as for the life of the appliance. Safe operation depends on observation and maintenance, which depend on adequate access to the appliances. In order for the installation to be considered readily accessible, personnel should be able to reach it without having to remove building elements or obstacles of any kind, or use climbing aids.

**603.1.6 Testing, diagrams and instructions.** After installation of the oil-burning equipment, operation and combustion performance tests shall be conducted to determine that the burner is in proper operating condition and that all accessory equipment, controls, and safety devices function properly.

❖ Testing of an appliance after installation is also required by the IMC and the appliance manufacturer's installation instructions.

**603.1.6.1 Diagrams.** Contractors installing industrial oil-burning systems shall furnish not less than two copies of diagrams showing the main oil lines and controlling valves, one copy of which shall be posted at the oil-burning equipment

and another at an *approved* location that will be accessible in case of emergency.

- ❖ For large systems, the piping and control valve layout may be complicated and extensive. In the event of an emergency, facility personnel or fire fighters might need access to control valves to protect piping and to limit the fire hazard.

**603.1.6.2 Instructions.** After completing the installation, the installer shall instruct the *owner* or operator in the proper operation of the equipment. The installer shall furnish the *owner* or operator with the name and telephone number of persons to contact for technical information or assistance and routine or emergency services.

- ❖ Appliances are more likely to be properly (safely) operated and maintained if the owner or operator is instructed in the operation of the equipment and given the necessary means to obtain technical and emergency services.

**603.1.7 Clearances.** Working clearances between oil-fired appliances and electrical panelboards and equipment shall be in accordance with NFPA 70. Clearances between oil-fired equipment and oil supply tanks shall be in accordance with NFPA 31.

- ❖ NFPA 70 requires working clearances around electrical equipment for protection of personnel. NFPA 31 requires clearances between appliances and oil-supply tanks to protect the oil tank from excessive heat and to lessen the fire hazard from any oil leakage.

**603.2 Chimneys.** Masonry chimneys shall be constructed in accordance with the *International Building Code*. Factory-built chimneys shall be installed in accordance with the *International Mechanical Code*. Metal chimneys shall be constructed and installed in accordance with NFPA 211.

- ❖ The *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) regulates masonry chimney construction in Chapter 21. Factory-built chimneys are regulated by Section 805 of the IMC. Metal chimneys are distinct from factory-built chimneys, are industrial occupancy related (e.g., smokestacks) and are regulated by NFPA 211 (see IMC commentary, Section 806.1).

**603.3 Fuel oil storage systems.** Fuel oil storage systems shall be installed in accordance with this code. Fuel-oil piping systems shall be installed in accordance with the *International Mechanical Code*.

- ❖ The code regulates the storage of fuel oil. The IMC regulates installation of the fuel oil distribution piping system.

**603.3.1 Fuel oil storage in outside, above-ground tanks.** Where connected to a fuel-oil piping system, the maximum amount of fuel oil storage allowed outside above ground without additional protection shall be 660 gallons (2498 L). The storage of fuel oil above ground in quantities exceeding 660 gallons (2498 L) shall comply with NFPA 31.

- ❖ To limit the potential fire hazard resulting from oil spillage, the code sets a quantity limitation on unpro-

TECTED storage. NFPA 31 requires protection, such as spill containment, for storage in excess of 660 gallons (2498 L). The storage of 660 gallons (2498 L) is allowed to be in any configuration of containers that does not exceed a total of 660 gallons (2498 L).

**603.3.2 Fuel oil storage inside buildings.** Fuel oil storage inside buildings shall comply with Sections 603.3.2.1 through 603.3.2.5 or Chapter 57.

- ❖ This section introduces Sections 603.3.2.1 through 603.3.2.5, which contain requirements for controlling the hazards associated with the storage of fuel oil inside of buildings. Fuel oil is defined in the IMC as “Kerosene or any hydrocarbon oil having a flash point not less than 100°F (38°C).” This would include Number 2 diesel fuel, which is classified as either a Class II or IIIA combustible liquid, depending on the refiner and the region where the fuel will be used. Number 2 diesel fuel is commonly used as a fuel source for diesel-driven electric generators.

The indicated sections have been revised to allow larger amounts of fuel oil in storage inside of buildings in response to increased fuel oil storage requirements for switch and data centers and similar telecommunications facilities. Such facilities are constructed to house large numbers of computers to serve as remote data centers for the protection of computer data or data switches for internet providers. To increase the likelihood that the data is always available, design professionals place a great deal of emphasis on the building’s electrical power supply. These types of uses consume large amounts of electrical power. Accordingly, large generators are installed to ensure that service is not disrupted. These generators have fairly demanding fuel requirements. Consider, for example, that a single 2-megawatt (2 million watt) generator can have a fuel consumption rate of 3-4 gallons/minute under full electrical load conditions. As a result, these facilities require a large volume of fuel. The fuel storage is commonly located inside of a building because many of these facilities are located in commercial or other densely populated areas of a community.

**603.3.2.1 Quantity limits.** One or more fuel oil storage tanks containing Class II or III *combustible liquid* shall be permitted in a building. The aggregate capacity of all such tanks shall not exceed 660 gallons (2498 L).

**Exception:** The aggregate capacity limit shall be permitted to be increased to 3,000 gallons (11 356 L) of Class II or III liquid for storage in protected above-ground tanks complying with Section 5704.2.9.7, where all of the following conditions are met:

1. The entire 3,000-gallon (11 356 L) quantity shall be stored in protected above-ground tanks.
2. The 3,000-gallon (11 356 L) capacity shall be permitted to be stored in a single tank or multiple smaller tanks.

3. The tanks shall be located in a room protected by an *automatic sprinkler system* complying with Section 903.3.1.1.

❖ This section correlates with Table 5003.1.1(1), Note i and Section 5701.2, Item 4, of the code and Table 307.1(1), Note i, of the IBC. Further, this section contains a specific exception to the maximum special quantity of 660-gallon (2498 L) inside storage of combustible liquids, where connected to a closed fuel oil piping system. This would apply to most oil-fired stationary equipment in industrial, commercial and residential occupancies. Note that this provision applies only to the aggregate storage of fuel oil and does not include the capacity of the piping system.

Where the need for an aggregate indoor storage quantity of fuel oil connected to a closed fuel oil piping system exceeds the special amount of 660 gallons (2498 L), the exception may be applied. The exception allows an almost five-fold increase in the quantity of fuel oil stored by recognizing the increased level of safety provided by protected above-ground tanks listed in accordance with UL 2085. These tanks have extensive regulations in Chapter 57, and the listing requirements further document their safety. Included in the design requirements for these tanks are the ability to survive a 2-hour pool fire test conducted in accordance with the UL 1709 fire exposure protocol; a limitation that all penetrations must be made through the top of the tank (to avoid the risk of a gravity-fed leak that might be associated with a connection below liquid level); and that piping connected to the tank must be provided with anti-siphon controls where needed to prevent a siphon risk, among others. The safety level, which allows increased storage, is further enhanced by requiring the room in which the tank is installed to be equipped with an automatic sprinkler system. See the commentary to the Section 202 definition of “Tank, protected above ground” and Section 5704.2.9.7.

**603.3.2.2 Restricted use and connection.** Tanks installed in accordance with Section 603.3.2 shall be used only to supply fuel oil to fuel-burning or generator equipment installed in accordance with Section 603.3.2.4. Connections between tanks and equipment supplied by such tanks shall be made using closed piping systems.

❖ This section makes it clear that the fuel oil storage quantity limits in Section 603.3.2 are applicable only to fuel oil supplies for oil-burning equipment and generators and then only when connected to a fuel oil piping system supplying such equipment. Fuel oil piping systems are regulated by Chapter 13 of the IMC.

**603.3.2.3 Applicability of maximum allowable quantity and control area requirements.** The quantity of *combustible liquid* stored in tanks complying with Section 603.3.2 shall

not be counted towards the maximum allowable quantity set forth in Table 5003.1.1(1), and such tanks shall not be required to be located in a *control area*.

❖ This section clearly states that the fuel oil quantity in Section 603.3.2 is a “special quantity” that is outside the scope of the maximum allowable quantity per control area (MAQ) provisions of Chapter 50, including any requirement to install the tank in a control area in accordance with Section 5003.8.3. Table 5003.1.1(1), Note i, is also correlated with these provisions and indicates that the MAQ provisions of the table do not apply to fuel oil storage complying with Section 603.3.2.

The origins of the “special quantity” were in an ad-hoc hazardous materials committee constituted by one of the legacy model code groups. As the committee developed updated regulations pertaining to flammable and combustible liquids, it concluded that a closed fuel oil storage and piping system feeding oil-fired building service equipment should not be penalized for providing sufficient fuel oil on-site for long-term operation of such systems. Accordingly, the ad-hoc committee, using NFPA 31 as a guide, created the original provisions of Section 603.3 and its subsections to provide that relief.

**603.3.2.4 Installation.** Tanks and piping systems shall be installed and separated from other uses in accordance with Section 915 and Chapter 13, both of the *International Mechanical Code*, as applicable.

**Exception:** Protected above-ground tanks complying with Section 5704.2.9.7 shall not be required to be separated from surrounding areas.

❖ Section 915 of the IMC addresses liquid-fueled internal combustion engines and turbines and permanently installed equipment and appliances powered by internal combustion engines and turbines. Engine-driven electrical generators for private use are becoming more popular, as are engine-driven cooling appliances and heat pumps. Such equipment is also used to power fire pumps, generators, water pumps, refrigeration machines and other stationary equipment. Section 915 of the IMC also references NFPA 37, which addresses the fire safety of this kind of equipment including requirements for enclosures, controls, fuel supplies, exhaust systems, cooling systems and combustion air.

Chapter 13 of the IMC complements the code’s fuel oil storage provisions and regulates the design and installation of fuel oil piping systems. The regulations reference construction standards for above-ground and underground storage tanks, material standards for piping systems (both above ground and underground) and extensive requirements for the proper assembly of system piping and components.

The exception here, as in Section 603.3.2.1, recog-

nizes the increased safety provided by protected above-ground tanks. See the commentary to Section 603.3.2.1 for a discussion of those tanks and their enhanced safety.

**603.3.2.5 Tanks in basements.** Tanks in *basements* shall be located not more than two stories below grade plane.

- ❖ This section prohibits tank installations more than two stories below grade because the further an incident is below grade, the greater challenge for the fire department to mitigate it. This is consistent with the control area approach in Table 5003.8.3.2, which also limits control areas to two levels below grade.

**603.3.3 Underground storage of fuel oil.** The storage of fuel oil in underground storage tanks shall comply with NFPA 31.

- ❖ Section 603.3 does not require that fuel oil tanks be installed underground; however, there may be circumstances under which such an installation is either desirable or advisable. The code user is directed to NFPA 31 for specific requirements applicable to the installation of underground combustible liquid storage tanks.

**603.4 Portable unvented heaters.** Portable unvented fuel-fired heating equipment shall be prohibited in occupancies in Groups A, E, I, R-1, R-2, R-3 and R-4.

**Exceptions:**

1. *Listed* and *approved* unvented fuel-fired heaters, including portable outdoor gas-fired heating appliances, in one- and two-family *dwelling*s.
  2. Portable outdoor gas-fired heating appliances shall be allowed in accordance with Section 603.4.2.
- ❖ Portable unvented fuel-fired heating equipment refers to portable space heaters, such as LP-gas fired or kerosene-fueled appliances. This section would also apply to movable gas-fired appliances that connect to gas convenience outlets with gas hose connectors. This section does not apply to permanently installed appliances. Portable space-heating appliances are moved around at will by the occupants and might be placed too close to combustibles or where they are susceptible to being hit, tipped over, etc. Because of potential misuse, such appliances are considered an unacceptable risk in the listed, higher life hazard occupancies. Exception 1 is based on the assumption that, in one- and two-family dwellings, the occupants will take greater care in the use of such appliances. Exception 2 is based on the provisions of Section 603.4.2 and its subsections, which provide strict regulation of portable outdoor gas-fired heating appliances in all occupancies.

**603.4.1 Prohibited locations.** Unvented fuel-fired heating equipment shall not be located in, or obtain combustion air from, any of the following rooms or spaces: sleeping rooms, bathrooms, toilet rooms or storage closets.

- ❖ The intent of this section is to prevent fuel-fired appliances from being installed in rooms and spaces where the combustion process could pose a threat to

occupants. Potential threats include depleted oxygen levels; elevated levels of carbon dioxide, nitrous oxides, carbon monoxide, and other combustion gases; ignition of combustibles; and elevated levels of flammable gases.

In small rooms, such as bedrooms and bathrooms, the doors are typically closed when the room is occupied, which could allow combustion gases to build up to life-threatening levels. In bedrooms, sleeping occupants would not be alert to or aware of impending danger. This section is parallel in its intent with Section 303.3 of both the IMC and the IFGC. Note that, as a subsection of Section 603.4, this section is addressing portable appliances in Groups A, E, I and R (see also IFGC commentary, Section 303.3).

**603.4.2 Portable outdoor gas-fired heating appliances.**

Portable gas-fired heating appliances located outdoors shall be in accordance with Sections 603.4.2.1 through 603.4.2.3.4.

- ❖ This section introduces Sections 603.4.2.1 through 603.4.2.3.4, which contain requirements for controlling the hazards associated with portable gas-fired heating appliances located outdoors. In many jurisdictions, LP-gas-fired portable heaters, also called patio heaters, are being utilized in outdoor areas of restaurants, sidewalk cafes, hotel dining areas, outdoor smoking areas and retail sites in increasing numbers. These heaters are also readily available to consumers at local home and building supply locations. These sections provide regulations to allow for the conditional use of outdoor patio heaters and establishes general safety requirements for the storage and use of such heaters (see Commentary Figure 603.4.2).

**603.4.2.1 Location.** Portable outdoor gas-fired heating appliances shall be located in accordance with Sections 603.4.2.1.1 through 603.4.2.1.4.

- ❖ This section introduces Sections 603.4.2.1.1 through 603.4.2.1.4, which contain requirements for controlling the location hazards associated with portable outdoor gas-fired heating appliances, sometimes called “patio heaters.”

**603.4.2.1.1 Prohibited locations.** The storage or use of portable outdoor gas-fired heating appliances is prohibited in any of the following locations:

1. Inside of any occupancy where connected to the fuel gas container.
2. Inside of tents, canopies and membrane structures.
3. On exterior balconies.

**Exception:** As allowed in Section 6.20 of NFPA 58.

- ❖ These “patio heaters” are not designed or listed for indoor use because they are unvented appliances. The potential fire and life safety hazard of LP-gas warrants their prohibition inside of occupied buildings and structures, making this section consistent with the prohibitions of containers inside of buildings in NFPA 58.

**Figure 603.4.2**  
**PORTABLE OUTDOOR GAS-FIRED**  
**HEATING APPLIANCE/PATIO HEATER**  
 (Photo courtesy of Infrared Dynamics, Yorba Linda, CA)

**603.4.2.1.2 Clearance to buildings.** Portable outdoor gas-fired heating appliances shall be located not less than 5 feet (1524 mm) from buildings.

- ❖ The 5-foot (1524 mm) separation reduces the likelihood that operating portable outdoor gas-fired heating appliances will come in contact with heat-damageable building surfaces or material that is easily ignited.

**603.4.2.1.3 Clearance to combustible materials.** Portable outdoor gas-fired heating appliances shall not be located beneath, or closer than 5 feet (1524 mm) to combustible decorations and combustible overhangs, awnings, sunshades or similar combustible attachments to buildings.

- ❖ The 5-foot (1524 mm) separation reduces the likelihood that operating portable outdoor gas-fired heating appliances will come in contact with combustible construction or material that is easily ignited.

**603.4.2.1.4 Proximity to exits.** Portable outdoor gas-fired heating appliances shall not be located within 5 feet (1524 mm) of *exits* or *exit discharges*.

- ❖ In order to not compromise the means of egress in a potential fire or other emergency evacuation scenario

and to prevent LP-gas from entering the building and finding an ignition source in case of a leak, portable outdoor gas-fired heating appliances must be kept a minimum of 5 feet (1524 mm) from any exit or exit discharge.

**603.4.2.2 Installation and operation.** Portable outdoor gas-fired heating appliances shall be installed and operated in accordance with Sections 603.4.2.2.1 through 603.4.2.2.4.

- ❖ This section introduces Sections 603.4.2.2.1 through 603.4.2.2.4, which contain requirements for controlling the installation and operation hazards associated with portable outdoor gas-fired heating appliances.

**603.4.2.2.1 Listing and approval.** Only *listed* and *approved* portable outdoor gas-fired heating appliances utilizing a fuel gas container that is integral to the appliance shall be used.

- ❖ Even though portable outdoor gas-fired heating appliances can be listed under the standard ANSI Z83.26/CSA 2.37 for natural gas or LP-gas (propane) use, this section makes it clear that only appliances employing an integral LP-gas container can be used. The safety feature here is that the gas hoses used to connect natural gas-fired appliances to an external fuel source are eliminated, thus eliminating the hazard of wear-and-tear effects on the hose and the possibility of persons tripping over the hoses, the latter reducing the risk of personal injury or heaters tipping over. Another safety feature required by the ANSI standard is the connection between the LP-gas cylinder and the hose supplying the appliance's burner. The standard requires the hose connected to the appliance to be equipped with a Compressed Gas Association (CGA) 790 fitting as described in CGA V-1. A CGA 790 fitting provides three separate safety features. First, the fitting has a thermal link that is designed to activate at temperatures of 200°F to 250°F (93°C – 121°C), thus stopping the flow of LP-gas in the event of a fire. Second, the fitting requires a positive connection to the cylinder before LP-gas can flow into the appliance. Finally, the fitting is equipped with an internal excess flow control valve, which is designed to stop the flow of a gas or liquid in the event of hose or pipe rupture.

**603.4.2.2.2 Installation and maintenance.** Portable outdoor gas-fired heating appliances shall be installed and maintained in accordance with the manufacturer's instructions.

- ❖ Compliance with the appliance manufacturer's installation and maintenance instructions is a fundamental requirement of all I-Codes and those instructions are an enforceable extension of the code because they are typically an integral part of the appliances, listing, as required by Section 603.4.2.2.1. Federal, state, county or municipal laws might supercede part of the installation instructions or could be applied in addition to the requirements in the instructions.

**603.4.2.2.3 Tip-over switch.** Portable outdoor gas-fired heating appliances shall be equipped with a tilt or tip-over switch that automatically shuts off the flow of gas if the appliance is tilted more than 15 degrees (0.26 rad) from the vertical.

- ❖ For safety, listed commercial heaters feature a safety switch that immediately shuts the unit off if it senses that the heater is tilted more than 15 degrees (0.26 rad) from vertical. This is especially important given these heaters can be over 7 feet (2137 mm) tall and weigh over 80 pounds (36 kg), depending on the design or manufacturer. This safety feature reduces the likelihood of personal injury and the heating element coming into contact with combustible material.

**603.4.2.2.4 Guard against contact.** The heating element or combustion chamber of portable outdoor gas-fired heating appliances shall be permanently guarded so as to prevent accidental contact by persons or material.

- ❖ This safety feature reduces the likelihood of personal injury and the heating element coming into direct contact with persons or combustible material.

**603.4.2.3 Gas containers.** Fuel gas containers for portable outdoor gas-fired heating appliances shall comply with Sections 603.4.2.3.1 through 603.4.2.3.4.

- ❖ This section introduces Sections 603.4.2.3.1 through 603.4.2.3.4, which contain requirements for controlling the hazards associated with fuel gas containers for portable outdoor gas-fired heating appliances.

**603.4.2.3.1 Approved containers.** Only *approved* DOTn or ASME gas containers shall be used.

- ❖ This section is consistent with Chapter 61 and the provisions of NFPA 58, which is the LP-gas referenced standard in that chapter of the code. Using only DOTn and ASME containers increases the likelihood of the appliance being safe because the containers are built to exacting standards.

**603.4.2.3.2 Container replacement.** Replacement of fuel gas containers in portable outdoor gas-fired heating appliances shall not be conducted while the public is present.

- ❖ In order to avoid exposing the public to the potential for a gas leak during cylinder replacement, the portable outdoor gas-fired heating appliance being serviced must either be removed to a nonpublic area or the area in which it is being used must be cleared of patrons while the container exchange is in progress.

**603.4.2.3.3 Container capacity.** The maximum individual capacity of gas containers used in connection with portable outdoor gas-fired heating appliances shall not exceed 20 pounds (9 kg).

- ❖ The maximum size of the gas container to be used in portable outdoor gas-fired heating appliances is the same as those typically used in gas grills and is dictated by the listing standard.

**603.4.2.3.4 Indoor storage prohibited.** Gas containers shall not be stored inside of buildings except in accordance with Section 6109.9.

- ❖ Requirements for the storage of idle replacement containers of LP-gas are specified in this section. Indoor storage of 20-pound (9 kg) LP-gas cylinders in a building that is accessible to the public is a violation of Section 6109.9. Both ANSI Z83.26/CSA 2.37 and Section 603.4.2.3.3 limit the volume of the LP-gas containers to 20 pounds (9 kg). Containers must also be qualified to be filled in accordance with the requirements in NFPA 58. Section 6109 provides regulations for the storage of containers awaiting use, which is applicable to replacement containers for portable outdoor gas-fired heating appliances.

**603.5 Heating appliances.** Heating appliances shall be *listed* and shall comply with Sections 603.5.1 and 603.5.2.

- ❖ The IMC and the IFGC require that all space-heating appliances be listed and labeled.

**603.5.1 Guard against contact.** The heating element or combustion chamber shall be permanently guarded so as to prevent accidental contact by persons or material.

- ❖ The injury and ignition protection feature required by this section is typically designed into the appliance.

**603.5.2 Heating appliance installation and maintenance.** Heating appliances shall be installed and maintained in accordance with the manufacturer's instructions, the *International Building Code*, the *International Mechanical Code*, the *International Fuel Gas Code* and NFPA 70.

- ❖ Depending upon the type of fuel utilized, appliance installation and maintenance can be subject to the requirements of multiple codes, including the IBC, the IMC, the IFGC, and NFPA 70 in addition to the appliance manufacturer's instructions.

**603.6 Chimneys and appliances.** Chimneys, incinerators, smokestacks or similar devices for conveying smoke or hot gases to the outer air and the stoves, furnaces, fireboxes or boilers to which such devices are connected, shall be maintained so as not to create a fire hazard.

- ❖ A primary function of the code is to reduce or eliminate fire hazards through proper maintenance of appliances and systems that are potential fire and life safety hazards.

**603.6.1 Masonry chimneys.** Masonry chimneys that, upon inspection, are found to be without a flue liner and that have open mortar joints which will permit smoke or gases to be discharged into the building, or which are cracked as to be dangerous, shall be repaired or relined with a *listed* chimney liner system installed in accordance with the manufacturer's instructions or a flue lining system installed in accordance with the requirements of the *International Building Code* and appropriate for the intended class of chimney service.

- ❖ See Section 2113 of the IBC, Section 801.16 of the IMC and Sections 501.12, 501.13 and 503.5 of the IFGC for information on masonry chimney liners and masonry chimneys.

**603.6.2 Metal chimneys.** Metal chimneys which are corroded or improperly supported shall be repaired or replaced.

- ❖ See the commentary to Section 603.2.

**603.6.3 Decorative shrouds.** Decorative shrouds installed at the termination of factory-built chimneys shall be removed except where such shrouds are *listed* and *labeled* for use with the specific factory-built chimney system and are installed in accordance with the chimney manufacturer's instructions.

❖ This section is retroactive in that it requires removal of a previously installed trim item. Section 805.6 of the IMC and Section 503.5.4 of the IFGC prohibit the installation of decorative shrouds not meeting the listing criteria. The code addresses those noncomplying shrouds that were illegally installed (see IMC commentary, Section 805.6, and IFGC commentary, Section 503.5.4).

**603.6.4 Factory-built chimneys.** Existing factory-built chimneys that are damaged, corroded or improperly supported shall be repaired or replaced.

❖ Defective or inadequately supported chimneys could leak flue gas and could fail structurally, resulting in separation, collapse, a fire hazard and a life safety hazard. This section is consistent with the maintenance focus of the code.

**603.6.5 Connectors.** Existing chimney and vent connectors that are damaged, corroded or improperly supported shall be repaired or replaced.

❖ See the commentary to Section 603.6.4.

**603.7 Discontinuing operation of unsafe heating appliances.** The *fire code official* is authorized to order that measures be taken to prevent the operation of any existing stove, oven, furnace, incinerator, boiler or any other heat-producing device or appliance found to be defective or in violation of code requirements for existing appliances after giving notice to this effect to any person, *owner*, firm or agent or operator in charge of the same. The *fire code official* is authorized to take measures to prevent the operation of any device or appliance without notice when inspection shows the existence of an immediate fire hazard or when imperiling human life. The defective device shall remain withdrawn from service until all necessary repairs or *alterations* have been made.

❖ When a heat-producing appliance or system is determined to be unsafe, the fire code official is required to notify the owner or agent of the building as the first step in correcting the difficulty. This notice may describe the repairs and improvements necessary to correct the deficiency and keep the system in operation or require the unsafe equipment or system to be removed or replaced. The notice must specify a time frame in which the corrective actions must occur. Additionally, the notice should require the immediate response of the owner or agent.

If the owner or agent is not available, public notice of the declaration would be enough to comply with this section. The fire code official may also determine that the system must be disconnected to correct an unsafe condition and must give written notice to that effect; however, an immediate disconnection can be

ordered if it is essential for protection of public health and safety.

**603.7.1 Unauthorized operation.** It shall be a violation of this code for any person, user, firm or agent to continue the utilization of any device or appliance (the operation of which has been discontinued or ordered discontinued in accordance with Section 603.7) unless written authority to resume operation is given by the *fire code official*. Removing or breaking the means by which operation of the device is prevented shall be a violation of this code.

❖ Appliances or systems removed from service in accordance with Section 603.7 may be sealed or otherwise secured in a manner approved by the fire code official and may only be returned to service upon written authorization of the fire code official.

**603.8 Incinerators.** Commercial, industrial and residential-type incinerators and chimneys shall be constructed in accordance with the *International Building Code*, the *International Fuel Gas Code* and the *International Mechanical Code*.

❖ See the commentary to Section 907.1 of the IMC, Section 606.1 of the IFGC and Section 2113 of the IBC.

**603.8.1 Residential incinerators.** Residential incinerators shall be of an *approved* type.

❖ Residential incinerators have gone out of use today but may still be found in older homes and in rural areas.

**603.8.2 Spark arrestor.** Incinerators shall be equipped with an effective means for arresting sparks.

❖ Spark arrestor chimney caps are designed with a screened outlet that prevents the escape of burning embers and particles.

**603.8.3 Restrictions.** Where the *fire code official* determines that burning in incinerators located within 500 feet (152 m) of mountainous, brush or grass-covered areas will create an undue fire hazard because of atmospheric conditions, such burning shall be prohibited.

❖ The fire code official must determine whether incinerator use would present an unacceptable risk of wild fires in timber, brush and grass-covered areas. For wildland-urban interface areas, see the *International Wildland-Urban Interface Code*<sup>®</sup> (IWUIC<sup>®</sup>). The local air-quality agency may also have restrictions.

**603.8.4 Time of burning.** Burning shall take place only during *approved* hours.

❖ The jurisdiction must determine the periods that would be safe for burning and those that would be unsafe. Consideration must be given to daylight, prevailing winds, ambient temperatures, impact on air quality, moisture levels and presence of observers and supervisory personnel.

**603.8.5 Discontinuance.** The *fire code official* is authorized to require incinerator use to be discontinued immediately if

the *fire code official* determines that smoke emissions are offensive to occupants of surrounding property or if the use of incinerators is determined by the *fire code official* to constitute a hazardous condition.

- ❖ The fire code official can prohibit incinerator use if it would be a nuisance or a health or fire hazard. Coordination with the local air-quality agency may also be necessary.

**603.8.6 Flue-fed incinerators in Group I-2.** In Group I-2 occupancies, the continued use of existing flue-fed incinerators is prohibited.

- ❖ This type of incinerator is hazardous and would not comply with current code requirements. This section is simply making sure that such incinerators are no longer used.

**603.8.7 Incinerator inspections in Group I-2.** Incinerators in Group I-2 occupancies shall be inspected not less than annually in accordance with the manufacturer's instructions. Inspection records shall be maintained on the premises and made available to the *fire code official* upon request

- ❖ Incinerators pose a hazard to the building and its occupants if not properly maintained. This is more of a concern in Group I-2 occupancies where the residents are at particular risk from such hazards.

**603.9 Gas meters.** Above-ground gas meters, regulators and piping subject to damage shall be protected by a barrier complying with Section 312 or otherwise protected in an *approved* manner.

- ❖ Vehicle impact protection is necessary to prevent gas leakage resulting from impact damage to gas service equipment. Protection can be accomplished by location alone or by the construction of barriers as prescribed by Section 312. Barriers would be required only where the gas service equipment is located where vehicle impact is likely to occur.

## SECTION 604

### EMERGENCY AND STANDBY POWER SYSTEMS

**604.1 General.** Emergency power systems and standby power systems required by this code or the *International Building Code* shall comply with Sections 604.1.1 through 604.1.8.

- ❖ This section simply states that all required emergency and standby power comply with various subsections. These subsections provide more detailed direction on how such systems are required to be installed. These provisions are consistent with the standards referenced by the code and provide the basic information to the code official.

**604.1.1 Stationary generators.** Stationary emergency and standby power generators required by this code shall be *listed* in accordance with UL 2200.

- ❖ The provisions of this section apply only to generator sets that are chosen and permanently installed for the purpose of providing an emergency or standby power

supply for the required, fixed building facilities indicated in Section 604.2. Section 2.37 of UL 2200 defines a stationary unit as "An engine generator that is intended to be hard wired and/or permanently installed." The section would not apply to mobile units such as truck-, trailer- or skid-mounted or other non-fixed, nonpermanent units. Such nonpermanently installed units would not be approved for purposes of complying with the requirements of Section 604. Similarly, stationary generator sets that are installed for purposes other than to supply emergency or standby power required by the code would not be required to be listed to UL 2200.

**604.1.2 Installation.** Emergency power systems and standby power systems shall be installed in accordance with the *International Building Code*, NFPA 70, NFPA 110 and NFPA 111.

- ❖ Emergency power systems are intended to provide electrical power for life safety systems, such as egress illumination, emergency communications and processes involving the handling and use of hazardous materials. In other words, emergency power is required where the loss of normal power would endanger occupants. Such systems are covered in Article 700 of NFPA 70 and one of their key features is the required response time of 10 seconds or less. The time between loss of normal power and the provision of emergency power must be kept very short to prevent putting occupants at risk. This is especially important during an emergency event, such as a building fire, but is important at all times to prevent occupant panic, which could happen if a crowded building is suddenly plunged into darkness.

Standby power systems are covered in Article 701 of NFPA 70 and are intended to provide electrical power for loads not as critical in terms of transfer time as those requiring emergency power. Standby power loads include smoke control systems; certain elevators; certain hazardous material operations; smoke-proof enclosure systems; illumination; heating, ventilating and air-conditioning (HVAC) systems; refrigeration and sewage pumps. Standby power systems must provide power within 60 seconds of failure of primary power.

Sources of power for emergency power systems (NFPA 70, Section 701-11) include storage batteries, generators, uninterruptible power supplies and separate services. Sources of power for standby systems include those allowed for emergency systems plus a source that is taken from a point of connection ahead of the normal service disconnecting means.

NFPA 110 addresses the performance criteria and "nuts and bolts" of emergency and standby power systems and separates them into types, classes and levels relative to maximum response time, minimum required operation time and life safety importance factor, respectively. NFPA 111 addresses stored emergency power supply systems and is similar in coverage to NFPA 110. Stored energy systems typically rely on batteries that store chemical energy.

**604.1.3 Load transfer.** Emergency power systems shall automatically provide secondary power within 10 seconds after primary power is lost, unless specified otherwise in this code. Standby power systems shall automatically provide secondary power within 60 seconds after primary power is lost unless specified otherwise in this code.

❖ These provisions are consistent with NFPA 70 and provide clarity to the code official regarding one of the key differences between standby and emergency power. This was discussed in more detail in the commentary to Section 604.1.2.

**604.1.4 Load duration.** Emergency power systems and standby power systems shall be designed to provide the required power for a minimum duration of 2 hours without being refueled or recharged, unless specified otherwise in this code.

❖ In order to properly design emergency and standby power systems, the minimum load duration must be known. This section provides a default minimum 2-hour duration for systems unless another load duration is specified. For instance, emergency responder radio coverage systems are required to provide standby power for 24 hours.

**604.1.5 Uninterruptable power source.** An uninterrupted source of power shall be provided for equipment where required by the manufacturer's instructions, the listing, this code or applicable referenced standards.

❖ In some cases an uninterruptable power supply is required. Uninterruptible power supplies are different from emergency and standby power supplies in that there is no transfer time allowed. This is necessary for equipment with volatile memories or that are generally sensitive to any loss of power. An uninterruptible power source must be provided if required by the equipment manufacturer's instructions; the listing of the equipment; the code; or applicable referenced standards, such as NFPA 72.

**604.1.6 Interchangeability.** Emergency power systems shall be an acceptable alternative for installations that require standby power systems.

❖ An emergency power system, given its more rapid transfer time, is an acceptable substitute for a standby power system. It will simply result in a faster-reacting system, which will only improve performance.

**604.1.7 Group I-2 occupancies.** In Group I-2 occupancies, where an essential electrical system is located in flood hazard areas established in Section 1612.3 of the *International Building Code* and where new or replacement essential electrical system generators are installed, the system shall be located and installed in accordance with ASCE 24.

❖ This provision provides a necessary link to ASCE 24 *Flood Resistant Design and Construction* for Group I-2 essential electrical systems. There have been losses of such systems due to flooding where the standard was not properly addressed. These types of facilities, such as hospitals and nursing homes, need

to have continued operation during flood events. Hurricane Katrina was a good example of such power being lost during flooding. This provision will ensure that new Group I-2 occupancies installing such systems and those replacing systems that have been substantially damaged by a flood will be installed correctly.

ASCE 24 provides the designer with the minimum requirements and expected performance for the design and construction of buildings and structures in flood hazard areas. It is not a restatement of all of the National Flood Insurance Program regulations, but offers additional specificity, some additional requirements, and some limitations. Buildings designed according to ASCE 24 are better able to resist flood loads and flood damage. See the commentary to Section 1612.3 of the IBC for additional information on this topic.

**604.1.8 Maintenance.** Existing installations shall be maintained in accordance with the original approval and Section 604.4.

❖ In order for existing generators to continue to serve the purpose for which they were installed, they must be properly maintained. This section simply provides the mechanism to ensure this maintenance. The maintenance level is linked to the original installation approval. Section 604.4 provides detailed maintenance requirements.

**604.2 Where required.** Emergency and standby power systems shall be provided where required by Sections 604.2.1 through 604.2.16.

❖ Fires or natural events can cause the loss of utility power as a result of either damage to equipment and wiring or fire-fighter action to shut off power to eliminate sources of ignition and danger to personnel.

Sections 604.2.1 through 604.2.16 list locations throughout buildings and facilities where emergency or standby power is required. In some cases, the requirements are occupancy- or use-specific and in others the requirements are system- or equipment-specific. Generally, the requirements are related to life safety-oriented systems within buildings, such as a fire alarm system or elevators used for egress for those with disabilities. Recall that emergency and standby power systems have different characteristics, and subsequent sections will require one or the other (see commentary, Section 604.1.2).

**604.2.1 Elevators and platform lifts.** Standby power shall be provided for elevators and platform lifts as required in Sections 607.2, 1009.4, and 1009.5.

❖ Elevators can be a component of an accessible means of egress in accordance with Section 1009.4 and must, therefore, be dependable at all times. Without backup power, an elevator could be a dead end for someone with physical disabilities who is trying to egress a building (see commentary, Section 1009.4).

Platform lifts are allowed to be used as part of an accessible means of egress only when they are

allowed as part of an accessible route, in accordance with Section 1109.8, Items 1 through 10, of the IBC. When this is the case, the platform lift could be a dead end for someone with physical disabilities if power to the platform lift were to be lost; therefore, standby power is required, in accordance with Section 604 or ASME A18.1.

The reference to Section 607.2 addresses how standby power is to be provided to elevators where required elsewhere. These requirements are the same as those found in Section 3003 of the IBC. Primarily, these requirements apply to high-rise buildings (see commentary, IBC Section 403.4.8.3). Also note that the IBC has specific standby power requirements in Sections 3007.8 and 3008.8 for fire service access elevators and occupant evacuation elevators, respectively. These requirements are more restrictive than those found in Section 607.2 of the code and Section 3003 of the IBC. See commentary for Section 607.2.

**604.2.2 Emergency alarm systems.** Emergency power shall be provided for emergency alarm systems as required by Section 414 of the *International Building Code*.

❖ Emergency alarm systems required by Section 908 of the code and Section 908 of the IBC are systems that provide warning of dangerous conditions involving hazardous materials. Emergency alarm systems must be available at all times and therefore require the use of an emergency power system. See commentary for Section 908 of the code and Sections 414.5.2 and 908 of the IBC.

**604.2.3 Emergency responder radio coverage systems.** Standby power shall be provided for emergency responder radio coverage systems as required in Section 510.4.2.3. The standby power supply shall be capable of operating the emergency responder radio coverage system for a duration of not less than 24 hours.

❖ Loss of power during an emergency situation is likely and emergency responders will require the use of their radios for an extended period of time in many cases. This section and Section 510.4.2.3 require that standby power be available for 24 hours.

**604.2.4 Emergency voice/alarm communication systems.** Emergency power shall be provided for emergency voice/alarm communication systems as required in Section 907.5.2.2.5. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

❖ Emergency voice/alarm communication systems are required by Section 907.5.2.2.5 to include an emergency power source. Certain Group A occupancies and covered malls are two of the many occupancies and building types that require emergency voice/alarm communication systems.

**604.2.5 Exit signs.** Emergency power shall be provided for *exit* signs as required in Section 1013.6.3. The system shall be

capable of powering the required load for a duration of not less than 90 minutes.

❖ Emergency power is warranted for exit signage illumination since guiding occupants to the exits is certainly a life safety function (see commentary, Section 1013.6.3). Note that this section specifies a time duration of not less than 90 minutes for exit sign illumination. This specific duration would take precedence over the general 2-hour duration specified in Section 604.1.4.

**604.2.6 Group I-2 occupancies.** Essential electrical systems for Group I-2 occupancies shall be in accordance with Section 407.10 of the *International Building Code*.

❖ Emergency power systems are required to comply with NFPA 99 by the Center for Medicare/Medicaid Services (CMS) in order for a federally licensed healthcare facility to receive federal reimbursement funds. Section 407.10 of the IBC provides a direct reference to NFPA 99 for the design and construction of emergency power systems in Group I-2. See the commentary to Section 407.10 of the IBC.

**604.2.7 Group I-3 occupancies.** Power-operated sliding doors or power-operated locks for swinging doors in Group I-3 occupancies shall be operable by a manual release mechanism at the door. Emergency power shall be provided for the doors and locks in accordance with Section 604.

Exceptions:

1. Emergency power is not required in facilities where provisions for remote locking and unlocking of occupied rooms in Occupancy Condition 4 are not required as set forth in the *International Building Code*.
2. Emergency power is not required where remote mechanical operating releases are provided.

❖ In an emergency situation involving power loss, occupants in detention and correctional facilities are at the mercy of door-locking mechanisms and those who control such locks; thus, emergency power is warranted. For a discussion of Exception 1, see the commentary to Sections 408.4.1 and 408.4.2 of the IBC. Exception 2 recognizes the use of mechanical operating releases controlled remotely as eliminating the need for emergency power.

**604.2.8 Hazardous materials.** Emergency and standby power shall be provided in occupancies with hazardous materials as required in the following sections:

1. Sections 5004.7 and 5005.1.5 for hazardous materials.
2. Sections 6004.2.2.8 and 6004.3.4.2 for highly toxic and toxic gases.
3. Section 6204.1.11 for organic peroxides.

❖ Where hazardous materials and processes are housed, occupant safety could be dependent on one or more ventilation, treatment, temperature control,

alarm or detection system. Thus, emergency or standby power is required, depending upon the nature of the material hazard presented (see commentary to code sections referenced in Items 1 through 3).

**604.2.9 High-rise buildings.** Standby power and emergency power shall be provided for high-rise buildings as required in Section 403 of the *International Building Code*, and shall be in accordance with Section 604.

- ❖ Occupants of high-rise buildings are at greater risk due to longer egress travel times, difficult fire-fighter access and the danger of vertical spread of fire and smoke. In accordance with this chapter and Sections 403.4.8, some loads in a high-rise building will require standby power and some will require emergency power (see commentary for Section 403.4.8 of the IBC).

**604.2.10 Horizontal sliding doors.** Standby power shall be provided for horizontal sliding doors as required in Section 1010.1.4.3. The standby power supply shall have a capacity to operate not fewer than 50 closing cycles of the door.

- ❖ Power-operated doors could be an obstruction to egress if the primary power supply fails; therefore, standby power is required to maintain door operation (see commentary, Section 1010.1.4.3).

**604.2.11 Hydrogen fuel gas rooms.** Standby power shall be provided for hydrogen fuel gas rooms as required by Section 5808.7.

- ❖ Ventilation and gas detection are critical to the ongoing safe operation of a hydrogen fuel gas room. Therefore, both ventilation and gas detection systems are required by Section 5808.7 to be provided with standby power. See the commentary to Section 5808.7.

**604.2.12 Means of egress illumination.** Emergency power shall be provided for *means of egress* illumination in accordance with Sections 1008.3 and 1104.5.1.

- ❖ The path of travel to all exits must be illuminated to guide occupants and allow for safe egress; therefore, emergency power for illumination is necessary (see commentary, Section 1008.3).

**604.2.13 Membrane structures.** Standby power shall be provided for auxiliary inflation systems in permanent membrane structures in accordance with Section 2702 of the *International Building Code*. Auxiliary inflation systems shall be provided in temporary air-supported and air-inflated membrane structures in accordance with Section 3103.10.4.

- ❖ Air-supported and air-inflated structures would collapse on the occupants if the inflation systems were to fail. Section 3102.8.1.1 of the IBC requires redundant inflation equipment that would be as worthless as the primary system in the event of power failure; therefore, standby power is required. Emergency power is required for all exit signs in temporary tents and membrane structures (see commentary, IBC Section 3102.8.2). Note that temporary air-supported

and air-inflated membrane structures require auxiliary power. However, the auxiliary power is not specifically standby power in accordance with Section 604.1. Section 3103.10.4 sets out specific criteria as to how this is to be provided. The time it takes to provide this power is 60 seconds, which is the same transfer time required for standby power in Section 604.1.3.

**604.2.14 Semiconductor fabrication facilities.** Emergency power shall be provided for semiconductor fabrication facilities as required in Section 2703.15.

- ❖ Where hazardous materials are utilized in Group H-5 hazardous production materials (HPM) facilities, many systems are depended on to protect the occupants from exposure to hazardous materials, including exhaust/ventilation systems, gas cabinet exhaust systems, gas detection systems, alarm systems and suppression systems. Loss of power would endanger the occupants; thus, emergency power is essential for these occupancies. For the complete list of required systems, see Section 2703.15 and its commentary.

**604.2.15 Smoke control systems.** Standby power shall be provided for smoke control systems as required in Section 909.11.

- ❖ Smoke control systems are intended to maintain a tenable environment in certain buildings to allow the occupants ample time to evacuate or relocate to protected areas. As such, smoke control systems are life safety systems and must be dependable (see commentary, Section 909.11). Such systems are more likely to be needed during a power loss than typical building systems such as HVAC.

**604.2.16 Underground buildings.** Emergency and standby power shall be provided in underground buildings as required in Section 405 of the *International Building Code* and shall be in accordance with Section 604.

- ❖ In the event of power failure, occupants could be underground without light, ventilation and numerous required life safety systems. These structures are analogous to inverted high-rise buildings. See Sections 405.8.1 and 405.8.2 of the IBC, which require standby power and emergency power for specified loads, respectively.

**604.3 Critical circuits.** Cables used for survivability of required critical circuits shall be listed in accordance with UL 2196. Electrical circuit protective systems shall be installed in accordance with their listing requirements.

- ❖ The standard referenced, UL 2196, is the ANSI-approved standard for tests of fire-resistive cables. NFPA 20 (fire pumps) and NFPA 72 (fire alarm) include selective survivability requirements to assure integrity of certain critical circuits. NFPA 70 does not specify the applicable standard within the mandatory provisions of the code, but recognizes electrical circuit protective systems as alternatives to listed cables. An electrical circuit protective system is a field

assembly of components that must be installed according to the listing requirements and manufacturer's instructions in order to maintain the listing for the system. There are more than two dozen electrical circuit protective systems listed in the UL Fire Resistance Directory.

**604.4 Maintenance.** Emergency and standby power systems shall be maintained in accordance with NFPA 110 and NFPA 111 such that the system is capable of supplying service within the time specified for the type and duration required.

❖ This section introduces requirements for maintenance of all elements of emergency and standby power systems. The two standards referenced are for emergency and standby power systems and stored electrical energy emergency and standby power systems, respectively. NFPA 110 is geared toward power sources, such as diesel-driven generators, while NFPA 111 is geared toward power supplies, such as stationary lead-acid battery systems. See also Section 604.1.8, which requires the same system maintenance as was originally approved.

**604.4.1 Schedule.** Inspection, testing and maintenance of emergency and standby power systems shall be in accordance with an approved schedule established upon completion and approval of the system installation.

❖ Standby power and emergency power are useful only if they continue to work over the life of both the building and its associated equipment; therefore, this section specifically focuses on the maintenance of such systems. The primary specifications of these secondary power supplies are that they be able to supply power within the specified length of time.

This section requires that a specific schedule be created at the completion of the installation of the system to encourage regular maintenance of the power systems.

**604.4.2 Records.** Records of the inspection, testing and maintenance of emergency and standby power systems shall include the date of service, name of the servicing technician, a summary of conditions noted and a detailed description of any conditions requiring correction and what corrective action was taken. Such records shall be maintained.

❖ Documentation of maintenance is key, in that it highlights what specifically was inspected and tested and where potential problems exist. Also, the information about the inspector and inspection agency in the document allows for further reference in the future. This provides a level of accountability. These documents must be made available to the fire code official upon request.

As a result of a review of Recommendation 2(c) of the National Institute of Standards and Technology (NIST) Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections (including this section), to comprehensively address recordkeeping requirements. Section 107.3 provides standardized

recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2 and 107.3.

**604.4.3 Switch maintenance.** Emergency and standby power system transfer switches shall be included in the inspection, testing and maintenance schedule required by Section 604.4.1. Transfer switches shall be maintained free from accumulated dust and dirt. Inspection shall include examination of the transfer switch contacts for evidence of deterioration. When evidence of contact deterioration is detected, the contacts shall be replaced in accordance with the transfer switch manufacturer's instructions.

❖ One of the most important elements of emergency and standby power systems is the ability for the primary power to be switched to the secondary power supply within the specified time; therefore, this section pays specific attention to the long-term reliability of the transfer switches. This includes inspection for cleanliness and signs of deterioration.

**604.5 Operational inspection and testing.** Emergency power systems, including all appurtenant components, shall be inspected and tested under load in accordance with NFPA 110 and NFPA 111.

**Exception:** Where the emergency power system is used for standby power or peak load shaving, such use shall be recorded and shall be allowed to be substituted for scheduled testing of the generator set, provided that appropriate records are maintained.

❖ This section requires that emergency power systems be tested and inspected as specified in NFPA 110 and 111. There is an exception to testing emergency power when the emergency power system is either used for peak power periods or for standby power. The use during peak hours means that on a fairly regular basis the power supply will be tested. In terms of the use of emergency power for standby power, the capacity of both types of secondary power systems is the same. The two differ on when they will activate; therefore, testing the system as a standby power supply is adequate when the emergency power system is used as standby power.

**604.5.1 Transfer switch test.** The test of the transfer switch shall consist of electrically operating the transfer switch from the normal position to the alternate position and then return to the normal position.

❖ This section specifically prescribes the sequence of events for testing transfer switches. The switch must

move from the normal position to the alternate position and back again. As noted earlier in this commentary, emergency power must be available within a maximum of 10 seconds upon the loss of primary power, whereas standby power is to be available within 60 seconds. The transfer switches, therefore, must work within the specified time.

**604.6 Emergency lighting equipment.** Emergency lighting shall be inspected and tested in accordance with Sections 604.6.1 through 604.6.2.1.

❖ This section introduces the requirements for regular testing of emergency lighting equipment installed in accordance with Section 1008. While Section 604.4 requires that emergency power systems be inspected and tested in accordance with the referenced standards, NFPA 111 Section 1.1.4.1, Item 4, specifically exempts battery unit equipment from being covered by the maintenance provisions of that standard and NFPA 110 does not apply. These sections will fill that gap in maintenance coverage by providing for the testing of the most common type of emergency lighting found in smaller buildings, i.e., battery unit emergency lighting equipment (see Commentary Figure 604.6).

**604.6.1 Activation test.** An activation test of the emergency lighting equipment shall be completed monthly. The activation test shall ensure the emergency lighting activates automatically upon normal electrical disconnect and stays sufficiently illuminated for not less than 30 seconds.

❖ This section requires a monthly 30-second function test of battery unit emergency lighting equipment to verify that the unit is holding a charge, that all connected bulbs or luminaires are operational and that the transfer switch functions properly. This test must be conducted by turning off the normal power supply circuit that serves the unit, not by simply pressing the “test” button on the unit. It is important to note that since NFPA 70 typically requires a lock-on device to

be provided on branch circuit breakers powering unit equipment, those lock-ons must be reinstalled upon completion of the test.

**604.6.1.1 Activation test record.** Records of tests shall be maintained. The record shall include the location of the emergency lighting tested, whether the unit passed or failed, the date of the test and the person completing the test.

❖ Accurate, up-to-date records are required to document the history of equipment inspection, testing and maintenance. Record keeping is not intended simply to prove to the fire code official that required inspection, testing and maintenance are being performed, but to assist the owner or his or her agent in performing these functions. A well-kept log helps an owner or technician determine how the equipment is performing over time and assists the building owner in understanding the responsibilities associated with having this equipment installed in the building. These records must be kept on the premises of the affected building. Where a complex of buildings exists, a centralized location for record storage will aid the owner and the fire code official. Similarly, buildings, such as warehouses, that are typically unoccupied but are located adjacent to an occupied building, such as an office, can have their records maintained in the office building so that they are protected and secured.

As a result of a review of Recommendation 2(c) of the NIST Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections (including this section), to comprehensively address recordkeeping requirements. Section 107.3 provides standardized recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2 and 107.3.

**604.6.2 Power test.** For battery-powered emergency lighting, a power test of the emergency lighting equipment shall be completed annually. The power test shall operate the emergency lighting for not less than 90 minutes and shall remain sufficiently illuminated for the duration of the test.

❖ Section 1008.3.4 requires that emergency lighting for means of egress have a duration of 90 minutes. This section complements that requirement by requiring a 90-minute operational test of battery units annually to verify the condition of the battery, unit-powered bulbs or luminaires and unit circuitry. As with the activation test in Section 604.6.1, this test should be conducted by turning off the normal power supply to the unit. The determination of whether the unit remains “suffi-

ciently illuminated” for the full 90-minute test should be based on the performance requirements for emergency lighting for means of egress established in Section 1008.3.5.

**604.6.2.1 Power test record.** Records of tests shall be maintained. The record shall include the location of the emergency lighting tested, whether the unit passed or failed, the date of the test and the person completing the test.

❖ See the commentary to Section 604.6.1.1.

**604.7 Supervision of maintenance and testing.** Routine maintenance, inspection and operational testing shall be overseen by a properly instructed individual.

❖ This section requires a minimum level of qualifications for the testing of emergency and standby power systems. Only trained personnel should do the testing and maintenance of these systems. This is consistent with Section 107.4. See the commentary to that section.

**SECTION 605**

**ELECTRICAL EQUIPMENT, WIRING AND HAZARDS**

**605.1 Abatement of electrical hazards.** Identified electrical hazards shall be abated. Identified hazardous electrical conditions in permanent wiring shall be brought to the attention of the responsible code official. Electrical wiring, devices, appliances and other equipment that is modified or damaged and constitutes an electrical shock or fire hazard shall not be used.

❖ Maintenance of electrical systems and services to achieve compliance with the requirements of NFPA 70 is required. The leading causes of electrical fires include inadequate or improper maintenance; non-conforming modifications to existing installations; failure to maintain clearances around electrical equipment and devices; and improper use of electrical equipment and devices. A detailed analysis of the causes of residential electrical fires by the U.S. Consumer Products Safety Commission suggests that misuse and improper modifications to conforming electrical systems are the leading causes of these fires.

**605.2 Illumination.** Illumination shall be provided for service equipment areas, motor control centers and electrical panelboards.

❖ Adequate lighting in electrical service distribution equipment areas is required to facilitate the location of the electrical service shutoff during a fire or other emergency and to minimize potential hazards during maintenance or repair work. Although not required, this lighting should be connected to an emergency or standby power source to permit continued illumination when power to service equipment is interrupted during maintenance repair activities or emergencies.

**605.3 Working space and clearance.** A working space of not less than 30 inches (762 mm) in width, 36 inches (914 mm) in depth and 78 inches (1981 mm) in height shall be provided

in front of electrical service equipment. Where the electrical service equipment is wider than 30 inches (762 mm), the working space shall be not less than the width of the equipment. Storage of materials shall not be located within the designated working space.

**Exceptions:**

1. Where other dimensions are required or allowed by NFPA 70.
2. Access openings into attics or under-floor areas which provide a minimum clear opening of 22 inches (559 mm) by 30 inches (762 mm).

❖ Adequate clearance serves two important purposes: physical separation of combustibles from heat-producing electrical devices and equipment to minimize the possibility of ignition, and providing adequate work space to perform maintenance and repair work safely (see Commentary Figure 605.3). The exceptions note that NFPA 70 may allow different dimensions than those prescribed in this section. Additionally, the lack of space in areas such as attics and underfloor areas is recognized by also allowing a smaller opening width.

**605.3.1 Labeling.** Doors into electrical control panel rooms shall be marked with a plainly visible and legible sign stating ELECTRICAL ROOM or similar approved wording. The disconnecting means for each service, feeder or branch circuit originating on a switchboard or panelboard shall be legibly and durably marked to indicate its purpose unless such purpose is clearly evident.

❖ In addition to the illumination required in Section 605.2, additional labeling is required for the electrical equipment to assist emergency responders in identifying and then shutting down electrical service controls during a fire or other emergency.

**605.4 Multiplug adapters.** Multiplug adapters, such as cube adapters, unfused plug strips or any other device not complying with NFPA 70 shall be prohibited.

❖ The intent of this section is to prohibit conditions that could lead to the overloading of building electrical cir-

cuits that, in turn, could result in a fire. The devices intended to be regulated by this section are referred to as a “multiplug adapter” but are more correctly identified as a “current tap.” Underwriters Laboratories, Inc. (UL), in its Guide Information for the listing category EMDV, defines “current tap” as follows: “A male and female contact device that, when connected to an outlet receptacle or cord set, provides multiple outlets or outlet configurations. An outlet configuration may consist of a slot configuration, or provision for the connection of flexible cord.” An adapter, on the other hand, is defined there as “a device that adapts one blade or slot configuration to another (including a grounding adapter for a non-grounding receptacle).” The term “cube adapter” (more correctly “cube tap”) refers to the shape of the device, i.e., cube-shaped. They can also be known as “octopus taps.”

Overcurrent protection interrupts power to an outlet only when connected loads exceed the current rating of the overcurrent device for a specified amount of time. When multiplug adaptors are used for several appliances, such devices may produce enough heat to ignite nearby combustibles in the time it takes to trip the overcurrent protection device. Simultaneous operation of many small loads may cause dangerous localized resistance heating without tripping the overcurrent protection device. Additionally, these devices may result in loose electrical connections because of the weight of the cords pulling on them.

The use of these devices may also indicate that the building’s electrical wiring is inadequate for the connected loads or occupancy demands. These devices are intended for temporary use only, not at a fixed location or in place of wiring complying with NFPA 70.

The code does allow for the use of listed, relocatable power taps complying with specific criteria mentioned in Sections 605.4.1 through 605.4.3. Commentary Figure 605.4 shows the difference between a multiplug adapter and a power tap.

**605.4.1 Power tap design.** Relocatable power taps shall be of the polarized or grounded type, equipped with overcurrent protection, and shall be *listed* in accordance with UL 1363.

❖ This section sets out the basic requirements for relocatable power taps (RPTs). The testing requirements of UL 1363 are applied to relocatable, cord-connected power taps rated at 250 volts AC or less and 20 amps or less. These devices are intended only for indoor use as a temporary extension of a branch circuit for general use to supply home workshop tools, computers, audio and video equipment, etc. They consist of an attachment plug and a length of flexible cord terminating in an enclosure containing one or more receptacles and may also be provided with fuses or other supplemental overcurrent protection, switches, line surge suppressors or indicator lights. The flexible cord length is dependent on the listing of the particular device, but power taps have been listed for lengths up to 25 feet (7620 mm). The scope of UL 1363 indicates that RPTs are neither intended to be connected in series nor used with medical equipment.

**605.4.2 Power supply.** Relocatable power taps shall be directly connected to a permanently installed receptacle.

❖ The restrictions on power taps are similar to those on extension cords. Power taps should not be used as a substitute for building wiring. Relocatable power taps are intended to be plugged directly into a permanently installed receptacle and are not intended to be connected in series or connected to other power taps or extension cords. They are also not intended for use outdoors, at construction sites and similar hard-use locations.

**605.4.3 Installation.** Relocatable power tap cords shall not extend through walls, ceilings, floors, under doors or floor coverings, or be subject to environmental or physical damage.

❖ To prevent use as a substitute for permanent wiring, power taps cannot be placed in locations such as within or through walls, under doors or on building surfaces, furnishings, cabinets or similar structures where they would be subject to physical damage. This section would prohibit relocatable power taps from being plugged into a receptacle in one room to power a device in another room.

**605.5 Extension cords.** Extension cords and flexible cords shall not be a substitute for permanent wiring. Extension cords and flexible cords shall not be affixed to structures, extended through walls, ceilings or floors, or under doors or floor coverings, nor shall such cords be subject to environmental damage or physical impact. Extension cords shall be used only with portable appliances.

❖ Frequent or improper use of extension cords in place of permanent fixed wiring is another indication of inadequate electrical wiring capacity or incompatible

demands (see Commentary Figure 605.5). Physical damage to extension cords caused by concealment or inadequate maintenance may result in localized resistance heating, shorts or ground faults.

The amount of electrical current that any extension cord can safely conduct is limited by the size of its conductor, its insulation type and its environment. This principle is often not understood by the general public. As a result, extension cords are commonly overloaded by connecting appliances and other loads in excess of the cord's capacity.

Overloading of extension cords causes an increase in the conductor's temperature. This increase in temperature can exceed the temperature rating of the conductor insulation, causing it to melt, decompose or burn. The burning insulation can ignite other combustible materials. The resulting loss of conductor insulation can also cause a short circuit or ground fault that can act as a source of ignition. The buildup of heat in an extension cord is often made worse by excessive cord length and by the insulating effect of rugs that often cover extension cords. Extension cords are much more susceptible to physical damage than permanent wiring. Damage to extension cords increases the likelihood of shorts and poor connections, both of which can cause a fire.

In addition to the fire hazard, extension cords pose a tripping hazard to occupants and, when damaged, can pose an electrical shock hazard. Securing flexible cords to a wall baseboard, door jambs, etc., with nails, staples or other fasteners to eliminate tripping hazards can create another dangerous condition by pinching or piercing the cord and causing shorts or faults that could lead to ignition.

Additionally, as a way of limiting the use of extension cords, their use is restricted to portable appliances. The reference to "portable" primarily denotes smaller, often-relocated appliances, such as a fan or a power tool. Extension cords must not be used with major appliances or equipment, such as refrigerators,

which are obviously not portable. See the definitions for "Portable equipment" and "Portable appliance" in NFPA 70 Sections 520.2 and 550.2, respectively.

**605.5.1 Power supply.** Extension cords shall be plugged directly into an *approved* receptacle, power tap or multiplug adapter and, except for *approved* multiplug extension cords, shall serve only one portable appliance.

❖ This restriction means that multiple extension cords must not be connected to one another. Additionally, extension cords are limited to one appliance unless they are specifically approved multiplug extension cords.

**605.5.2 Ampacity.** The ampacity of the extension cords shall be not less than the rated capacity of the portable appliance supplied by the cord.

❖ Although most building occupants may have difficulty understanding ampacity, which is the amount of electrical current that a particular conductor is capable of handling without exceeding its temperature limits, it is extremely important. If an appliance demands a higher electrical current than the extension cord is intended to handle, the extension cord will be overloaded causing overheating and a potential fire. Familiarity with the types of extension cords available for sale and the general relationships to common appliances will help with the enforcement of this section.

**605.5.3 Maintenance.** Extension cords shall be maintained in good condition without splices, deterioration or damage.

❖ When extension cords are damaged, they become potential shock hazards and a source of ignition.

**605.5.4 Grounding.** Extension cords shall be grounded where serving grounded portable appliances.

❖ If an extension cord serves an appliance that requires a grounding conductor to avoid potential shock, that cord must provide a grounding conductor.

**605.6 Unapproved conditions.** Open junction boxes and open-wiring splices shall be prohibited. *Approved* covers shall be provided for all switch and electrical outlet boxes.

❖ Without covers, connections made in junction boxes may be subject to physical damage. Such damage may loosen electrical connections, resulting in high-resistance arcing. Switches and outlet boxes are subject to arcing from loose connections and reduced clearances between contacts as they age. Accumulation of dirt and debris in open electrical boxes creates an ignitable fuel concentration. Fires in open electrical boxes may spread to wire or cable insulation or other fuels in electrical and mechanical concealed spaces. Furthermore, unprotected electrical connections are electrical shock hazards to personnel working in concealed spaces.

**605.7 Appliances.** Electrical appliances and fixtures shall be tested and *listed* in published reports of inspected electrical equipment by an *approved* agency and installed and maintained in accordance with all instructions included as part of such listing.

❖ The fire code official should look for the listing mark of an approved testing or inspection agency on the appliance and may request the agency's published report showing the listing to verify that the appliance meets an applicable standard for electrical safety. Fire code officials experiencing difficulties interpreting the marking or listing of an agency, as in the case of a laboratory not located within the United States, should consult representatives of the agency or the U.S. Consumer Products Safety Commission (CPSC) for assistance.

**605.8 Electrical motors.** Electrical motors shall be maintained free from excessive accumulations of oil, dirt, waste and debris.

❖ Internal heating is commonly associated with the operation of electrical motors. Excessive accumulations of dust, oil, grease, dirt or other debris may be easily ignited by the internal frictional heating of electrical motor components.

**605.9 Temporary wiring.** Temporary wiring for electrical power and lighting installations is allowed for a period not to exceed 90 days. Temporary wiring methods shall meet the applicable provisions of NFPA 70.

**Exception:** Temporary wiring for electrical power and lighting installations is allowed during periods of construction, remodeling, repair or demolition of buildings, structures, equipment or similar activities.

❖ In some cases, because of a specific need and the temporary nature of the need, temporary wiring is allowed for a period of not more than 90 days. This allowance is primarily aimed at needs such as for holiday lighting. The exception allows temporary wiring to exceed 90 days for certain activities, such as remodeling or general construction of a building. Section 590 of NFPA 70 contains specific requirements for temporary wiring.

The term "temporary wiring" is not referring here to the use of power taps or extension cords (see commentary, Sections 605.4 and 605.5). The requirements for temporary wiring are less restrictive than those for permanent wiring but are much more rigorous than the requirements for the use of power taps and extension cords.

**605.9.1 Attachment to structures.** Temporary wiring attached to a structure shall be attached in an *approved* manner.

❖ When wiring is specifically attached to a structure, care must be taken to make sure that the attachment will not damage the wiring in a way that would cause resistance heating in localized areas of the wiring (see commentary, Section 605.5).

**605.10 Portable, electric space heaters.** Where not prohibited by other sections of this code, portable, electric space heaters shall be permitted to be used in all occupancies other than Group I-2 and in accordance with Sections 605.10.1 through 605.10.4.

**Exception:** The use of portable, electric space heaters in which the heating element cannot exceed a temperature of 212°F (100°C) shall be permitted in nonsleeping staff and employee areas in Group I-2 occupancies.

❖ Portable, electric space heaters are a readily available, commonly used source of supplementary heat for homes or workplaces, but should not be relied on to replace a building's fixed heating system. Because a portable, electric space heater's heating element operates at high temperatures, improper use of the heater creates a fire risk. This section provides minimum safety requirements for the use of portable, electric space heaters that have historically been carelessly or incorrectly installed or used. However, because Group I-2 occupancies have a higher life hazard that results in a longer evacuation time, the use of these devices in such occupancies is prohibited. These provisions also correlate the code with federal regulations for these facilities. The exception recognizes the reduced life hazard in nonpatient staff areas of Group I-2 occupancies; limiting the portable heater temperature will reduce the incidence of fire from these devices.

**605.10.1 Listed and labeled.** Only *listed* and *labeled* portable, electric space heaters shall be used.

❖ Using only tested, listed and labeled portable, electric space heaters provides both the consumer and the fire code official with an increased level of confidence that the heater has been thoroughly and carefully examined by an independent agency concerned with public safety. An important part of the product listing is the manufacturer's use and care booklet that should be read and carefully followed before using a portable, electric space heater for the first time and periodically thereafter. An appropriate standard that could be used to examine and list these heaters would be UL 1278.

**605.10.2 Power supply.** Portable, electric space heaters shall be plugged directly into an *approved* receptacle.

❖ Because of the amount of current required for an electric space heater, its listing will limit the length of the power supply cord provided with the unit to prevent overheating of the conductors. Using an extension cord or other temporary wiring device defeats the purpose of the limited-length cord and can lead to conductor overheating or damage to the heater itself. The heater's power supply cord should be kept away from high traffic areas to prevent the cord from being damaged or tripped over. Power supply cords should also not be run under rugs or furniture where they could be walked on or have heavy objects set on them. This could cause a damaged cord to overheat and cause a fire.

**605.10.3 Extension cords.** Portable, electric space heaters shall not be plugged into extension cords.

❖ See the commentaries to Sections 605.10.2 and 605.5.

**605.10.4 Prohibited areas.** Portable, electric space heaters shall not be operated within 3 feet (914 mm) of any combustible materials. Portable, electric space heaters shall be operated only in locations for which they are *listed*.

❖ Because portable electric space heaters have hot and arcing or sparking parts inside of them, adequate clearance from combustible materials must be maintained to avoid ignition of the combustibles. Likewise, flammable liquid vapors could be liberated during liquid transfer or in the event of a spill during travel to the heater where the arcing or sparking components could cause ignition.

**605.11 Solar photovoltaic power systems.** Solar photovoltaic power systems shall be installed in accordance with Sections 605.11.1 through 605.11.2, the *International Building Code* or *International Residential Code*, and NFPA 70.

❖ Among the most popular alternative energy sources are solar photovoltaic (PV) power systems. A number of United States electric utility power suppliers offer incentives for the installation of PV systems on buildings because such systems offer the property owners the ability to generate their own electricity and, in many cases, sell excess electricity back to the utility provider. Such an arrangement is a benefit to the utility provider because it reduces the provider's power generation demand, which in turn can control the rates that commercial and residential customers pay.

According to the U.S. Energy Information Administration, approximately 21,200 PV cells and modules were shipped domestically in 1999; by 2008, the number shipped was over 524,200. As the number of PV power systems increases, economy of scale will continue to reduce the systems costs, making them more common on commercial and residential buildings (see Commentary Figure 605.11).

PV systems are designed to convert light energy

into direct current (DC) electricity. They have no moving parts and do not contain fluids. The light-to-electricity conversion begins at the PV cell, which is commonly a semiconductor device that generates electricity when exposed to light. To be effective, PV cells are assembled into PV modules, which are then assembled into PV panels. The panels are assembled onto a frame or a flexible substrate, which then can be affixed to the roof of buildings to create a PV array. The PV array and its modules are wired together and generally operate as a series electrical circuit. PV array are required by NFPA 70 to have a fuse or other means of branch-circuit protection to prevent them from being overloaded. While not required, a PV array is commonly equipped with a blocking diode. A blocking diode is analogous to a check valve in a piping system because it limits the direction the electrons can travel. The blocking diode prevents electrical current from one power supply from finding entry into another. In PV systems, the blocking diode protects each individual PV panel if other panels fail and prevents the withdrawal of electricity from the system during the nighttime (see Commentary Figure 605.11).

The ever-increasing demand for alternative power sources brings with it hazards to confront emergency responders. The greatest danger facing emergency responders operating in proximity to solar energy collection systems is the lack of knowledge needed to operate safely around these systems. Some of the potential hazards associated with PV systems are tripping hazards and falls for fire fighters operating on the roof, earlier roof collapse due to the added dead load and electric shock. The provisions of Sections 605.11 through 605.11.2 were developed to provide for the proper installation of PV systems and to address the potential hazards to fire fighters. This section requires compliance with the IBC or *International Residential Code*<sup>®</sup> (IRC<sup>®</sup>), as applicable, and NFPA 70.

Relevant provisions of the IBC and IRC are IBC Sections 1505, 1512 and 3111 and IRC Sections R324, R902, R905 and R907, as applicable.

The reference to NFPA 70 would require compliance with Section 690 of NFPA 70, which addresses requirements such as marking of equipment and the type of materials that are permitted. Section 605.11 focuses primarily on creating pathways where fire fighters can perform manual ventilation operations on roofs.

**605.11.1 Access and pathways.** Roof access, pathways, and spacing requirements shall be provided in accordance with Sections 605.11.1.1 through 605.11.1.3.3.

#### Exceptions:

1. Detached, nonhabitable Group U structures including, but not limited to, parking shade structures, carports, solar trellises and similar structures.

2. Roof access, pathways and spacing requirements need not be provided where the fire chief has determined that rooftop operations will not be employed.

❖ This section introduces a major element of PV system design: the requirement to provide access and paths so fire fighters can perform the important task of manual ventilation by cutting one or more holes in a building roof. The provisions in Sections 605.11.1.1 through 605.11.1.3.3 address the placement of PV arrays on building roofs. It should be noted that these requirements do not apply to buildings regulated by the IRC. See the commentary to Section 102.5 for a discussion of the relationship between the code and the IRC.

Exception 1 to this section recognizes that the installation of PV systems on detached Group U occupancy structures will not require ventilation and therefore does not need to be regulated by this section.

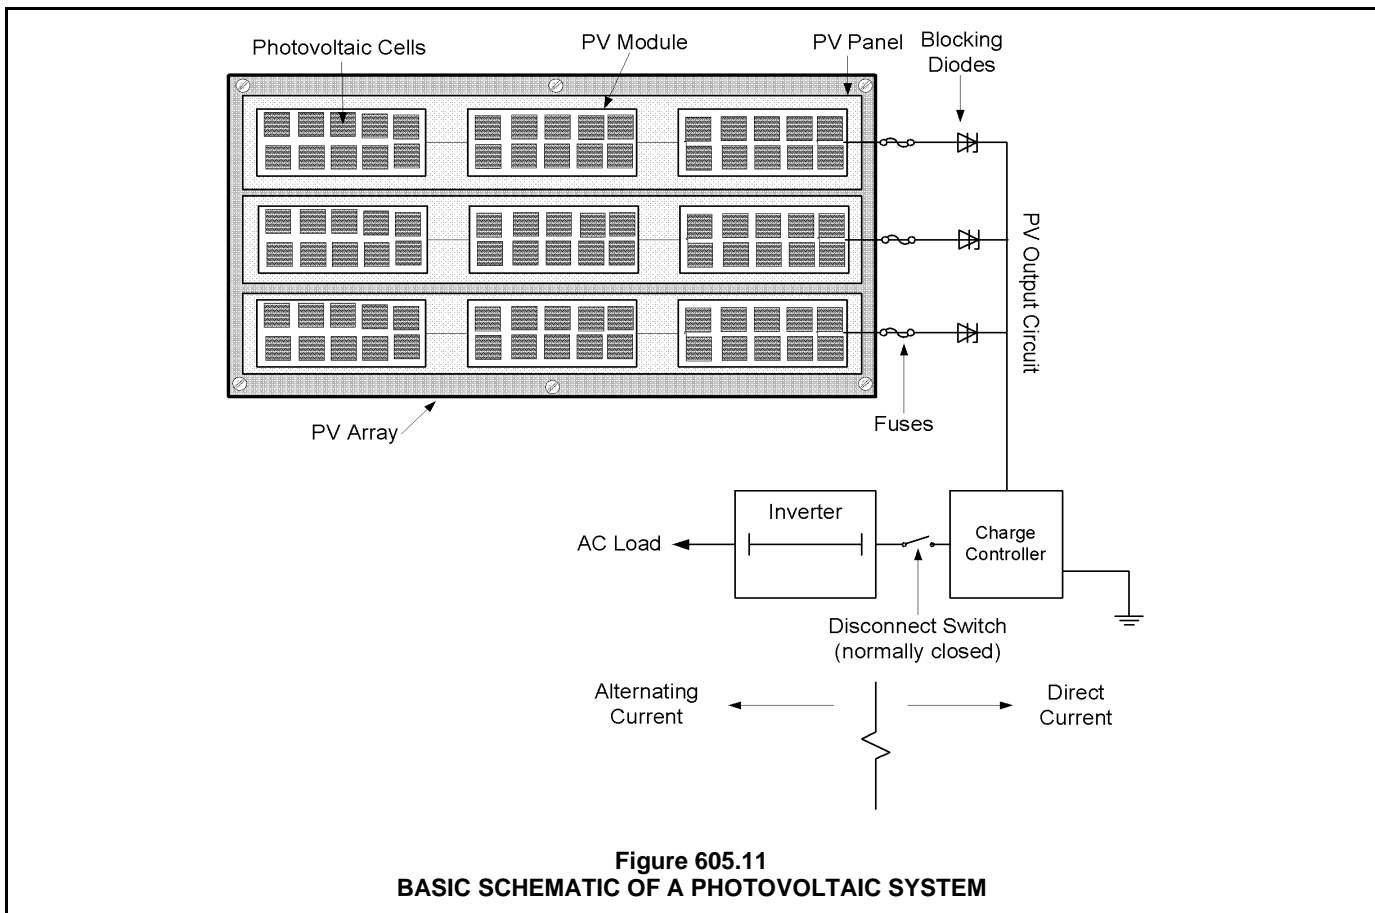

Exception 2 exempts PV arrays from the spacing requirements when the fire chief indicates that vertical manual ventilation practices will not be employed. Conditions that could be considered under this exception include, but are not limited to, proximity and type of adjacent exposures; alternative access opportunities (as from adjoining roofs); adequate ventilation opportunities beneath solar arrays that are sufficiently elevated, spaced or set back from other

rooftop equipment; installation of automatic ventilation devices or new technology, methods, or other innovations that ensure adequate fire department access, pathways and ventilation opportunities. Note that a construction permit in accordance with Section 105.7.15 would still be required.

**605.11.1.1 Roof access points.** Roof access points shall be located in areas that do not require the placement of ground ladders over openings such as windows or doors, and located at strong points of building construction in locations where the access point does not conflict with overhead obstructions such as tree limbs, wires or signs.

❖ Roof access points are areas where ladder placement would not be over openings so as to obstruct ingress or egress of personnel, interfere with the use of openings for ventilation or expose the ground ladder and its users to heat, smoke or fire erupting from openings. Ladder placement must also be located at strong points of building construction so that there is less risk of collapse while fighting a fire. Overhead obstructions must also be taken into account. Having PV panels and modules limits the locations where fire fighters can place ladders, therefore it is more important that these factors be addressed as part of the installation process.

Although specific emphasis is not provided within this section, the fire code official should be involved in the determination of access points.

**Figure 605.11**  
**BASIC SCHEMATIC OF A PHOTOVOLTAIC SYSTEM**

**605.11.1.2 Solar photovoltaic systems for Group R-3 buildings.** Solar photovoltaic systems for Group R-3 buildings shall comply with Sections 605.11.1.2.1 through 605.11.1.2.5.

**Exception:** These requirements shall not apply to structures designed and constructed in accordance with the *International Residential Code*.

❖ This section introduces the PV system access requirements for residential buildings (see Commentary Figure 605.11.1.2). Note that the Group R-3 buildings focused on are typically one- and two-family dwellings that fall outside the scope of the IRC. As noted in Section 605.11, the IRC addresses one- and two-family dwellings that fall within the scope of that code. The requirements in Section R324 are very similar to those found in Sections 605.11.1.2 through 605.11.1.2.5.

**Figure 605.11.1.2  
INSTALLATION OF A PV ARRAY  
ON AN R-3 OCCUPANCY**

**605.11.1.2.1 Size of solar photovoltaic array.** Each photovoltaic array shall be limited to 150 feet (45 720 mm) by 150 feet (45 720 mm). Multiple arrays shall be separated by a 3-foot-wide (914 mm) clear access pathway.

❖ This section establishes a maximum size of the solar array. This provides a manageable size for fire fighters. Multiple arrays are permitted but must be separated by 3 feet between so that there is access between each array.

**605.11.1.2.2 Hip roof layouts.** Panels and modules installed on Group R-3 buildings with hip roof layouts shall be located

in a manner that provides a 3-foot-wide (914 mm) clear access pathway from the eave to the ridge on each roof slope where panels and modules are located. The access pathway shall be at a location on the building capable of supporting the fire fighters accessing the roof.

**Exception:** These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

❖ Where PV arrays are installed on the roofs of Group R-3 buildings, a minimum 3-foot (914 mm) access pathway must be left from the eave to the roof ridge so fire fighters have an unobstructed area in which to cut ventilation openings. The exception exempts low-slope roofs (i.e., a slope that is 2:12 or less) because of the reduced hazards of such flatter roofs.

**605.11.1.2.3 Single-ridge roofs.** Panels and modules installed on Group R-3 buildings with a single ridge shall be located in a manner that provides two, 3-foot-wide (914 mm) access pathways from the eave to the ridge on each roof slope where panels and modules are located.

**Exception:** This requirement shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

❖ Where PV arrays are installed on the roofs of Group R-3 buildings, a minimum of two 3-foot (914 mm) access pathways must be left from the eave to the roof ridge so fire fighters have an unobstructed area in which to cut ventilation openings. The exception exempts low-slope roofs (i.e., a slope that is 2:12 or less) due to the reduced hazards of such flatter roofs.

**605.11.1.2.4 Roofs with hips and valleys.** Panels and modules installed on Group R-3 buildings with roof hips and valleys shall not be located closer than 18 inches (457 mm) to a hip or a valley where panels/modules are to be placed on both sides of a hip or valley. Where panels are to be located on only one side of a hip or valley that is of equal length, the panels shall be permitted to be placed directly adjacent to the hip or valley.

**Exception:** These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

❖ Where installed on both sides of a roof hip or valley, PV arrays on the roofs of Group R-3 buildings must be located so they create a minimum 3-foot (914 mm) clearance between the PV arrays on opposing sides of the roof hip or valley so fire fighters have an unobstructed area in which to cut ventilation openings. The exception exempts low-slope roofs (i.e., a slope that is 2:12 or less) because of the reduced hazards of such flatter roofs.

**605.11.1.2.5 Allowance for smoke ventilation operations.** Panels and modules installed on Group R-3 buildings shall be located not less than 3 feet (914 mm) from the ridge in order to allow for fire department smoke ventilation operations.

**Exception:** Panels and modules shall be permitted to be located up to the roof ridge where an alternative ventilation method *approved* by the fire chief has been provided or where the fire chief has determined vertical ventilation techniques will not be employed.

❖ Manual ventilation is most effective when accomplished at the highest portion of the roof above the fire. This section establishes an obstruction-free zone within 3 feet (914 mm) of the roof ridge in order to optimize the area available for effective ventilation, allowing for a 2-foot (609.6 mm) trench cut.

The exception addresses the fact that in some cases vertical ventilation techniques or alternative techniques will not be used. This allows the panels and modules to be located higher up on the roof. Note that Exception 2 to Section 605.11.1 makes a similar allowance.

**605.11.1.3 Other than Group R-3 buildings.** Access to systems for buildings, other than those containing Group R-3 occupancies, shall be provided in accordance with Sections 605.11.1.3.1 through 605.11.1.3.3.

**Exception:** Where it is determined by the fire code official that the roof configuration is similar to that of a Group R-3 occupancy, the residential access and ventilation requirements in Sections 605.11.1.2.1 through 605.11.1.2.5 shall be permitted to be used.

❖ This section introduces PV system access requirements for other than Group R-3 buildings. The exception recognizes that nonresidential buildings are often constructed in a residential configuration and authorizes the fire code official to allow the provisions for Group R-3 construction styles to be used. The access and ventilation requirements are not occupancy specific but are affected most by the construction configuration.

**605.11.1.3.1 Access.** There shall be a minimum 6-foot-wide (1829 mm) clear perimeter around the edges of the roof.

**Exception:** Where either axis of the building is 250 feet (76 200 mm) or less, the clear perimeter around the edges of the roof shall be permitted to be reduced to a minimum 4 foot wide (1290 mm).

❖ PV arrays installed on the roofs of nonresidential buildings must be located so they create a minimum 6-foot (1829 mm) clearance between the PV array and roof edge so fire fighters have an unobstructed area in which to move and operate when cutting ventilation openings. The exception provides some flexibility for smaller buildings where less access to the roof is needed, therefore a reduced width of 4 feet is acceptable. Nongravity-operated smoke and heat vents require more access by the fire department to provide ventilation and require a 4-foot width around the vent.

**605.11.1.3.2 Pathways.** The solar installation shall be designed to provide designated pathways. The pathways shall meet the following requirements:

1. The pathway shall be over areas capable of supporting fire fighters accessing the roof.
2. The centerline axis pathways shall be provided in both axes of the roof. Centerline axis pathways shall run where the roof structure is capable of supporting fire fighters accessing the roof.
3. Pathways shall be a straight line not less than 4 feet (1290 mm) clear to roof standpipes or ventilation hatches.
4. Pathways shall provide not less than 4 feet (1290 mm) clear around roof access hatch with not less than one singular pathway not less than 4 feet (1290 mm) clear to a parapet or roof edge.

❖ Pathways must be established in the design of the solar installation and meet the requirements listed in this section. Placing the pathways over or adjacent to structural elements of the building provides a stable walking platform for personnel who will likely be carrying additional heavy equipment up to the roof. Straight pathways with a 4-foot (1290 mm) clearance to tripping and other hazards help provide a safe working environment for personnel assigned to roof-top operations.

**605.11.1.3.3 Smoke ventilation.** The solar installation shall be designed to meet the following requirements:

1. Arrays shall be not greater than 150 feet (45 720 mm) by 150 feet (45 720 mm) in distance in either axis in order to create opportunities for fire department smoke ventilation operations.
2. Smoke ventilation options between array sections shall be one of the following:
  - 2.1. A pathway 8 feet (2438 mm) or greater in width.
  - 2.2. A 4-foot (1290 mm) or greater in width pathway and bordering roof skylights or gravity-operated dropout smoke and heat vents on not less than one side.
  - 2.3. A 4-foot (1290 mm) or greater in width pathway and bordering all sides of nongravity-operated dropout smoke and heat vents.
  - 2.4. A 4-foot (1290 mm) or greater in width pathway and bordering 4-foot by 8-foot (1290 mm by 2438 mm) “venting cutouts” every 20 feet (6096 mm) on alternating sides of the pathway.

❖ This section establishes design options for providing adequate space among and around the PV arrays for safe fire department ventilation operations. Note that skylights and gravity-operated smoke and heat vents are only required to provide access on one side. Skylights are not intended to serve a ventilation purpose. In addition, gravity-operated smoke and heat vents will automatically provide ventilation if needed. Non-

gravity-operated smoke and heat vents will require more intervention from the fire department, therefore more access to those vents will be needed.

**605.11.2 Ground-mounted photovoltaic arrays.** Ground-mounted photovoltaic arrays shall comply with Section 605.11 and this section. Setback requirements shall not apply to ground-mounted, free-standing photovoltaic arrays. A clear, brush-free area of 10 feet (3048 mm) shall be required for ground-mounted photovoltaic arrays.

❖ This section applies all requirements for rooftop PV systems to ground-mounted PV systems except for the access, pathway and smoke ventilation clearance requirements since the physical hazards of a ground-mounted system are reduced. For visibility and service and emergency access, a clear zone around the arrays is required.

**605.12 Abandoned wiring in plenums.** Accessible portions of abandoned cables in air-handling plenums shall be removed. Cables that are unused and have not been tagged for future use shall be considered abandoned.

❖ This section introduces a concept that has long been in NFPA 70 and NFPA 90A—that plenums (see Chapter 2 commentary to the definition of “Plenum”) are intended specifically to be a part of the air distribution system. Plenums are also used legitimately for stringing communications and data cables as well as utility pipes, sprinkler pipes and similar items. However, such items often are not removed from the plenum when they become obsolete. For example, when an updated data system is installed in a facility (which can occur every 18 to 24 months), it is not unusual for old wires to be cut out of the system but left in place with a new wiring system added on top of them (see Commentary Figure 605.12).

The suspended ceiling tile systems that often enclose plenums are not intended to support any significant weight and can, therefore, easily be overwhelmed by the added weight of storage or abandoned materials such as cables (see commentary to IBC Section 808.1.1.1). Recently, a plenum space fuel load study showed how the safety of fire fighters is compromised by the weight of these abandoned cables. It pointed out that plenum space fuel loads and wiring issues are serious concerns for fire fighters during interior fire-fighting operations and its key recommendation was that abandoned wiring be removed.

Although the primary reason to require the removal of abandoned materials in plenums is the elimination of unnecessary weight, fire safety considerations should also be taken into account, as should the practical consideration that the HVAC design airflow through the plenum could be adversely affected. Such a requirement was long believed not to be enforceable primarily because fire code inspectors would rarely spend their time looking into plenums in existing buildings. However, the danger presented by the fire load of storage or abandoned materials is well-documented. Thus, there should be no signifi-

cant difficulty in having inspectors identify the existence of abandoned products—especially abandoned cables—classify them as storage and require their removal. Note that only the “accessible portions” of abandoned cables must be removed because there is no intent to cause potential damage to the building or facility by attempting to remove cables or circuits that are strung through walls, floors or other building elements. Where some cables are left in place because they are intended to be reused at a future date, they must be clearly identified as such by affixing a tag. See also Section 315.6.

## SECTION 606 MECHANICAL REFRIGERATION

[M] **606.1 Scope.** Refrigeration systems shall be installed in accordance with the *International Mechanical Code*.

❖ Chapter 11 of the IMC, in conjunction with ASHRAE 15 and IAR 2 provides complete coverage for the design, installation and maintenance of refrigeration systems.

**Figure 605.12  
ABANDONED WIRING IN PLENUM**

**[M] 606.2 Refrigerants.** The use and purity of new, recovered and reclaimed refrigerants shall be in accordance with the *International Mechanical Code*.

❖ Refrigeration equipment is designed to operate with a specific type or types of refrigerant. Using the wrong refrigerant or a contaminated refrigerant could cause equipment damage or loss of operating efficiency. Refrigerant types differ in how they react with system lubricants, seals, gaskets and other components.

Existing equipment may have to be converted to a different type of refrigerant or charged with refrigerant recovered from it or another system; however, it would be an unnecessary risk to charge new equipment with any refrigerant other than that specified by the equipment manufacturer. See the commentary to Section 1102.2 of the IMC.

**[M] 606.3 Refrigerant classification.** Refrigerants shall be classified in accordance with the *International Mechanical Code*.

❖ The classification of refrigerants is based on ASHRAE 34, which numbers and classifies refrigerants in accordance with their potential hazards. In the IMC, refrigerants are identified by their number, which is preceded by the letter “R” (for example, R-22). Trademark names of manufacturers, such as “Freon,” are not used. The refrigerant number, name and chemical formula can be found in IMC Table 1103.1.

Each refrigerant is classified into a safety group that is based on two factors: flammability and toxicity. The safety group in which an individual refrigerant is classified relates to the potential hazard to building occupants and fire fighters and is one of the factors used to determine the maximum quantities of refrigerants allowed by the IMC. See the commentary to Section 1103.1 of the IMC.

**[M] 606.4 Change in refrigerant type.** A change in the type of refrigerant in a refrigeration system shall be in accordance with the *International Mechanical Code*.

❖ The intent of this section is to keep the local fire code official up-to-date on the status of large refrigeration systems and systems containing toxic and/or flammable refrigerants. See the commentary to Section 1101.8 of the IMC.

**606.5 Access.** Refrigeration systems having a refrigerant circuit containing more than 220 pounds (100 kg) of Group A1 or 30 pounds (14 kg) of any other group refrigerant shall be accessible to the fire department at all times as required by the *fire code official*.

❖ Where any one or more refrigeration circuits contain more than the specified quantity limits, the room or building housing the system or systems must be constructed with fire department access for emergency response, inspection and hazard assessment. Refrigerants of other than Group A1 tend to be more flammable or toxic. This section could require that the fire

department be given keys to refrigeration machinery rooms and buildings.

**606.6 Testing of equipment.** Refrigeration equipment and systems having a refrigerant circuit containing more than 220 pounds (100 kg) of Group A1 or 30 pounds (14 kg) of any other group refrigerant shall be subject to periodic testing in accordance with Section 606.6.1. Records of tests shall be maintained. Tests of emergency devices or systems required by this chapter shall be conducted by persons trained and qualified in refrigeration systems.

❖ This section sets forth which refrigeration systems are subject to periodic testing and states that records of such testing must be maintained. Minimum qualifications are also required for testing personnel.

As a result of a review of Recommendation 2(c) of the NIST Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections (including this section), to comprehensively address recordkeeping requirements. Section 107.3 provides standardized recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2, 107.3, 107.4 and 606.6.1.

**606.6.1 Periodic testing.** The following emergency devices or systems shall be periodically tested in accordance with the manufacturer’s instructions and as required by the *fire code official*.

1. Treatment and flaring systems.
2. Valves and appurtenances necessary to the operation of emergency refrigeration control boxes.
3. Fans and associated equipment intended to operate emergency ventilation systems.
4. Detection and alarm systems.

❖ The devices and systems listed in this section are critical life safety and fire protection elements; therefore, it is imperative that they be tested periodically to assess their condition and dependability. Failure of the safety systems could lead to deadly consequences for building occupants and fire personnel entering the building in an emergency situation. See also the commentary to Section 1109.1 of the IMC.

**606.7 Emergency signs.** Refrigeration units or systems having a refrigerant circuit containing more than 220 pounds (100 kg) of Group A1 or 30 pounds (14 kg) of any other group refrigerant shall be provided with *approved* emergency

signs, charts and labels in accordance with NFPA 704. Hazard signs shall be in accordance with the *International Mechanical Code* for the classification of refrigerants listed therein.

- ❖ Signs, charts and labels are necessary to assist emergency response personnel in carrying out their duties to protect building occupants and protect themselves from the hazards associated with refrigerant chemicals (see IMC Table 1103.1).

**606.8 Refrigerant detector.** Machinery rooms shall contain a refrigerant detector with an audible and visual alarm. The detector, or a sampling tube that draws air to the detector, shall be located in an area where refrigerant from a leak will concentrate. The alarm shall be actuated at a value not greater than the corresponding TLV-TWA values shown in the *International Mechanical Code* for the refrigerant classification. Detectors and alarms shall be placed in *approved* locations. The detector shall transmit a signal to an *approved* location.

- ❖ Section 1105.3 of the IMC refers to the code for refrigerant detector requirements. Refrigerant detectors provide early warning of refrigerant leakage. Such leakage could result in a significant fire or health hazard if not discovered and stopped or if occupants are not evacuated from the building. Machinery rooms are required by the IMC where refrigerant quantities exceed specified limits.

Detector location is critical to early leakage warning and should comply with the detector manufacturer's instructions. The required detectors must be designed for application with the refrigerant or refrigerants used in the machinery room. Because machinery rooms are unattended most of the time, once the refrigerant gas is detected at the levels noted in this section, a local alarm must be initiated and a signal must be transmitted to an approved location remote from the machinery room, such as a security room or fire command center, or possibly to an on-duty, on-site technician via pager or cell phone. The alarm is intended to alert those both inside the area of detection and in the immediate vicinity to prevent harm to those outside the area of refrigerant gas release. The notification to an approved location provides timely information to those who must take a role in emergency response, whereas the local alarm is a warning for those in the vicinity of the release. As a first step in the mitigation of the hazards of fugitive refrigerant gas, the required detectors have the additional important role of activating the emergency ventilation/exhaust systems in the machinery rooms required by Sections 1105.6.3 and 1106.3 of the IMC (see the definition of "Machinery room" and Table 1103.1, both in the IMC).

**606.9 Remote controls.** Where flammable refrigerants are used and compliance with Section 1106 of the *International Mechanical Code* is required, remote control of the mechanical equipment and appliances located in the machinery room as required by Sections 606.9.1 and 606.9.2 shall be provided

at an approved location immediately outside the machinery room and adjacent to its principal entrance.

- ❖ Emergency controls located outside of the machinery room enclosure will allow shutdown of the compressors and related equipment without requiring someone to enter the room and risk being exposed to refrigerant or fire. This arrangement would also permit equipment shutdown by fire-fighting personnel without the risk of fire spreading into or out of the fire-resistance-rated enclosure. The controls must be located near the entrance to the machinery room so that their location is conspicuous. The controls should be labeled and color coded so that their purpose is obvious. Such controls are customarily painted red to make them readily identifiable as emergency devices.

**606.9.1 Refrigeration system emergency shutoff.** A clearly identified switch of the break-glass type or with an *approved* tamper-resistant cover shall provide off-only control of refrigerant compressors, refrigerant pumps and normally closed automatic refrigerant valves located in the machinery room. Additionally, this equipment shall be automatically shut off when the refrigerant vapor concentration in the machinery room exceeds the vapor detector's upper detection limit or 25 percent of the LEL, whichever is lower.

- ❖ The intent of this section of the code is to provide a safe environment for emergency response personnel when responding to an incident in a refrigeration room. Shutting down compressors and related refrigeration equipment could be necessary to prevent a hazardous condition from worsening and to allow the room to be safely entered. The emergency "kill" switch must be a tamper-resistant type (similar to manual fire alarm boxes) that requires more than one action to actuate it. To prevent an accidental startup, the switch must be capable of only stopping the controlled machinery, not restarting it. The switch must not affect the operation of life safety systems, such as detectors and exhaust equipment, and must not affect room and egress lighting. In addition to the manual switch, the required refrigerant room detector must also shut down the same equipment when the vapor concentration exceeds the lesser of the detector's upper detection limit or 25 percent of the refrigerant's lower explosive limit (LEL).

**606.9.2 Ventilation system.** A clearly identified switch of the break-glass type or with an approved tamper-resistant cover shall provide on-only control of the machinery room ventilation fans.

- ❖ For the same reasoning stated in the commentary to Section 606.9.1, a remote switch is required that is not connected to the exhaust system. Although not specifically stated, the intent is for the remote control to activate the emergency mode of operation (see IMC commentary, Section 1106.5.2). To maximize the dependability of the exhaust systems, ASHRAE 15 requires that they be powered from independent dedicated electrical branch circuits.

**606.10 Emergency pressure control system.** Permanently installed refrigeration systems containing more than 6.6 pounds (3 kg) of flammable, toxic or highly toxic refrigerant or ammonia shall be provided with an emergency pressure control system in accordance with Sections 606.10.1 and 606.10.2.

❖ Technological advances in refrigeration system control equipment now make it possible to provide an automatic emergency control system to replace key functions of the traditional emergency control box. The automatic controls required by Sections 606.10.1 through 606.10.2.2 provide a means of mitigating an overpressure condition prior to operation of emergency pressure-relief vents and, most likely, prior to the arrival of emergency responders. The automatic valves also eliminate the need for emergency responders to decipher the condition of a system in an attempt to determine whether operation of manual crossover valves in an emergency control box would be of benefit in mitigating a system malfunction. The 6.6-pound (3 kg) threshold parallels existing provisions in Section 606.11. This section parallels Section 1105.9 of the IMC to increase the likelihood that designers don't miss this design requirement in the code. Note that these provisions are intended for permanently installed systems versus portable systems such as agricultural cooling trailers used in fields and at processing facilities. This is specifically clarified by the term "permanently installed."

Overall, these provisions add a requirement for a fully redundant safety control system in lieu of a manual system that has proven itself to be rarely, if ever, utilized by the fire service. This favorably resolves long-standing concerns regarding the potential for harm caused by an untrained person operating valves in an emergency control box. There is no condition where removal of refrigerant from a refrigeration system by the fire service is considered advisable. In contrast, automatic transfer of excess pressure to another zone of the system in conjunction with stopping the pressure source (i.e., the compressors) can safely mitigate an overpressure condition.

**606.10.1 Automatic crossover valves.** Each high- and intermediate-pressure zone in a refrigeration system shall be provided with a single automatic valve providing a crossover connection to a lower pressure zone. Automatic crossover valves shall comply with Sections 606.10.1.1 through 606.10.1.3.

❖ The requirement for a single crossover valve between systems is based on the traditional industry practice of providing a single manual crossover valve in the emergency control box. In the unlikely event that a fire causes an overpressure condition, allowing system zones to automatically interconnect creates a much larger heat sink to limit pressure buildup while safely containing refrigerant. If the exposure fire continues to grow, emergency relief vents can protect the refrigeration system and automatic reseating valves

can automatically limit the release of refrigerant to the amount necessary to maintain the system within design limits. In contrast, most emergency responders would not possess the expertise to properly cycle a manual valve in an emergency control box to limit the release of refrigerant to the minimum amount necessary for safety.

**606.10.1.1 Overpressure limit set point.** Automatic crossover valves shall be arranged to automatically relieve excess system pressure to a lower pressure zone if the pressure in a high- or intermediate-pressure zone rises to within 90 percent of the set point for emergency pressure relief devices.

❖ This section provides a safety buffer between activation of the emergency pressure control system (EPCS) and operation of a relief valve. Because of variances in operational tolerances among relief valves and because some relief valves may begin to seep at 90 percent of their rated operating pressure, it is appropriate to have the EPCS shut down a system if system pressure rises to 90 percent of the relief valve set pressure. This further reduces the potential for any release from a system that has malfunctioned and overpressurized.

**606.10.1.2 Manual operation.** Where required by the *fire code official*, automatic crossover valves shall be capable of manual operation.

❖ This section authorizes the local fire code official to require manual control capabilities for the crossover valve. Although this provision is not regarded as necessary by the industry, it is recognized that some fire departments will prefer to have the manual control capability for backup.

**606.10.1.3 System design pressure.** Refrigeration system zones that are connected to a higher pressure zone by an automatic crossover valve shall be designed to safely contain the maximum pressure that can be achieved by interconnection of the two zones.

❖ This provision requires lower pressure zones to be capable of handling additional pressure added by a crossover condition without overpressurizing or operating the emergency relief vents on the lower zone. The legacy codes did not address this concern, given the assumption that someone operating a manual bypass valve in the emergency control box would be knowledgeable with regard to system limitations; however, this may or may not be true. Nevertheless, the legacy codes never required the low pressure side of the system to handle the high-side pressure, and as a result, some systems with emergency control boxes present the potential for an emergency responder to overpressurize a system zone by fully opening a manual crossover valve too quickly. The resulting overpressure condition could cause operation of a relief vent or even a failure in the piping system.

**606.10.2 Automatic emergency stop.** An automatic emergency stop feature shall be provided in accordance with Sections 606.10.2.1 and 606.10.2.2.

❖ This establishes applicability of the requirements for the additional safety feature of an emergency stop feature in refrigeration systems.

**606.10.2.1 Operation of an automatic crossover valve.** Operation of an automatic crossover valve shall cause all compressors on the affected system to immediately stop. Dedicated pressure-sensing devices located immediately adjacent to crossover valves shall be permitted as a means for determining operation of a valve. To ensure that the automatic crossover valve system provides a redundant means of stopping compressors in an overpressure condition, high-pressure cutout sensors associated with compressors shall not be used as a basis for determining operation of a crossover valve.

❖ The intent of this section is for the automatic crossover system to have a fully redundant means of stopping compressors. Compressors are ordinarily provided with automatic high-pressure cutout controls, but this section requires that these controls not be used to satisfy the requirement. An additional set of controls can be required to serve as a backup means of preventing a severe overpressure condition that could cause operation of an emergency relief vent.

**606.10.2.2 Overpressure in low-pressure zone.** The lowest pressure zone in a refrigeration system shall be provided with a dedicated means of determining a rise in system pressure to within 90 percent of the set point for emergency pressure relief devices. Activation of the overpressure sensing device shall cause all compressors on the affected system to immediately stop.

❖ The lowest pressure zone of a system cannot be arranged to bleed pressure to another system zone since crossing the lowest pressure zone to a higher pressure zone would most likely result in reverse flow. However, by providing a redundant emergency stop control, which would disengage the compressor, an overpressure condition should be automatically mitigated. Overpressure on a low-pressure zone would most likely result from a defrost line from the high side that is stuck in the open position, and stopping the compressor will disengage the pressure source for the defrost system. Note that compressors will only cut out if an overpressure condition occurs. If the emergency condition involves a leak on the low side, compressors will continue to operate, which is beneficial in pumping down the low side for this type of event.

**606.11 Storage, use and handling.** Flammable and combustible materials shall not be stored in machinery rooms for refrigeration systems having a refrigerant circuit containing more than 220 pounds (100 kg) of Group A1 or 30 pounds

(14 kg) of any other group refrigerant. Storage, use or handling of extra refrigerant or refrigerant oils shall be as required by Chapters 50, 53, 55 and 57.

**Exception:** This provision shall not apply to spare parts, tools and incidental materials necessary for the safe and proper operation and maintenance of the system.

❖ Storage of materials could introduce additional hazards in rooms already considered to be hazardous because of large quantities of refrigerants in the system circuits and machines.

**606.12 Discharge and termination of pressure relief and purge systems.** Pressure relief devices, fusible plugs and purge systems discharging to the atmosphere from refrigeration systems containing flammable, toxic or highly toxic refrigerants or ammonia shall comply with Sections 606.12.3 through 606.12.5.

❖ Discharge systems are intended to treat, incinerate or absorb flammable or toxic refrigerants that would otherwise be released unaltered into the atmosphere. Release would result from the operation of pressure relief devices or intentional dumping of refrigerant in an emergency. Specific requirements are found in the subsections for each type of refrigeration system.

**606.12.1 Standards.** Refrigeration systems and the buildings in which such systems are installed shall be in accordance with ASHRAE 15.

❖ This section is simply making sure that all ammonia refrigeration systems comply with ASHRAE 15 in addition to the requirements of Section 606.12. This section parallels Section 1105.8 of the IMC, which also references ASHRAE 15.

**606.12.1.1 Ammonia refrigeration.** Refrigeration systems using ammonia refrigerant and the buildings in which such systems are installed shall comply with IAR-2 for system design and installation and IAR-7 for operating procedures.

❖ This reference provides appropriate referenced standards for refrigeration system design and installation and for operating procedures. These standards are considered essential for facilities with ammonia refrigeration systems as a basis of providing for the safety of these facilities, as well as surrounding communities.

**606.12.2 Fusible plugs and rupture members.** Discharge piping and devices connected to the discharge side of a fusible plug or rupture member shall have provisions to prevent plugging the pipe in the event the fusible plug or rupture member functions.

❖ This section is intended to ensure that, through the use of discharge piping and devices, the emergency pressure relief system will not become obstructed in the event that a fusible plug or rupture member operates and causes debris to be ejected into the relief system.

**606.12.3 Flammable refrigerants.** Systems containing more than 6.6 pounds (3 kg) of flammable refrigerants having a density equal to or greater than the density of air shall discharge vapor to the atmosphere only through an *approved* treatment system in accordance with Section 606.12.6 or a flaring system in accordance with Section 606.12.7. Systems containing more than 6.6 pounds (3 kg) of flammable refrigerants having a density less than the density of air shall be permitted to discharge vapor to the atmosphere provided that the point of discharge is located outside of the structure at not less than 15 feet (4572 mm) above the adjoining grade level and not less than 20 feet (6096 mm) from any window, ventilation opening or *exit*.

❖ Where they have a density greater than air (i.e., are heavier than air) and pose the hazard of collecting in low points, which could bring them into contact with ignition sources, flammable refrigerants (A2, B2, A3, B3) must be incinerated in a flaring system (see Section 6004.2.2.7.1). The second sentence of the provision is derived from ANSI/ASHRAE 15 and recognizes the reduced hazard of lighter-than-air flammable refrigerants by allowing them to discharge to the atmosphere without incineration or treatment since they would either dissipate into the air or flare at the point of discharge. Because of their flammability hazard, however, the point of discharge must be located out of reach from grade and well away from building openings. Note that these provisions apply only to systems that contain more than 6.6 pounds (3 kg) of refrigerant because systems containing smaller quantities are considered “small systems” and their relative hazard is considered insignificant.

**606.12.4 Toxic and highly toxic refrigerants.** Systems containing more than 6.6 pounds (3 kg) of toxic or highly toxic refrigerants shall discharge vapor to the atmosphere only through an *approved* treatment system in accordance with Section 606.12.6 or a flaring system in accordance with Section 606.12.7.

❖ Toxic refrigerants, like flammable refrigerants, must be treated to reduce their toxicity or be destroyed by incineration (see Section 6004.2.2.7.1).

**606.12.5 Ammonia refrigerant.** Systems containing more than 6.6 pounds (3 kg) of ammonia refrigerant shall discharge vapor to the atmosphere in accordance with one of the following methods:

1. Directly to atmosphere where the *fire code official* determines, on review of an engineering analysis prepared in accordance with Section 104.7.2, that a fire, health or environmental hazard would not result from atmospheric discharge of ammonia.
2. Through an *approved* treatment system in accordance with Section 606.12.6.
3. Through a flaring system in accordance with Section 606.12.7.
4. Through an *approved* ammonia diffusion system in accordance with Section 606.12.8.

5. By other *approved* means.

**Exception:** Ammonia/water absorption systems containing less than 22 pounds (10 kg) of ammonia and for which the ammonia circuit is located entirely outdoors.

❖ This section is more restrictive than ASHRAE 15 in that it requires the discharge to be treated in one of the listed methods. Item 1 recognizes that there are some cases, such as at remote facilities, where atmospheric discharge of ammonia would pose no danger to people or property. Further, it provides a basis in the code for permitting relief lines on ammonia refrigeration systems to discharge to the atmosphere when an appropriate analysis, accepted by the fire code official, has shown that such discharge can be accomplished safely. In such cases, a flaring or water diffusion system would serve no beneficial purpose, since ammonia is naturally biodegradable. Items 2 through 4 allow the use of one of three methods, including treatment systems, flaring system or an ammonia diffusion system.

Item 5 recognizes that engineered designs can be used to activate an alarm and automatically stop the leak rather than relying on manual means to stop the leak and a water tank to treat whatever release may occur before manual intervention can be accomplished.

The exception recognizes the reduced hazard in smaller systems where the ammonia circuit is completely outdoors.

**606.12.6 Treatment systems.** Treatment systems shall be designed to reduce the allowable discharge concentration of the refrigerant gas to not more than 50 percent of the IDLH at the point of exhaust. Treatment systems shall be in accordance with Chapter 60.

❖ See the commentary to Section 6004.2.2.7. “Immediately Dangerous to Life and Health (IDLH)” is defined in Section 202.

**606.12.7 Flaring systems.** Flaring systems for incineration of flammable refrigerants shall be designed to incinerate the entire discharge. The products of refrigerant incineration shall not pose health or environmental hazards. Incineration shall be automatic upon initiation of discharge, shall be designed to prevent blowback and shall not expose structures or materials to threat of fire. Standby fuel, such as LP-gas, and standby power shall have the capacity to operate for one and one-half the required time for complete incineration of refrigerant in the system. Standby electrical power, where required to complete the incineration process, shall be in accordance with Section 604.

❖ Destruction of refrigerant by incineration is supposed to render the discharge harmless, so obviously the flames and the combustion byproducts do not pose a hazard themselves. Because most refrigerants would not support combustion unaided, a fuel source is necessary to sustain incineration.

**606.12.8 Ammonia diffusion systems.** Ammonia diffusion systems shall include a tank containing 1 gallon of water for

each pound of ammonia (8.3 L of water for each 1 kg of ammonia) that will be released in 1 hour from the largest relief device connected to the discharge pipe. The water shall be prevented from freezing. The discharge pipe from the pressure relief device shall distribute ammonia in the bottom of the tank, but not lower than 33 feet (10 058 mm) below the maximum liquid level. The tank shall contain the volume of water and ammonia without overflowing.

❖ Ammonia is readily absorbed by water; therefore, an ammonia discharge into a water tank would be chemically held in the tank. The water tank may have to be heated to prevent it from freezing, which would block the discharge pipe and make the water useless for absorbing ammonia. The deeper the discharge pipe extends below the water surface, the greater the pressure the discharge would have to overcome to escape from the pipe. A 33-foot (10 058 mm) depth of water would exert a pressure approximately equal to sea level atmospheric pressure [14.7 psi (101 kPa)].

**606.13 Discharge location for refrigeration machinery room ventilation.** Exhaust from mechanical ventilation systems serving refrigeration machinery rooms containing flammable, toxic or highly toxic refrigerants, other than ammonia, capable of exceeding 25 percent of the LFL or 50 percent of the IDLH shall be equipped with *approved* treatment systems to reduce the discharge concentrations to those values or lower.

❖ In previous editions of the code, this section required the discharge of mechanical ventilation systems serving refrigeration machinery rooms utilizing anhydrous ammonia to be directed to a treatment system to reduce the toxicity to 50 percent of its IDLH value, the same as the more hazardous refrigerants. This section now permits the mechanical ventilation system to exhaust directly to the atmosphere when anhydrous ammonia is the refrigerant. Anhydrous ammonia is classified by Table 1103.1 of the IMC as a corrosive liquefied compressed gas. It is not a toxic or highly toxic gas, as defined in Section 202 of the code, nor does it meet the definition of a flammable gas. It has a vapor density of 0.597, making it lighter than air, and is extremely hygroscopic (a Latin word literally meaning “water seeking”), thus it aggressively absorbs water. Anhydrous ammonia’s water-absorbing abilities can be of benefit to fire fighters, who can use hose or master streams to control anhydrous ammonia if it is leaking.

Exclusion of anhydrous ammonia from the requirement of this section also provides correlation with Section 1105.8 of the IMC, which addresses pressure relief systems for refrigeration systems. The IMC requires pressure relief devices be terminated in accordance with the requirements of American Society of Refrigeration and Air Conditioning Engineers (ASHRAE) Standard 15, Safety Standard for Refrigeration Systems. ASHRAE 15 requires pressure relief devices serving ammonia refrigeration equipment to be terminated outside of buildings and permits these devices to discharge to the atmosphere.

**606.14 Notification of refrigerant discharges.** The *fire code official* shall be notified immediately when a discharge becomes reportable under state, federal or local regulations in accordance with Section 5003.3.1.

❖ Emergency personnel must be informed of a discharge so that they can respond appropriately. The refrigerant discharge notification requirements of this section parallel those required for all hazardous materials in Section 5003.3.1. There is no reason for different requirements for refrigerants than for other hazardous materials.

**606.15 Records.** A record of refrigerant quantities brought into and removed from the premises shall be maintained.

❖ Emergency personnel must be able to maintain accurate assessments of the dangers they may face and the hazards the public may face in and around buildings housing refrigeration systems.

As a result of a review of Recommendation 2(c) of the NIST Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections (including this section), to comprehensively address recordkeeping requirements. Section 107.3 provides standardized recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2 and 107.3.

**606.16 Electrical equipment.** Where refrigerants of Groups A2, A3, B2 and B3, as defined in the *International Mechanical Code*, are used, refrigeration machinery rooms shall conform to the Class I, Division 2 hazardous location classification requirements of NFPA 70.

**Exception:** Ammonia machinery rooms that are provided with ventilation in accordance with Section 1106.3 of the *International Mechanical Code*.

❖ This section mirrors the text of Section 1106.4 of the IMC and is included in the code because, in some jurisdictions, the fire code official is designated to inspect classified electrical equipment. A reference to classified electrical requirements here is consistent with the approach taken in Chapters 50 and 57 for other hazardous materials and flammable liquids, and it provides the fire code official with the provisions that are to be enforced.

The exception for ammonia refrigerant is consistent with requirements of NFPA 70 and is included here to avoid possible confusion regarding the need for classified electrical equipment in ammonia machinery rooms. Because ammonia can combust within a lim-

ited range of concentrations in the air, the fire code official might be led to believe that classified electrical equipment should be provided in ammonia storage and use areas; however, when such areas are ventilated to maintain ammonia vapor in a concentration that is outside of the flammable range, there is no need for classified electrical equipment.

**SECTION 607  
ELEVATOR OPERATION,  
MAINTENANCE AND FIRE SERVICE KEYS**

**607.1 Emergency operation.** Existing elevators with a travel distance of 25 feet (7620 mm) or more shall comply with the requirements in Chapter 11. New elevators shall be provided with Phase I emergency recall operation and Phase II emergency in-car operation in accordance with ASME A17.1.

❖ Elevators are often used as a tool by emergency personnel when responding to fires and other emergencies. Due to these needs, the elevators must be capable of providing certain functions such as recall and emergency operation.

This section establishes requirements for both new and existing elevators. Existing elevators that travel 25 feet (635 mm) or more above or below the main level must, as a minimum, be equipped with emergency operation capabilities that comply with ASME A17.3 as required by Section 1103.3.2. New elevator installations are held to more restrictive guidelines for increased cost effectiveness and must have both emergency recall (Phase I) and emergency in-car operation (Phase II) to comply with ASME A17.1 for any amount of travel distance. The ASME standards are safety codes for elevators and escalators: ASME A17.3 is for existing elevators and ASME A17.1 for new elevator installations.

**607.2 Standby power.** In buildings and structures where standby power is required or furnished to operate an elevator, standby power shall be provided in accordance with Section 604. Operation of the system shall be in accordance with Sections 607.2.1 through 607.2.4.

❖ This section states how standby power is to be supplied to elevators when required by other sections, such as Section 604.2.17. The requirements from this section are the same as those located in Chapter 30 of the IBC.

**607.2.1 Manual transfer.** Standby power shall be manually transferable to all elevators in each bank.

❖ This section requires that whenever necessary, all elevators in each bank of elevators must be equipped for manual transfer to standby power. All elevators, however, would not need to operate on standby power at the same time; they would have to have manual transfer capability.

**607.2.2 One elevator.** Where only one elevator is installed, the elevator shall automatically transfer to standby power within 60 seconds after failure of normal power.

❖ When a building has a single elevator, it must be automatically transferred to standby power within 60 seconds. The 60 seconds is a reflection of the NFPA 70 requirements for standby power.

**607.2.3 Two or more elevators.** Where two or more elevators are controlled by a common operating system, all elevators shall automatically transfer to standby power within 60 seconds after failure of normal power where the standby power source is of sufficient capacity to operate all elevators at the same time. Where the standby power source is not of sufficient capacity to operate all elevators at the same time, all elevators shall transfer to standby power in sequence, return to the designated landing and disconnect from the standby power source. After all elevators have been returned to the designated level, not less than one elevator shall remain operable from the standby power source.

❖ When there is more than one elevator operating off of a common system, the elevators must all be transferred to standby power within 60 seconds. When only one elevator needs to be available during a loss of power, all elevators must still have the ability to run on standby power. Specifically, all elevators must initially connect to the standby power system and then, in sequence, return to the designated floor where all but one would be disconnected from the standby power.

**607.2.4 Machine room ventilation.** Where standby power is connected to elevators, the machine room ventilation or air conditioning shall be connected to the standby power source.

❖ This section reduces the likelihood that the equipment running the elevators will overheat during a loss of power because standby power is also required to power the ventilation or air conditioning for those areas. Note that this would also address machine spaces, control rooms and control spaces.

**[BE] 607.3 Emergency signs.** An *approved* pictorial sign of a standardized design shall be posted adjacent to each elevator call station on all floors instructing occupants to use the exit stairways and not to use the elevators in case of fire. The sign shall read: IN FIRE EMERGENCY, DO NOT USE ELEVATOR. USE EXIT STAIRS.

**Exceptions:**

1. The emergency sign shall not be required for elevators that are part of an accessible *means of egress* complying with Section 1009.4.
2. The emergency sign shall not be required for elevators that are used for occupant self-evacuation in accordance with Section 3008 of the *International Building Code*.

❖ Because of the needs of fire fighters and the possible risks posed by the use of elevators during a fire, sig-

nage is required that prohibits the use of elevators by building occupants during a fire emergency. The need to evacuate all occupants regardless of their physical abilities is becoming a more important issue and, in some cases, elevators are specifically used for such purposes. Elevators used as part of the means of egress must comply with Section 1009.4.

**607.4 Fire service access elevator lobbies.** Where fire service access elevators are required by Section 3007 of the *International Building Code*, fire service access elevator lobbies shall be maintained free of storage and furniture.

❖ The fire service access elevator in high-rise buildings over 120 feet (3657 mm) in height above fire department vehicle access, as now required by Section 403.6.1 of the IBC, is a tool which enhances fire fighters' abilities to gain access to the fire floor and undertake necessary operational staging activities in a protected area. This section complements the provisions of the fire service access elevator provisions contained in Section 3007 of the IBC by requiring that fire service access elevator lobbies always be fully and immediately accessible by the fire service without impediment by storage or furniture and the fire load that some items might present. It is not unusual, especially in Group R-1 occupancies, to see tables, chairs, sofas or the like placed in areas opposite elevator entrances for aesthetic purposes in what may now be a required fire service access elevator lobby. This section would prohibit that practice. It should also be noted that the provisions of this section apply to noncombustible storage and furnishings, as well as combustible (see the IBC commentary, Sections 403.6.1 and 3007).

**607.5 Occupant evacuation elevator lobbies.** Where occupant evacuation elevators are provided in accordance with Section 3008 of the *International Building Code*, occupant evacuation elevator lobbies shall be maintained free of storage and furniture.

❖ This section is similar in intent to Section 607.4 for fire service access elevators except that the focus is providing adequate space for those awaiting evacuation via the elevators. If storage or furnishings are allowed, it takes away from that space and also will cause more people to wait outside the protected lobby. Placing combustibles within the lobby also creates potential fire hazards.

**607.6 Water protection of hoistway enclosures.** Methods to prevent water from infiltrating into a hoistway enclosure required by Section 3007.4 and Section 3008.4 of the *International Building Code* shall be maintained.

❖ Sections 3007.4 and 3008.4 of the IBC require that hoistway openings be protected from water originating from sprinklers activated outside of the elevator lobby. This is critical to extend the use of elevators during a fire. The methods used are not prescribed in the IBC but often will require some level of maintenance

to make sure they will be available during a fire. This section creates the maintenance mechanism.

**607.7 Elevator key location.** Keys for the elevator car doors and fire-fighter service keys shall be kept in an *approved* location for immediate use by the fire department.

❖ The fire service often responds to elevator emergencies and other emergencies that require the use or operation of the elevators and associated components. Most elevators will have at least five or six key-switched functions, including those for standby power transfer, Phase I emergency elevator recall (hall switch located in the elevator lobby at the designated level), Phase II in-cab emergency operation, inspection function, normal lighting and fan operation. Ready access to elevator keys is an important factor in the timely and efficient response to emergency situations. Because experience has shown that this important safety element is often overlooked, this section requires that elevator keys be kept in a location approved by the fire code official to ensure immediate access. Many elevator installers will provide, as part of their package, an elevator key box (see Commentary Figure 607.7), which will accommodate all of the required operating keys, plus an appropriate hoistway access key or tool for fire department use in accessing the hoistway in case of an elevator emergency. Elevator inspection reports should note the presence and locations of the keys. Inspectors may verify the availability of the keys during periodic fire safety inspections and prefire planning surveys.

**Figure 607.7**  
**TYPICAL ELEVATOR KEY BOX**

**607.8 Standardized fire service elevator keys.** Buildings with elevators equipped with Phase I emergency recall, Phase II emergency in-car operation, or a fire service access eleva-

tor shall be equipped to operate with a standardized fire service elevator key approved by the *fire code official*.

**Exception:** The owner shall be permitted to place the building's nonstandardized fire service elevator keys in a key box installed in accordance with Section 506.1.2.

❖ When fire departments and other emergency response agencies respond to emergencies, their ability to quickly access the location of the emergency can be the deciding factor of a successful response. Elevators are increasingly being relied upon for emergency operations and their importance has been highlighted by adding Section 3007 to the IBC requiring the installation of fire service access elevators and providing requirements for the installation of occupant evacuation elevators. One of the difficulties the fire service and other emergency response agencies have when accessing facilities and attempting to use elevators is the number of nonstandardized keys that may not be available at the time of response. Even when emergency responders are provided the necessary keys in case of response, the correct key may have to be identified from a large collection of keys for any one building. In larger jurisdictions, the sheer number of keys makes possession of them unwieldy for the emergency responders. An elevator key is an important tool to fire fighters. The key allows fire fighters to access the interior of the shaft housing an elevator cabin to initiate rescue in case of a malfunction or the loss of building power. More often, an elevator key is used to capture and control an elevator in emergencies. This section establishes new requirements for elevator keys used by the fire service that will only apply to those buildings that have elevators with Phase I or Phase II emergency service or to those buildings equipped with a fire service access elevator.

The exception recognizes that many jurisdictions have elevators built prior to the introduction of a standard elevator key and, as a result, each building with an elevator requires its own elevator key, and authorizes the jurisdiction to require the installation of a key box to house nonstandardized elevator keys (see commentary, Section 506.1.2).

**607.8.1 Requirements for standardized fire service elevator keys.** Standardized fire service elevator keys shall comply with all of the following:

1. All fire service elevator keys within the jurisdiction shall be uniform and specific for the jurisdiction. Keys shall be cut to a uniform key code.
2. Fire service elevator keys shall be of a patent-protected design to prevent unauthorized duplication.
3. Fire service elevator keys shall be factory restricted by the manufacturer to prevent the unauthorized distribution of key blanks. Uncut key blanks shall not be permitted to leave the factory.

4. Fire service elevator keys subject to these rules shall be engraved with the words "DO NOT DUPLICATE."

❖ This section requires that keys for any new elevators installed in the jurisdiction use a unique but standard format, regardless of elevator manufacturer or model. Standardizing the type of elevator key creates a consistent arrangement for fire fighters who utilize the elevators for EMS incidents or for the deployment of personnel and equipment in a multiple-story fire fighting operation. The keys must be manufactured to prevent unauthorized duplication.

**607.8.2 Access to standardized fire service keys.** Access to standardized fire service elevator keys shall be restricted to the following:

1. Elevator owners or their authorized agents.
2. Elevator contractors.
3. Elevator inspectors of the jurisdiction.
4. *Fire code officials* of the jurisdiction.
5. The fire department and other emergency response agencies designated by the *fire code official*.

❖ Access to or possession of a key that can take control of an elevator in a building is an area of vulnerability for buildings that was not previously addressed with simple key designs being utilized. In addition to the limitations placed on the unauthorized duplication and distribution of standardized elevator keys in Section 607.8.3, this section specifies exactly to whom the keys will be accessible. This list includes only those persons who have a vested interest in the building, the elevator equipment or the protection of the building.

**607.8.3 Duplication or distribution of keys.** A person shall not duplicate a standardized fire service elevator key or issue, give, or sell a duplicated key unless in accordance with this code.

❖ This section provides for a level of security for the standardized key by prohibiting its unauthorized duplication and distribution. Note that Section 607.8.1 requires that keys be stamped or embossed with a duplication prohibition warning.

**607.8.4 Responsibility to provide keys.** The building owner shall provide up to three standardized fire service elevator keys where required by the *fire code official*, upon installation of a standardized fire service key switch or switches in the building.

❖ This section establishes the responsibility of the building owner to provide at least three keys of the same standard design when an elevator is equipped with Phase I and II fire-fighter service or is a fire service access elevator. Multiple keys allow fire companies to use multiple elevators to carry personnel and equipment to the fire floor or swiftly remove multiple injured or otherwise incapacitated persons from upper or lower floors.

**SECTION 608  
STATIONARY STORAGE BATTERY SYSTEMS**

**608.1 Scope.** Stationary storage battery systems having an electrolyte capacity of more than 50 gallons (189 L) for flooded lead-acid, nickel cadmium (Ni-Cd) and valve-regulated lead-acid (VRLA), or more than 1,000 pounds (454 kg) for lithium-ion and lithium metal polymer, used for facility standby power, emergency power or uninterruptible power supplies shall comply with this section and Table 608.1.

❖ This section applies to certain sizes of stationary storage battery systems that are used for standby power, emergency power or uninterruptible power systems. It does not apply to individual stationary storage batteries such as are used in vehicles or other similar applications. The requirements apply to flooded lead-acid batteries having an electrolyte capacity of more than 50 gallons (189 L) and to VRLA, and to lithium-ion and lithium metal polymer batteries having an electrolyte capacity of more than 1,000 pounds (454 kg).

These requirements were developed in response to the concern that applying the generic hazardous materials requirements of the code to battery systems was inappropriate and unnecessary. Stationary storage batteries generally contain sulfuric acid, which is considered a corrosive liquid. In most cases, the battery system electrolyte would exceed the MAQs established in Chapter 50, which would lead to battery rooms being classified as a Group H occupancy. Generally, these types of systems have had a good safety record and, if the guidelines set out in Section 608 are followed, pose a very low hazard to the building, its occupants and emergency respond-

ers. In many cases, such systems are found in buildings with very low occupant loads, such as telephone company exchanges.

There are some very specific differences in the two types of batteries, recombinant and nonrecombinant, that should be understood in applying the requirements of Section 608. First, recombinant batteries are designed so that if punctured or damaged, they would not spill because the electrolyte is immobilized in an absorptive glass mat or by a gelling agent. Second, recombinant batteries do not routinely emit hydrogen gas to the atmosphere, as do nonrecombinant stationary storage batteries. Recombinant batteries vent hydrogen only when the internal pressure exceeds the ambient pressure; therefore, hydrogen release is still an issue and ventilation is still required.

Nonrecombinant (flooded) stationary storage batteries, on the other hand, are more likely to have a spill but routinely emit hydrogen to the atmosphere and thus are not as highly subject to pressure buildup. Also, recombinant batteries are often used in locations where the flooded types have not traditionally been used, such as in cabinets in a business occupancy. Nonrecombinant batteries are more typically used in locations such as a phone company exchange with a low occupant load.

Table 608.1 provides a convenient summary of battery requirements contained in this section.

**608.2 Safety caps.** Safety caps for stationary storage battery systems shall comply with Sections 608.2.1 and 608.2.2.

❖ See the commentary to Sections 608.2.1 and 608.2.2 for discussion of these essential safety devices for batteries.

**TABLE 608.1  
BATTERY REQUIREMENTS**

REQUIREMENT	NONRECOMBINANT BATTERIES		RECOMBINANT BATTERIES		OTHER BATTERIES
	Vented (Flooded) Lead Acid Batteries	Vented (Flooded) Nickel-Cadmium (Ni-Cd) Batteries	Valve Regulated Lead-Acid (VRLA) Cells	Lithium-Ion Cells	Lithium Metal Cells
Safety caps	Venting caps (608.2.1)	Venting caps (608.2.1)	Self-sealing flame-arresting caps (608.2.2)	No caps	No caps
Thermal runaway management	Not required	Not required	Required (608.3)	Not required	Required (608.3)
Spill control	Required (608.5)	Required (608.5)	Not required	Not required	Not required
Neutralization	Required (608.5.1)	Required (608.5.1)	Required (608.5.2)	Not required	Not required
Ventilation	Required (608.6.1; 608.6.2)	Required (608.6.1; 608.6.2)	Required (608.6.1; 608.6.2)	Not required	Not required
Signage	Required (608.7)	Required (608.7)	Required (608.7)	Required (608.7)	Required (608.7)
Seismic protection	Required (608.8)	Required (608.8)	Required (608.8)	Required (608.8)	Required (608.8)
Smoke detection	Required (608.9)	Required (608.9)	Required (608.9)	Required (608.9)	Required (608.9)

**608.2.1 Nonrecombinant batteries.** Vented lead-acid, nickel-cadmium or other types of nonrecombinant batteries shall be provided with safety venting caps.

❖ Pressures can build up within batteries as a result of the creation of hydrogen and oxygen, making a method of pressure relief necessary. The types of batteries regulated by this section vent hydrogen and oxygen to the atmosphere. Flooded batteries vent regularly whereas valve-regulated battery systems vent when the internal pressure exceeds ambient pressures. Because of this potential for pressure buildup, safety-venting caps are required. For additional information on nonrecombinant batteries, see the commentary to the definition of that term.

**608.2.2 Recombinant batteries.** VRLA batteries shall be equipped with self-resealing flame-arresting safety vents.

❖ Self-resealing vents are an integral part of the design of VRLA batteries. Flame-arresting vents are needed to prevent a static spark (or other flame source) outside the battery from propagating to the interior of the battery where oxygen or hydrogen may have accumulated during normal operation of the battery. For additional information on recombinant batteries, see the commentary to the definition of that term.

**608.3 Thermal runaway.** VRLA and lithium metal polymer battery systems shall be provided with a *listed* device or other *approved* method to preclude, detect and control thermal runaway.

❖ Under certain extreme conditions of high ambient temperature or charging rate, VRLA and lithium metal polymer batteries may experience a phenomenon known as “thermal runaway.” This is a condition that occurs in a battery (especially valve-regulated types) when charging energy results in heat generation within the battery greater than the heat dissipated, causing an uncontrolled rise in battery temperature. Under these conditions, a battery may generate excessive heat that can cause failure through cell dry-out or, in rare cases, rupture or melting of the battery.

Lithium metal polymer batteries are constructed with an internal means of thermal runaway management. Each battery is equipped with an internal heating system that is located within the electrochemical stack of anodes and cathodes. This heating element ensures that the battery temperature limits are not exceeded when the battery is being charged or discharged. The thermal runaway management system and batteries are commonly listed in accordance with UL 1642 and UL 1989.

**608.4 Room design and construction.** Enclosure of stationary battery systems shall comply with the *International Building Code*. Battery systems shall be allowed to be in the same room with the equipment they support.

❖ This section requires that battery rooms meet the basic construction requirements of the IBC. Section and Table 509 of the IBC treat rooms housing stationary storage battery systems as incidental use areas

based on the electrolyte capacity of the system. In that case, though no different occupancy group is assigned to it, the battery room’s fire-resistance rating must be 1 or 2 hours, depending upon the occupancy group or groups from which it must be separated in the building in which it is located. The construction of the battery room must also comply with the material requirements of the IBC for the type of construction required for the building. Additionally, there is no requirement for separating the equipment that the battery system supports from the battery system itself.

**608.4.1 Separate rooms.** Where stationary batteries are installed in a separate equipment room accessible only to authorized personnel, they shall be permitted to be installed on an open rack for ease of maintenance.

❖ Ease of access to the battery system components is important for the safety of maintenance personnel. Where access to battery rooms is restricted to only authorized personnel, exposure to the public or building occupants is reduced, thus eliminating the need for any out-of-the-ordinary public safety arrangements of the system components.

**608.4.2 Occupied work centers.** Where a system of VRLA, lithium-ion, or other type of sealed, nonventing batteries is situated in an occupied work center, it shall be allowed to be housed in a noncombustible cabinet or other enclosure to prevent access by unauthorized personnel.

❖ In order to prevent tampering or accidental contact with the battery system when installed in an occupied work area, this section requires enclosure of the battery system in a cabinet. VRLA battery systems are often listed under UL 1778, which places similar design and construction requirements on cabinetized systems.

**608.4.3 Cabinets.** Where stationary batteries are contained in cabinets in occupied work centers, the cabinet enclosures shall be located within 10 feet (3048 mm) of the equipment that they support.

❖ Placing battery system cabinets within 10 feet (3048 mm) of the equipment served by the system will limit the number of devices that can be powered by the system due to the voltage drop associated with longer or multiple conductor runs. Having a substantial clearance between the battery cabinet and powered equipment also reduces the likelihood of an ignition in the event that battery gassing has occurred within the cabinet, which could result in an explosive mixture when air is introduced upon opening the cabinet for maintenance. The clearance required by this section will also enhance the safety of personnel who may have to secure and work on equipment served by the battery system by placing the secondary power supply near enough to the powered equipment to ensure line-of-sight supervision of the secured battery system during equipment repair or maintenance.

**608.5 Spill control and neutralization.** An *approved* method and materials for the control and neutralization of a

spill of electrolyte shall be provided in areas containing lead-acid, nickel-cadmium or other types of batteries with free-flowing liquid electrolyte. For purposes of this paragraph, a “spill” is defined as any unintentional release of electrolyte.

**Exception:** VRLA, lithium-ion, lithium metal polymer or other types of batteries with immobilized electrolyte shall not require spill control.

- ❖ Batteries that contain a free-flowing liquid electrolyte pose the same containment problems as any other corrosive liquid hazardous material, but the containment and neutralization provisions in this section are performance based and neither specifically require spill control in the form of containment nor a specific method of neutralization. The quantity of neutralization material required to be available would be greater for these less-viscous electrolytes, however, because of their mobility and the rapidity with which they can spread and the potential scope of the spread. See the commentary to Section 5004.2.1 for further discussion of spill control strategies. The exception recognizes the reduced spill control hazard of sealed batteries that contain a higher-viscosity electrolyte.

**608.5.1 Nonrecombinant battery neutralization.** For battery systems containing lead acid, nickel cadmium or other types of batteries with free-flowing electrolyte, the method and materials shall be capable of neutralizing a spill of the total capacity from the largest cell or block to a pH between 5.0 and 9.0.

- ❖ This section is fairly performance-based and neither specifically requires spill control in the form of containment, nor a specific method of neutralization. Instead, it states that a capability to control and neutralize a spill equal to the liquid content of the largest single battery cell or block (not the whole battery) to a pH between 5.0 and 9.0 must be available. In the case of flooded lead-acid batteries, this may require initial containment followed by neutralization.

**608.5.2 Recombinant battery neutralization.** For VRLA or other types of batteries with immobilized electrolyte, the method and material shall be capable of neutralizing a spill of 3.0 percent of the capacity of the largest cell or block in the room to a pH between 5.0 and 9.0.

**Exception:** Lithium-ion and lithium metal polymer batteries shall not require neutralization.

- ❖ This section is fairly performance-based and neither specifically requires spill control in the form of containment, nor a specific method of neutralization. Instead, it states that a capability to control and neutralize a spill equal to the 3 percent of the liquid content of the largest single battery cell or block (not the whole battery) housed in the battery room to a pH between 5.0 and 9.0 must be available. Typically, either sodium-bicarbonate powder or a liquid buffering solution is provided within the room where the battery system is located for use by trained personnel.

The electrolyte in VRLA batteries is immobilized by either the addition of a gelling agent or by being absorbed in a fiberglass mat (i.e., a sponge). This immobilization creates a situation where a spill of the electrolyte is highly unlikely. A typical accident where a VRLA battery case is broken results in a slight drip or a slow ooze of material out of the battery that cannot be characterized as a spill. Accordingly, spill control, as prescribed in Section 608.5, for flooded lead-acid batteries is not necessary. The exception recognizes the reduced spill control hazard and accompanying neutralization needs of sealed batteries that contain a higher-viscosity electrolyte.

**608.6 Ventilation.** Ventilation of stationary storage battery systems shall comply with Sections 608.6.1 and 608.6.2.

- ❖ With good air circulation around a battery, hydrogen accumulation is normally not a problem. The gas mixture is explosive when hydrogen in air exceeds 4 percent by volume; however, if relatively large batteries are confined in small rooms, exhaust fans must be installed to vent the room constantly or to be turned on automatically when hydrogen accumulation exceeds a certain level. Battery cabinets must also be vented to the atmosphere. Sparks or flames can ignite these hydrogen mixtures above the LEL, so ignition sources must be carefully managed. See the commentary to Sections 608.6.1 and 608.6.2 for discussion of the ventilation requirements for battery rooms and cabinets.

**608.6.1 Room ventilation.** Ventilation shall be provided in accordance with the *International Mechanical Code* and the following:

1. For flooded lead-acid, flooded Ni-Cd and VRLA batteries, the ventilation system shall be designed to limit the maximum concentration of hydrogen to 1.0 percent of the total volume of the room; or
2. Continuous ventilation shall be provided at a rate of not less than 1 cubic foot per minute per square foot (1 ft<sup>3</sup>/min/ft<sup>2</sup>) [0.0051 m<sup>3</sup>/s · m<sup>2</sup>] of floor area of the room.

**Exception:** Lithium-ion and lithium metal polymer batteries shall not require additional ventilation beyond that which would normally be required for human occupancy of the space in accordance with the *International Mechanical Code*.

- ❖ Basic battery room ventilation, as with any other building area, must comply with the requirements of the IMC. Generally, with lead-acid battery systems, the main concern is the production of hydrogen and oxygen within an enclosed space. Hydrogen has a wide flammability range and is the lightest element on the Periodic Table of Elements, having an atomic number of 1. The gas mixture is explosive when the amount of hydrogen in air exceeds 4 percent by volume. To address the concern of hydrogen generation and containment in small areas, a minimum ventilation criterion is set. This section provides two methods of compliance from which the designer may

choose. The first is performance based and states that the maximum concentration of hydrogen must be limited to 1.0 percent of the total volume of the room. This method requires an analysis of plausible failure scenarios to justify the ventilation rate ultimately chosen. The second method simply requires continuous ventilation at a rate no less than 1 cubic foot per minute per square foot [ $1 \text{ ft}^3/\text{min}/\text{ft}^2$  or  $0.0051 \text{ m}^3/(\text{s} \times \text{m}^2)$ ] of room area. The exception recognizes the reduced fugitive gas hazard of sealed batteries that contain a higher viscosity electrolyte.

**608.6.2 Cabinet ventilation.** Where VRLA batteries are installed inside a cabinet, the cabinet shall be *approved* for use in occupied spaces and shall be mechanically or naturally vented by one of the following methods:

1. The cabinet ventilation shall limit the maximum concentration of hydrogen to 1 percent of the total volume of the cabinet during the worst-case event of simultaneous “boost” charging of all the batteries in the cabinet.
2. Where calculations are not available to substantiate the ventilation rate, continuous ventilation shall be provided at a rate of not less than 1 cubic foot per minute per square foot [ $1 \text{ ft}^3/\text{min}/\text{ft}^2$  or  $0.0051 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of floor area covered by the cabinet. The room in which the cabinet is installed shall be ventilated as required in Section 608.6.1.

❖ This section addresses the increasingly common practice of placing VRLA battery systems in cabinets. Ventilation of VRLA battery cabinets is treated in the same manner as VRLA battery rooms in Section 608.6.1 (see commentary, Section 608.6.1).

**608.6.3 Supervision.** Mechanical ventilation systems where required by Sections 608.6.1 and 608.6.2 shall be supervised by an *approved* central, proprietary or remote station service or shall initiate an audible and visual signal at a constantly attended on-site location.

❖ The ventilation systems in Sections 608.6.1 and 608.6.2 are required and reduce the likelihood that the concentration of hydrogen will reach 1 percent or present an explosion hazard. Without a supervised system or a signal at a constantly attended location, the required ventilation system could fail without warning, allowing hydrogen concentrations to build to hazardous levels.

Monitoring natural ventilation, which is specifically allowed by Section 608.6.2, is extremely difficult (if not impossible in some cases), extremely expensive and would force a huge financial burden on battery cabinet manufacturers to add mechanical ventilation systems, hydrogen detectors or flow sensors, for little or no apparent improvement in safety. Accordingly, this section mandates the supervision of both the required room and cabinet ventilation only where mechanical systems are employed to provide adequate notification of a system failure.

**608.7 Signage.** Signs shall comply with Sections 608.7.1 and 608.7.2.

❖ See the commentaries to Sections 608.7.1 and 608.7.2 for discussion of the hazard warning sign requirements for battery rooms.

**608.7.1 Equipment room and building signage.** Doors into electrical equipment rooms or buildings containing stationary battery systems shall be provided with *approved* signs. The signs shall state that:

1. The room contains energized battery systems.
2. The room contains energized electrical circuits.
3. The battery electrolyte solutions, where present, are *corrosive* liquids.

❖ Because of the possible hazards associated with exposure to corrosive electrolytes, energized electrical circuits and the presence of hydrogen and oxygen, specific signage is needed to make building occupants and emergency responders aware of the potential dangers in the building or areas thereof.

**608.7.2 Cabinet signage.** Cabinets shall have exterior labels that identify the manufacturer and model number of the system and electrical rating (voltage and current) of the contained battery system. There shall be signs within the cabinet that indicate the relevant electrical, chemical and fire hazards.

❖ Battery cabinets must be marked with technical data about the system so that emergency responders may properly judge the degree of hazard presented by the system. Because of the possible hazards associated with exposure to corrosive liquids, energized electrical circuits and the presence of hydrogen and oxygen, specific signage is needed to make building occupants and emergency responders aware of the potential dangers that could exist in the cabinet.

**608.8 Seismic protection.** The battery systems shall be seismically braced in accordance with the *International Building Code*.

❖ Because battery systems pose hazards of corrosive liquid spills and because they are used for essential standby power, emergency power or uninterruptible power supplies, this section requires seismic bracing of the systems. Generally, these systems are located in racks that carry a fairly heavy load because of the liquid contained within the batteries. Chapter 16 of the IBC contains seismic protection requirements.

**608.9 Smoke detection.** An *approved* automatic smoke detection system shall be installed in accordance with Section 907.2 in rooms containing stationary battery systems.

❖ Except for a fire involving hydrogen, battery room fires are likely to be slow-growing and smoldering; therefore, a smoke detection system is required for early detection and warning in accordance with Section 907.2.23 where the system electrolyte capacity exceeds 50 gallons (189 L).

## SECTION 609 COMMERCIAL KITCHEN HOODS

**[M] 609.1 General.** Commercial kitchen exhaust hoods shall comply with the requirements of the *International Mechanical Code*.

❖ Rather than including detailed commercial hood requirements here, the code simply references the IMC for hood design (see IMC commentary, Section 507).

**[M] 609.2 Where required.** A Type I hood shall be installed at or above all commercial cooking appliances and domestic cooking appliances used for commercial purposes that produce grease vapors.

**Exception:** A Type I hood shall not be required for an electric cooking appliance where an approved testing agency provides documentation that the appliance effluent contains 5 mg/m<sup>3</sup> or less of grease when tested at an exhaust flow rate of 500 cfm (0.236 m<sup>3</sup>/s) in accordance with UL 710B.

❖ A Type I hood (see definition of “Hood, Type I” in Section 202) is required for all appliances used for commercial cooking as defined in Section 202. In addition to the specific cooking appliances identified in the definition, further examples of commercial cooking appliances that require a commercial kitchen exhaust system are griddles (flat or grooved); tilting skillets or woks; braising and frying pans; roasters; pastry ovens; pizza ovens; charbroilers; salamanders and upright broilers; infrared broilers and open-burner stoves; ranges; and barbecue equipment. Further, the definition of “Commercial cooking appliances” defines a food service establishment as “...any building or portion thereof used for the preparation and serving of food.”

The term “grease” refers to animal and vegetable fats and oils that are used to cook foods or that are a byproduct of cooking foods. Cooking appliances are used for commercial purposes when the appliance is primarily used for the preparation of food for compensation, trade or services rendered. When the nature of the cooking produces grease or smoke, a Type I hood is required. The intent is not to require a Type I hood where there is a possibility of food being burned and producing smoke. For example, smoke that is produced when toast is burned does not mean that a Type I hood is required over a toaster.

Section 609 does not require exhaust hoods for cooking equipment or appliances installed outdoors where the grease-laden vapors, etc., discharge directly to the outside atmosphere, nor is this chapter intended to regulate cooking appliances installed in vehicles or towed trailers (see definition of “Commercial cooking appliances”). Note that cooking appliances installed outdoors but located under a roof should be evaluated for installation under a Type I

hood just as if they were located inside a building having enclosing walls.

The exception recognizes the growing use of small electrical appliances used for cooking, such as in small sandwich shops and convenience stores, where little or no grease is produced. The installation of a Type I hood in these small establishments would create the expense of the hood and the energy costs of running the fan and tempering the makeup air where grease emissions are minimal or nonexistent. The grease emission threshold requirement is consistent with NFPA 96 and the testing procedure is done in accordance with Section 17 of UL 710B. In order for an appliance to qualify for use without a Type I hood it must be tested by an approved agency and shown that the effluent contains 5 mg/m<sup>3</sup> or less of grease when tested at an exhaust flow rate of 500 cfm. See also the IMC definitions of “Light-,” “Medium-,” “Heavy-” and “Extra-heavy duty cooking appliances” as well as IMC Section 507.2.

**609.3 Operations and maintenance.** Commercial cooking systems shall be operated and maintained in accordance with Sections 609.3.1 through 609.3.4.

❖ The provisions of this section introduce Sections 609.3.1 through 609.3.4, which contain requirements for controlling the hazards associated with the operation and maintenance of commercial cooking systems.

**609.3.1 Ventilation system.** The ventilation system in connection with hoods shall be operated at the required rate of air movement, and classified grease filters shall be in place when equipment under a kitchen grease hood is used.

❖ The hood must be designed to adequately collect and exhaust fumes, smoke and vapors from the area over which it is installed. To accomplish this, the hood must cause an airflow pattern that will sweep and direct the fumes, smoke and vapors from the cooking surfaces into the hood inlet.

The IMC specifies the minimum quantity of exhaust air necessary for effective removal of cooking vapors and the approximate amount of makeup air necessary for proper operation. The quantity of required exhaust is as much a function of the operational characteristics of the cooking equipment as it is a function of the size of the cooking surface or the exhaust hood opening area and the presence of walls and side panels. Manufacturer recommendations must be followed where applicable.

Approved grease filters prevent large amounts of grease from collecting in the hood, in exhaust ducts, on fan blades and at the exhaust system termination. The accumulation of grease can cause blockage in ducts, cause equipment failure and create a fire hazard. It therefore makes sense to have grease filters in place whenever commercial cooking equipment is used.

**609.3.2 Grease extractors.** Where grease extractors are installed, they shall be operated when the commercial-type cooking equipment is used.

❖ As noted in the commentary for Section 609.3.1, it is imperative that grease removal devices operate when commercial cooking equipment is used. Grease extractors and similar grease removal devices range from simple designs, such as a configuration of baffles, to elaborate hot water scrubbers and electrostatic precipitators. The devices must be installed to comply with the IMC and the manufacturer’s installation instructions.

**609.3.3 Cleaning.** Hoods, grease-removal devices, fans, ducts and other appurtenances shall be cleaned at intervals as required by Sections 609.3.3.1 through 609.3.3.3.

❖ The provisions of this section introduce Sections 609.3.3.1 through 609.3.3.3, which contain requirements for controlling the hazards associated with grease accumulation in commercial cooking systems. This includes appliances that produce grease-laden vapors, the hood, any grease extractors, the exhaust duct and the exhaust fan. The date of the cleaning and the extent of the work performed must be documented and be maintained on the premises.

**609.3.3.1 Inspection.** Hoods, grease-removal devices, fans, ducts and other appurtenances shall be inspected at intervals specified in Table 609.3.3.1 or as *approved* by the *fire code official*. Inspections shall be completed by qualified individuals.

❖ A regular inspection schedule must be maintained to prevent the accumulation of grease residue within the exhaust system. The hood, grease removal devices, ducts, fans, fire suppression system discharge nozzles and other components of the system must be cleaned regularly to prevent excessive accumulation of grease. The frequency of such cleaning can vary depending on the amount and type of usage; however, at a minimum, the equipment must be inspected at the intervals indicated in Table 609.3.3.1. Commercial cooking equipment exhaust systems may be viewed in some respects as a combustible material conveying system inasmuch as the grease carried within the duct is very combustible under the right conditions. As such, the inspection of the system should be entrusted only to persons trained and qualified in system inspection practices. While there are no identified nationally recognized criteria for gauging if an individual is or is not qualified to perform this work, several companies have developed their own certification programs for establishing requirements for individuals who supervise the cleaning of commercial cooking operations. In any case, the fire code official will make the final determination in accordance with Section 102.8.

**TABLE 609.3.3.1  
COMMERCIAL COOKING SYSTEM INSPECTION FREQUENCY**

TYPE OF COOKING OPERATIONS	FREQUENCY OF INSPECTION
High-volume cooking operations such as 24-hour cooking, charbroiling or wok cooking	3 months
Low-volume cooking operations such as places of religious worship, seasonal businesses and senior centers	12 months
Cooking operations utilizing solid fuel-burning cooking appliances	1 month
All other cooking operations	6 months

❖ Inspection frequencies are established in this table, which is based on the volume of cooking being performed, the type of cooking operation and the type of fuel used. The most restrictive requirement is for cooking operations using solid fuels, such as barbecue pits and meat smokers. When these or similar appliances use a solid fuel such as wood or charcoal, a minimum monthly inspection frequency is required. Cooking operations that use charbroilers or woks require a minimum 3-month inspection frequency, as do high volume cooking operations such as are found in 24-hour restaurants. The frequency of inspection is reduced to 12 months for lower intensity cooking activities including, but not limited to, seasonal businesses, places of worship and facilities for the care of senior citizens. All other cooking operations are subject to a 6-month inspection frequency. Depending on the nature of the commercial cooking activities, a single kitchen could have activities that require different inspection frequencies. For example, a restaurant that serves smoked meats would require that the appliance used for the preparation of the meat be inspected monthly, while other equipment would require inspection every 3 or 6 months, depending on the volume of cooking being performed.

**609.3.3.2 Grease accumulation.** If during the inspection it is found that hoods, grease-removal devices, fans, ducts or other appurtenances have an accumulation of grease, such components shall be cleaned in accordance with ANSI/KECA C 10.

❖ Frequent cleaning of exhaust systems is essential to the fire safety of cooking establishments to eliminate the potentially flammable and highly dangerous collection of grease within the exhaust system. The most common cleaning method is hand scraping, which requires that a person remove the hood filters and the access doors in the exhaust ductwork and physically scrape the accumulated grease from the interior surfaces of the exhaust system. Done properly, this method is effective but far from perfect. Regular inspection and diligence by the owner and the fire

code official are needed to achieve the desired level of cleanliness of the exhaust system.

A frequently asked question about grease accumulation is, "How much of an accumulation is enough to warrant a cleaning?" Grease buildup in a commercial cooking exhaust system and the frequency with which the system must be cleaned depend on several factors, including but not limited to: the types of appliances under the hood, the type of grease-removal devices in use, exhaust velocity within the system, number of joints in the ductwork, changes in direction of the duct run, temperature of the grease-laden air being exhausted, efficiency of the exhaust fan and whether the duct is insulated or exposed to the outdoors. Just as the frequency of inspection in Table 609.3.3.1 varies based on the intensity of the cooking operation, so does the rate of grease accumulation. The referenced standard, ANSI/KECA C-10, provides requirements to determine the frequency and necessity for commercial kitchen exhaust system cleaning through inspection procedures. In addition, the standard defines acceptable methods for cleaning exhaust systems and components and sets standards for acceptable cleanliness.

**609.3.3.3 Records.** Records for inspections shall state the individual and company performing the inspection, a description of the inspection and when the inspection took place. Records for cleanings shall state the individual and company performing the cleaning and when the cleaning took place. Such records shall be completed after each inspection or cleaning and maintained.

❖ Adequate records of inspections and cleanings not only provide documentation of the required inspections and the resulting cleanings but are also essential in establishing a workable cleaning schedule. A record of all cleaning must be maintained by the person or party responsible for the system. The records must indicate the method of cleaning and the time between cleanings as well as what components were cleaned.

As a result of a review of Recommendation 2(c) of the NIST Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections (including this section), to comprehensively address recordkeeping requirements. Section 107.3 provides standardized recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2 and 107.3.

**609.3.3.3.1 Tags.** When a commercial kitchen hood or duct system is inspected, a tag containing the service provider name, address, telephone number and date of service shall be provided in a conspicuous location. Prior tags shall be covered or removed.

❖ This section details the markings required to visually confirm serviceability of commercial kitchen hood and duct systems. The text is consistent with the requirements set forth in ANSI/KECA C-10, as referenced in Section 609.3.3.2.

**609.3.4 Extinguishing system service.** Automatic fire-extinguishing systems protecting commercial cooking systems shall be serviced as required in Section 904.12.6.

❖ See commentary, Section 904.12.6.

**609.4 Appliance connection to building piping.** Gas-fired commercial cooking appliances installed on casters and appliances that are moved for cleaning and sanitation purposes shall be connected to the piping system with an appliance connector listed as complying with ANSI Z21.69. The commercial cooking appliance connector installation shall be configured in accordance with the manufacturer's installation instructions. Movement of appliances with casters shall be limited by a restraining device installed in accordance with the connector and appliance manufacturer's instructions.

❖ This requirement is intended to end the practice of replacing listed flexible piping with residential flexible piping. Residential flexible piping is more easily damaged when the cooking equipment is moved for cleaning, thus causing a fire/life safety problem with gas leaks and fires. This section also intends to limit the distance the appliances can be moved for cleaning to further protect the connection.

## SECTION 610 COMMERCIAL KITCHEN COOKING OIL STORAGE

**610.1 General.** Storage of cooking oil (grease) in commercial cooking operations utilizing above-ground tanks with a capacity greater than 60 gal (227 L) installed within a building shall comply with Sections 610.2 through 610.7 and NFPA 30. For purposes of this section, cooking oil shall be classified as a Class IIIB liquid unless otherwise determined by testing.

❖ In these times of increasing interest in alternative fuels, used cooking oil has benefits in that it can be recycled for commercial cooking operations. It can also be chemically modified into biodiesel and used as fuel for mobile or stationary equipment. Because it can be recycled and reused, many restaurants and similar businesses that perform commercial cooking operations have found that capturing used cooking oil reduces waste disposal costs. As a result, the food service industry is seeking options for the safe storage of waste cooking oils in buildings and, as such, there has arisen a large market for collecting and recycling used cooking oil (grease) from commercial

cooking operations. This is sometimes done using a system designed to store the used cooking oil on-site in an above-ground tank. These systems typically include wheeled recovery carts and hoses (see Commentary Figure 610.2) to assist in transferring the grease from the cooking appliance to the storage tank, and from the storage tank to a recovery truck. Some systems include heating elements that assist in keeping the grease in a form that is easily pumped to the recovery truck. This arrangement could create a problem if the system is not properly designed and installed. Without the requirements of Section 610 addressing the storage of cooking oils, many installations may not be installed with the safety features needed to protect employees and the public.

It should be noted that this section also addresses fresh cooking oil versus used, spent or inedible cooking oil. These oils need to be stored in tanks and related components that are food grade. That is why there are specific requirements for nonmetallic tanks. Most metallic tanks, as required by this section, could not meet these specifications.

This section also specifies that, for the application of these requirements, cooking oils are classified as Class IIIB liquids in accordance with the definition of “Combustible liquids” in Chapter 2 of the code. These liquids have a closed-cup-flash-point temperature greater than 200°F (93.33°C). Flash point and ignition temperatures for common cooking oils are shown in Commentary Figure 610.1 and the data confirms that this classification is correct.

Note that installation of the cooking oil storage tank and its piping will require a construction permit in accordance with Section 105.7.8.

**610.2 Metallic storage tanks.** Metallic cooking oil storage tanks shall be listed in accordance with UL 142 or UL 80, and shall be installed in accordance with the tank manufacturer’s instructions.

❖ This section requires storage tanks for cooking oil storage to be listed as complying with either UL 142 or UL 80. Both standards are limited to shop-fabricated above-ground storage tanks (ASTs) designed

to operate at atmospheric pressure. Both standards require tanks to be constructed of carbon steel meeting a certain specification and, before shipment, to be tested at the factory to confirm they are liquid tight. Tanks constructed to UL 80 have a maximum volume of 660 gallons (2271.25 L) versus UL 142, which does not limit the volume of ASTs. Installations of metallic ASTs for cooking oil storage also must comply with the manufacturer’s installation instructions (see Commentary Figure 610.2).

**Figure 610.2**  
**COOKING OIL STORAGE TANK AND RECOVERY CART**  
(Photo courtesy of Darling International Inc., Irving, TX)

COOKING OIL TYPE	FLASH POINT TEMPERATURE (°F)	IGNITION TEMPERATURE (°F)
Canola oil	450	626
Corn oil	490	740
Cotton seed oil	486	650
Palm oil	323	600
Peanut oil	540	833
Soybean oil	549	833
Sunflower seed oil	550	Undetermined

For SI: °C = (°F - 32)/1.8.

**Figure 610.1**  
**COOKING OIL FLASH POINT AND IGNITION TEMPERATURES**

**610.3 Nonmetallic storage tanks.** Nonmetallic cooking oil storage tanks shall be installed in accordance with the tank manufacturer's instructions and shall also comply with all of the following:

1. Tanks shall be listed for use with cooking oil, including maximum temperature to which the tank will be exposed during use.
  2. Tank capacity shall not exceed 200 gallons (757 L) per tank.
- ❖ As discussed in Section 610.1, cooking oil that has not been previously used needs to be stored in food grade tanks. Typically, nonmetallic tanks are more appropriate for nonused cooking oil. These provisions are not limited to fresh cooking oil and can be utilized for used, spent and inedible cooking oils. This section sets out the requirements for basic construction and capacity of such tanks. Essentially, a listing for use with cooking oil is required, as is making sure that the maximum temperature limits associated with the tank match the application in which the tank is used.
- The tanks are limited in size to 200 gallons. Metallic tanks have the potential for much larger capacities, as discussed in the commentary for Section 610.2.

**610.4 Cooking oil storage system components.** Cooking oil storage system components shall include but are not limited to piping, connections, fittings, valves, tubing, hose, pumps, vents and other related components used for the transfer of cooking oil, and are permitted to be of either metallic or non-metallic construction.

- ❖ This section simply describes what components make up a cooking oil storage system. Section 610.4.1 addresses the design and construction requirements for these components. This section also notes that these components are permitted to be either metallic or nonmetallic. The allowance for types of materials will depend on the requirements in Section 610.4.1.

**610.4.1 Design standards.** The design, fabrication and assembly of system components shall be suitable for the working pressures, temperatures and structural stresses to be encountered by the components.

- ❖ The performance-based language provided in this section requires that it be determined that the system's intended use is consistent with all the components of the system.

**610.4.2 Components in contact with heated oil.** System components that come in contact with heated cooking oil shall be rated for the maximum operating temperatures expected in the system.

- ❖ Cooking oil storage system components may be exposed to elevated temperatures, such as when draining spent oil from deep fat fryers. Manufacturers must document that components can withstand the highest temperature to be expected during normal operations to avoid component deterioration or failure from heat exposure.

**610.5 Tank venting.** Normal and emergency venting shall be provided for cooking oil storage tanks.

- ❖ This section and the UL tank standards referenced in Section 610.2 require ASTs to be equipped with a normal vent and an emergency vent.

**610.5.1 Normal vents.** Normal vents shall be located above the maximum normal liquid line, and shall have a minimum effective area not smaller than the largest filling or withdrawal connection. Normal vents shall be permitted to vent inside the building.

- ❖ Tanks are vented to maintain the internal tank pressure within the design operating range. Low pressure can increase the generation of vapors while high pressure can damage the tank or piping system. Any pressure outside of the design pressure range (which could be caused if the vent line were not located above the highest level of liquid) can have an adverse effect on the operation of the system as well as the piping and equipment. This section is also consistent with Section 21.4.3 of NFPA 30.

While this section establishes the size of the normal vent line as being the same as the largest inflow or outflow connection, it should be noted that Section 21.4.3.3 of NFPA 30 also states that the minimum vent size must be 1 $\frac{1}{4}$  inches inside diameter.

Recognizing the reduced hazard of Class IIIB liquids, this section does not require the normal vent for a cooking oil AST installed indoors to be terminated outside the building. Note, however, that Section 5704.2.7.3.3 of the code allows this condition only where the tank is equipped with a normally closed pressure/vacuum vent.

**610.5.2 Emergency vents.** Emergency relief vents shall be located above the maximum normal liquid line, and shall be in the form of a device or devices that will relieve excessive internal pressure caused by an exposure fire. For nonmetallic tanks, the emergency relief vent shall be allowed to be in the form of construction. Emergency vents shall be permitted to vent inside the building.

- ❖ All ASTs for cooking oil storage require an emergency vent that will relieve excessive internal pressure caused by exposure to fires in accordance with Section 5704.2.7.4 of the code; however, the emergency vents for ASTs storing Class IIIB liquids are generally permitted to discharge inside the building in accordance with that section.

**610.6 Heating of cooking oil.** Electrical equipment used for heating cooking oil in cooking oil storage systems shall be listed to UL 499 and shall comply with NFPA 70. Use of electrical immersion heaters shall be prohibited in nonmetallic tanks.

- ❖ Many cooking oil storage tank systems will contain internal heaters to keep the oil above its melting temperature so that it can be efficiently removed by a recovery vacuum truck. This section requires that the electrical equipment associated with the heating of cooking oil be listed and its design and installation must comply with NFPA 70. Note that this section

does not require any temperature controls to ensure the cooking oil is not heated above its flash point temperature. See the commentary to Section 5701.5 for a discussion of the impact of heating combustible liquids above their flash point.

**610.7 Electrical equipment.** Electrical equipment used for the operation of cooking oil storage systems shall comply with NFPA 70.

- ❖ The phrase “cooking oil storage system” as used in this section could lead to the incorrect assumption that it is listed as a complete assembly of components. Fire code officials will need to evaluate the electrical equipment separately for compliance with the code and NFPA 70.

### SECTION 611 HYPERBARIC FACILITIES

**611.1 General.** Hyperbaric facilities shall be inspected, tested and maintained in accordance with NFPA 99.

- ❖ Section 425 of the IBC requires that hyperbaric facilities, regardless of occupancy, comply with NFPA 99 for installation. This section provides the maintenance requirements so that such facilities continue to operate safely. The standard provides detailed responsibilities for testing and inspecting these facilities, such as requirements for an on-site hyperbaric safety director and for training.

**611.2 Records.** Records shall be maintained of all testing and repair conducted on the hyperbaric chamber and associated devices and equipment. Records shall be available to the *fire code official*.

- ❖ This section requires that records be kept to document compliance with the maintenance and testing requirements of NFPA 99 for the benefit of the facility owner and the fire code official.

As a result of a review of Recommendation 2(c) of the NIST Charleston, South Carolina Sofa Superstore Fire Report, changes were made to Sections 107.2 and 107.3, along with 49 other sections, to comprehensively address recordkeeping requirements. Section 107.3 provides standardized recordkeeping requirements for periodic inspection, testing, servicing and other operational and maintenance requirements of the code and makes it clear that records must be maintained on the premises or another approved location and that copies of records must be provided to the fire code official upon request. Section 107.3 also makes it clear that records must be maintained for a period of not less than 3 years unless a different time interval is specified in the code or a referenced standard, and that the fire code official is authorized to prescribe the form and format of such records. See the commentaries to Sections 107.2 and 107.3.

# Chapter 7: Fire and Smoke Protection Features

## General Comments

This chapter sets forth general fire safety precautions for existing buildings and structures. In general, these requirements are intended to maintain required fire-resistance ratings and limit fire spread.

Chapter 7 is divided into four sections. Section 701 gives the general scope of the chapter and provides the basis for enforcement of its provisions. Section 702 provides applicable definitions. Section 703 describes the required maintenance of fire-resistance-rated assemblies, opening protectives and fire doors. Section 704 defines the enclosure requirements for shafts in existing buildings.

## Purpose

The maintenance of assemblies required to be fire-resistance rated is a key component in a passive fire protection philosophy. This chapter reinforces this component and further regulates floor openings, which are a leading cause of fire spread and smoke migration through buildings.

---

## SECTION 701 GENERAL

**701.1 Scope.** The provisions of this chapter shall govern maintenance of the materials, systems and assemblies used for structural fire resistance and fire-resistance-rated construction separation of adjacent spaces to safeguard against the spread of fire and smoke within a building and the spread of fire to or from buildings. New buildings shall comply with the *International Building Code*.

❖ This section establishes the scope of Chapter 7, introduces the requirements for maintaining the integrity of fire-resistance-rated assemblies (see Section 703) and prescribes the types of floor opening protection required in existing buildings (see Section 704). The provisions of Chapter 7 apply to the ongoing maintenance of the materials, assemblies and systems used to protect against the passage of fire and smoke within and between buildings. The assemblies outlined herein provide various degrees of protection. The required fire-resistance rating varies with the potential fire hazard associated with type of construction, occupancy, height and area of the building and degree of protection for different elements of the means of egress. The potential fire hazard associated with various occupancies is reflected in the *International Building Code*® (IBC®). Chapter 7 of the IBC provides the details and the extent of the protection (horizontal and vertical continuity); however, the actual fire-resistance-rated construction is mandated by provisions in Chapters 4, 5, 6, 7 and 10 of the IBC.

**701.2 Unsafe conditions.** Where any components in this chapter are not maintained and do not function as intended or do not have the *fire resistance* required by the code under which the building was constructed, remodeled or altered,

such component(s) or portion thereof shall be deemed an unsafe condition, in accordance with Section 110.1.1. Components or portions thereof determined to be unsafe shall be repaired or replaced to conform to that code under which the building was constructed, remodeled, altered or this chapter, as deemed appropriate by the *fire code official*.

Where the extent of the conditions of components is such that any building, structure or portion thereof presents an imminent danger to the occupants of the building, structure or portion thereof, the *fire code official* shall act in accordance with Section 110.2.

❖ This section is intended to clarify to code officials, designers, contractors and property owners that a building's fire-resistance-rated construction must be maintained at the original level of safety required by the codes that were applicable when the building was constructed or last remodeled. Failure to maintain fire-resistant components to that level of safety will result in the component being declared unsafe in accordance with Section 110.1.1 of the code and repair or restoration being required.

Code provisions, which require maintenance to a level of safety required by an often-unknown code or an unknown edition of a known code, are sometimes viewed as problematic and unenforceable. However, communities should have some record of when a building was constructed, and knowing the year of construction should make it relatively easy to determine an edition of the code that was published close to or prior to that year. In many communities, local architectural historical research can also be helpful in doing architectural historical research to determine the year of construction. These types of methods for determining the originally applicable code, if any, could be viewed

as haphazard and arbitrary, but they can be considered better than trying to make a building constructed 30, 50 or 100 years ago comply with today's requirements. In the event that no information of any kind can be found to shed light on an original construction date, this chapter provides for an acceptable level of safety and can be retroactively required where deemed appropriate by the fire code official.

This section also provides that where component conditions are so bad due to lack of maintenance as to constitute a clear and present threat to the safety of the occupants, the fire code official must take the steps required by Section 110.2.

**SECTION 702  
DEFINITIONS**

**702.1 Definitions.** The following terms are defined in Chapter 2:

**DRAFTSTOP.**

**FIRE-RESISTANT JOINT SYSTEM.**

**FIREBLOCKING.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

**SECTION 703**

**FIRE-RESISTANCE-RATED CONSTRUCTION**

**703.1 Maintenance.** The required *fire-resistance rating* of fire-resistance-rated construction, including, but not limited to, walls, firestops, shaft enclosures, partitions, *smoke barriers*, floors, fire-resistive coatings and sprayed fire-resistant materials applied to structural members and fire-resistant joint systems, shall be maintained. Such elements shall be visually inspected by the *owner* annually and properly repaired, restored or replaced where damaged, altered, breached or penetrated. Records of inspections and repairs shall be maintained. Where concealed, such elements shall not be required to be visually inspected by the *owner* unless the concealed space is accessible by the removal or movement of a panel, access door, ceiling tile or similar movable entry to the space. Openings made therein for the passage of pipes, electrical conduit, wires, ducts, air transfer openings and holes made for any reason shall be protected with *approved* methods capable of resisting the passage of smoke and fire. Openings through fire-resistance-rated assemblies shall be protected by self- or automatic-closing doors of *approved* construction meeting the fire protection requirements for the assembly.

❖ The code mandates that all equipment, systems, devices and safeguards required by the current and

previously adopted codes be maintained in good working order (see Section 102.1). This section reiterates that requirement specifically for fire-resistance-rated assemblies in existing buildings.

Once a building is occupied, its component parts are often damaged, altered or penetrated for installation of new piping, wiring and the like. These actions may reduce the effectiveness of assemblies that must be fire-resistance rated. This section requires the building owner, annually, to visually inspect non-concealed elements and that any damage to a fire-resistance-rated assembly be repaired in a manner that restores the original required performance characteristics. Concealed elements must be visually inspected if they may be accessed by a door, removable ceiling tile, access panel or the like. Similarly, if a fire-resistance-rated assembly is altered or penetrated, the alteration or penetration must comply with the applicable requirements of the IBC for the particular type of alteration or penetration.

This section also requires that written records of maintenance and repairs to rated assemblies must be kept and should indicate the date, time and the name of the person conducting the inspection or repair for each rated assembly. These records must be maintained by the owner and made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

**703.1.1 Fireblocking and draftstopping.** Required *fireblocking* and draftstopping in combustible concealed spaces shall be maintained to provide continuity and integrity of the construction.

❖ Fireblocking and draftstopping (see the Chapter 2 commentary for the definitions “Fireblocking” and “Draftstop”) slow the spread of fire and the products of combustion through concealed spaces within a building. To fulfill their intended function, fireblocking and draftstopping must be properly maintained. Most frequently, damage or repairs to other building components, such as mechanical piping, results in fireblocking or draftstopping being removed and not properly replaced. This section specifically requires that when fireblocking and draftstopping required by the IBC are damaged, removed or otherwise altered, they must be replaced or restored.

**703.1.2 Smoke barriers and smoke partitions.** Required *smoke barriers* and smoke partitions shall be maintained to prevent the passage of smoke. Openings protected with *approved* smoke barrier doors or smoke dampers shall be maintained in accordance with NFPA 105.

❖ Smoke barriers divide areas of a building into separate smoke compartments to create an area of safety for occupants. A smoke barrier is designed and installed in accordance with IBC Section 709 to resist fire and smoke spread so that occupants can be evacuated or relocated to adjacent smoke compartments (see the commentary to the definitions of “Smoke barrier” and “Smoke compartment” in Chap-

ter 2). This concept has proven effective in Group I-2 and I-3 occupancies, and Sections 407.5 and 408.6 of the IBC identify where smoke barriers are required in those occupancies. Smoke barriers may also be utilized in other applications, such as part of a smoke control system (see Section 909.5 of the code), separation of accessible areas of refuge in accessible means of egress (see Section 1009.6.4 of the code), compartmentation of underground buildings (see Section 405.4.2 of the IBC) and elevator lobbies in underground buildings (see Section 405.4.3 of the IBC), FSAE lobbies (3007.6.2) and occupant evacuation elevator lobbies (3008.6.2) among others. Other than the wall itself, all of the elements in the smoke barrier that can potentially allow smoke travel through the smoke barrier are required to have a quantified resistance to leakage. This includes doors, joints, through penetrations and dampers. The maximum leakage limits are as established in the individual code sections referenced above for each element. A smoke barrier is not intended or expected to be exposed to fire for extended periods and is, therefore, not required to have a fire-resistance rating exceeding 1 hour. Also, the occupancies in which smoke barriers are required are generally required to be sprinklered by Section 903 of the code. Smoke barriers are to be continuous from outside wall to outside wall and from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, deck or slab. The provisions require the barrier to be continuous through all concealed and interstitial spaces, including suspended ceilings and the space between the ceiling and the floor or roof sheathing, deck or slab above. Smoke barriers are not required to extend through interstitial spaces if the space is designed and constructed such that fire and smoke will not spread from one smoke compartment to another; therefore, the construction assembly forming the bottom of the interstitial space must provide the required fire-resistance rating and be capable of resisting the passage of smoke from the spaces below.

Smoke partitions are nonrated walls that serve to resist the spread of fire and the unmitigated movement of smoke for an unspecified period of time. Their primary purpose is to prevent the ready and quick passage of smoke into corridors in Group I-2 or for elevator lobby protection in a sprinklered building. Unlike 1-hour fire-resistance-rated smoke barriers, unless required by the IBC, smoke partitions are not required to have a fire-resistance rating. Smoke partitions are intended to provide less protection than a smoke barrier, and therefore are not required to be continuous through the concealed spaces and through the ceiling. The construction of a smoke partition is prescribed in Section 710 of the IBC; however, the level of performance or a method of testing them is not provided.

Because these assemblies and their opening protectives are critical life safety components of a build-

ing, they must be maintained throughout the life of the building. Opening protective maintenance provisions for these types of assemblies are contained in NFPA 105. For further information on incidental uses, smoke barriers and smoke partitions, see the commentary to Sections 509, 709 and 710 of the IBC, respectively.

**703.1.3 Fire walls, fire barriers and fire partitions.** Required *fire walls*, *fire barriers* and *fire partitions* shall be maintained to prevent the passage of fire. Openings protected with *approved* doors or fire dampers shall be maintained in accordance with NFPA 80.

❖ Fire walls, fire barriers and fire partitions are also key components in a passive fire- and life-safety design. Fire walls constructed in accordance with Section 706 of the IBC serve to create separate buildings (see the commentary to the definition of “Area, building” in Chapter 2 of the code); therefore, all applicable provisions of the code are applied individually to the building on each side of the fire wall. As such, the fire wall must also provide the same protection afforded by exterior walls, namely: structural integrity, structural independence and adequate fire resistance for exposure protection.

Fire barriers constructed in accordance with Section 707 of the IBC provide a higher degree of protection than fire partitions, but lack the inherent structural integrity of fire walls and, unlike fire partitions, there are no circumstances under which a fire barrier wall is permitted to terminate at a ceiling. Fire barriers are used for a variety of purposes, including but not limited to, separating exits and certain areas of refuge, mixed occupancies and incidental use areas, shafts, floor opening enclosures, hazardous materials control areas and fire areas. It is important to note that, since fire barriers are intended to provide a reliable subdivision of areas, the construction that structurally supports the assembly is required to provide and maintain at least the same hourly fire-resistance rating as the fire barrier being supported.

Fire partitions constructed in accordance with Section 708 of the IBC are wall assemblies that enclose exit access corridors; separate tenant spaces in covered malls, dwelling units and sleeping units; and separate elevator lobbies from the balance of a floor. Openings in fire partitions must be properly protected, but the total area of openings in a fire partition is not limited. Unlike the continuity requirements for fire walls and fire barriers, fire partition continuity must only be continuous from floor slab to the floor slab or roof deck above or to the ceiling of a fire-resistance-rated floor/ceiling or roof/ceiling assembly. Although fire partitions must normally be supported by construction having a comparable fire-resistance rating in buildings of Type IIB, IIIB and VB construction, as defined in the IBC, Section 708.4 of that code does not require such supportive construction for sleeping units and tenant separations and exit access corridor walls.

The IBC includes requirements for fire-resistance rating, continuity and opening and penetration protection in these types of assemblies. Because these assemblies and their opening protectives are critical life safety components of a building, they must be maintained throughout the life of the building. Opening protective maintenance provisions for these types of assemblies are contained in NFPA 80. For further information on fire walls, fire barriers and fire partitions, see the commentaries to Sections 706, 707 and 708 of the IBC, respectively.

**703.2 Opening protectives.** Opening protectives shall be maintained in an operative condition in accordance with NFPA 80. Where allowed by the *fire code official*, the application of field-applied labels associated with the maintenance of opening protectives shall follow the requirements of the *approved* third-party certification organization accredited for *listing* the opening protective. Fire doors and *smoke barrier* doors shall not be blocked or obstructed, or otherwise made inoperable. Fusible links shall be replaced promptly whenever fused or damaged. Fire door assemblies shall not be modified.

❖ Openings in fire-resistance-rated assemblies must be protected to prevent the passage of fire in accordance with Section 716 of the IBC. After opening protectives are installed and approved, they may become damaged, corroded or otherwise less effective than required. This section specifically requires that all opening protectives required by the IBC be maintained in compliance with NFPA 80 so that they can perform their intended function, which is to prevent the passage of smoke, fire or combustion products through openings in fire-resistance-rated walls, ceilings and shafts during a fire emergency. Sections 703.2.2 and 703.2.3 of the code indicate specific points of inspection and enforcement regarding these doors. Prohibited modifications to fire door assemblies include the attachment of materials, cutting, boring holes or other alterations that could affect the performance of the door as a fire protection-rated assembly.

This section also addresses the very real issue of maintaining labeled opening protectives by requiring field-applied labels to follow the requirements of the third-party certification organization, which is accredited for listing the specific opening protective. The relabeling of existing fire doors is a common practice and due to the importance of the rating requirements a level of monitoring by a third party to ensure the labeling matches the rating of the door assembly is necessary.

In the listing documentation, there are specific criteria for field application of labels. One of the criteria is whether the local fire code official allows this practice, and this section provides guidance in this area to the fire code official. IBC Section 716.5.7.1 requires that new fire doors or new fire door assemblies must be labeled at the factory (see the definition of “Labeled” in Chapter 2 of the code). However, it is not uncommon for an existing fire door to have either a

damaged or missing label, or a label that has been painted over or otherwise obscured. The fire code official needs to make a determination as to whether field application of the label is acceptable or not. If field application is allowed, then the certification organization can follow the proper criteria for labeling the opening protective.

Proper maintenance necessitates that the manufacturer’s installation instructions and the listing organization’s instructions are followed in order to maintain the listing and proper operation of the assemblies and devices as required by the code, the manufacturer and the listing organization.

**703.2.1 Signs.** Where required by the *fire code official*, a sign shall be permanently displayed on or near each fire door in letters not less than 1 inch (25 mm) high to read as follows:

1. For doors designed to be kept normally open: FIRE DOOR—DO NOT BLOCK.
2. For doors designed to be kept normally closed: FIRE DOOR—KEEP CLOSED.

❖ Any door in a fire-resistance-rated wall assembly represents a potential “weak link” in maintaining the degree of compartmentation intended by the code. That is the reason for requiring a rated assembly. The IBC calls for adequate opening protection in the form of a door with a specified fire protection rating. This section allows the fire code official to require signage on or near the rated doors to make the occupants aware of the importance of the door as a fire- and life-safety feature. Also, see the commentary to Section 703.2.2 for a discussion on door closing and the improper use of props to hold doors open.

**703.2.2 Hold-open devices and closers.** Hold-open devices and automatic door closers, where provided, shall be maintained. During the period that such device is out of service for repairs, the door it operates shall remain in the closed position.

❖ The only devices acceptable for holding fire doors open are fire-detector-activated automatic-closing devices that automatically close the doors (or allow the doors to swing closed using self-closing devices) in the event of a fire. Numerous devices, such as electromagnetic hold-opens, pneumatic systems and systems of pulleys and weights connected to a fusible link, are available.

The detection method for the closing device must be consistent with the purpose of the opening protective; that is, doors in smoke barriers must be activated by smoke detectors. Heat detectors or fusible links are adequate where maintenance of the fire-resistance rating alone is required.

Where smoke-detector-activated automatic door closers are used and the detectors are interconnected with a required fire alarm system, the devices and wiring methods must be checked for compatibility with the fire alarm system control panel before installation. Some fire alarm control equipment is compatible only with the manufacturer’s automatic smoke

detectors. Fire detectors used for automatic door release service in buildings that are not equipped with a fire alarm system must comply with Section 907.3.

A common violation of fundamental safety principles, as well as this section of the code, is having wooden or rubber wedges, or kick-down-type door hold-opens prop open fire doors or smoke barrier doors. This renders them totally ineffective as opening protectives. Building maintenance personnel who do not understand the purpose of these doors often do this to aid movement of people, equipment or air in a hallway or other area without realizing the potential hazard to life safety if a fire were to occur. This violation is especially problematic as it pertains to means of egress stairwells or horizontal exit doors as well. For further information on door closing requirements for fire doors, see Section 716.5.9 of the IBC.

**703.2.3 Door operation.** Swinging fire doors shall close from the full-open position and latch automatically. The door closer shall exert enough force to close and latch the door from any partially open position.

❖ Fire doors must be closed to be effective. Swinging fire doors should be frequently checked to make sure they close and latch on their own power from any position.

**703.3 Ceilings.** The hanging and displaying of salable goods and other decorative materials from acoustical ceiling systems that are part of a fire-resistance-rated horizontal assembly, shall be prohibited.

❖ This section is only applicable to acoustical ceiling systems that are a component of an approved fire-resistance-rated floor/ceiling or roof/ceiling assembly required to be rated by the type of construction of the building. Fire-resistance-rated floor/ceiling and roof/ceiling assemblies must be tested using the methods in ASTM E119 to demonstrate a fire-resistance rating. Locating a substantial fuel load and additional weight directly beneath an acoustical ceiling, however, may expose the ceiling to a direct fire source and weight overload not contemplated in the ASTM E119 testing and that could breach the ceiling, which is an integral part of the tested assembly. Depending on the contribution of the ceiling to the overall fire-resistance rating, this may result in the assembly not functioning as the code intends or failing completely.

New acoustical ceiling systems, whether or not they are a component of an approved fire-resistance-rated assembly, are required to comply with Section 808 of the IBC. Section 808.1.1 of the IBC requires that acoustical ceiling systems comply with the manufacturer's installation instructions. Section 808.1.1.1 of the IBC further requires compliance with several ASTM standards that govern the installation of such systems. Those standards do not contemplate the addition of loads to the metal support framework of the system beyond the load of the system itself plus light fixtures, or other components that might be part of the approved design. Adding any weight to the system beyond that which it was

designed for and approved by the building official could lead to failure of the system and should only be done after a review of the structural components by a registered design professional.

**703.4 Testing.** Horizontal and vertical sliding and rolling fire doors shall be inspected and tested annually to confirm proper operation and full closure. Records of inspections and testing shall be maintained.

❖ Annual tests are intended to determine that required fire doors operate freely and close completely. Where fusible links are used as the releasing mechanism, the link may be temporarily removed rather than activated during testing. Fusible links in poor condition must be replaced as part of the maintenance of fire-resistance components. Smoke detectors and heat detectors other than fusible links must be tested as required by the manufacturer's instructions (see NFPA 72 for recommended testing procedures for various fire detectors).

This section also requires that written records of inspection and testing of opening protectives must be kept and should indicate the date, the time and the name of the person conducting the inspection or repair for each rated assembly. These records must be maintained by the owner and should be made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

## SECTION 704 FLOOR OPENINGS AND SHAFTS

**704.1 Enclosure.** Interior vertical shafts including, but not limited to, *stairways*, elevator hoistways, service and utility shafts, that connect two or more stories of a building shall be enclosed or protected as required in Chapter 11. New floor openings in existing buildings shall comply with the *International Building Code*.

❖ Vertical openings that are not properly protected can act as a chimney for smoke, hot gases and products of combustion. Unprotected floor openings have been a major contributing factor in many large loss-of-life fires. Unless indicated otherwise, Chapter 11 retroactively requires the enclosure of vertical openings between floors with approved fire barriers. See commentary, Sections 1103.4 through 1103.4.10.

**704.2 Opening protectives.** Where openings are required to be protected, opening protectives shall be maintained self-closing or automatic-closing by smoke detection. Existing fusible-link-type automatic door-closing devices are permitted if the fusible link rating does not exceed 135°F (57°C).

❖ This section requires that fire door assemblies provided for protection of openings in vertical enclosures be self-closing or automatic-closing in order to maintain the integrity of the vertical opening enclosure. This section also recognizes that some opening protectives in existing buildings may already be

## FIRE AND SMOKE PROTECTION FEATURES

equipped with heat-actuated closing devices rather than the smoke-detector-actuated devices otherwise required by the section. Such devices are allowed to continue in service, provided that the temperature rating of their fusible element is as low as is available [i.e., 135°F (57°C)] to provide the fastest possible operation in the event of a fire. In the event that an existing fusible link on an opening protective is rated higher than the maximum 135°F (57°C) allowed by this section, it would need to be removed and the door maintained as self-closing or be replaced with a smoke-detector-actuated closer in accordance with this section and Section 907.3. New opening protectives must comply with Section 716 of the IBC. See the commentary to that section for further information.

### Bibliography

The following resource material was used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code*. Washington, DC: International Code Council, 2014.

# Chapter 8: Interior Finish, Decorative Materials and Furnishings

## General Comments

This chapter is consistent with the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), which regulates the interior finishes of buildings through the regulation of their flame spread potential. The code goes beyond interior finishes, also regulating furnishings and vegetation in buildings in certain occupancies. Additionally, the code addresses interior finishes and decorative materials in existing buildings.

This chapter is related to fire growth and spread potential in terms of the immediate effect on building occupants. The flame spread characteristics of certain materials will affect the potential fire scenarios within a building. Fire-resistance-rated construction, which is dealt with in Chapter 7 of both the IBC and this code, is more concerned with the spread of fire throughout the structure once the fire has reached a substantial size, with an emphasis on structural failure during a fire.

The regulation of flame spread can be traced back to large life-loss events, such as the Coconut Grove nightclub fire that killed 492 people in 1942. This fire was thought to have started when a light bulb in a basement cocktail lounge came in contact with the cotton cloth that had been applied to the ceiling for decorative purposes. Post-fire testing of the cotton cloth indicated that it had a flame spread rating of 2,500, more than 33 times the maximum allowable flame spread in today's codes. This factor, in addition to a series of problems with the egress system, led to one of the worst fire disasters in history. The need for these regulations was

further emphasized after The Station nightclub fire in West Warwick, Rhode Island, where 100 people died in February 2003. The soundproofing material in the nightclub was not approved for such use and was a major factor in the fire growth.

In addition to flame spread ratings of surface materials, certain furnishing types and vegetation, such as Christmas trees, pose a significant fire hazard because of their potential fire size and intensity. The materials used in furnishings have changed dramatically from past materials and many more plastics are now used for both decoration and furnishings. Plastics not only burn more vigorously than materials like cotton and wood, but also produce more toxic fire effluents.

## Purpose

The overall purpose of Chapter 8 is to regulate interior finishes, furnishings and vegetation so they do not significantly add to or create fire hazards in buildings. The provisions tend to aim at occupancies with specific risk characteristics, such as vulnerability of occupants, density of occupants, lack of familiarity with the building and societal expectations of importance. Since this is a fire code, there is an emphasis on both new and existing buildings.

More information on the development of this chapter and its sections, as well as all other revised provisions of the code, can be found in the *Complete Revision History to the 2015 I-Codes*.

---

## SECTION 801 GENERAL

**801.1 Scope.** The provisions of this chapter shall govern interior finish, interior trim, furniture, furnishings, decorative materials and decorative vegetation in buildings. Existing buildings shall comply with Sections 803 through 808. New buildings shall comply with Sections 804 through 808, and Section 803 of the *International Building Code*.

❖ This chapter reflects the same scope of issues as Chapter 8 of the IBC but has a slightly different emphasis. Fire codes are intended to address fire hazards of buildings and facilities over their life span; therefore, there is greater emphasis on the furnishings and contents of buildings and on the maintenance of flame spread indexes over time. Section

803 requires the same flame spread indexes as the IBC. Generally, regulating the combustibility of contents is a fairly difficult task once the building is occupied and is considered existing. Because of this difficulty, only some combustible contents and decorative materials are regulated in a limited number of occupancies. More specifically, the use of combustible furnishings, contents and decorative materials in Group A occupancies is addressed because of the high occupant load and the lack of familiarity of most occupants with the building. The type of furniture allowed in Group I occupancies is limited because of the vulnerability of the occupants and the likely fire scenarios that may occur when the building is non-sprinklered.

**SECTION 802  
DEFINITIONS**

**802.1 Definitions.** The following terms are defined in Chapter 2:

**FLAME SPREAD.**

**FLAME SPREAD INDEX.**

**INTERIOR FLOOR-WALL BASE.**

**SITE-FABRICATED STRETCH SYSTEM.**

**SMOKE-DEVELOPED INDEX.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see commentary, Sections 201 through 201.4).

**SECTION 803  
INTERIOR WALL AND CEILING FINISH  
AND TRIM IN EXISTING BUILDINGS**

**803.1 General.** The provisions of this section shall limit the allowable fire performance and smoke development of interior wall and ceiling finishes and interior wall and ceiling trim in existing buildings based on location and occupancy classification. Interior wall and ceiling finishes shall be classified in accordance with Section 803 of the *International Building Code*. Such materials shall be grouped in accordance with ASTM E84, as indicated in Section 803.1.1, or in accordance with NFPA 286, as indicated in Section 803.1.2.

**Exceptions:**

1. Materials having a thickness less than 0.036 inch (0.9 mm) applied directly to the surface of walls and ceilings.
  2. Exposed portions of structural members complying with the requirements of buildings of Type IV construction in accordance with the *International Building Code* shall not be subject to interior finish requirements.
- ❖ This section specifically addresses existing buildings, whereas Sections 804 through 808 address both new and existing buildings. This section provides two methods for compliance with interior wall and ceiling finish fire performance requirements. Both are fire test methods that address the potential for flame to spread.
- The first test—ASTM E84, also known as the “Steiner tunnel” or the “tunnel test”—has been around for many years. The second test method referenced is NFPA 286, which is called a “room corner test.” These two tests will be discussed further in the commentary for Sections 803.1.1 and 803.1.2, respectively. Requirements for interior wall and ceiling finishes and interior wall and ceiling trim within exist-

ing buildings are based upon occupancy. Section 803.3 and Table 803.3 address these occupancy limitations in more detail.

There are two exceptions to Section 803.1 that would allow materials without testing. They are very thin materials, less than or equal to 0.036 inch (0.9 mm) in thickness, when applied directly to the wall, and exposed structural members in Type IV construction. These exceptions are the same as those in the IBC.

Note that Section 803 also addresses the following:

- Textiles and expanded vinyl used as a wall or ceiling finish.
- Limitations on the use of foam.
- Polyethylene and polypropylene used as interior finish.
- Site-fabricated stretch systems.

**803.1.1 Classification in accordance with ASTM E84.** Interior finish materials shall be grouped in the following classes in accordance with their flame spread and smoke-developed index where tested in accordance with ASTM E84.

Class A: flame spread index 0–25; smoke-developed index 0–450.

Class B: flame spread index 26–75; smoke-developed index 0–450.

Class C: flame spread index 76–200; smoke-developed index 0–450.

❖ Wall and ceiling interior finish and trim materials are required to have limits on flame spread and smoke-developed indexes as prescribed in Section 803.3, based upon occupancy. ASTM E84 is one of the tests available to demonstrate compliance with the requirements of Section 803. This test method has been around since 1944 [see Commentary Figure 803.1.1(1)]. It is the primary method used but, as noted earlier, NFPA 286 is an alternative test, which is discussed in the commentary for Section 803.1.2. ASTM E84 is intended to determine the relative burning behavior of materials on exposed surfaces, such as ceilings and walls, by visually observing the flame spread along the test specimen [see Commentary Figure 803.1.1(2)]. Flame spread and smoke density indexes are then reported. The test method is not appropriate for materials that are not capable of supporting themselves, or of being supported in the test tunnel. There may also be concerns with materials that drip, melt or delaminate and that are very thin. A distinction is made, therefore, for textile wall or ceiling coverings, expanded vinyl wall or ceiling coverings, wood veneers applied on site, foam plastic insulation materials, high density polyethylene and polypropylene and site-fabricated stretch systems (see Sections 803.5, 803.6, 803.7 and 803.8, 803.9 and 803.10).

ASTM E84 establishes a flame spread index based on the area under a curve when the actual flame spread distance is plotted as a function of time. The code has divided the acceptable range of flame

spread indexes (0–200) into three classes: Class A (0–25), Class B (26–75) and Class C (76–200). For all three classes, the code has established a common acceptable range of smoke-developed index of 0–450. An indication of relative fire performance is as follows: an inorganic reinforced-cement board has a flame spread and smoke-developed index of zero, while select grade red oak wood flooring has a flame spread and smoke-developed index of 100. Not to preclude more detailed information resulting from an ASTM E84 test report, Commentary Figure

803.1.1(3) identifies the typical flame spread properties of certain building materials.

**803.1.2 Classification in accordance with NFPA 286.** Interior wall or ceiling finishes shall be allowed to be tested in accordance with NFPA 286. Finishes tested in accordance with NFPA 286 shall comply with Section 803.1.2.1. Interior wall and ceiling finish materials tested in accordance with NFPA 286 and meeting the acceptance criteria of Section 803.1.2.1 shall be allowed to be used where a Class A classification in accordance with ASTM E84 is required.

❖ The alternative test method for determining compliance for interior wall and ceiling finish and trim, other than textiles, is found in test standard NFPA 286. This test is known as a “room corner” fire test and is similar to that referenced for textile wall coverings in Section 803.5 (see NFPA 265) [see Commentary Figures 803.1.2(1) and 803.1.2(2)]. In this test, materials are mounted covering three walls of the compartment (excluding the wall containing the door) and the ceiling. In the case where testing is only for ceiling finish properties, the sample only needs to be mounted on the ceiling. Then a fire source consisting of a gas burner is placed in one corner, flush against both walls (furthest from the doorway) of the compartment with the following exposure conditions:

- 40 kilowatts (kW) for 5 minutes; then
- 160 kW for 10 minutes.

**Figure 803.1.1(1)  
ASTM E84 TUNNEL TEST**

**Figure 803.1.1(2)  
FLAME IN TUNNEL TEST**

Material	Flame spread
Glass-fiber sound-absorbing blanks	15 to 30
Mineral-fiber sound-absorbing panels	10 to 25
Shredded wood fiberboard (treated)	20 to 25
Sprayed cellulose fibers (treated)	20
Aluminum (with baked enamel finish on one side)	5 to 10
Asbestos-cement board	0
Brick or concrete block	0
Cork	175
Gypsum board (with paper surface on both sides)	10 to 25
Northern pine (treated)	20
Southern pine (untreated)	130 to 190
Plywood paneling (untreated)	75 to 275
Plywood paneling (treated)	100
Carpeting	10 to 600
Concrete	0

**Figure 803.1.1(3)  
TYPICAL FLAME SPREAD OF COMMON MATERIALS**

The test then measures heat release and smoke release through the collection of the fire effluents and measurement of oxygen concentrations in the exhaust duct. Heat release is calculated by the oxygen consumption principle, which has shown that heat release is a function of the decrease in oxygen concentration in the fire effluents. Thus, exhaust duct measurements include temperatures, pressures and smoke values for use in the calculations. Temperatures and heat fluxes are also measured in the room. This generally provides a more realistic

Figure 803.1.2(1)  
ROOM CORNER TEST

Figure 803.1.2(2)  
FLAME IN ROOM CORNER TEST

understanding of the fire hazard associated with the materials (see also Section 803.5.1 for more details on the room corner test concept).

The NFPA 286 test method does not contain pass/fail criteria; however, the code provides such criteria in Section 803.1.2.1.

**803.1.2.1 Acceptance criteria for NFPA 286.** The interior finish shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
3. Flashover, as defined in NFPA 286, shall not occur.
4. The peak heat release rate throughout the test shall not exceed 800 kW.
5. The total smoke released throughout the test shall not exceed 1,000 m<sup>2</sup>.

❖ As noted in Section 803.1.2, there are two levels of exposure during an NFPA 286 fire test in order to better represent a growing fire: 40 kW fire size for 5 minutes and 160 kW for 10 minutes. The 40 kW exposure represents the beginning of a fire where the initial spread is critical; therefore, the stated criteria is that the fire cannot spread to the ceiling. The 160 kW exposure is obviously a more intense fire situation and the criteria relates to preventing flashover (as defined by NFPA 286) and the extent of flame spread throughout the entire test assembly. There is also a total smoke production criterion of 1,000 m<sup>2</sup>. It should be noted that the criteria used in NFPA 286 and NFPA 265 to determine if flashover has occurred would include any two of the following:

- Heat release exceeds 1 mega watt (MW).
- Heat flux at the floor exceeds 20 kW/m<sup>2</sup>.
- Average upper layer temperature exceeds 1112°F (600°C).
- Flames exit the doorway.
- Autoignition of paper target on the floor occurs.

It should be noted that there is an additional criteria when applying NFPA 286 for new buildings, which is a maximum peak heat release rate of 800 kW. The reasoning for this criterion relates to the fact that some poorer performing materials can achieve compliance with the flashover criteria but could have a higher peak heat release rate.

**803.2 Stability.** Interior finish materials regulated by this chapter shall be applied or otherwise fastened in such a manner that such materials will not readily become detached where subjected to room temperatures of 200°F (93°C) for not less than 30 minutes.

❖ Interior finishes are not to become detached for a minimum of 30 minutes under exposure to elevated temperatures [200°F (93°C)]. No standard test method has yet been developed to evaluate this requirement. Some sections of the IBC, however, do offer some

additional guidance. For example, the performance of the method of attachment of finish materials during a fire-resistance test will usually be an adequate indication of performance. The stability criterion is necessary because, if these materials were to fall off of walls or the ceiling during a fire, they may contribute to the fire and increase the hazard beyond what is typically expected.

**803.3 Interior finish requirements based on occupancy.** Interior wall and ceiling finish shall have a flame spread index not greater than that specified in Table 803.3 for the group and location designated.

❖ The requirements for flame spread indexes for interior finish materials applied to walls and ceilings are contained in Table 803.3. The referenced test for determining flame spread indexes is ASTM E84, which establishes a relative measurement of flame spread across the surface of the material. The classifications

used in Table 803.3 are defined in Section 803.1.1 (see the commentary to Section 803.1.1 for additional information on the uses and limitations of the test procedure). Again, NFPA 286 can be used as an alternative to ASTM E84. Passing NFPA 286 means that the material would be considered to be equivalent to a Class A material.

**TABLE 803.3.** See below.

❖ This table prescribes the minimum requirements for interior finishes applied to walls and ceilings; therefore, the use of a Class A material in an area that requires a minimum Class B material is always allowed. Likewise, when the table requires Class C materials, Classes A and B can also be used. The requirements are based on the use of the space. To determine the applicable criteria, first determine whether the space is an exit passageway, interior exit stairway or interior exit ramp; a corridor; or a room or

**TABLE 803.3**

S	C	C	C	B	B	C
U	No Restrictions			No Restrictions		

For SI: 1 inch = 25.4 mm, 1 square foot = 0.0929 m<sup>2</sup>.

- a. Class C interior finish materials shall be allowed for wainscoting or paneling of not more than 1,000 square feet of applied surface area in the grade lobby where applied directly to a noncombustible base or over furring strips applied to a noncombustible base and fireblocked as required by Section 803.11 of the *International Building Code*.
- b. In exit enclosures of buildings less than three stories in height of other than Group I-3, Class B interior finish for nonsprinklered buildings and Class C for sprinklered buildings shall be permitted.
- c. Requirements for rooms and enclosed spaces shall be based upon spaces enclosed by partitions. Where a fire-resistance rating is required for structural elements, the enclosing partitions shall extend from the floor to the ceiling. Partitions that do not comply with this shall be considered as enclosing spaces and the rooms or spaces on both sides shall be considered as one. In determining the applicable requirements for rooms and enclosed spaces, the specific occupancy thereof shall be the governing factor regardless of the group classification of the building or structure.
- d. Lobby areas in Group A-1, A-2 and A-3 occupancies shall not be less than Class B materials.
- e. Class C interior finish materials shall be allowed in Group A occupancies with an occupant load of 300 persons or less.
- f. In places of religious worship, wood used for ornamental purposes, trusses, paneling or chancel furnishing shall be allowed.
- g. Class B material is required where the building exceeds two stories.
- h. Class C interior finish materials shall be allowed in administrative spaces.
- i. Class C interior finish materials shall be allowed in rooms with a capacity of four persons or less.
- j. Class B materials shall be allowed as wainscoting extending not more than 48 inches above the finished floor in corridors.
- k. Finish materials as provided for in other sections of this code.
- l. Applies when the vertical exits, exit passageways, corridors or rooms and spaces are protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

enclosed space. Interior finishes in spaces that are not separated from a corridor (for example, waiting areas in business or health care facilities) must comply with the requirements for a corridor space. As shown in the table, the code places a higher emphasis on the allowable flame spread index for exits than for enclosed rooms because of the critical nature and relative importance of maintaining exit integrity to aid in building evacuation. Numerous notes amend the basic requirements of Table 803.3. Notes a through l apply only where specifically referenced in the table.

**Note a**

A limited amount of combustible wainscoting or other paneling material does not appreciably reduce the level of safety of an exit element; therefore, up to 1,000 square feet (93 m<sup>2</sup>) of Class C wainscoting or paneling is permitted by Note a in a grade-level lobby used as an exit element when applied in accordance with Section 803.3 of the IBC.

**Note b**

This note allows the reduction of flame spread indexes in exit enclosures in buildings less than three stories high, not including Group I-3 occupancies. The time required to exit a building less than three stories is much shorter than that for taller buildings and enough time usually exists to use other exit enclosures.

**Note c**

Because the intended use of certain rooms in buildings is sometimes more hazardous than the group classification for the overall building, the finish classification must be determined by the group and occupancy classification for the room or area. Additionally, rooms or enclosed spaces not properly separated from one another must be looked at as a single space for the purposes of applying flame spread index requirements.

**Note d**

This note allows lobbies in Group A-1, A-2 and A-3 occupancies to be Class B instead of Class A. This is likely a result of the low fire load in such areas.

**Note e**

Note e recognizes that with a relatively small number of occupants, egress is accomplished more quickly and the activities tend to be more structured and manageable than with a large number of occupants. When the design occupant load is 300 or less in rooms or spaces of Group A-1 and A-2 occupancies, the interior finish materials may be Class C instead of Class B for rooms and enclosed spaces.

**Note f**

This note correlates with the allowance in Section 807.5.1.3 for places of religious worship.

**Note g**

The time required for exiting increases with the number of stories of the structure. Interior finish

materials can play a major role in fire spread within a structure. Because of the materials stored and used within a Group H occupancy, interior wall and ceiling finish materials with high heat release (or flame spread) potential can have a significant impact on the way a fire spreads throughout the building. To abate the hazard of rapid fire growth, Note g places a further restriction of a minimum of a Class B classification on interior finishes of enclosed spaces within sprinklered buildings when the building exceeds two stories.

**Note h**

Spaces that are used as offices in Group I-2 and I-4 occupancies have a low occupant load, the activity in those spaces is generally not very hazardous and the occupants are not as vulnerable as the general population of those facilities, partially because of their knowledge of the exits; therefore, Class C materials are allowed in administrative spaces.

**Note i**

Rooms in Group I-2 and I-4 occupancies with low occupant loads (four or less) pose a low risk and are quickly evacuated; therefore, Class C finish materials are appropriate.

**Note j**

In Group I-3 occupancy corridors, Note j allows interior finish materials, such as wainscoting, that are a maximum height of 48 inches (1219 mm) above the floor to be Class B. This reduction from Class A is based on full-scale fire research demonstrating that Class B wall finish used on the lower 4 feet (1219 mm) of a corridor wall is not likely to spread fire because fire primarily spreads on ceilings and upper walls before affecting the lower portions of walls.

**Note k**

This note is referenced in the title of Table 803.3 and refers to other sections of the code that may have further restrictions or allowances for material classification for specific uses.

**Note l**

Sprinklered facilities provide more protection to occupants than nonsprinklered facilities. In many instances, materials with lower restrictions on fire performance may be used, as shown in Table 803.3. The footnote clarifies what areas of the building need to be sprinklered in order to qualify for these reductions in interior finish classifications.

**803.4 Fire-retardant coatings.** The required flame spread or smoke-developed index of surfaces in existing buildings shall be allowed to be achieved by application of *approved* fire-retardant coatings, paints or solutions to surfaces having a flame spread index exceeding that allowed. Such applications shall comply with NFPA 703 and the required fire-retardant properties shall be maintained or renewed in accordance with the manufacturer's instructions.

❖ Many times, fire retardants can be used to reduce the flame spread index of a material that, without treatment, has an index higher than permissible. It should

be recognized that the most desirable situation is to have a material that has a specific flame spread rating or has been tested and passed in accordance with NFPA 286. It is also recognized that in existing buildings there are often situations where such an approach is not possible and the application of fire retardants is the only solution. Flame retardants may either be factory or field applied. A wide variety of proprietary flame retardants for field application are on the market. Both factory- and field-applied products may require reapplication to sustain the flame retardancy of a particular article. When reviewing an installation, the fire code official should require the owner or other responsible person to submit a manufacturer's or contractor's certificate documenting a given treatment. This documentation should specify if a particular treatment must be repeated and, if so, at what intervals. If no retreatment interval is specified, the manufacturer's or contractor's warranty should be recognized as the retreatment interval because it is the longest period for which that individual accepts responsibility for the product's performance. Fire code officials evaluating flame-retardant treatments should carefully evaluate the performance conditions of these preparations. Many of them are not intended to be exposed to direct sunlight, high humidity or weather. Flame-retardant treatment must be used or applied in a manner consistent with the manufacturer's instructions.

There are several methods of increasing the flame resistance of materials. The strategy is either to slow

the ignition process or control combustion itself. Commentary Figure 803.4 lists various methods and whether they can be achieved in the field.

It should also be noted that in more recent times there has been growing concern over the use of polybrominated diphenyl ethers (PBDE) to achieve flame resistance due to the possible health effects. Some states, including California, have passed legislation to ban the use of such products. Several manufacturers have also begun a voluntary phase-out of such chemicals. Federal legislation is also under consideration.

**803.5 Textiles.** Where used as interior wall or ceiling finish materials, textiles, including materials having woven or nonwoven, napped, tufted, looped or similar surface, shall comply with the requirements of this section.

❖ This section is primarily intended to apply to carpet and carpet-like wall or ceiling coverings that include textile materials having woven or nonwoven, napped, tufted, looped or similar surfaces. If not addressed, these easily ignitable materials can contribute extensively to a fire.

**803.5.1 Textile wall or ceiling coverings.** Textile wall or ceiling coverings shall comply with one of the following:

1. The wall or ceiling covering shall have a Class A flame spread index in accordance with ASTM E84 or UL 723, and be protected by automatic sprinklers installed in accordance with Section 903.3.1.1 or 903.3.1.2.
2. The wall covering shall meet the criteria of Section 803.5.1.1 when tested in the manner intended for use in

METHOD OF ACHIEVING FLAME RESISTANCE	APPROPRIATE USE	APPLICATION	OTHER INFORMATION
Chemical	Synthetics; Plastics	Chemical added during manufacturing process  Example: Polymers	Actual chemical change occurs  Changes the behavior of materials
Impregnation	Absorbent or porous materials; not wood (too dense)	In the field by spray or immersion	Sometimes done at wet pulp stage (Paper, acoustical tile and building panels)
Coating	Nonabsorbant materials  Example: Wood paneling, ceiling tiles, etc.	In the field by spray, brush or roller application	Actively inhibits flame spread or simply provides a noncombustible surface  Needs periodic renewal per manufacturer
Pressure Impregnation	Dense, nonabsorbent materials such as wood	Only during manufacturing	Replaces air pockets with fire-retardant solution  Chemical deposits while drying  Vacuum-pressure methods are used to impregnate materials  Far more effective than impregnation alone

**Figure 803.4  
APPLIED FLAME-RETARDANT COATINGS**

accordance with NFPA 265 using the product-mounting system, including adhesive, of actual use.

3. The wall or ceiling covering shall meet the criteria of Section 803.1.2.1 when tested in accordance with NFPA 286 using the product-mounting system, including adhesive, of actual use.
- ❖ This section requires that textile materials on walls or ceilings have a Class A flame spread index and be located in a sprinklered area in accordance with NFPA 13 or 13R. As an alternative to a Class A flame spread index and sprinklers, testing in accordance with NFPA 265 may be used for textile wall coverings. Just as discussed for NFPA 286, NFPA 265 is known as a full-scale room corner fire test. This test helps to determine the contribution of textile wall coverings to overall fire growth and spread in a compartment fire. Past research conducted with this kind of configuration has shown that flame spread indexes produced by ASTM E84 or UL 723 may not reliably predict the fire behavior of textile wall coverings in realistic fire scenarios. Thus, NFPA 265 is based on a more reliable test procedure, developed at the University of California. The research findings are described in a report from the University of California Fire Research Laboratory titled, "Room Fire Experiments of Textile Wall Coverings." The NFPA 265 test is only slightly different from NFPA 286. NFPA 286 is more severe in three ways:

1. The gas diffusion burner used to expose the material on the wall in the room fire test starts with a heat release rate exposure of 40 kW for the first 5 minutes in both tests, but it is then followed by 150 kW for 10 minutes in NFPA 265 and 160 kW for 10 minutes in NFPA 286.
2. The gas burner is placed 2 inches (51 mm) from each of the walls in NFPA 265, whereas it is placed flush against both walls in NFPA 286.
3. The test sample is mounted on the walls only in NFPA 265, whereas it is mounted on both the walls and ceiling in NFPA 286.

A key result of the difference in intensity and location of the gas burner is that the burner flame does not reach the ceiling during the 150 kW exposure (while it does reach the ceiling during the 160 kW exposure in NFPA 286). Therefore, NFPA 265 is not considered suitable for testing ceiling coverings.

It should be noted that the code does not require measurement of smoke release from materials tested to NFPA 265 unless the material is newly introduced, but does have a smoke pass/fail criterion for NFPA 286. NFPA 265 has two test methods, but the code only allows the use of Method B. In the Method A test protocol, 2-foot-wide (610 mm) strips of the material are mounted on the two walls closest to the corner with the burner, whereas in the Method B test protocol the sample is mounted completely covering three walls (except for the wall containing the door). There-

fore, Method B is more severe. This test method does not contain pass/fail criteria, just as NFPA 286 does not. The code therefore provides such criteria, based on the use of only the Method B test protocol from NFPA 265, in Section 803.5.1.1. It should be noted that the IBC also only allows the use of Method B from NFPA 265. The code applies to existing buildings and the IBC would only apply to new buildings with regard to this particular test.

**803.5.1.1 Method B test protocol.** During the Method B protocol, the textile wall covering or expanded vinyl wall covering shall comply with the following:

1. During the 40-kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremities of the samples on the 8-foot by 12-foot (203 by 305 mm) walls.
3. Flashover, as defined in NFPA 265, shall not occur.
4. For newly introduced wall and ceiling coverings, the total smoke released throughout the test shall not exceed 1,000 m<sup>2</sup>.

❖ The criteria are very similar to those used in NFPA 286. The pass/fail criteria in the code are as follows:

The flame cannot spread to the ceiling when the textile is exposed to the burner at 40 kW.

With the burner at 150 kW, the following criteria must be met:

- Flashover, as defined by NFPA 265, must not occur.
- The fire cannot reach the outer areas of the 8-foot by 12-foot (2438 mm by 8657 mm) wall.
- Newly introduced wall coverings are limited to a total smoke release of 1,000 m<sup>2</sup>.

**803.5.2 Newly introduced textile wall and ceiling coverings.** Newly introduced textile wall and ceiling coverings shall comply with one of the following:

1. The wall or ceiling covering shall have a Class A flame spread index in accordance with ASTM E84 or UL 723, and be protected by automatic sprinklers installed in accordance with Section 903.3.1.1 or 903.3.1.2. Test specimen preparation and mounting shall be in accordance with ASTM E2404.
2. The wall covering shall meet the criteria of Section 803.5.1.1 when tested in the manner intended for use in accordance with NFPA 265 using the product-mounting system (including adhesive) of actual use.
3. The wall or ceiling covering shall meet the criteria of Section 803.1.2.1 when tested in accordance with NFPA 286 using the product-mounting system (including adhesive) of actual use.

❖ This section is basically the same as Section 803.5.1 with one exception focused on preparing test specimens for the tunnel test (ASTM E84). The reason for this difference is that existing materials would possi-

bly be out of compliance since they were tested prior to the development of ASTM E2404, which has specific mounting requirements for materials during the test. It was felt reasonable in existing buildings to hold new textile wall and ceiling coverings to this higher standard. The correct specimen preparation and mounting method for textile, paper and vinyl wall and ceiling coverings tested in accordance with the ASTM E84 (Steiner tunnel) test is ASTM E2404. The ASTM E05 Committee on Fire Standards developed a standard practice for test specimen preparation and mounting, ASTM E2404, for textile, paper or vinyl wall or ceiling coverings specifically to provide a mandatory, standardized way of preparing test specimens and mounting them in the tunnel. This replaced optional guidance on mounting methods found in the appendix of ASTM E84 and ensures testing consistency.

This section also allows the use of NFPA 265 and NFPA 286 with the same criteria as cited in Section 803.5.1. Note that NFPA 265 is not applicable for the testing of ceiling materials due to the limitations of that test (see commentary, Section 803.5.1).

**803.6 Expanded vinyl wall or ceiling coverings.** Expanded vinyl wall or ceiling coverings shall comply with one of the following:

1. The wall or ceiling covering shall have a Class A flame spread index in accordance with ASTM E84 or UL 723, and be protected by automatic sprinklers installed in accordance with Section 903.3.1.1 or 903.3.1.2. Test specimen preparation and mounting shall be in accordance with ASTM E2404.
2. The wall covering shall meet the criteria of Section 803.5.1.1 when tested in the manner intended for use in accordance with NFPA 265 using the product-mounting system (including adhesive) of actual use.
3. The wall or ceiling covering shall meet the criteria of Section 803.1.2.1 when tested in accordance with NFPA 286 using the product-mounting system (including adhesive) of actual use.

❖ This section contains the same criteria as Section 803.5.2 but is specific to expanded vinyl wall or ceiling coverings. It allows all three tests of ASTM E84 with products mounted in compliance with ASTM E2404 and in sprinklered buildings.

This section also differs in that it does not limit the requirements to newly introduced materials but instead will cover any expanded vinyl wall or ceiling coverings. See also the commentary to Sections 803.5.2 and 803.5.1.

**803.7 Facings or wood veneers intended to be applied on site over a wood substrate.** Facings or veneers intended to be applied on site over a wood substrate shall comply with one of the following:

1. The facing or veneer shall have a Class A, B or C flame spread index and smoke-developed index, based on the requirements of Table 803.3, in accordance with

ASTM E84 or UL 723. Test specimen preparation and mounting shall be in accordance with ASTM E2404.

2. The facing or veneer shall meet the criteria of Section 803.1.2.1 when tested in accordance with NFPA 286 using the product-mounting system, including adhesive, described in Section 5.8.9 of NFPA 286.

❖ This section addresses the correct mounting method for wall coverings in ASTM E84 (namely ASTM E2404), to detail the proper way to test facings or wood veneers intended to be applied over a wood substrate. They are to be treated the same way as any other wall or ceiling covering applied “on site” to a wood substrate, but differently from panels where the facing or veneer is applied in the factory over the wood substrate and the entire panel is installed. A separate proposal addresses factory-produced panels. This section allows the use of either ASTM E84 or NFPA 286. As noted, the ASTM E2404 mounting method must be applied if the ASTM E84 test method is chosen.

**803.8 Foam plastic materials.** Foam plastic materials shall not be used as interior wall and ceiling finish unless specifically allowed by Section 803.8.1 or 803.8.2. Foam plastic materials shall not be used as interior trim unless specifically allowed by Section 803.8.3.

❖ This section allows foam plastic interior wall and ceiling finish materials to be used in accordance with Section 803.8.1 or 803.8.2. The ASTM E84 test has the potential to produce misleading fire test results when used to test foam plastic interior wall and ceiling finish materials. In particular, if the foam plastics have low density, the amount of material may be insufficient for the ASTM E84 Steiner tunnel test to properly evaluate the plastics’ flame spread characteristics. Moreover, if the foams are thermoplastic, they are likely to melt and fall away from the flame front when exposed in the test and provide artificially low flame spread information on the surface of the test sample, and thus give an inaccurate indication of the fire hazard. It was thus generally agreed, in the early 1970s, that foam insulation products should be assessed for combustibility with a test that represents more realistically the way the materials behave in actual applications, and tests, such as UL 1715, UL 1040, FM 4880 and NFPA 286, were developed for such purposes to be used instead of ASTM E84.

**803.8.1 Combustibility characteristics.** Foam plastic materials shall be allowed on the basis of fire tests that substantiate their combustibility characteristics for the use intended under actual fire conditions, as indicated in Section 2603.9 of the *International Building Code*. This section shall apply both to exposed foam plastics and to foam plastics used in conjunction with a textile or vinyl facing or cover.

❖ This section requires that when foam plastics are used as interior wall or ceiling finish, they must meet the requirements of Section 2603.9 of the IBC. The IBC states that foam plastic is not permitted to be used exposed as interior finish unless it has been

tested under actual fire conditions. The IBC requires foam plastic insulation to be tested in accordance with a standard such as FM 4880, UL 1040, NFPA 286 or UL 1715, all of which are large-scale fire tests measuring heat release. NFPA 286 does not have pass/fail criteria; they are contained in Section 803.1.2 of the code. This section also clarifies that covering the foam plastic with a vinyl or textile cover (as is often done in high school gymnasiums) will not change the requirements, so that the same tests should be applied to the covered foam.

**803.8.2 Thermal barrier.** Foam plastic material shall be allowed if it is separated from the interior of the building by a thermal barrier in accordance with Section 2603.4 of the *International Building Code*.

❖ Another option the code allows is to use foam plastic when it is separated from the room interior by means of a thermal barrier, so that the foam plastic is not exposed and is not actually used as interior finish. This section refers the user to Section 2603.4 of the IBC to address how this is to be accomplished. Section 2603.4 of the IBC requires a 1/2-inch (12.7 mm) gypsum wallboard or equivalent thermal barrier. Section 2603.4 of the IBC also provides criteria for testing equivalent thermal barriers.

**803.8.3 Trim.** Foam plastic shall be allowed for trim in accordance with Section 804.2.

❖ See the commentary to Section 804.2.

**[BF] 803.9 High-density polyethylene (HDPE) and polypropylene (PP).** Where high-density polyethylene or polypropylene is used as an interior finish it shall comply with Section 803.1.2.

❖ High-density polyethylene (HDPE) and polypropylene (PP) are thermoplastics that give off considerable energy and produce a pooling flammable liquid fire when they burn. Recent full-scale room-corner tests of HDPE using NFPA 286 have demonstrated a significant hazard. These tests had to be terminated prior to the standard 15-minute duration due to flash-over occurring while there was still much of the product left to burn. Extensive flammable liquid pool fires occurred during the tests, yet this same material, when tested in accordance with the tunnel test, ASTM E84, is often given a flame spread index of 25 or less. However, the resulting test is so intense some labs will not test HDPE partitions due to the damage such tests can do to the tunnel. This section ensures that when using HDPE partitions they will be formulated in such a manner as to reduce the hazard that they present by specifically requiring compliance with NFPA 286. The following are some of the data gleaned from one of the NFPA 286 tests: Peak Heat Release Rate 1733 kW; Total Heat Released 121 MJ; Peak Heat Flux to the Floor 35.2 kW/m<sup>2</sup>; Peak Average Ceiling Temperature 805°C, 1481°F. Polypropylene is very similar in material and fire performance.

**[BF] 803.10 Site-fabricated stretch systems.** Where used as newly installed interior wall or interior ceiling finish materials, site-fabricated stretch systems containing all three components described in the definition in Chapter 2 shall be tested in the manner intended for use, and shall comply with the requirements of Section 803.1.1 or 803.1.2. If the materials are tested in accordance with ASTM E84 or UL 723, specimen preparation and mounting shall be in accordance with ASTM E2573.

❖ Site-fabricated stretch systems are interior finish materials that are stretched taut across walls or ceilings with a frame that holds a fabric and core. These systems are now being used extensively because they can stretch to cover decorative walls and ceilings with unusual looks and shapes. The systems consist of three parts: a fabric (or vinyl), a frame and an infill core material. Therefore, they must be fire tested like all other interior wall and ceiling materials, using either ASTM E84 (the Steiner tunnel test) or NFPA 286 (the room-corner test). The ASTM Committee on Fire Standards (ASTM E05) has issued ASTM E2573, a standard practice for specimen preparation and mounting of site-fabricated stretch systems. It is not a test method but rather a mounting method that was developed specifically for use when testing these materials in the ASTM E84 Steiner tunnel test. Until now, there was no correct mandatory way to test these systems. The testing has often been done of each component separately instead of testing the composite system. That is an inappropriate way to test and not the safe way to conduct the testing. Now that a consensus standard method of testing exists, the code recognizes it.

It is important to note that these materials are not curtains or drapes because they are not free hanging like curtains. Therefore, it would be inappropriate for them to be tested using NFPA 701, a test for vertically hanging fabrics, or any other test that was developed for free-hanging materials.

As previously stated, it is important to test all components together. If the system in question does not contain all three components of site-fabricated stretch systems, then such systems should be tested in a manner appropriate to their use. In particular, systems that contain a stretch membrane only and no core material have been shown to behave very differently in a fire situation than site-fabricated stretch systems. It is important that the correct mounting method be used for each system.

## SECTION 804 INTERIOR WALL AND CEILING TRIM AND INTERIOR FLOOR FINISH IN NEW AND EXISTING BUILDINGS

**804.1 Interior trim.** Material, other than foam plastic, used as interior trim in new and existing buildings shall have minimum Class C flame spread and smoke-developed indices,

when tested in accordance with ASTM E84 or UL 723, as described in Section 803.1.1. Combustible trim, excluding handrails and guardrails, shall not exceed 10 percent of the specific wall or ceiling areas to which it is attached.

❖ In accordance with Section 801.1, Section 804.1 addresses both new and existing buildings whereas Section 803 is applicable only to existing buildings. In occupancies of any group, unless otherwise noted in the code, the minimum classification of all trim must be at least Class C. Additionally, combustible trim may not exceed 10 percent of the area of the individual wall or ceiling in which it is located. The 10-percent calculation does not need to include handrails and guardrails. Although a Class C flame spread index may be lower than the flame spread index required for a particular building or facility, this quantity of combustible material will not significantly increase the fuel load.

**804.1.1 Alternative testing.** When the interior trim material has been tested as an interior finish in accordance with NFPA 286 and complies with the acceptance criteria in Section 803.1.2.1, it shall not be required to be tested for flame spread index and smoke-developed index in accordance with ASTM E84.

❖ This section is a clarification of the testing requirements for interior finishes. Chapter 8 of the IBC and Section 803.1.2 of the code already make it clear that any material that meets the criteria of Section 803.1.2.1 is permitted to be used for interior finish. The criteria for interior trim (whether a foam plastic or not) are basically just less severe and apply to smaller areas only. If the material is allowed to be used to cover the entire wall or ceiling, it is also allowed to be used to cover 10 percent of it.

**804.2 Foam plastic.** Foam plastic used as interior trim shall comply with Sections 804.2.1 through 804.2.4.

❖ As noted in Section 803.8.3, foam plastic is allowed as interior trim under certain conditions. This section introduces Sections 804.2.1 through 804.2.4 which establish that some dense foam plastic materials may be used as interior trim if the thickness, width and area of coverage is specifically limited.

**804.2.1 Density.** The minimum density of the interior trim shall be 20 pounds per cubic foot (320 kg/m<sup>3</sup>).

❖ This section establishes a minimum density of 20 pounds per cubic foot (pcf) (320 kg/m<sup>3</sup>) for foam interior trim. A minimum instead of a maximum density is specified because the denser the foam plastic material, the less likely it is that it will generate misleading ASTM E84 test results due to having insufficient material for fire testing of the foam.

**804.2.2 Thickness.** The maximum thickness of the interior trim shall be 1/2 inch (12.7 mm) and the maximum width shall be 8 inches (203 mm).

❖ Even though other trim materials are not limited in dimension, the maximum thickness and width of foam

plastic trim is limited to 1/2 inch (12.7 mm) and 8 inches (203 mm), respectively. These dimensions were selected because they were typical of the maximums being produced at the time this provision was included in the code.

**804.2.3 Area limitation.** The interior trim shall not constitute more than 10 percent of the specific wall or ceiling area to which it is attached.

❖ Trim cannot constitute more than 10 percent of the individual area of the wall and ceiling of a room. This limitation is simply a restatement of the general requirement for all combustible trim, which appears in Section 804.1.

**804.2.4 Flame spread.** The flame spread index shall not exceed 75 where tested in accordance with ASTM E84 or UL 723. The smoke-developed index shall not be limited.

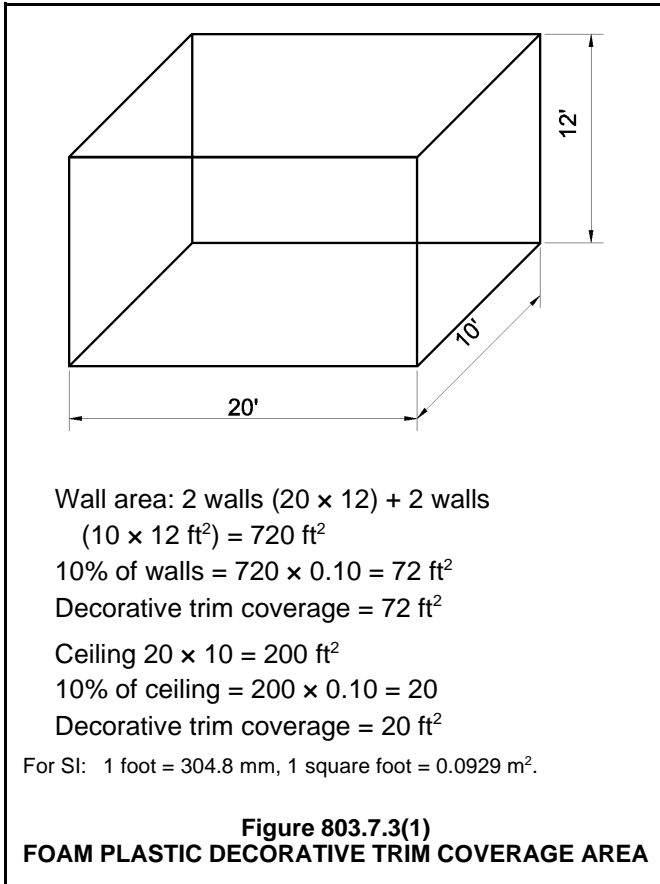

**Exception:** When the interior trim material has been tested as an interior finish in accordance with NFPA 286 and complies with the acceptance criteria in Section 803.1.2.1, it shall not be required to be tested for flame spread index in accordance with ASTM E84 or UL 723.

❖ This section specifically calls out a numerical flame spread index limitation of 75 for foam plastic used as trim, which is a Class B flame spread index. The value of 75 was selected to be consistent with the requirement for foam plastic insulation, even though other materials used as trim are permitted to have flame spread indexes of up to 200 in many locations. No thermal barrier is required for the use of foam plastic as trim and the smoke-developed index is not limited. It should be noted that Section 2604 of the IBC, which regulates the use of foam plastic as trim for new construction, has essentially identical requirements to those found in this section. Neither this section nor Section 2603.4.1.11 of the IBC requires a thermal barrier for interior trim [see Commentary Figures 803.7.3(1) and 803.7.3(2)]. The exception recognizes the stringency of testing in accordance with NFPA 286 as being equivalent to this section.

**804.3 New interior floor finish.** New interior floor finish and floor covering materials in new and existing buildings shall comply with Sections 804.3.1 through 804.3.3.2.

**Exception:** Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not composed of fibers.

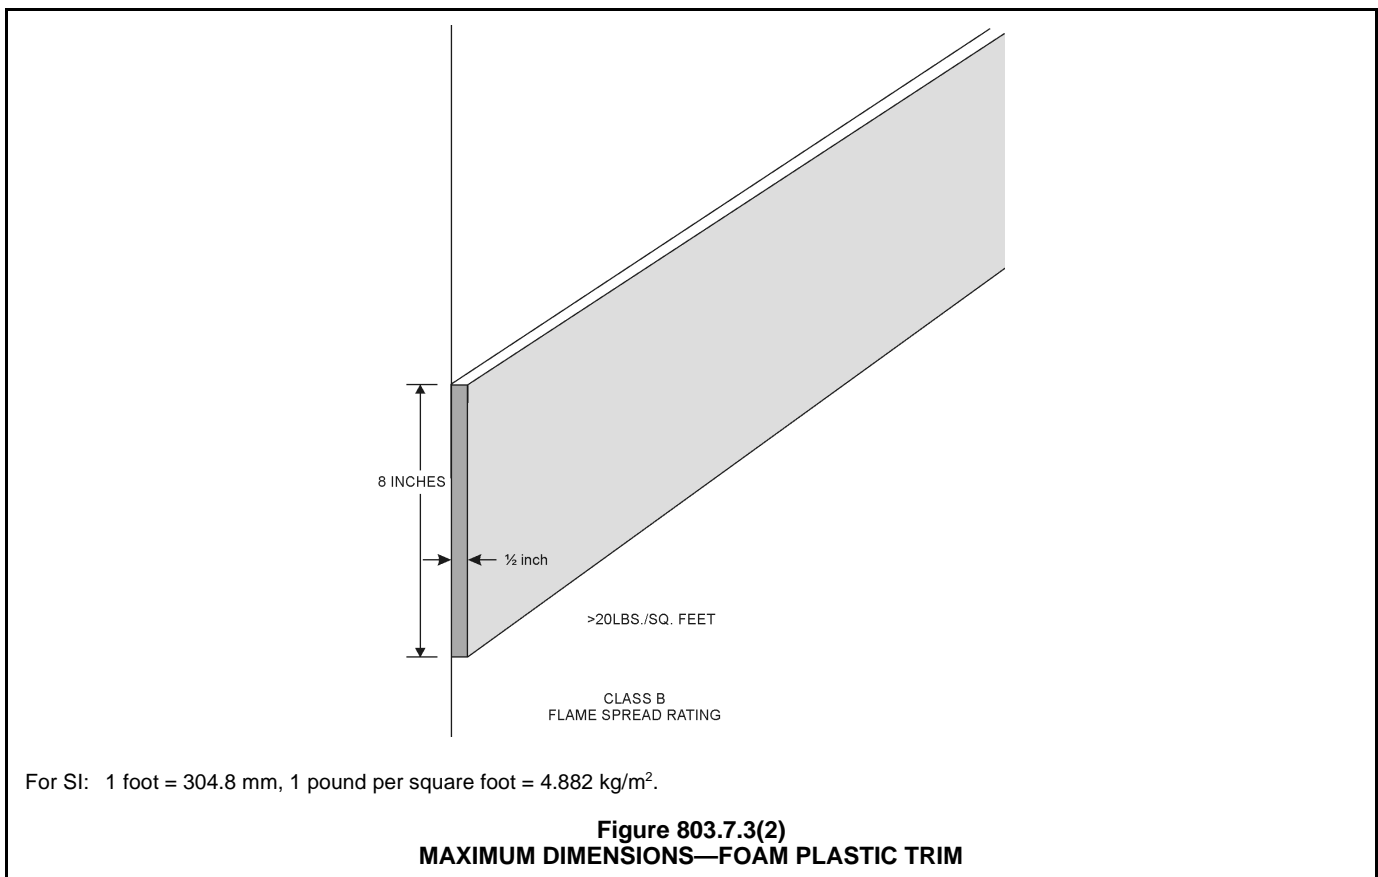

❖ This section regulates the design and installation of floor finish and floor covering materials and is identical to Section 804 of the IBC. Since Section 804.3 is located within a section that could apply to both existing and new buildings it is specifically clarified that these requirements are only applicable to new flooring. Traditional floor coverings, such as wood, vinyl, terrazzo and other resilient floor covering material, must be exempt from this section since they generally contribute minimally to a fire. The focus is on textile floor coverings such as carpets.

**804.3.1 Classification.** Interior floor finish and floor covering materials required by Section 804.3.3.2 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm<sup>2</sup> or greater; Class II, 0.22 watts/cm<sup>2</sup> or greater.

❖ The use of a classification system eliminates the need to state the actual critical radiant flux value for a product to meet the identification requirements of Section 804.3. Over the years, a classification system has been found to be much easier for the industry to follow and still provides the building official with the information required to verify compliance. The test required to measure the combustibility of floor coverings is NFPA 253. This standard is a radiant floor panel test, which basically simulates materials subjected to heat from a fire above. The primary concern with flooring is related to the spread of a fire that has already been ignited within a space or room to a different room. Commentary Figure 804.3.1 shows the test apparatus. The critical heat flux indicates the threshold value above which flame spread occurs in the testing environment.

**804.3.2 Testing and identification.** Interior floor finish and floor covering materials shall be tested by an *approved* agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the interior floor finish or floor covering classification in accordance

with Section 804.3.1. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer's product identification shall be furnished to the *fire code official* upon request.

❖ The only method to ascertain that a floor meets the criteria of this section is to request a copy of the test report for the specific material being installed; therefore, it is critical that the carpeting be properly identified in order to verify that acceptable materials are being provided in the appropriate locations. The identification is to be provided on the material itself since a manufacturer's designation is required.

**804.3.3 Interior floor finish requirements.** New interior floor coverings materials shall comply with Sections 804.3.3.1 and 804.3.3.2, and interior floor finish materials shall comply with Section 804.3.1.

❖ Sections 804.3.3.1 and 804.3.3.2 prescribe when the pill test for floor covering material is applicable and which occupancies and locations require a Class I or Class II classification in accordance with NFPA 253. Section 804.3.1 specifies the criteria for Classes I and II. More information about the specific test is discussed in Section 804.3.1. Generally the focus is on more critical areas, such as exit passageways, interior exit stairways and exit access corridors.

**Figure 804.3.1**  
**RADIANT FLOOR PANEL TEST (NFPA 253)**

**804.3.3.1 Pill test.** In all occupancies, new floor covering materials shall comply with the requirements of the DOC FF-1 "pill test" (CPSC 16 CFR Part 1630) or of ASTM D2859.

❖ DOC FF-1, also referred to as the "Methenamine Pill Test," was developed as a means of preventing the distribution of highly flammable soft floor coverings within the United States. The test essentially evaluates the performance of the floor covering when subject to a cigarette-type ignition by using a small methenamine tablet. All carpeting greater than 24 square feet (2.2 m<sup>2</sup>) in area sold in the United States is required by federal law to pass this test procedure as a minimum.

**804.3.3.2 Minimum critical radiant flux.** In all occupancies, new interior floor finish and floor covering materials in enclosures for *stairways* and *ramps*, *exit passageways*, *corridors* and rooms or spaces not separated from *corridors* by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall be not less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I-4, M, R-1, R-2 and S.

**Exception:** Where a building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials shall be permitted in any area where Class I materials are required and materials complying with DOC FF-1 "pill test" (CPSC 16 CFR Part 1630) or with ASTM D2859 shall be permitted in any area where Class II materials are required.

❖ This section prescribes the minimum requirements for interior floor finish materials that are used in interior exit stairways, exit passageways and exit access corridors. The criteria are based on the occupancy classification and the relationship of the space to the egress system. Similar to Table 803.3, the occupancy classification designation is meant to apply to the actual occupancy of the space and not necessarily the overall building classification.

Classifications I and II as used in this section are defined in Section 804.3.1 and are based on the results of the NFPA 253 test procedure.

Recognizing the ability of automatic sprinkler systems to control a fire and the minimal contribution of interior floor finishes to the early stages of fire growth, the exception allows the required interior floor finish ratings to be reduced when an automatic sprinkler system is provided throughout the building. The reference to Section 903.3.1.1 or 903.3.1.2 clarifies that the system is to be installed in accordance with NFPA 13 or 13R. In cases where Class II materials are required and an automatic sprinkler system is provided, the minimum requirement is that the material simply meet the DOC FF-1 test criteria.

**804.4 Interior floor-wall base.** Interior floor-wall base that is 6 inches (152 mm) or less in height shall be tested in accordance with NFPA 253 and shall be not less than Class II. Where a Class I floor finish is required, the floor-wall base shall be Class I. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watt/cm<sup>2</sup> or greater; Class II, 0.22 watts/cm<sup>2</sup> or greater.

**Exception:** Interior trim materials that comply with Section 804.1.

❖ In trimming out the interior of a building, rather than install separate baseboards or materials, in many cases the floor covering material is simply seamlessly turned up for a few inches or used at the intersection of the floor and the wall, thus becoming the floor-wall base trim. Previously, these materials could have been considered as interior trim in accordance with Section 804.1 and would have been required to be tested in accordance with ASTM E84 even though the floor covering may be required to be tested in accordance with NFPA 253. Based on the small amount of material used, it is very difficult to test these materials in a reliable manner, upside down in the ASTM E84 test method. This section addresses the issue of testing and regulation of wall base interior floor finish trim materials and eliminates the difficulty of testing these materials in a reliable manner.

Because of their location at the floor line, wall base materials are not likely to be involved in a fire until the floor covering is also involved, usually at room flashover. Thus, it is reasonable that wall base materials meet the same criteria as floor coverings. This is true since in some applications, for sanitary reasons, the floor covering is seamlessly turned up on the wall to form a wall base. Thus, the proposal specifies that the wall base be tested in accordance with NFPA 253 as required for floor coverings and has requirements for its use. This section also limits the height of the wall base such that its application is controlled in a similar manner as the 10-percent limitation for interior trim. The exception recognizes that some materials used as interior finish trim that meet the flammability requirements of Section 804.1 can be used in this specific application without the need for additional testing.

## SECTION 805 UPHOLSTERED FURNITURE AND MATTRESSES IN NEW AND EXISTING BUILDINGS

❖ Furnishings and contents are subjects that codes have not addressed very strongly in the past. Ultimately, the fire hazard potential within a building depends heavily upon what is in the building and where it is placed. First, the burning characteristics of the materials will vary and the location of the material will change the characteristics of a fire. For instance, a couch within a small compartment will create a

much different fire event than the same couch burning in a large open atrium (see Commentary Figure 805.1). The compartment may be limited by the amount of oxygen available, while the atrium fire will be limited only by the amount of combustibles to burn because oxygen will be plentiful; therefore, the compartment is likely to reach flashover while the atrium will not. Generally, upholstered furniture and mattresses are the largest fire hazards in most residential buildings because mattresses or upholstered furniture are the only products typically present where people live that can cause room flashover on their own.

**805.1 Group I-1, Condition 2.** The requirements in Sections 805.1.1 through 805.1.2 shall apply to facilities in Group I-1, Condition 2.

❖ This section introduces Sections 805.1.1 through 805.1.2.3 which contain requirements for controlling the hazards associated with upholstered furniture and mattresses in new and existing Group I-1, Condition 2 occupancies. Group I-1, Condition 2 occupancies contain, in a supervised setting, more than 16 persons on a 24-hour basis because of age, mental disability or other reasons. It should be noted that Group I-1, Condition 2 occupancies have occupants who need limited assistance both verbally and physically to evacuate whereas occupants of Group I-1, Condition 1 do not need such assistance. The provisions throughout the I-Codes differentiate between these two types of occupancy classifications. In general, these occupants are considered more vulnerable than the general population and have had a history of starting fires in beds or upholstered furniture. There is also more of a concern than with a Group I-2 occupancy over occupants having the ability to purposely start a fire. This is less likely in an assisted living setting but more likely in a halfway house setting; therefore, limitations on combustibility of upholstered furniture and mattresses are also required. Reducing ignitability and combustibility will significantly reduce the level of fire hazard. The requirements are slightly different than for Group I-2 occupancies in that different tests and performance criteria are required because of the nature of the hazards.

**805.1.1 Upholstered furniture.** Newly introduced upholstered furniture shall meet the requirements of Sections 805.1.1.1 through 805.1.1.3.

❖ This section informs the user that two aspects of upholstered furniture are regulated: the ignitability by cigarettes and the maximum allowable heat release in accordance with ASTM E1537.

**805.1.1.1 Ignition by cigarettes.** Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261.

2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

❖ This section focuses on the ignitability of furniture when exposed to lighted cigarettes and is consistent with Section 805.2.1.1 for Group I-2 occupancies and Section 805.3.1.1 for Group I-3 detention and correctional facilities. It offers an alternative test (NFPA 261) for approval of cigarette ignition resistance of newly introduced upholstered furniture in Group I-1 occupancies (board and care facilities). The same test method is already permitted for use in Group I-2 and I-3 occupancies. The difference between NFPA 260 and NFPA 261 is that NFPA 260 uses an overall classification system that looks at the cigarette ignition behavior of the individual components that may be found in upholstered furniture while NFPA 261 specifically looks at ignitability of a mock-up of upholstered furniture. It presents a method for study of the ignitability of the furniture mock-up and a technique to measure the char length, and limits the maximum char length to 1.5 inches (38.1 mm). In fact, results from NFPA 261 are more likely to be predictive of real fire behavior.

The previously existing exception to this section for upholstered furniture in rooms or spaces protected by an approved NFPA 13 automatic sprinkler system has been deleted because: a. Sprinklers have no effect on controlling smoldering ignition (ignition by cigarettes), since they require an increase in room temperature to act and there will be no increase in room temperature until well after the upholstered furniture which fails the cigarette test has erupted into flames; and b. Newly introduced upholstered furniture is very likely to meet smoldering ignition requirements. The trade association for manufacturers of residential upholstered furniture, Upholstered Furniture Action Council (UFAC), its sister organization, American Furniture Manufacturers Association (AFMA) and the trade association for manufacturers of institutional and contract upholstered furniture, Business and Institutional Furniture Manufacturers Association (BIFMA), require that their members comply with the smoldering resistance test. UFAC requires NFPA 260 (equivalent to ASTM E1353 and the UFAC test) and BIFMA requires NFPA 261 (equivalent to ASTM E1352). Note that this section does not affect existing upholstered furniture.

**805.1.1.2 Heat release rate.** Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 megajoules (MJ).

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ The two tests specified in this section measure the overall combustibility of furniture. When a building is sprinklered in accordance with NFPA 13, this section does not apply. Upholstered furniture must be tested to either ASTM E1537 or California Technical Bulletin 133 (which are basically the same test, but ASTM E1537 has no pass/fail criteria). This test uses a full-scale calorimeter, with the furniture item either in a standard room or under a hood. A full-scale calorimeter allows a representative piece of furniture to be burned and the products of combustion to be collected and analyzed in the exhaust duct by measuring gases (principally oxygen) in order to measure heat release. The test also measures weight loss during the test [see Commentary Figure 805.1.1.2(1) for a representation of the test]. The acceptance criteria set by the code are as follows:

- Peak heat release is limited to 80 kW; and
- Total energy (or heat) release within the first 10 minutes cannot exceed 25 megajoules (MJ).

Limitations are placed on the maximum intensity and fire effluents produced by restricting the peak heat release rate and the amount of combustibles actually burned. The total energy release of 25 MJ could be translated to a steady fire as follows, where:

$$X = \text{Steady fire heat release rate expressed in kW:}$$

$$X \times 10 \text{ minutes} = 25 \text{ MJ}$$

$$(10 \text{ minutes} = 600 \text{ sec and } 25 \text{ MJ} = 25,000 \text{ kJ})$$

$$X \times 600 \text{ sec} = 25,000 \text{ kJ}$$

$$X = 25,000 \text{ kJ}/600 \text{ sec} = 41.66 \text{ kJ/sec}$$

$$X = 41.66 \text{ kJ/sec} = 41.66 \text{ kW} \sim 42 \text{ kW heat release rate}$$

A steady fire of 42 kW (133 kJ/sec) for 10 minutes will result in a total energy release of 25 MJ.

Because fires in more realistic conditions do not burn steadily and vary in their characteristics, the criterion is given in the form of a peak heat release rate and total energy release. To provide a better understanding, if the fire were burning at the maximum peak heat release rate of 80 kW for the first 10 minutes, the total energy output would be 75 MJ, [80 kW (kJ/sec) H 10 minutes (600 sec) = 48,000 kJ = 48 MJ], which is well over the criterion of 25 MJ. A fire burning at a steady rate from start to finish is not realistic because fires must go through an initial growth stage before a peak heat release rate will be reached, followed by a decay phase; therefore, because a realistic fire will not burn at the peak heat release rate from the start of the fire, it is possible for a piece of furniture to have a peak heat release rate of 80 kW and still stay within the 25 MJ limitation. Commentary Figure 805.1.1.2(2) demonstrates the difference between a steady fire and a more realistic unsteady fire. As stated in the exceptions, the heat release rates will not apply to buildings sprinklered in

accordance with NFPA 13. Sections 805.2.1.2 and 805.3.1.2 address the heat release rate limitations for upholstered furniture in the same manner. It should be noted that Section 805.3.1.2 does not reference California Technical Bulletin 133.

See also the commentary for mattresses in Section 805.1.2.

**805.1.1.3 Identification.** Upholstered furniture shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.1.1.1 and 805.1.1.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary for the definition of “Labeled” in Section 202.

**805.1.2 Mattresses.** Newly introduced mattresses shall meet the requirements of Sections 805.1.2.1 through 805.1.2.3.

❖ Sections 805.1.2.1 and 805.1.2.2 deal with the combustibility of mattresses. Section 805.1.2.1 focuses on initial ignition and the ability of a mattress to sustain a fire; Section 805.1.2.2 is focused primarily on the burning characteristics of mattresses.

**805.1.2.1 Ignition by cigarettes.** Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

❖ This section sets a maximum char length of 2 inches (51 mm) when the mattress is tested under DOC 16 CFR, Part 1632. This test is a mandatory regulation for all mattresses sold in the United States. More specifically, it is part of the regulations governed by the Consumer Products Safety Commission (CPSC) under the Department of Commerce (DOC). Sections 805.2.2.1 and 805.3.2.1 have the same reference and requirements for Group I-2 and I-3 occupancies.

Thus, mattresses that fail to meet the 16 CFR 1632 test will be those sold either before the CPSC regulation went into effect (in 1972) or outside of the United States.

**805.1.2.2 Heat release rate.** Newly introduced mattresses shall have limited rates of heat release when tested in accordance with ASTM E1590 or California Technical Bulletin 129, as follows:

1. The peak rate of heat release for the single mattress shall not exceed 100 kW.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single mattress during the first 10 minutes of the test shall not exceed 25 MJ.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ As noted, an occupant smoking in bed and initiating a mattress fire is a major fire hazard in Group I-1, Condition 2 occupancies. This section, like Section 805.1.1.2, limits combustibility by restricting the peak heat release rate and on the total energy output in the first 10 minutes of burning. These limitations vary slightly from those for upholstered furniture. Each mattress is allowed a maximum heat release rate of 100 kW, whereas each upholstered furniture item is limited to 80 kW. The total energy (or heat) release limitation is the same as for upholstered furniture items, which is 25 MJ in the first 10 minutes. As with upholstered furniture, these restrictions are not applicable in buildings sprinklered in accordance with NFPA 13. The tests that determine the peak heat release rate and total energy (or heat) release are specific to mattresses. These tests are detailed in ASTM E1590 and California Technical Bulletin 129

(which are the same test, except that ASTM E1590 does not have pass/fail criteria). These tests, like that referenced in Section 805.1.1.2, make use of a full scale calorimeter to measure the products of combustion. There are two differences between ASTM E1537 and ASTM E1590: the object being tested (see commentary, Section 805.1.1.2) and the ignition source. Both tests use a gas burner, but they are different in geometry, gas flow rate, duration of gas flow and position of flame application. Section 805.2.2.2 contains the same restrictions and testing requirements on combustibility for mattresses in Group I-2 occupancies, Section 805.3.2.2 for Group I-3 detention and correctional facilities and Section 805.4.2.2 for Group R-2 dormitories.

**805.1.2.3 Identification.** Mattresses shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.2.2.1 and 805.2.2.2.

❖ This section provides the fire code official with a valuable tool in evaluating and approving mattresses in Group I-2 occupancies. In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary for the definition of “Labeled” in Section 202.

**805.2 Group I-2, nursing homes and hospitals.** The requirements in Sections 805.2.1 through 805.2.2 shall apply to nursing homes and hospitals classified in Group I-2.

❖ This section introduces Sections 805.2.1 through 805.2.2.3 which contain requirements for controlling the hazards associated with upholstered furniture and mattresses in new and existing Group I-2 occupancies. Occupants of nursing homes (Group I-2, Condition 1) and hospitals (Group I-2, Condition 2) are considered more vulnerable than the general population. Many of the patients of nursing homes and hospitals are confined because of respirators, IVs and other medical equipment and may not be capable of self-preservation. Hospital employees may have to make several trips into the fire area to assist in evacuating patients; therefore, it is imperative that every effort be made to preserve the integrity of the corridors and minimize the fuel loading caused by furnishings and contents, such as upholstered furniture and mattresses.

Historically, fires have been ignited through the use of cigarettes in bed or falling asleep while smoking in a chair. In addition to these hazards, such occupancies usually have additional medical oxygen sources within their rooms. This section, therefore, states several ignitability and combustibility limitations for upholstered furniture and mattresses that might be introduced into such occupancies.

**805.2.1 Upholstered furniture.** Newly introduced upholstered furniture shall meet the requirements of Sections 805.2.1.1 through 805.2.1.3.

❖ This section informs the user that two aspects of upholstered furniture are regulated: the ignitability by

cigarettes and the maximum allowable heat release in accordance with ASTM E1537.

**805.2.1.1 Ignition by cigarettes.** Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following: (a) mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261 or (b) the components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

**Exception:** Upholstered furniture belonging to the patients in sleeping rooms of nursing homes (Group I-2), provided that a smoke detector is installed in such rooms. Battery-powered, single-station smoke alarms shall be allowed.

❖ The exception allows nursing home patients to bring their furniture with them into their rooms without having to comply with the test requirements provided that the basic protection of a system smoke detector (in buildings equipped with a fire alarm system) or a battery-operated smoke alarm is present in the room (see commentary, Section 805.1.1.1). Note that all new Group I-2, Condition 1 occupancies are required to be equipped throughout with an automatic sprinkler system. Additionally, Section 1105.8 requires an automatic sprinkler system in existing Group I-2 occupancies. This requirement is retroactive, which means it applies regardless of whether work is being done to the building.

**805.2.1.2 Heat release rate.** Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ This section is identical to Section 805.1.1.2 and focuses on the potential heat release rate of upholstered furniture if a fire occurs (see commentary, Section 805.1.1.2).

**805.2.1.3 Identification.** Upholstered furniture shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.2.1.1 and 805.2.1.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this infor-

mation would be extremely difficult to verify in the field. See the commentary to the definition of “Labeled” in Section 202.

**805.2.2 Mattresses.** Newly introduced mattresses shall meet the requirements of Sections 805.2.2.1 through 805.2.2.3.

❖ Sections 805.2.2.1 and 805.2.2.2 deal with the combustibility of mattresses. Section 805.2.2.1 focuses on initial ignition and the ability of a mattress to sustain a fire; Section 805.2.2.2 is focused primarily on the burning characteristics of mattresses.

**805.2.2.1 Ignition by cigarettes.** Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

❖ This section is the same as Sections 805.1.2.1 and 805.3.2.1 and requires compliance with DOC 16 CFR Part 1632 (see commentary, Section 805.1.2.1).

**805.2.2.2 Heat release rate.** Newly introduced mattresses shall have limited rates of heat release when tested in accordance with ASTM E1590 or California Technical Bulletin 129, as follows:

1. The peak rate of heat release for the single mattress shall not exceed 100 kW.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single mattress during the first 10 minutes of the test shall not exceed 25 MJ.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ This section is the same as Section 805.1.2.2 in limiting the maximum heat release rate and the total energy release (see commentary, Section 805.1.2.2).

**805.2.2.3 Identification.** Mattresses shall bear the label of an *approved agency*, confirming compliance with the requirements of Sections 805.2.2.1 and 805.2.2.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary to the definition of “Labeled” in Section 202.

**805.3 Group I-3, detention and correction facilities.** The requirements in Sections 805.3.1 through 805.3.2 shall apply to detention and correction facilities classified in Group I-3.

❖ This section introduces Sections 805.3.1 through 805.3.2.3, which contain requirements for controlling the hazards associated with upholstered furniture and mattresses in new and existing Group I-3 detention and correctional occupancies. These facilities have a higher likelihood of incendiary activities, and because of the restrictions on movement, the occupants are placed in a more vulnerable position than the general

public; therefore, combustibility limitations are placed on furniture and mattresses.

**805.3.1 Upholstered furniture.** Newly introduced upholstered furniture shall meet the requirements of Sections 805.3.1.1 through 805.3.1.3

❖ This section informs the user that two aspects of upholstered furniture are regulated: the ignitability by cigarettes and the maximum allowable heat release in accordance with ASTM E1537.

**805.3.1.1 Ignition by cigarettes.** Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261.
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

❖ These requirements are the same as those found in Sections 805.1.1.1 and 805.2.1.1 (see commentary, Section 805.1.1.1).

**805.3.1.2 Heat release rate.** Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E1537, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.
2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

❖ See the commentary to Section 805.1.1.2.

**805.3.1.3 Identification.** Upholstered furniture shall bear the label of an *approved agency*, confirming compliance with the requirements of Sections 805.3.1.1 and 805.3.1.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary to the definition of “Labeled” in Section 202.

**805.3.2 Mattresses.** Newly introduced mattresses shall meet the requirements of Sections 805.3.2.1 through 805.3.2.3.

❖ Sections 805.3.2.1 and 805.3.2.2 deal with the combustibility of mattresses. Section 805.3.2.1 focuses on initial ignition and the ability of a mattress to sustain a fire; Section 805.3.2.2 focuses primarily on the burning characteristics of mattresses.

**805.3.2.1 Ignition by cigarettes.** Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

❖ This section is the same as Sections 805.1.2.1 and 805.3.2.1 and requires compliance with DOC 16 CFR Part 1632 (see commentary, Section 805.1.2.1).

**805.3.2.2 Fire performance tests.** Newly introduced mattresses shall be tested in accordance with Section 805.3.2.2.1 or 805.3.2.2.2.

❖ This section provides two options for fire tests: ASTM E1590, which is a cone calorimeter test, and Annex A3 of ASTM F1085, which provides a simple burn test to determine how much mass the mattress will lose with this exposure.

**805.3.2.2.1 Heat release rate.** Newly introduced mattresses shall have limited rates of heat release when tested in accordance with ASTM E1590 or California Technical Bulletin 129, as follows:

1. The peak rate of heat release for the single mattress shall not exceed 100 kW.
2. The total energy released by the single mattress during the first 10 minutes of the test shall not exceed 25 MJ.

❖ This section is the same as Section 805.1.2.2 in limiting the maximum heat release rate and the total energy (or heat) release (see commentary, Section 805.1.2.2).

**805.3.2.2.2 Mass loss test.** Newly introduced mattresses shall have a mass loss not exceeding 15 percent of the initial mass of the mattress where tested in accordance with the test in Annex A of ASTM F1085.

❖ The test in Annex A3 of ASTM F1085 was developed originally for use in detention and correctional occupancies and is a very severe test that is a reasonable (and less expensive) alternative to ASTM E1590. This test is very simple, can be conducted at any facility and does not require the use of an instrumented fire test lab. The test can be described in a few words: it involves rolling up a mattress, placing it at an angle (for example by holding it with a brick), introducing newspaper into the volume surrounding the rolled up mattress and igniting the newspaper with a match.

If mattress materials melt away from the flame with flaming drips they may “pass” the ASTM E1590 test; however, melting would result in a failure of the ASTM F1085 Annex A test. In this test, the material that flames on the floor will keep burning the mattress itself.

Commentary Figure 805.3.2.2.2 provides a table that shows the results using the ASTM F1085 Annex A3 test for a number of mattresses in two studies (one in 1980 and one in 2003) and it also shows whether the mattresses meet the ASTM E1590 requirements in the code. It is clear from the table that mattresses will either burn up almost completely or lose very little mass. The ASTM F1085 test will not pass mattresses that fail ASTM E1590.

The test from Annex A3 of ASTM F1085 is also described in Section 10.2 of ASTM F1870 (Standard Guide for Selection of Fire Test Methods for the Assessment of Upholstered Furnishings in Detention and Correctional Facilities) as a test method “Designed for Detention and Correction Facilities.”

**805.3.2.3 Identification.** Mattresses shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.3.2.1 and 805.3.2.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary to the definition of “Labeled” in Section 202.

**805.4 Group R-2 college and university dormitories.** The requirements of Sections 805.4.1 through 805.4.2.3 shall apply to college and university dormitories classified in Group R-2, including decks, porches and balconies.

❖ This section introduces Sections 805.4.1 through 805.4.2.3, which contain requirements for controlling the hazards associated with upholstered furniture and mattresses in new and existing Group R-2 college

MATTRESS	ASTM F1085 MASS LOSS %	ASTM E1590 PER SECTION 805.3.2.2.1 PASS OR FAIL
1 (2003)	1.22	Pass
2 (2003)	9.47	Pass
3 (2003)	3.30	Pass
4 (2003)	100	Fail
5 (2003)	100	Fail
1 (1980)	100	Fail
2 (1980)	100	Fail
3 (1980)	98.5	Fail
4 (1980)	91.1	Fail
5 (1980)	91	Fail
6 (1980)	83.1	Fail
7 (1980)	44.7	Fail
8 (1980)	3.0	Pass

**Figure 805.3.2.2.2  
ANNEX A3 ASTM F1085 TEST RESULTS**

and university dormitories. Fire represents a significant risk to life and property in dormitory occupancies, particularly at residential schools, colleges and universities. The large number of young people living in close proximity to one another creates the potential for a relatively small fire to have serious and possibly fatal consequences. According to NFPA fire loss data, there are an average of 1,425 fires each year in dormitories causing \$6.3 million in direct property damage. For these reasons, upholstered furniture and mattresses in dormitories must comply with the same requirements for fire performance as those in Group I-1, I-2 and I-3 occupancies. The test methods and criteria are identical to those in Sections 805.1, 805.2 and 805.3 of the code. Section 805.3.2.2.2 provides an option for a mass loss test for mattresses.

Note that this section also includes upholstered furniture and mattresses on porches, decks and balconies, which, for this particular occupancy, can be frequently found in such locations. Since the decks, porches or balconies are likely not sprinklered, this would severely limit or eliminate the allowance of such items in these areas. Many jurisdictions have specifically banned furniture such as couches from these areas. These provisions are not as strict but will limit the potential for fires to spread to the structure.

Section 805.4 provides the fire code official and college and university campus housing authorities with the needed authority to limit the combustibility of student-owned furnishings. Those furnishings can include both upholstered furniture and mattresses, which are the high-fuel items in Group R-2 dormitory occupancies. Strictly enforced, these provisions, coupled with the limitations on the use of open flames in Group R-2 dormitories found in Section 308.4.1, should provide a much-improved level of fire safety in these occupancies.

**805.4.1 Upholstered furniture.** Newly introduced upholstered furniture shall meet the requirements of Sections 805.4.1.1 through 805.4.1.3

❖ This section informs the user that two aspects of upholstered furniture are regulated: the ignitability by cigarettes and the maximum allowable heat release in accordance with recognized standards.

**805.4.1.1 Ignition by cigarettes.** Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1½ inches (38 mm) when tested in accordance with NFPA 261.

2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

❖ These requirements are the same as those found in Sections 805.1.1.1, 805.2.1.1 and 805.3.1.1 (see commentary, Section 805.1.1.1).

**805.4.1.2 Heat release rate.** Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

**Exception:** Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ This section is identical to Sections 805.1.1.2 and 805.2.1.2 and focuses on the potential heat release rate of upholstered furniture if a fire occurs (see commentary, Section 805.1.1.2).

**805.4.1.3 Identification.** Upholstered furniture shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.4.1.1 and 805.4.1.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary for the definition of “Labeled” in Section 202.

**805.4.2 Mattresses.** Newly introduced mattresses shall meet the requirements of Sections 805.4.2.1 through 805.4.2.3.

❖ Sections 805.4.2.1 and 805.4.2.2 deal with the combustibility of mattresses. Section 805.4.2.1 focuses on initial ignition and the ability of a mattress to sustain a fire; Section 805.4.2.2 focuses primarily on the burning characteristics of mattresses.

**805.4.2.1 Ignition by cigarettes.** Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

❖ This section is the same as Sections 805.1.2.1, 805.2.2.1 and 805.3.2.1 and requires compliance

with DOC 16 CFR Part 1632 (see commentary, Section 805.1.2.1).

**805.4.2.2 Heat release rate.** Newly introduced mattresses shall have limited rates of heat release when tested in accordance with ASTM E1590 or California Technical Bulletin 129, as follows:

1. The peak rate of heat release for the single mattress shall not exceed 100 kW.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single mattress during the first 10 minutes of the test shall not exceed 25 MJ.

**Exception:** Mattresses in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ This section is the same as Sections 805.1.2.2, 805.2.2.2 and 805.3.2.2.1 in limiting the maximum heat release rate and the total energy (or heat) release (see commentary, Section 805.1.2.2).

**805.4.2.3 Identification.** Mattresses shall bear the label of an *approved agency*, confirming compliance with the requirements of Sections 805.4.2.1 and 805.4.2.2.

❖ In order to achieve verifiable compliance, labeling by an approved agency is required. Otherwise, this information would be extremely difficult to verify in the field. See the commentary to the definition of “Labeled” in Section 202.

## SECTION 806 DECORATIVE VEGETATION IN NEW AND EXISTING BUILDINGS

**806.1 Natural cut trees.** Natural cut trees, where allowed by this section, shall have the trunk bottoms cut off not less than 0.5 inch (12.7 mm) above the original cut and shall be placed in a support device complying with Section 806.1.2.

❖ This section focuses on the fire hazards posed by vegetation within a building. The majority of this section deals specifically with fresh Christmas trees. Natural cut trees, such as Christmas trees, within buildings pose a significant fire threat to occupants if they are not properly cared for. Because of the symmetric way in which these trees are normally groomed, the large surface area of the foliage and the amount of airspace throughout the branches, fires have the potential to burn very efficiently and vigorously if the tree is dry. The National Institute of Standards and Technology (NIST) website has the following statements: “The National Fire Protection Association (NFPA) reports that there are an estimated annual average of 210 home structure fires that begin with Christmas trees. Based on data from 2002 through 2005, these fires caused an average of 24 civilian deaths, 27 civilian injuries, and \$13.3 mil-

lion in direct property damage per year. The NFPA analysis also shows that although the number of Christmas tree fires is low, these fires represent a higher level of hazard. On average, one of every nine Christmas tree fires resulted in a fatality compared to an average of one death per 75 nonconfined home structure fires overall. Further, 49 percent of Christmas tree fires spread beyond the room of origin. The fires that spread beyond the room of origin caused 94 percent of the associated fatalities. The percentage of trees involved in structure fires represents an extremely small portion of the total number of natural Christmas trees sold in the United States each year, which is estimated at 30 million. The moisture content of each tree can play a dominant role in determining the fire hazard it represents. Properly maintaining a cut Christmas tree is important to retaining a high moisture content in the needles of the tree to limit accidental ignition and prevent rapid flame spread. A tree that has dry needles can readily ignite with a flaming source and generate heat release rates that are capable of causing flashover in residential scale rooms. The above statistics addressed home structure fires and natural Christmas trees, which are required by the IFC to be kept moist and fresh at all times.”

In tests performed at NIST in 1999 to better understand the severity of Christmas tree fires, eight Scotch pine Christmas trees were placed in a room at 73°F (23°C) at approximately 50-percent relative humidity for approximately three weeks. Seven of the eight trees were given no additional moisture; the eighth tree was watered according to local rules for trees within business occupancies. This required the tree to be cut in a certain manner and placed in a stand with at least a 2-gallon (7.6 L) capacity. The seven dry trees were ignited and burned intensely; however, the tree that had been watered continuously throughout the three weeks could not be ignited. The peak heat releases from the dry trees ranged from approximately 1,600 kW to 5,000 kW within about 50 to 80 seconds of ignition [see Commentary Figure 806.1(1) for a summary of results and Commentary Figure 806.1(2) for a graphical representation of Test No. 3]. These test results demonstrate that the proper care for trees (i.e., making sure that the tree remains humid or wet) makes a significant difference on the fire hazard presented. This section requires at least 1/2 inch (12.7 mm) of tree trunk to be removed above the original cut to optimize the tree’s ability to absorb water to maintain a minimum level of moisture. This section also requires a support device (tree stand or equivalent) that meets the criteria of Section 806.1.2. Such devices are intended to bring the correct amount of moisture into contact with the tree. The specifics of this section cannot realistically be monitored in all buildings within a jurisdiction. The focus must be on occupancies

such as assembly or mercantile. All occupancies benefit, however, because there is now a method that a fire department could use to educate the general public on the treatment of Christmas trees. This tool can be helpful in fire prevention within a jurisdiction.

**806.1.1 Restricted occupancies.** Natural cut trees shall be prohibited within ambulatory care facilities and Group A, E, I-1, I-2, I-3, I-4, M, R-1, R-2 and R-4 occupancies.

**Exceptions:**

1. Trees located in areas protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2 shall not be prohibited in Groups A, E, M, R-1 and R-2.

2. Trees shall be allowed within *dwelling units* in Group R-2 occupancies.

❖ Although trees that have been properly watered and handled are less hazardous, there is still a concern that they should not be located in certain occupancies and specific uses. The occupancies listed in this section are those where the occupant load is high, occupants are vulnerable or the potential hazards that exist if the tree is not properly handled are too great. These occupancies and specific uses include ambulatory care facilities and Group A, E, I-1, I-2, I-3, I-4, M, R-1 and R-2 occupancies. There are exceptions for Group A, E, M, R-1 and R-2 occupancies when the trees are located in areas that are sprinklered in

TEST NO.	WEIGHT (kg)		HEIGHT (m)	WIDTH <sup>a</sup> (m)	MOISTURE CONTENT (%)
	Before Test	After Test			
1	17.2	6.8	2.6	1.7	30
2	15.9	8.2	2.7	1.3	27
3	20.0	6.8	2.3	1.7	30
4	9.5	5.0	2.5	1.2	30
5	19.1	8.6	2.5	1.7	28
6	12.7	7.7	2.5	1.1	32
7	18.6	7.7	3.1	1.5	25
8	28.1	28.1	2.7	1.4	36

(From NIST Report FR 4010)

a. The width is measured at the widest point of the tree.

**Figure 806.1(1)  
SUMMARY OF TREE PARAMETERS**

(From NIST Report FR 4010)

**Figure 806.1(2)  
GRAPH OF HEAT RELEASE RATE VERSUS TIME FOR TEST NUMBER 3**

accordance with NFPA 13 or 13R, as applicable, and for trees within individual dwelling units in Group R-2. Essentially, the only occupancies that would be completely prohibited from having cut trees are institutional occupancies because of the vulnerability of the occupants and, in some cases, concerns for incendiary tendencies of some occupants.

**806.1.2 Support devices.** The support device that holds the tree in an upright position shall be of a type that is stable and that meets all of the following criteria:

1. The device shall hold the tree securely and be of adequate size to avoid tipping over of the tree.
2. The device shall be capable of containing a minimum two-day supply of water.
3. The water level, when full, shall cover the tree stem not less than 2 inches (51 mm). The water level shall be maintained above the fresh cut and checked not less than once daily.

❖ This section is intended to prevent the tree from tipping over, potentially into an ignition source, and ensure that the support device is designed and used to keep the water supply to the tree at a useful level. More specifically, Item 1 requires the device to prevent the tree from tipping; Item 2 states that the device must be capable of holding a two-day water supply; and Item 3 requires a minimum coverage of water to 2 inches (51 mm) above the bottom of the stem. The water level must be checked at least once daily to verify that an adequate supply remains. The restrictions in Section 806.1.1 are in place because the provisions in Section 806.1.2 are generally difficult for a fire department to monitor. Having a sprinkler system or generally prohibiting natural cut trees in higher risk occupancies provides a redundancy to deal with the potential hazards.

**806.1.3 Dryness.** The tree shall be removed from the building whenever the needles or leaves fall off readily when a tree branch is shaken or if the needles are brittle and break when bent between the thumb and index finger. The tree shall be checked daily for dryness.

❖ Lack of moisture is the primary problem with natural cut trees within buildings. This section describes a daily test to assist in evaluating whether the tree is considered too dry to remain in the building.

**806.2 Artificial vegetation.** Artificial decorative vegetation shall meet the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701. Meeting the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701 shall be documented and certified by the manufacturer in an *approved* manner. Alternatively, the artificial decorative vegetation item shall be tested in accordance with NFPA 289, using the 20 kW ignition source, and shall have a maximum heat release rate of 100 kW.

❖ Much of the attention of Section 806 has been focused on natural vegetation, primarily Christmas trees. This section addresses artificial vegetation,

which generally contains a high concentration of plastic material in the form of plastic artificial leaves. The goal, therefore, is to reduce initial ignitability by treating artificial vegetation with flame retardants to improve fire performance or to use materials that have inherently better fire performance. Artificial decorative vegetation is required by this section to be tested either to the flame propagation performance criteria of NFPA 701 or in accordance with NFPA 289 using the 20 kW ignition source and with a maximum allowed heat release rate of 100 kW.

NFPA 289 is a furniture calorimeter heat release fire test specifically developed for these types of products. NFPA 289 uses a propane gas burner as the ignition source. The 20 kW gas burner ignition source in NFPA 289 was specifically designed with the intent of being a substitute for UL 1975 and would be suitable as an ignition source for Christmas trees.

As discussed extensively in Section 806.1, there are substantial fire safety requirements for natural Christmas trees; however, testing in accordance with NFPA 701 was the only option until this requirement was added.

**806.3 Obstruction of means of egress.** The required width of any portion of a *means of egress* shall not be obstructed by decorative vegetation. Natural cut trees shall not be located within an exit, corridor, or a lobby or vestibule.

❖ Decorative vegetation is often placed in a location that does not normally accommodate combustibles. This section restricts locations so that the vegetation does not block the egress width and increase the fire hazard in such areas. For example, this would likely prohibit trees in main lobby areas of a movie theater.

**806.4 Open flame.** Candles and open flames shall not be used on or near decorative vegetation. Natural cut trees shall be kept a distance from heat vents and any open flame or heat-producing devices at least equal to the height of the tree.

❖ This section addresses the primary ignition hazards associated with decorative vegetation. More specifically, candles should never be placed on or near Christmas trees. Also, heat sources such as vents may pose an ignition hazard in addition to being a source of airflow that could dry out a tree, making it more susceptible to ignition.

**806.5 Electrical fixtures and wiring.** The use of unlisted electrical wiring and lighting on natural cut trees and artificial decorative vegetation shall be prohibited. The use of electrical wiring and lighting on artificial trees constructed entirely of metal shall be prohibited.

❖ Decorations are quite often used year after year on Christmas trees. Some of this decor consists of lights that are not specifically listed and can fail and become very hot, potentially posing an ignition source. Additionally, this wiring may arc and create an ignition source. In fact, it has been found that many Christmas tree fires have actually been started by the decorative lights on them. Therefore, this section simply prohibits the use of unlisted wiring or light-

ing (such lights and ornaments are listed in accordance with UL 588). Additionally, because of the shock and ignition potential resulting from a short or direct contact of part of the tree with one of the light sockets, electrical wiring and lighting is not allowed on metal trees.

**SECTION 807  
DECORATIVE MATERIALS OTHER  
THAN DECORATIVE VEGETATION IN NEW  
AND EXISTING BUILDINGS**

**807.1 General.** Combustible decorative materials, other than decorative vegetation, shall comply with Sections 807.2 through 807.5.6.

❖ The requirements in this section apply to decorative materials other than vegetation. The bulk of the requirements in this section are applicable to all occupancy groups. Section 807.3 is applicable to all groups, except Group I-3, as combustible decorative materials are prohibited (See Section 807.5.4). Decorative materials must be noncombustible or meet the flame propagation performance criteria of Section 806.4 and NFPA 701. Note that Section 807.5 is occupancy based and addresses combustible decorative materials that may not comply with Section 807.3, such as artwork in classrooms. Instead, specific limitations on amounts and types of materials are provided. The occupancies addressed include Group A, E, I and R-2 dormitories.

**807.2 Limitations.** The following requirements shall apply to all occupancies:

1. Furnishings or decorative materials of an explosive or highly flammable character shall not be used.
2. Fire-retardant coatings in existing buildings shall be maintained so as to retain the effectiveness of the treatment under service conditions encountered in actual use.
3. Furnishings or other objects shall not be placed to obstruct exits, access thereto, egress therefrom or visibility thereof.
4. The permissible amount of noncombustible decorative materials shall not be limited.

❖ This section addresses some basic hazards with certain finishes and materials associated with decorative materials. These are discussed below.

1. This is a general statement prohibiting furnishings and contents or decorative materials that pose an extreme fire potential. These materials tend to have a significant impact on fire size in a building.
2. In many cases, the IBC and the code allow use of certain combustible or flammable materials based on the application of a fire-retardant coating (see commentary, Section 803.4).

3. Similar to Section 806.3, this section prohibits any decorations or other objects from obstructing the means of egress, including visibility.
4. It is clarified that noncombustible decorative materials are not limited, as they pose no fire hazard. It is important that they comply with Item 3 in terms of obstruction of the means of egress.

**807.3 Combustible decorative materials.** In other than Group I-3, curtains, draperies, fabric hangings and other similar combustible decorative materials suspended from walls or ceilings shall comply with Section 807.4 and shall not exceed 10 percent of the specific wall or ceiling area to which they are attached.

Fixed or movable walls and partitions, paneling, wall pads and crash pads applied structurally or for decoration, acoustical correction, surface insulation or other purposes shall be considered *interior finish*, shall comply with Section 803 and shall not be considered *decorative materials* or furnishings.

**Exceptions:**

1. In auditoriums in Group A, the permissible amount of curtains, draperies, fabric hangings and other similar combustible decorative material suspended from walls or ceilings shall not exceed 75 percent of the aggregate wall area where the building is equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1, and where the material is installed in accordance with Section 803.11 of the *International Building Code*.
2. In Group R-2 dormitories, within sleeping units and dwelling units, the permissible amount of curtains, draperies, fabric hangings and other similar decorative materials suspended from walls or ceilings shall not exceed 50 percent of the aggregate wall areas where the building is equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.
3. In Group B and M occupancies, the amount of combustible fabric partitions suspended from the ceiling and not supported by the floor shall comply with Section 807.4 and shall not be limited.

❖ Meeting the flame propagation performance criteria of NFPA 701, which is required by Section 807.4, does not mean that materials will not burn, only that they are going to spread flame relatively slowly. These materials are, therefore, limited to a maximum of 10 percent of the total wall or ceiling area of the space under consideration. Unlike incidental trim, decorative materials are not necessarily distributed evenly throughout the room. Additionally, consideration of the long-term maintenance of the materials, including possible periodic retreatment, should be taken into account.

In any occupancy classification, when a movable wall, partition, paneling, wall pads or crash pads

cover larger areas, they need to be dealt with as interior finishes instead of as decorative materials.

The first two exceptions relate to the 10-percent limitation in Section 807.3. Exception 1 is for Group A auditoriums that would allow 75-percent coverage of the walls and ceilings (instead of the limit of 10 percent) if the space is sprinklered in accordance with NFPA 13 and the material is applied in accordance with Section 803.11 of the IBC.

Exception 2 allows an increased amount of decorative materials in Group R-2 dormitories. An allowance of up to 50 percent is provided as long as the building is equipped throughout with an automatic sprinkler system. The reference to Section 903.3.1 allows the use of a NFPA 13 or 13R system as applicable. This allowance is likely provided as it is more realistic to what is typically found in dormitories and is more easily managed from an enforcement standpoint. The sprinklers provide the necessary protection to allow such an increase.

Exception 3 of this section clarifies that, in Group B and M occupancies, fabric partitions suspended from the ceiling but not physically contacting the floor should be treated as decorative materials similar to curtains or draperies and comply with the flame propagation performance heat release criteria of Section 807.4. These partitions are also permitted to be unlimited. This is with or without the use of sprinklers within a building.

**807.4 Acceptance criteria and reports.** Where required to exhibit improved fire performance, curtains, draperies, fabric hangings and other similar combustible decorative materials suspended from walls or ceilings shall be tested by an *approved* agency and meet the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701 or exhibit a maximum rate of heat release of 100 kW when tested in accordance with NFPA 289, using the 20 kW ignition source. Reports of test results shall be prepared in accordance with the test method used and furnished to the *fire code official* upon request.

- ❖ One of the standard test methods used to evaluate the ability of a material to propagate flame is NFPA 701, which contains two test methods. Test 1 is less severe than Test 2 and uses smaller specimens. Test 1 is intended for lighter weight materials and single layer fabrics: the limit is a linear density of 700 g/m<sup>2</sup> (21 oz/yd<sup>2</sup>). Test 2 is intended for higher density materials and multilayered fabrics. It also applies to vinyl-coated fabric blackout linings and lined draperies using any density, because they have been shown to give misleading results using Test 1. NFPA 701 sets out the types of materials, including fabrics that should be tested using each method.

Essentially, NFPA 701 provides a mechanism to distinguish between materials that allow flames to spread quickly and those that do not when using a small fire exposure.

Materials tested only to NFPA 701 are not permitted for use as interior finish materials, but instead are generally used as shades, swags, curtains and other similar materials. These tests are used to determine whether materials propagate flame beyond the area exposed to the ignition source. They are not intended to indicate whether the material tested will resist the propagation of flame under fire exposures more extreme than the test conditions.

It should be noted that the historic “small-scale test” is no longer accepted.

The other standard test method that can be used is NFPA 289. This test method quantifies the contribution of materials to heat and smoke release when subjected to different ignition sources. This test method also determines the potential for growth of a fire and the fire-spread of a given material when exposed to an ignition source in a controlled environment. See the commentary to Section 807.5.1.1 for a more detailed discussion of this test method.

**807.5 Occupancy-based requirements.** In occupancies specified, combustible decorative materials not complying with Section 807.3 shall comply with Sections 807.5.1 through 807.5.6.

- ❖ The provisions of Sections 807.5.1 through 807.5.6 address the vulnerability of occupants by addressing hazards likely found in certain occupancies. Group A occupancies are generally densely populated with occupants being unfamiliar with their surroundings. Such occupancies are also more likely to contain a large amount of decorative materials, such as stage scenery or exhibit booths utilizing foam plastics. Group E, I and R-2 dormitories have the potential to deal with a large amount of decorative materials and storage. Occupants in Group E, I and R-2 dormitories are also considered more vulnerable than other occupancies, such as Group B or M, because of occupant age or infirmity and occupancies such as dormitories where the occupants sometimes place themselves at increased risks. Group I-3, as will be discussed, should not have any combustible decorative materials. It is important to stress that this section specifically addresses materials that do not meet the requirements of NFPA 701, as is required in Section 807.3.

**807.5.1 Group A.** In Group A occupancies, the requirements in Sections 807.5.1.1 through 807.5.1.4 shall apply.

- ❖ The requirements in Sections 803.5.1.1 through 803.5.1.4 are specific to Group A occupancies. These particular requirements are fairly specific to activities and uses that occur in Group A occupancies, such as trade shows and movie theaters. Generally, fire hazards are moderate in Group A occupancies. The concerns are more closely related to the high occupant density and the occupants’ lack of familiarity with the building.

**807.5.1.1 Foam plastics.** Exposed foam plastic materials and unprotected materials containing foam plastic used for decorative purposes or stage scenery or exhibit booths shall have a maximum heat release rate of 100 kW when tested in accordance with UL 1975, or when tested in accordance with NFPA 289 using the 20 kW ignition source.

**Exceptions:**

1. Individual foam plastic items or items containing foam plastic where the foam plastic does not exceed 1 pound (0.45 kg) in weight.
2. Cellular or foam plastic shall be allowed for trim in accordance with Section 804.2.

❖ As discussed in Section 803.8, foam plastics can produce misleading results when tested to ASTM E84. In some instances, they can burn vigorously and at high rates of heat release. Group A occupancies tend to contain materials for stages, movie theaters and exhibit halls. These uses will likely have combustible scenery or exhibit booths that contain foam plastics. Therefore, because the occupants are unlikely to be familiar with the premises, and the hazards presented by these combustibles can be high, a heat release rate limit of 100 kW, when tested in accordance with UL 1975 or NFPA 289, is placed on foam plastic materials used in Group A occupancies.

In the past, restrictions on the combustibility of materials were based on the heat content of the materials instead of the rate at which the heat content is released. The problem with using heat content (which can be equated to “potential energy” of the material) as the limitation criterion is that it does not provide a good understanding of the rate at which the “potential energy” is released. The rate at which heat is released is a more important characteristic of fire and is a measure of the intensity of the fire. UL 1975 and NFPA 289 are furniture calorimeter types of tests that assess the actual heat release rate based on the exposure of the foam plastics to a specific heat input (340-gram wood crib for UL 1975 and 20kW propane gas burner ignition source for NFPA 289) as specified in the test.

Some alternatives to testing are provided in the exceptions, which primarily focus on limiting the amount of combustibles. The exceptions give two prescriptive approaches with no direct relationship to the actual combustibility of the foam plastic except to limit the amount used. Exception 1 is related to plastic display items, such as a small statue. Exception 2 relates specifically to decorative trim and directs the code user to the requirements for that material found in Section 804.2 (see commentary, Section 804.2).

**807.5.1.2 Motion picture screens.** The screens upon which motion pictures are projected in new and existing buildings of Group A shall either meet the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701 or shall comply with the requirements for a Class

B interior finish in accordance with Section 803 of the *International Building Code*.

❖ Movie screens are not considered interior finish and, therefore, would not be addressed by Chapter 8 of the IBC. These screens consist of a fabric base covered with a thin coating impregnated with reflective glass beads. Movie screens are generally fairly large and typically take up most of the front wall of a movie theater; therefore, the flame spread characteristics must be addressed. Because movie theaters tend to be densely occupied, a material with a high rate of flame spread can pose a significant hazard. Screens can comply in one of two ways. The screen must meet the applicable flame propagation performance criteria set out in NFPA 701 Test Method 1 or 2 (which focus on combustibles such as curtains, shades and window treatments, but are not appropriate for wall coverings), or qualify as a Class B interior finish material in accordance with ASTM E84. NFPA 286, which is also found in Section 803, would be a viable alternative for testing. It should be noted that the historic “small-scale test” in NFPA 701 is no longer accepted.

**807.5.1.3 Wood use in places of religious worship.** In places of religious worship, wood used for ornamental purposes, trusses, paneling or chancel furnishing shall not be limited.

❖ Places of religious worship are generally open spaces. The occupants, because of the nature of the activities in these assemblies, tend to be orderly. For this reason, wood, which is a combustible material, is allowed extensively as a finish material without restriction.

**807.5.1.4 Pyroxylin plastic.** Imitation leather or other material consisting of or coated with a pyroxylin or similarly hazardous base shall not be used.

❖ Use of pyroxylin plastics, also known as cellulose nitrate plastics, in Group A occupancies as imitation leather or other materials is strictly prohibited because of the normally high occupant loads of such occupancies. This type of material is very hazardous because it will begin decomposition at temperatures starting at 300°F (149°C), and has the potential to develop explosive atmospheres with high heat emission once it ignites. Because cellulose nitrate tends to become somewhat unstable and is easily ignitable, its use has generally declined. Specifically, use of cellulose nitrate for motion picture film was discontinued in 1951.

**807.5.2 Group E.** Group E occupancies shall comply with Sections 807.5.2.1 through 807.5.2.3.

❖ Group E occupancies are occupancies used by six or more persons for educational purposes through the 12th grade or buildings and structures used for educational, supervision or personal care services for

more than five children over the age of 2½ years. This section regulates the amount of combustibles within corridors, lobbies and classrooms by regulating clothing, personal effects and artwork.

**807.5.2.1 Storage in corridors and lobbies.** Clothing and personal effects shall not be stored in *corridors* and lobbies.

**Exceptions:**

1. *Corridors* protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.
2. *Corridors* protected by an *approved fire alarm system* installed in accordance with Section 907.
3. Storage in metal lockers, provided the minimum required egress width is maintained.

❖ Materials, such as clothing, other personal effects and artwork, have the potential for creating a fire hazard within the main path of egress travel. This section allows the storage of clothing and other personal effects within these areas only if corridors and lobbies contain one of the following features:

- Sprinkler system.
- Fire alarm system.
- Metal lockers for storage.

The sprinkler system must meet the requirements of NFPA 13. The fire alarm system must be approved by the fire code official. The fire alarm system is intended to specifically focus on the contents of the corridors and would typically be a smoke detection system. The system is not intended to be required throughout.

**807.5.2.2 Artwork in corridors.** Artwork and teaching materials shall be limited on the walls of *corridors* to not more than 20 percent of the wall area.

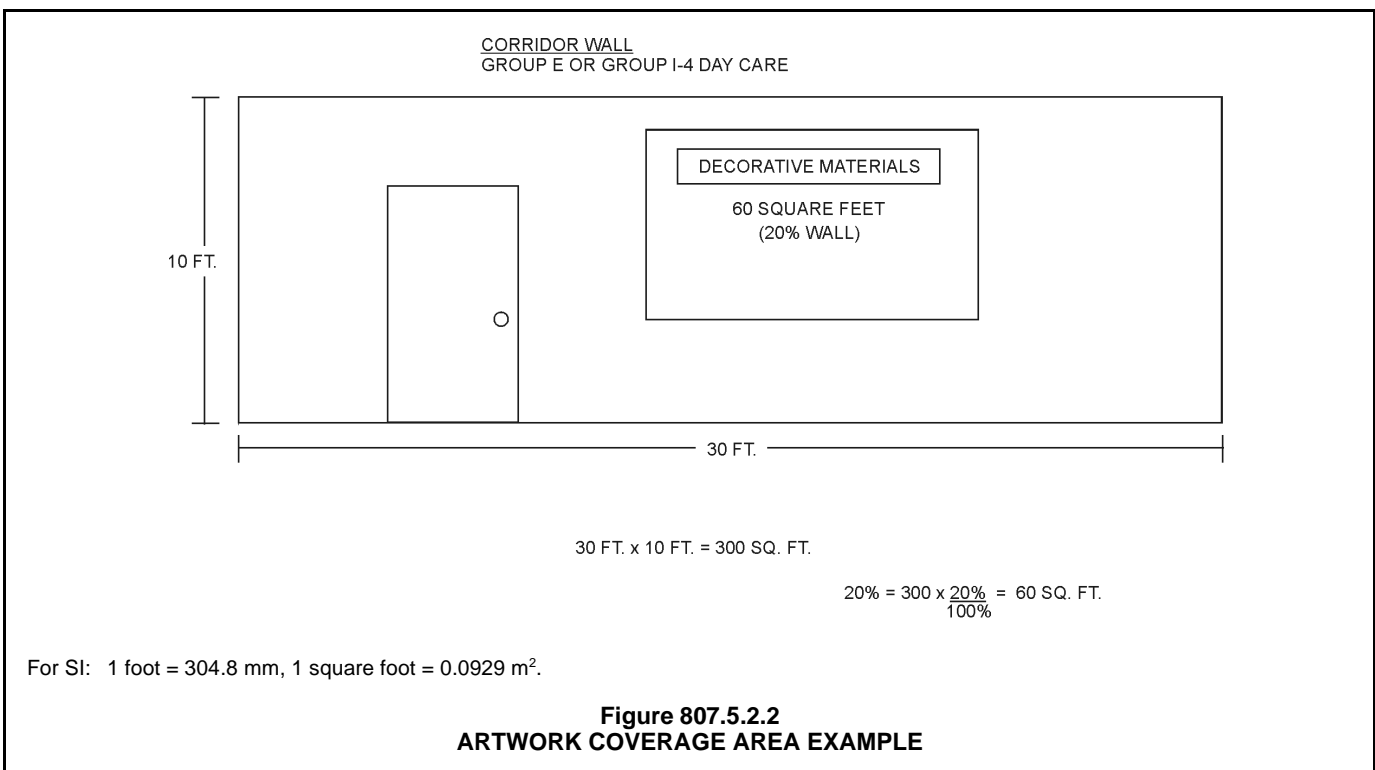

❖ Educational occupancies tend to display various artwork and related educational materials on the walls of classrooms and corridors. This section limits the potential combustibility levels of artwork in critical areas of the means of egress system; therefore, decorations or artwork can cover no more than 20 percent of the corridor walls. See Commentary Figure 807.5.2.2 for representation of the 20-percent coverage area.

**807.5.2.3 Artwork in classrooms.** Artwork and teaching materials shall be limited on walls of classrooms to not more than 50 percent of the specific wall area to which they are attached.

❖ This is consistent with requirements for restrictions on artwork in the corridors. The limit is less restrictive at 50 percent versus the 20 percent that is permitted for corridors. This relates to the fact that the corridors make up the more critical portion of the exit access for the building.

**807.5.3 Groups I-1 and I-2.** In Group I-1 and I-2 occupancies, combustible *decorative materials* shall comply with Sections 807.5.3.1 through 807.5.3.4.

❖ Sections 807.5.3.1 through 807.5.3.4 provide a series of requirements for care facilities where the occupants are at increased level of risk due to their physical and cognitive limitations. In Group I-1 and I-2 occupancies, the occupants are present 24 hours a day with varying levels of care depending on the type

of occupancy. Section 407.2.1 of the IBC allows waiting or similar areas to be open to corridors. These types of spaces typically have magazines, bulletin boards with paper notices tacked to them, and other combustible items not treated with flame retardants or tested to NFPA 701. Allowing a specified percentage of untreated, combustible decorative materials in Group I-1 and I-2 buildings equipped throughout with an automatic sprinkler system will not exceed the “ordinary occupancy” classification outlined in NFPA 13, nor does it increase the fire loading above what is currently permitted. These requirements offer consistent language to aid enforcement and a guide to providers to determine compliance within their facilities. The intent of these requirements is to eliminate the haphazard and inconsistent application of these provisions in facilities nationwide.

**807.5.3.1 Group I-1 and I-2 Condition 1 within units.** In Group I-1 and Group I-2 Condition 1 occupancies, equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, within sleeping units and dwelling units, combustible decorative materials placed on walls shall be limited to not more than 50 percent of the wall area to which they are attached.

❖ This section is focused on the sleeping units and dwelling units within Group I-1, which are typically assisted living and similar occupancies, and Group I-2 Condition 1, which are nursing homes. Since the requirements are focused within the sleeping and dwelling unit, the requirements are more lenient than those associated with the main exit access. Similar to the artwork restrictions for classrooms, such spaces are permitted to have 50 percent of the wall area occupied by combustible decorative materials. It should be noted that Group I-2 occupancies require the retroactive installation of sprinklers in accordance with Section 1105.8. All new Group I occupancies require the installation of an automatic sprinkler system.

**807.5.3.2 In Group I-1 and I-2 Condition 1 for areas other than within units.** In Group I-1 and Group I-2 Condition 1 occupancies, equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, combustible decorative materials placed on walls in areas other than within dwelling and sleeping units shall be limited to not more than 30 percent of the wall area to which they are attached.

❖ This section focuses on the same occupancies as Section 807.5.3.1, but on areas outside the sleeping and dwelling units. The allowance in sprinklered buildings is 30 percent versus the 50 percent in Section 807.5.3.1. These areas tend to expose a greater percentage of the building occupants to the hazards of combustible decorative materials. It should be noted that Group I-2 occupancies require the retroactive installation of sprinklers in accordance with Sec-

tion 1105.8. All new Group I occupancies require the installation of an automatic sprinkler system.

**807.5.3.3 In Group I-2 Condition 2.** In Group I-2 Condition 2 occupancies, equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, combustible decorative materials placed on walls shall be limited to not more than 30 percent of the wall area to which they are attached.

❖ This section is the same as Section 807.5.3.2, except that it is focused on hospitals—specifically, areas of the hospital where more occupants are exposed to combustible decorative materials. As noted in Sections 807.5.3.1 and 807.5.3.2, all Group I-2 occupancies require the retroactive installation of an automatic sprinkler system. Note that Section 1105.8 only requires sprinkler installation from the story containing the Group I-2 occupancy to the level of exit discharge.

**807.5.3.4 Other areas in Groups I-1 and I-2.** In Group I-1 and I-2 occupancies, in areas not equipped throughout with an *approved automatic sprinkler system*, combustible decorative materials shall be of such limited quantities that a hazard of fire development or spread is not present.

❖ This section addresses Group I-1 and I-2 occupancies. The focus is on areas of such buildings where an automatic sprinkler system does not provide coverage. As noted, Group I-2 occupancies require the retroactive installation of an automatic sprinkler system but Group I-1 occupancies do not. Although Group I-2 occupancies should be provided with sprinklers, there may be transitional periods where this is not the case. This requirement in general is nonspecific and generally gives authority to the fire code official to address situations that appear hazardous.

**807.5.4 Group I-3.** In Group I-3, combustible *decorative materials* are prohibited.

❖ Due to the nature of such occupancies, where occupants have a tendency to start fires, combustible decorative materials are prohibited.

**807.5.5 Group I-4.** Group I-4 occupancies shall comply with the requirements in Sections 807.5.5.1 through 807.5.5.3.

❖ A Group I-4 day care facility is an occupancy that cares for people of any age for less than 24 hours per day. Most often, these facilities are for small children not yet able to attend school, but also included are adult day care facilities. These occupancies will have features similar to those of Group E occupancies; therefore, the same restrictions on combustibles in corridors, lobbies and classrooms exist. The key issue here is that the occupants of Group I-4 facilities are often not capable of self-preservation without some level of assistance; therefore, combustibles must be kept to a minimum, especially in critical portions of the means of egress system.

**807.5.5.1 Storage in corridors and lobbies.** Clothing and personal effects shall not be stored in *corridors* and lobbies.

**Exceptions:**

1. *Corridors* protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.
2. *Corridors* protected by an *approved fire alarm system* installed in accordance with Section 907.
3. Storage in metal lockers, provided the minimum required egress width is maintained.

❖ See the commentary to Section 807.5.2.1.

**807.5.5.2 Artwork in corridors.** Artwork and teaching materials shall be limited on walls of *corridors* to not more than 20 percent of the wall area.

❖ See the commentary to Section 807.5.2.2.

**807.5.5.3 Artwork in classrooms.** Artwork and teaching materials shall be limited on walls of classrooms to not more than 50 percent of the specific wall area to which they are attached.

❖ See the commentary to Section 807.5.2.3.

**807.5.6 Dormitories in Group R-2.** In Group R-2 dormitories, within sleeping units and dwelling units, the combustible decorative materials shall be of limited quantities such that a hazard of fire development or spread is not present.

❖ This section is consistent with the needs of facilities where occupants often take unnecessary risks. This provides a mechanism for the fire code official to limit the potential hazards in such sleeping units and dwelling units. Note that Section 807.3, Exception 2 allows up to 50 percent of the aggregate wall areas to contain decorative materials if an automatic sprinkler system is provided.

**SECTION 808  
FURNISHINGS OTHER THAN UPHOLSTERED  
FURNITURE AND MATTRESSES OR DECORATIVE  
MATERIALS IN NEW AND EXISTING BUILDINGS**

**808.1 Wastebaskets and linen containers in Group I-1, I-2 and I-3 occupancies.** Wastebaskets, linen containers and other waste containers, including their lids, located in Group I-1, I-2 and I-3 occupancies shall be constructed of noncombustible materials or of materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> when tested in accordance with ASTM E1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation. Metal wastebaskets and other metal waste containers with a capacity of 20 gallons (75.7 L) or more shall be *listed* in accordance with UL 1315 and shall be provided with a noncombustible lid. Portable containers exceeding 32 gallons (121 L) shall be stored in an area classified as a waste and linen collection room and constructed in accordance with Table 509 of the *International Building Code*.

❖ Although residents of Group I-1, I-2 and I-3 occupancies are generally closely monitored, there is an

increased life safety risk in these facilities since in each type, the occupants have limited or no self-evacuation ability. Plastic containers can add a tremendous fuel load to a fire in a trash or linen container; many plastic containers will more than triple the fuel load in a fire situation. This section will control the fuel load for these containers that are used routinely throughout the facilities and will correlate the code with federal regulations for these facilities. Steps can be taken to reduce the impact of a fire once it has been ignited by limiting wastebaskets to those that can meet certain combustibility criteria in accordance with ASTM E1354. ASTM E1354 is a small-scale calorimeter test that measures heat flux output based on a given heat source. This concept is similar to that required in full-scale tests for upholstered furniture and mattresses in Section 805. It should be noted that this section is not focused on ignition prevention but instead assumes that ignition has occurred. The focus is reducing the contribution of the trash container to a fire.

Compliance with this test allows any material that can pass the test to be used. This may allow the use of fire-retardant plastics or other materials that will meet the criteria of the test. Generally, in larger areas of the facility, if a fire can be contained to a wastebasket, it will not spread but will simply burn out.

Since a larger wastebasket means a larger fire, this section also addresses larger metal wastebaskets by requiring compliance with UL 1315 and that they be equipped with a noncombustible lid. This increases the likelihood that the fire will stay contained to the wastebasket and possibly reduce the fire size by restricting the combustion process. The general performance of wastebaskets meeting the requirements of UL 1315 is as follows:

- Limit the external surface temperatures of the container bottom should their contents become ignited.
- Extinguish the fire.
- Contain the contents without contributing fuel to the fire.

See also the commentary to Sections 304.3.2, 304.3.4 and 318.1.

**808.2 Waste containers with a capacity of 20 gallons or more in Group R-2 college and university dormitories.** Waste containers, including their lids, located in Group R-2 college and university dormitories, and with a capacity of 20 gallons (75.7 L) or more, shall be constructed of noncombustible materials or of materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> when tested in accordance with ASTM E1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation. Metal wastebaskets and other metal waste containers with a capacity of 20 gallons (75.7 L) or more shall be *listed* in accordance with UL 1315 and shall be provided with a noncombustible lid. Portable containers exceeding 32 gallons (121 L) shall be stored in an area classified as a waste and linen collection room constructed in

accordance with Table 509 of the *International Building Code*.

- ❖ This section is similar to Section 808.1, but is applicable to larger capacity containers (exceeding 20 gallons) and is focused on Group R-2 college and university dormitories. The large waste containers in college and university dormitories should comply with the same requirements as any waste container in Group I-2 and I-3 occupancies. Most nonmetallic waste containers are manufactured from polyethylene, which has a fuel value over double that of newsprint and can generate a high heat release rate fire. These waste containers hold combustible waste (much of which is paper) while having very combustible walls. See the commentary to Section 808.1 for more information on the test methods prescribed.

**808.3 Signs.** Foam plastic signs that are not affixed to interior building surfaces shall have a maximum heat release rate of 150 kW when tested in accordance with UL 1975, or when tested in accordance with NFPA 289 using the 20-kW ignition source.

**Exception:** Where the aggregate area of foam plastic signs is less than 10 percent of the floor area or wall area of the room or space in which the signs are located, whichever is less, subject to the approval of the *fire code official*.

- ❖ This section correlates with the requirements in Section 402.6.4.4 of the IBC, which requires a limit on the combustibility of signs in covered mall buildings, though it should be noted that the requirements of the code are not specific to such buildings. The requirement of this section is that, when a foam plastic sign is tested in accordance with UL 1975 or NFPA 289 (see commentary, Section 807.5.1.1), a maximum heat release rate of 150 kW is allowed.

Note that smoke development is not part of the acceptance criteria.

The exception recognizes that a relatively small aggregate surface coverage of a room or space by these signs (i.e., when the aggregate area of foam plastic signs constitutes the lesser of 10 percent of the floor or wall area of the room or space in which the signs are located) does not present a sufficient enough hazard to require compliance with the section. However, specific approval by the fire code official is required.

**808.4 Combustible lockers.** Where lockers constructed of combustible materials are used, the lockers shall be considered interior finish and shall comply with Section 803.

**Exception:** Lockers constructed entirely of wood and non-combustible materials shall be permitted to be used wherever interior finish materials are required to meet a Class C classification in accordance with Section 803.1.1.

- ❖ Traditionally, lockers in schools (high schools, middle schools, universities), clubs, swimming pools and gymnasiums were constructed of steel. In recent years, the use of lockers constructed of combustible materials has become prevalent. These lockers typically line an entire wall (for example, a corridor in a

school) and are not regulated by the code. Lockers are not usually considered interior finish. The only other materials regulated by the code at present are interior trim, upholstered furniture, decorations, decorative vegetation, wastebaskets, linen containers and signs. Lockers do not fall into any of those categories.

Combustible lockers can present a significant fire load and, if ignited, are likely to spread fire the same way that interior finish materials spread fire. They are considered interior finish materials and regulated like all other interior finish materials for any occupancy. Plastic lockers have the benefit of being more immune to the effects of water from wet clothing and are generally very durable—but, with these benefits comes a fire hazard. The lockers by one manufacturer are constructed of  $\frac{3}{8}$ -inch-thick (9.52 mm) solid plastic bodies and heavy duty  $\frac{1}{2}$ -inch-thick (12.7 mm) doors. Typically the “solid plastic” used is either high-density polyethylene or polypropylene. Polypropylene, as discussed in the commentary to Section 803.9, is a thermoplastic that gives off considerable energy and produces a pooling flammable liquid fire when it burns.

### Bibliography

The following resource material was used in the preparation of the commentary for this chapter of the code:

DeLauter, L., J. Lee, G. Roadarmel and D.W. Stroup. “Scotch Pine Christmas Tree Fire Tests.” FR4010. Gaithersburg, MD: National Institute of Standards and Technology, US Department of Commerce, 1999.

# Chapter 9: Fire Protection Systems

## General Comments

The requirements of Chapter 9 are just one aspect of the overall fire protection system of a building or structure. All fire protection requirements contained in the code must be considered as a package or overall system. Noncompliance with any part of the overall system may cause other parts of the system to fail, which may result in an increased loss of life and property from the reduced level of protection.

Every effort must be made to verify the proper design and installation of a given fire protection system, especially those that result in construction alternatives and other code trade-offs.

The requirements in Chapter 9 are active fire safety provisions. They are directed at containing and extinguishing a fire once it has erupted. This chapter parallels and duplicates much of Chapter 9 in the *International Building Code*® (IBC®). The code, however, contains additional specific provisions that are applicable only to existing buildings. It also contains periodic testing criteria that are not duplicated in the IBC. Proper testing, inspection and maintenance of the various systems are critical to establish the reliability of the system. Additionally,

Chapter 9 references and adopts numerous National Fire Protection Association (NFPA) standards, including the acceptance testing criteria within the standard. The referenced standards will also contain more specific design and installation criteria than are found in this chapter. As noted in Section 102.7, where differences occur between code requirements and the referenced standard, the code provisions apply.

## Purpose

Fire protection systems may serve one or more purposes in providing adequate protection from fire. Chapter 9 prescribes the minimum requirements for an active system or systems of fire protection to perform the following functions: detecting a fire; alerting the occupants or fire department of a fire emergency; controlling smoke and controlling or extinguishing the fire. Generally, the requirements are based on the occupancy, the height and the area of the building, because these are the factors that most affect fire-fighting capabilities and the relative hazard of a specific space or area.

---

## SECTION 901 GENERAL

**901.1 Scope.** The provisions of this chapter shall specify where *fire protection systems* are required and shall apply to the design, installation, inspection, operation, testing and maintenance of all *fire protection systems*.

❖ Chapter 9 contains requirements for fire protection systems that may be installed or located in a building. These include automatic suppression systems; stand-pipe systems; fire alarm and detection systems; smoke control systems; smoke and heat vents and portable fire extinguishers. Besides indicating the conditions under which respective systems are required, this chapter contains the design, installation, maintenance, testing and operational criteria for fire protection systems. While the code requires proper maintenance for the reliability of the systems, the actual maintenance provisions (periodic testing, inspections and maintenance) may be contained in one of the referenced standards.

Chapter 9 is intended to apply to buildings of new construction or when deemed applicable because of a change in occupancy or an addition, unless specifically indicated to be applicable to existing buildings only.

The scoping provisions in Chapter 1 should be consulted for determining the proper requirements for additions, alterations and remodelings.

This chapter also addresses the requirements for fire command centers, fire department connections, fire pumps and emergency radio systems. These features all directly relate to the proper function of fire protection systems.

**901.2 Construction documents.** The *fire code official* shall have the authority to require *construction documents* and calculations for all *fire protection systems* and to require permits be issued for the installation, rehabilitation or modification of any *fire protection system*. *Construction documents* for *fire protection systems* shall be submitted for review and approval prior to system installation.

❖ The construction documents and related calculations for all fire protection systems must be reviewed before a permit is issued. The review is performed to determine compliance with the code requirements and the applicable provisions in the referenced standards.

Typical shop drawings for fire protection systems are usually not prepared during the initial submittal for a construction permit. Many jurisdictions require a separate submittal and issue a separate permit to the con-

tractor installing the system (see Section 901.3). Factors, such as classification of the hazard, amount of agent or water supply available and the design criteria, including the density or concentration to be achieved by the system, are to be included with the shop drawings. Specific equipment data sheets identifying sprinklers, pipe dimensions, power requirements for smoke detectors, etc., must also be included with the submittal in addition to any required calculations. See also the commentary to Section 907.1.1 regarding fire alarm system construction documents and Section 907.1.2 regarding fire alarm system shop drawings.

**901.2.1 Statement of compliance.** Before requesting final approval of the installation, where required by the *fire code official*, the installing contractor shall furnish a written statement to the *fire code official* that the subject *fire protection system* has been installed in accordance with *approved* plans and has been tested in accordance with the manufacturer's specifications and the appropriate installation standard. Any deviations from the design standards shall be noted and copies of the approvals for such deviations shall be attached to the written statement.

❖ A certificate or other approved written statement must be submitted to the fire code official with the proper documentation from the installing contractor specifying that the fire protection system has been installed in accordance with the requirements of the code. The certificate should also indicate that all required inspections and tests of the system have been conducted at the time of application for a certificate of occupancy.

The written statement is to indicate that the system has been installed in accordance with code requirements. As previously stated, contractors may have certificates that specify the criteria of the referenced standards since many of them contain sample certificates. While such certificates may be used, the contractor is required to certify that the system complies with the provisions of the code, which in some instances may vary from the referenced standards. These variations and any other variations involved in the installation, whether by change order, variance or field condition, must also be included with the written statement.

**901.3 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

❖ Section 105 requires permits of two separate but related types. Section 105.6 requires an operational permit. These permits are required to conduct certain types of businesses or hazardous operations that require a higher level of scrutiny from the fire code official. The second type of permit, required by Section 105.7, is the construction permit, which is required for the installation and modification of all fire protection systems.

**901.4 Installation.** *Fire protection systems* shall be maintained in accordance with the original installation standards for that system. Required systems shall be extended, altered or augmented as necessary to maintain and continue protection where the building is altered, remodeled or added to. *Alterations to fire protection systems* shall be done in accordance with applicable standards.

❖ This section emphasizes that systems installed and maintained in compliance with the codes and standards in effect at the time they were placed in service must remain operational at all times. It is not the intent of the code to require existing systems that are otherwise not being altered to comply with current code and standard requirements. An existing system, even if it does not meet current standards, is allowed to continue in service as long as it continues to provide no less quality in service than what was originally in place. Hence, if an alteration or expansion of the system is proposed, the key is whether or not the level of protection afforded by the system is the same or greater than what it was before the alteration or expansion was considered. Any added sections of the system must meet the requirements for new fire protection according to the system involved.

**901.4.1 Required fire protection systems.** *Fire protection systems* required by this code or the *International Building Code* shall be installed, repaired, operated, tested and maintained in accordance with this code. A *fire protection system* for which a design option, exception or reduction to the provisions of this code or the *International Building Code* has been granted shall be considered to be a required system.

❖ Fire protection systems that are required by Chapter 9 or by another section of either the IBC or the code must be considered as required systems. The fire protection system is an integral component of the protection features of the building and must be properly installed, repaired, operated, tested and maintained in accordance with the code. Improperly installed or maintained systems can fail to provide the anticipated protection and, in some cases, create a hazard in itself.

Although the code may not require a fire protection system for a specific building or portion of a building because of its occupancy, the fire protection system would still be considered a required system if some other code alternative, exception or reduction was taken based on the installation of that fire protection system. For example, a typical small office building may not require an automatic sprinkler system solely because of its Group B occupancy classification. However, if an exit access corridor fire-resistance-rating reduction is taken as allowed by Table 1020.1 for buildings equipped throughout with an NFPA 13 sprinkler system, that sprinkler system is now considered a required system. Code trade-offs, exceptions, reductions or other design options are not unique to the IBC. Such tradeoffs occur more than 60 times in the code.

**901.4.2 Nonrequired fire protection systems.** A *fire protection system* or portion thereof not required by this code or the *International Building Code* shall be allowed to be furnished for partial or complete protection provided such installed system meets the applicable requirements of this code and the *International Building Code*.

❖ A building owner or designer may elect to install a fire protection system that is not required in the code. Even though such a system is not required, it must comply with the applicable requirements of Chapter 9. This requirement is based on the concept that any fire protection system not installed as required by the code is lacking because it could give a false impression of properly installed protection.

For example, if a building owner chooses to install sprinkler protection in a certain area and that protection is not required by any provisions of the code, the system must be installed in accordance with NFPA 13 or 13R, as applicable and other applicable requirements of the code, such as water supply and supervision. The extent of the protection provided would not be regulated. Once the system is installed, it is subject to the same code requirements for maintenance and testing with which any other system would be required to comply.

If the optional sprinkler system is intended to be used to provide alternatives found elsewhere in the code, the system would cease to be voluntary. In such a case, it becomes a required system and subject to Section 901.4.1.

**901.4.3 Fire areas.** Where buildings, or portions thereof, are divided into *fire areas* so as not to exceed the limits established for requiring a *fire protection system* in accordance with this chapter, such *fire areas* shall be separated by *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both, having a fire-resistance rating of not less than that determined in accordance with Section 707.3.10 of the *International Building Code*.

❖ This section provides specific guidance on how a building needs to be divided into fire areas in order to avoid requiring a fire protection system to be installed. A single occupancy group would require fire barriers or horizontal assemblies in order to create multiple fire areas (see Table 707.3.10 of the IBC), each having an area below the threshold for fire protection system installation.

**901.4.4 Additional fire protection systems.** In occupancies of a hazardous nature, where special hazards exist in addition to the normal hazards of the occupancy, or where the *fire code official* determines that access for fire apparatus is unduly difficult, the *fire code official* shall have the authority to require additional safeguards. Such safeguards include, but shall not be limited to, the following: automatic fire detection systems, fire alarm systems, automatic fire-extinguishing systems, standpipe systems, or portable or fixed extinguishers. Fire protection equipment required under this section shall be

installed in accordance with this code and the applicable referenced standards.

❖ This section allows the fire code official to require fire protection safeguards beyond the minimum requirement of Chapter 9 when warranted by potential unsafe conditions. The provisions of the code cannot anticipate every occupancy condition. Hazardous material occupancies or buildings with limited fire department access are potentially a greater hazard to both building occupants and fire fighters. Any additional safeguards should be those needed to abate potential hazards. This section does not give the fire code official the right to require additional systems without cause. If the condition is adequately addressed by the code, then additional safeguards are not warranted. Should additional safeguards be deemed necessary, then the fire protection components regulated by this section must be considered required systems.

**901.4.5 Appearance of equipment.** Any device that has the physical appearance of life safety or fire protection equipment but that does not perform that life safety or fire protection function shall be prohibited.

❖ All required or provided life safety or fire protection-related equipment must be continued in use and be maintained to meet the requirements in effect at the time of the original installation. Nonrequired equipment that has been taken out of service or cannot function as intended must be dismantled and removed to prevent creating a false impression of protection.

Simply because a nonrequired system does not meet the current standards is neither cause to require its removal (see Section 901.4), nor a reason to require the system to be upgraded. As long as the system is maintained in the manner in which it was intended when installed, it can be allowed to continue.

**901.4.6 Pump and riser room size.** Where provided, fire pump rooms and *automatic sprinkler system* riser rooms shall be designed with adequate space for all equipment necessary for the installation, as defined by the manufacturer, with sufficient working space around the stationary equipment. Clearances around equipment to elements of permanent construction, including other installed equipment and appliances, shall be sufficient to allow inspection, service, repair or replacement without removing such elements of permanent construction or disabling the function of a required fire-resistance-rated assembly. Fire pump and *automatic sprinkler system* riser rooms shall be provided with a door(s) and an unobstructed passageway large enough to allow removal of the largest piece of equipment.

❖ Section 901.4.6 establishes that, where a pump or riser room is necessary, the rooms housing fire protection system risers or fire pumps and their components have adequate space to facilitate their maintenance. This section does not require the construction of a room to house fire protection systems;

however, if a room is provided, this section requires that it be adequately sized to allow for maintenance.

Instead of prescribing arbitrary dimensions, this provision bases the room area on clearances specified by the equipment manufacturers to ensure adequate space is available for its installation or removal. The design must provide enough area so that walls, finish materials and doors are not required to be removed during maintenance activities. The provision also prescribes that the size of the door serving a riser or pump room is of a size to accommodate the removal of the largest piece of equipment.

Given that the design of fire protection systems generally commences during the period that building construction drawings and specifications are being reviewed by the jurisdiction, it will be especially important for the building's designer to establish dialogue with the fire protection system contractor early in the design process to ensure that the room and at least one door can accommodate the largest equipment and provide the space needed for maintenance.

**901.5 Installation acceptance testing.** Fire detection and alarm systems, fire-extinguishing systems, fire hydrant systems, fire standpipe systems, fire pump systems, private fire service mains and all other *fire protection systems* and appurtenances thereto shall be subject to acceptance tests as contained in the installation standards and as *approved* by the *fire code official*. The *fire code official* shall be notified before any required acceptance testing.

- ❖ Fire protection systems must pass an acceptance test to determine that the system will operate as required by the code. Acceptance tests are usually part of the final inspection procedures. The referenced standards contain specific acceptance test procedures. In most instances, the acceptance test procedures require 100-percent operation of the testable system components to determine that they are operational and functioning as required. Often, the design professional may require additional testing that may be beyond the code requirements to verify that the system operates as designed. The design professional may also establish the appropriate testing criteria for special systems, such as smoke control systems. These proposed testing protocols, where not addressed elsewhere in the code, must be approved by the fire code official before being performed.

The inclusion of the requirement for acceptance tests in the code is not intended to assign responsibility for witnessing the tests. The responsibility to witness the acceptance test is an administrative issue that each municipality must address. Because the acceptance test is critical during design and construction and is a requirement of occupancy, the requirement is located in the code. The section also clarifies that it is the owner's responsibility to conduct the test and the role of the fire code official to witness the test. Typically, the owner will assign the responsibility of conducting the test to the installing contractor.

**901.5.1 Occupancy.** It shall be unlawful to occupy any portion of a building or structure until the required fire detection, alarm and suppression systems have been tested and *approved*.

- ❖ Partial occupancy of any structure must not be permitted unless all fire protection systems for the occupied areas have been tested and approved. Even so, the code assumes that full protection for all areas will be provided as quickly as possible. The installation of many fire protection systems and the associated code alternatives permitted for a given occupancy assume complete building protection and not just in the occupied areas. All partial occupancy conditions are subject to the final approval of the building official. Section 105.3.4 allows the fire code official to issue conditional occupancy permits.

If the building becomes vacant, this section would be applicable again. Here, occupancy is based on a certificate of occupancy. If the vacancy is in a tenant space of an otherwise fully protected building, then the fire protection system must be continued. The other tenants of the building are subject to the necessary continuation of the fire protection system. This is similar to partial occupancy. On the other hand, if a building is vacated completely and the certificate of occupancy is forfeited, then the entire building can be considered as unoccupied, and the fire protection systems can be discontinued. At such time, utilities can be disconnected and the building be declared nonhabitable. This option carries with it the burden of reuse because if the vacant, nonhabitable building is intended to be used again, it is subject to provisions in the IBC that would require the building to be certified as a new structure and may involve significant modifications in order to receive a new certificate of occupancy.

Often, insurance companies will require that automatic sprinkler systems be kept in operation during a vacancy. If such is the case, utilities will likely need to be kept in place in order to keep the system within operating temperature requirements. Buildings in which occupancy is discontinued for an extended period of time may be considered hazardous and require action to remediate the problem, possibly by demolition.

If the system being installed is a nonrequired system, then this section is not applicable and partial occupancy can be granted.

**901.6 Inspection, testing and maintenance.** Fire detection, alarm, and extinguishing systems, mechanical smoke exhaust systems, and smoke and heat vents shall be maintained in an operative condition at all times, and shall be replaced or repaired where defective. Nonrequired *fire protection systems* and equipment shall be inspected, tested and maintained or removed.

- ❖ Adequate maintenance, inspection and periodic testing of all fire protection systems, equipment and devices including equipment and systems related to mechanical smoke exhaust and smoke and heat

vents is necessary so that the systems are ready to perform their intended functions should fire occur.

An inspection consists of a visual check of a system or device to verify that it is in operating condition and free from defects or damage. Indicating valves, gauges and indicator lamps are a few of the features required by the codes to facilitate this activity. Obvious damage and the general condition of the system, particularly the presence of corrosion, both external and internal, must always be noted and recorded. Partially because they are less detailed, inspections are conducted more frequently than tests and maintenance. Because special knowledge and tools are not required, inspections may be performed by any reasonably competent person.

Periodic tests following standardized methods are intended to confirm the results of inspections, determine that all components function properly and that systems meet their original design specifications. Tools, devices or equipment are usually required for these tests.

Because tests are more detailed than inspections, they are usually conducted only once or twice per year in most cases. Some tests, however, may be required as frequently as bimonthly or quarterly (for example, some fire alarm system equipment) or as infrequently as 5-, 6- or 12-year intervals (for example, portable fire-extinguisher hydrostatic tests). Since specialized knowledge and equipment are required, testing is usually done by technicians or specialists trained in the proper conduct of the test methods involved.

Periodic maintenance keeps systems in good working order and may be used to repair damage or defects discovered during inspections or testing. Specialized tools and training are required to perform maintenance. Only properly trained technicians or specialists should perform required periodic maintenance. Most maintenance is required only as needed, but many manufacturers suggest or require regular periodic replacement of parts subject to wear or abuse.

Nonrequired fire protection systems, where installed, require the same level of maintenance as required systems. If required maintenance is not being done, there is no way to determine if the system will function as intended. Therefore, inadequately maintained, nonrequired systems must be removed to avoid creating a false impression of adequate protection.

**901.6.1 Standards.** *Fire protection systems* shall be inspected, tested and maintained in accordance with the referenced standards *listed* in Table 901.6.1.

- ❖ Specific requirements related to inspection practices, testing schedules and maintenance procedures are dependent on the type of fire protection system and its corresponding referenced NFPA standard as indicated in Table 901.6.1.

**TABLE 901.6.1  
FIRE PROTECTION SYSTEM MAINTENANCE STANDARDS**

SYSTEM	STANDARD
Portable fire extinguishers	NFPA 10
Carbon dioxide fire-extinguishing system	NFPA 12
Halon 1301 fire-extinguishing systems	NFPA 12A
Dry-chemical extinguishing systems	NFPA 17
Wet-chemical extinguishing systems	NFPA 17A
Water-based fire protection systems	NFPA 25
Fire alarm systems	NFPA 72
Smoke and heat vents	NFPA 204
Water-mist systems	NFPA 750
Clean-agent extinguishing systems	NFPA 2001

- ❖ This table lists the NFPA referenced standards to be used for the inspection, testing and maintenance criteria for various fire protection systems. Many of the testing and maintenance requirements are included elsewhere in Chapter 9 of the code.

**901.6.2 Records.** Records of all system inspections, tests and maintenance required by the referenced standards shall be maintained.

- ❖ Accurate, up-to-date records are required to document the history of system inspection, testing and maintenance. Record keeping is not intended simply to prove to the fire code official that required inspection, testing and maintenance are being performed, but to assist the owner or his or her agent in performing these functions. A well-kept log helps an owner or technician determine how the system is performing over time and how changes inside and outside of the protected premises are affecting system performance. For example, automatic sprinkler system main drain test results may indicate whether the public water supply is being degraded by development, thereby impairing sprinkler system capabilities. Similarly, a history of accidental alarms at a specific smoke detector may indicate that the device requires cleaning or maintenance.

**901.6.2.1 Records information.** Initial records shall include the name of the installation contractor, type of components installed, manufacturer of the components, location and number of components installed per floor. Records shall also include the manufacturers' operation and maintenance instruction manuals. Such records shall be maintained for the life of the installation.

- ❖ When the fire protection systems are first installed, an accurate inventory must be compiled so that future owners and officials can refer back to the documents for maintenance and operational requirements. Additionally, if a recall is required, the installation inventory will be able to identify if any of the components subject to the recall are installed. By including the installation contractor's information in the list, a resolution of any legal aspects of defective components

can be more readily obtained. Also, if operations or maintenance change during the life of the installation and a public notice is provided, the building owner will have the information necessary to know and apply the new requirements. The requirement to collect and maintain this information is already within many of the standards referenced in the code. This requirement gives the fire code official enforcement language and assists the building owner in understanding the responsibilities associated with having these fire protection systems installed in the building.

**901.7 Systems out of service.** Where a required *fire protection system* is out of service, the fire department and the *fire code official* shall be notified immediately and, where required by the *fire code official*, the building shall be either evacuated or an *approved* fire watch shall be provided for all occupants left unprotected by the shutdown until the *fire protection system* has been returned to service.

Where utilized, fire watches shall be provided with not less than one *approved* means for notification of the fire department and their only duty shall be to perform constant patrols of the protected premises and keep watch for fires.

❖ The protection afforded by a required fire protection system must not be diminished in any existing building except for the purpose of conducting tests, maintenance or repairs. The length of service interruptions must be kept to a minimum. The fire department and the fire code official must be notified of any service interruptions. They must carefully evaluate the continued operation or occupancy of buildings and structures where protection is interrupted. Whenever possible, all unaffected portions of the system should be kept in service. Until protection is restored, hazardous processes or operations should be suspended and alternative special protection should be considered in addition to an approved fire watch.

The code text only addresses when a required system is placed out of service. However, if a system is in place, even though it is not required by the code or the IBC, it would be an appropriate courtesy to inform the fire department of any fire protection system being discontinued or temporarily taken out of service. If the nonrequired system is to be placed out of service for an extended period of time, the fire code official has the authority to address the condition under Section 901.4.5 and require that the system be either placed back into operation or removed so as not to create a false impression of protection.

**901.7.1 Impairment coordinator.** The building *owner* shall assign an impairment coordinator to comply with the requirements of this section. In the absence of a specific designee, the *owner* shall be considered the impairment coordinator.

❖ The impairment coordinator is the person responsible for maintaining the building fire protection systems. The impairment coordinator may be the building owner or other designee, such as the plant manager or building engineer, if he or she is trained to comply with the provisions of Section 901.7.

**901.7.2 Tag required.** A tag shall be used to indicate that a system, or portion thereof, has been removed from service.

❖ When any fire protection system is taken out of service, it must be clearly identified with a visible tag that indicates the conditions of the impairment and who to notify. The tag is intended to alert building occupants and fire department personnel that the system in question is impaired. It must remain visibly in place until full protection is restored.

**901.7.3 Placement of tag.** The tag shall be posted at each fire department connection, system control valve, fire alarm control unit, fire alarm annunciator and *fire command center*, indicating which system, or part thereof, has been removed from service. The *fire code official* shall specify where the tag is to be placed.

❖ This section specifies some of the impaired locations where a tag must be used. Tagging a fire department connection, for example, is intended to alert the responding fire department that a normal operating condition does not exist for the portion of the system beyond the connection. While it is also important to tag system control valves, an impairment tag in the sprinkler riser room may not get noticed until accessed by fire department personnel. The final location of all impairment tags is subject to the approval of the fire code official.

**901.7.4 Preplanned impairment programs.** Preplanned impairments shall be authorized by the impairment coordinator. Before authorization is given, a designated individual shall be responsible for verifying that all of the following procedures have been implemented:

1. The extent and expected duration of the impairment have been determined.
2. The areas or buildings involved have been inspected and the increased risks determined.
3. Recommendations have been submitted to management or the building *owner/manager*.
4. The fire department has been notified.
5. The insurance carrier, the alarm company, the building *owner/manager* and other authorities having jurisdiction have been notified.
6. The supervisors in the areas to be affected have been notified.
7. A tag impairment system has been implemented.
8. Necessary tools and materials have been assembled on the impairment site.

❖ This section specifies the procedures that must be followed in a thorough preplanned impairment program. These procedures must be followed whenever systems are purposely impaired, such as for routine sprinkler system alarm testing. Proper notification of responsible parties eliminates the chance of false alarms, reduces disruption of normal business activities and encourages quick resumption of normal operations.

**901.7.5 Emergency impairments.** Where unplanned impairments occur, appropriate emergency action shall be taken to minimize potential injury and damage. The impairment coordinator shall implement the steps outlined in Section 901.7.4.

❖ Unplanned impairments, of course, go beyond typical testing and maintenance procedures but are also not necessarily indicative of a fire event. For example, an unplanned emergency impairment might occur if a sprinkler head or pipe was found leaking or was accidentally impacted by a fork-lift truck. To reduce water damage and to repair the sprinkler system, the valve controlling the water supply to the affected area would need to be closed, thereby impairing protection to the area protected by that portion of the sprinkler system. The impairment coordinator must follow the procedures in Section 901.7.4 to restore protection in minimum time.

**901.7.6 Restoring systems to service.** When impaired equipment is restored to normal working order, the impairment coordinator shall verify that all of the following procedures have been implemented:

1. Necessary inspections and tests have been conducted to verify that affected systems are operational.
2. Supervisors have been advised that protection is restored.
3. The fire department has been advised that protection is restored.
4. The building *owner*/manager, insurance carrier, alarm company and other involved parties have been advised that protection is restored.
5. The impairment tag has been removed.

❖ Regardless of whether a system is taken out of service for either a planned impairment or for an emergency, this section specifies the procedures to follow when restoring a system to service. By following these procedures, all responsible parties who were informed of the initial impairment will also be made aware that the system is now fully operational. Restoring the system to service assumes the affected part of the system has been corrected and is in proper working condition.

**901.8 Removal of or tampering with equipment.** It shall be unlawful for any person to remove, tamper with or otherwise disturb any fire hydrant, fire detection and alarm system, fire suppression system or other fire appliance required by this code except for the purpose of extinguishing fire, training purposes, recharging or making necessary repairs or where *approved by the fire code official*.

❖ Tampering or otherwise unauthorized altering of any fire protection system or component is illegal. A person who unlawfully tampers with equipment could face potential criminal charges. Tampering could include intentionally pulling a manual fire alarm box when no emergency exists, playing with matches to set off a smoke detector or flowing a city fire hydrant. The use of fire protection systems, equipment and

other fire appliances is limited to those people authorized to conduct repairs and maintenance unless approved by the fire code official.

**901.8.1 Removal of or tampering with appurtenances.** Locks, gates, doors, barricades, chains, enclosures, signs, tags or seals that have been installed by or at the direction of the *fire code official* shall not be removed, unlocked, destroyed, tampered with or otherwise vandalized in any manner.

❖ Tampering with or vandalizing appurtenances that are in place to prevent tampering with the system components is also prohibited. For example, sprinkler system control valves are routinely chained and locked in the open position in addition to being equipped with electronically monitored tamper switches. Gates at fire apparatus roads, authorized by Section 503.6 of the code, must not have the locks changed or operation altered unless approved by the fire code official. Any unauthorized removal or tampering with these types of devices is strictly prohibited.

**901.8.2 Removal of existing occupant-use hose lines.** The *fire code official* is authorized to permit the removal of existing occupant-use hose lines where all of the following conditions exist:

1. Installation is not required by this code or the *International Building Code*.
2. The hose line would not be utilized by trained personnel or the fire department.
3. The remaining outlets are compatible with local fire department fittings.

❖ The current code and the IBC do not require occupant-use hoses in as many locations as were required in previous editions of the codes and referenced standards. There also has been a shift in the philosophy of fire service leaders as to whether occupants should attempt to extinguish the fire via occupant-use hose stations or evacuate the structure. Most of the population is now being taught to evacuate the building, not to fight the fire. This shift is mainly due to the safety risk of having an untrained person attempting to fight a fire with more than a fire extinguisher. Another consideration was the ongoing cost to building owners to comply with maintenance and testing requirements for the hoses and their racks. Many jurisdictions have enacted local legislation or code changes to address this issue, and the addition of this new section updates the code to reflect conventional wisdom on this topic. This section provides safeguards in the form of several conditions for the fire code official to consider in formulating an approval for removal of occupant-use hoses. The first condition makes common sense where a new building of the same characteristics would not be required to have hose stations installed. The second condition assumes that there is not a trained fire brigade on the premises that might be qualified to use the hose stations as first responders

in, for example, an industrial setting. Condition 2 also recognizes that fire departments typically will not use private hose stations for fire attack due to the questionable quality of their maintenance. Condition 3 was included to ensure that any outlets that remain are useable by the fire department by requiring that their threads be compatible with local fire department fire hose fittings, such as American National Fire Hose Connection Screw Thread (NH).

**901.9 Termination of monitoring service.** For fire alarm systems required to be monitored by this code, notice shall be made to the *fire code official* whenever alarm monitoring services are terminated. Notice shall be made in writing, to the *fire code official* by the monitoring service provider being terminated.

❖ This section requires the monitoring service itself to notify the fire code official of service being terminated. Although the ultimate responsibility rests with the building owner, he or she is not cited in this section since if they discontinued the service, they would likely not understand the implications, and if they did would have no incentive to contact the fire code official.

**901.10 Recall of fire protection components.** Any *fire protection system* component regulated by this code that is the subject of a voluntary or mandatory recall under federal law shall be replaced with *approved, listed* components in compliance with the referenced standards of this code. The *fire code official* shall be notified in writing by the building owner when the recalled component parts have been replaced.

❖ This section provides the fire code official with a valuable tool for monitoring recalls. Under this provision, a code section can be cited that will allow the fire code official to enforce the provisions of the recall on systems within the jurisdiction. Product listings and compliance with reference standards are paramount in the effectiveness of fire protection systems. Companies may be under an agreement with federal agencies to “voluntarily” recall certain components or face legal action. While this is technically voluntary, it in no way reduces the need for the recall. To the extent that the company’s livelihood depends on the recall being performed properly, the action is not voluntary. This section allows the fire code official to compel the building owner to comply with the recall and replace the component with one that is not subject to suspicion.

**SECTION 902  
DEFINITIONS**

**902.1 Definitions.** The following terms are defined in Chapter 2:

- ALARM NOTIFICATION APPLIANCE.**
- ALARM SIGNAL.**
- ALARM VERIFICATION FEATURE.**

- ANNUNCIATOR.**
- AUDIBLE ALARM NOTIFICATION APPLIANCE.**
- AUTOMATIC.**
- AUTOMATIC FIRE-EXTINGUISHING SYSTEM.**
- AUTOMATIC SMOKE DETECTION SYSTEM.**
- AUTOMATIC SPRINKLER SYSTEM.**
- AUTOMATIC WATER MIST SYSTEM.**
- AVERAGE AMBIENT SOUND LEVEL.**
- CARBON DIOXIDE EXTINGUISHING SYSTEM.**
- CLEAN AGENT.**
- COMMERCIAL MOTOR VEHICLE.**
- CONSTANTLY ATTENDED LOCATION.**
- DELUGE SYSTEM.**
- DETECTOR, HEAT.**
- DRY-CHEMICAL EXTINGUISHING AGENT.**
- ELEVATOR GROUP.**
- EMERGENCY ALARM SYSTEM.**
- EMERGENCY VOICE/ALARM COMMUNICATIONS.**
- FIRE ALARM BOX, MANUAL.**
- FIRE ALARM CONTROL UNIT.**
- FIRE ALARM SIGNAL.**
- FIRE ALARM SYSTEM.**
- FIRE AREA.**
- FIRE DETECTOR, AUTOMATIC.**
- FIRE PROTECTION SYSTEM.**
- FIRE SAFETY FUNCTIONS.**
- FIXED BASE OPERATOR (FBO).**
- FOAM-EXTINGUISHING SYSTEM.**
- HALOGENATED EXTINGUISHING SYSTEM.**
- IMPAIRMENT COORDINATOR.**
- INITIATING DEVICE.**
- MANUAL FIRE ALARM BOX.**
- MULTIPLE-STATION ALARM DEVICE.**
- MULTIPLE-STATION SMOKE ALARM.**
- NOTIFICATION ZONE.**
- NUISANCE ALARM.**
- PRIVATE GARAGE.**
- RECORD DRAWINGS.**
- SINGLE-STATION SMOKE ALARM.**
- SLEEPING UNIT.**
- SMOKE ALARM.**
- SMOKE DETECTOR.**
- STANDPIPE SYSTEM, CLASSES OF.**  
Class I system.

Class II system.

Class III system.

**STANDPIPE, TYPES OF.**

Automatic dry.

Automatic wet.

Manual dry.

Manual wet.

Semiautomatic dry.

**SUPERVISING STATION.**

**SUPERVISORY SERVICE.**

**SUPERVISORY SIGNAL.**

**SUPERVISORY SIGNAL-INITIATING DEVICE.**

**TIRES, BULK STORAGE OF.**

**TRANSIENT AIRCRAFT.**

**TROUBLE SIGNAL.**

**VISIBLE ALARM NOTIFICATION APPLIANCE.**

**WET-CHEMICAL EXTINGUISHING AGENT.**

**WIRELESS PROTECTION SYSTEM.**

**ZONE.**

**ZONE, NOTIFICATION.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2, in another *International Code*<sup>®</sup> as indicated in Section 201.3 or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

Certain requirements in the code are based on code provisions in the IBC, *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>) and *International Plumbing Code*<sup>®</sup> (IPC<sup>®</sup>). A review of definitions included in those codes will aid in the understanding of many of the requirements contained in the code.

## **SECTION 903 AUTOMATIC SPRINKLER SYSTEMS**

**903.1 General.** *Automatic sprinkler systems* shall comply with this section.

❖ This section identifies the conditions requiring an automatic sprinkler system for all occupancies. The need for an automatic sprinkler system may depend on not only the occupancy but also the occupant load, fuel load, height and area of the building as well as fire-fighting capabilities. Section 903.2 addresses all occupancy conditions requiring an automatic sprinkler system. Section 903.3 contains the installation requirements for all sprinkler systems in addition to the requirements of NFPA 13, NFPA 13R and NFPA 13D. The supervision and alarm requirements for sprinkler systems are contained in Section 903.4,

whereas Section 903.5 refers to testing and maintenance requirements for sprinkler systems found in Section 901 and NFPA 25. Section 903.6 addresses existing buildings and references Chapter 11.

Unless specifically allowed by the code or the IBC, residential sprinkler systems installed in accordance with NFPA 13R or NFPA 13D are not recognized for reductions or exceptions permitted by other sections of this code or the IBC. NFPA 13 systems provide the level of protection associated with adequate fire suppression for all occupancies. NFPA 13R and NFPA 13D systems are intended more to provide adequate time for egress but not necessarily for complete suppression of the fire. Commentary Figure 903.2 lists examples of where the various sprinkler thresholds differ in application.

The area values contained in this section are intended to apply to fire areas, which are comprised of all floor areas bounded by fire barriers, fire walls or exterior walls. The minimum required fire-resistance rating of fire barrier assemblies that define a fire area is specified in Table 707.3.10 of the IBC. Because the areas are defined as fire areas, fire barriers, horizontal assemblies, fire walls or exterior walls are the only acceptable means of subdividing a building into smaller areas instead of installing an automatic sprinkler system. Whereas fire barriers and exterior walls define multiple fire areas within a single building, a fire wall defines separate buildings within one structure. Also note that some of the threshold limitations result in a requirement to install an automatic sprinkler system throughout the building while others may require only specific fire areas to be sprinklered.

Another important point is that one fire area may include floor areas in more than one story of a building (see the commentary to the definition of "Fire area" in Section 202).

The application of mixed occupancies and fire areas must be carefully researched. Often the required separation between occupancies for the purposes of applying the separated mixed-use option in Section 508.4 of the IBC will result in a separation that is less than what is required to define the boundaries of a fire area. It is possible to have two different occupancies within a given fire area, treated as separated uses but with code requirements applicable to both occupancies since they are not separated by the rating required for fire areas.

**903.1.1 Alternative protection.** Alternative automatic fire-extinguishing systems complying with Section 904 shall be permitted instead of automatic sprinkler protection where recognized by the applicable standard and *approved* by the *fire code official*.

❖ This section permits the use of an alternative automatic fire-extinguishing system when approved by the fire code official as a means of compliance with the occupancy requirements of Section 903. Although the use of an alternative extinguishing system allowed by Section 904, such as a carbon dioxide

system or clean-agent system, would satisfy the requirements of Section 903.2, it would not be considered an acceptable alternative for the purposes of exceptions, reductions or other code alternatives that would be applicable if an automatic sprinkler system were installed.

**903.2 Where required.** *Approved automatic sprinkler systems* in new buildings and structures shall be provided in the locations described in Sections 903.2.1 through 903.2.12.

**Exception:** Spaces or areas in telecommunications buildings used exclusively for telecommunications equipment, associated electrical power distribution equipment, batteries and standby engines, provided those spaces or areas are equipped throughout with an automatic smoke detection system in accordance with Section 907.2 and are separated from the remainder of the building by not less than 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or not less than 2-hour *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ Sections 903.2.1 through 903.2.12 identify the conditions requiring an automatic sprinkler system (see Commentary Figure 903.2). The type of sprinkler system must be one that is permitted for the specific occupancy condition. An NFPA 13R sprinkler system, for example, may not be installed to satisfy the sprinkler threshold requirements for a mercantile occupancy (see Section 903.2.7). As indicated in Section 903.3.1.2, the use of an NFPA 13R sprinkler system is limited to Group R occupancies not exceeding four stories in height.

There is one exception for those spaces or areas used exclusively for telecommunications equipment. The telecommunications industry has continually stressed the need for the continuity of telephone service, and the ability to maintain this service is of prime importance. This service is a vital link between the community and the various life safety services, including fire, police and emergency medical services. The integrity of this communications service can be jeopardized not only by fire, but also by water, from whatever the source.

It must be emphasized that the exception applies only to those spaces or areas that are used exclusively for telecommunications equipment. Historically, those spaces have a low incidence of fire events. Fires in telecommunications equipment are difficult to start and, if started, grow slowly, thus permitting early detection. Such fires are typically of the smoldering type, do not spread beyond the immediate area and generally self-extinguish.

Note, however, that this exception requires fire resistive separation from other portions of the building and, most importantly, that the building cannot qualify for any code trade-offs for fully sprinklered buildings.

**903.2.1 Group A.** An *automatic sprinkler system* shall be provided throughout buildings and portions thereof used as Group A occupancies as provided in this section. For Group A-1, A-2, A-3 and A-4 occupancies, the *automatic sprinkler*

*system* shall be provided throughout the story where the *fire area* containing the Group A-1, A-2, A-3 or A-4 occupancy is located, and throughout all stories from the Group A occupancy to, and including, the *levels of exit discharge* serving the Group A occupancy. For Group A-5 occupancies, the *automatic sprinkler system* shall be provided in the spaces indicated in Section 903.2.1.5.

❖ Group A occupancies are characterized by a significant number of people who are not familiar with their surroundings. The requirement for a suppression system reflects the additional time needed for egress. The extent of protection is also intended to extend to the occupants of the assembly group from unobserved fires in other building areas located between the story containing the assembly occupancy and all levels of exit discharge serving such occupancies. The only exception to the coverage is for Group A-5 occupancies that are open to the atmosphere. Such occupancies require only certain aspects to be sprinklered, such as concession stands (see commentary, Section 903.2.1.5).

The requirement for sprinklers is based on the location and function of the space. It is not dependent on whether or not the area is provided with exterior walls. IFC Committee Interpretation No. 25-05 to this section discusses this issue and states, in part, that “where no surrounding exterior walls are provided along the perimeter of the building, the building area is used to identify and determine applicable fire area.” Outdoor areas, such as pavilions and patios, may have no walls but will have an occupant load and other factors that identify the assembly occupancy as such. If any of the thresholds are reached requiring sprinkler protection, then sprinkler protection must be provided whether there are exterior walls or not.

**903.2.1.1 Group A-1.** An *automatic sprinkler system* shall be provided for *fire areas* containing Group A-1 occupancies and intervening floors of the building where one of the following conditions exists:

1. The *fire area* exceeds 12,000 square feet (1115 m<sup>2</sup>).
2. The *fire area* has an *occupant load* of 300 or more.
3. The *fire area* is located on a floor other than a *level of exit discharge* serving such occupancies.
4. The *fire area* contains a multitheater complex.

❖ Group A-1 occupancies are identified as assembly occupancies with fixed seating, such as theaters. In addition to the high occupant load associated with these types of facilities, egress is further complicated by the possibility of low lighting levels customary during performances. The fuel load in these buildings is usually of a type and quantity that would support fairly rapid fire development and sustained duration.

Theaters with stages pose a greater hazard. Sections 410.7 and 410.8 of the IBC require stages to be equipped with an automatic sprinkler system and standpipe system, respectively. The proscenium opening must also be protected. These features com-

pensate for the additional hazards associated with stages in Group A-1 occupancies.

This section lists four conditions that require installing a suppression system in a Group A-1 occupancy. Condition 1 requires that, if any one fire area of Group A-1 exceeds 12,000 square feet (1115 m<sup>2</sup>), the automatic sprinkler system is to be installed throughout the entire story where a Group A-1 occupancy is

located, regardless of whether the building is divided into more than one fire area. However, if all the fire areas are less than 12,000 square feet (1115 m<sup>2</sup>) (and less than the other thresholds) then sprinklers would not be required. Compartmentalization into multiple fire areas in compliance with Chapter 7 of the IBC is deemed an adequate alternative to sprinkler protection.

Occupancy	Threshold	Exception
All occupancies	Buildings with floor level > 55 feet above or below fire department vehicle access and occupant load ≥ 30	Open parking structures (F-2)
Assembly (A-1, A-3, A-4)	Fire area > 12,000 sq. ft. or fire area occupant load > 300 or fire area above/below level of exit discharge Multitheater complex (A-1 only)	None
Assembly (A-2)	Fire area > 5,000 sq. ft. or fire area occupant load ≥ 100 or fire area above/below level of exit discharge	None
Assembly (A-5)	Accessory areas > 1,000 sq. ft.	None
Ambulatory care facility (B)	≥ 4 care recipients incapable of self preservation or any care recipients incapable of self preservation above or below level of exit discharge	None
Educational (E)	Fire area > 12,000 sq. ft. or below level of exit discharge	Each classroom has exterior door at grade
Factory (F-1)	Fire area > 12,000 sq. ft. or fire area located > 3 stories above grade, or combined fire area > 24,000 sq. ft.	None
Mercantile (M)	Woodworking > 2,500 sq. ft. (F-1 only) Manufacture > 2,500 sq. ft. (F1), display and sale > 5,000 sq. ft. (M), storage > 2,500 sq. ft. (S-1) of upholstered furniture or mattresses.	
Storage (S-1)	Bulk storage of tires > 20,000 cu. ft. (S-1 only)	
High-hazard (H-1, H-2, H-3, H-4, H-5)	Sprinklers required	None
Institutional (I-1, I-2, I-3, I-4)	Sprinklers required	Daycare at level of exit discharge and each classroom has exterior exit door.
Residential (R)	Sprinklers required	None
Repair garage (S-1)	Fire area > 12,000 sq. ft. or > 2 stories above grade with fire area 10,000 sq. ft. or repair garage servicing vehicles in basement or servicing commercial motor vehicles in fire area > 5,000 sq. ft.	None
Parking garage (S-1)	Commercial motor vehicles parking area > 5,000 sq. ft.	None
Parking garage (S-2)	Fire area > 12,000 sq. ft. or fire area > 5,000 sq. ft. for storage of commercial motor vehicles; or beneath other groups.	Not if beneath Group R-3
Covered and open malls (914.2.1)	Sprinklers required	Attached open parking structures
High-rises (914.3.1)	Sprinklers required	Open garages; certain telecommunications equipment buildings
Unlimited area buildings (IBC 507)	A-3, A-4, B, F, M, S: 1 story. B, F, M, S: 2 story	One story F-2 or S-2

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>.

a. Thresholds located in Section 903.2 unless noted. See also Table 903.2.11.6 for additional required suppression systems.

**Figure 903.2**  
**SUMMARY OF OCCUPANCY-RELATED AUTOMATIC SPRINKLER THRESHOLDS<sup>a</sup>**

Condition 2 establishes the minimum number of occupants for which an automatic sprinkler system is considered necessary. The determination of the actual occupant load must be based on Section 1004.

Condition 3 accounts for occupant egress delay when traversing a stairway, requiring a sprinkler system regardless of the size of occupant load. In such cases alternative emergency escape elements such as windows may not be available, making the suppression needs all the greater. It is not necessary for the occupant load to exceed 300 on a level other than the level of exit discharge serving such occupancy. Any number of Group A-1 occupants on the alternative level would be cause to apply the requirement for sprinklers. The text does not make reference to “story” but uses the term “floor,” which could include mezzanines and basements.

Condition 4 states that a sprinkler system is required for multiplex theater complexes to account for the delay associated with the notification of adjacent compartmentalized spaces where the occupants may not be immediately aware of an emergency.

Note that as with Group A-2, A-3 and A-4 occupancies, when sprinklers are required they are required throughout the story where the Group A-2 fire area is located and throughout all intervening floors leading to all levels of exit discharge serving the Group A occupancy. See Section 903.2.1.

**903.2.1.2 Group A-2.** An automatic sprinkler system shall be provided for *fire areas* containing Group A-2 occupancies and intervening floors of the building where one of the following conditions exists:

1. The *fire area* exceeds 5,000 square feet (464 m<sup>2</sup>).
  2. The *fire area* has an *occupant load* of 100 or more.
  3. The *fire area* is located on a floor other than a *level of exit discharge* serving such occupancies.
- ❖ Group A-2 assembly occupancies are intended for food or drink consumption, such as banquet halls, nightclubs and restaurants. Occupancies in Group A-2 involve life safety factors, such as a high occupant density, flexible fuel loading, movable furnishings and limited lighting; therefore, they must be protected with an automatic sprinkler system under any of the listed conditions.

In the case of an assembly use, the purpose of the automatic sprinkler system is to provide life safety from fire as well as preserving property. By requiring fire suppression in areas through which the occupants may egress, including the level of exit discharge serving such occupancies, the possibility of unobserved fire development affecting the occupant egress is minimized.

The 5,000-square-foot (464 m<sup>2</sup>) threshold for the automatic sprinkler system reflects the higher degree of life safety hazard associated with Group A-2 occupancies. As alluded to earlier, Group A-2 occupancies could have low lighting levels, loud music, late

hours of operation, dense seating with ill-defined aisles and alcoholic beverage service. These factors in combination could delay fire recognition, confuse occupant response and increase egress time.

Although the calculated occupant load for a 5,000 square-foot (465 m<sup>2</sup>) space at 15 square feet (1.4 m<sup>2</sup>) per occupant would be over 100, the occupant load threshold in Condition 2 is meant to reflect the concern for safety in these higher density occupancies. Although the major reason for establishing the occupant threshold at 100 was due to several recent nightclub incidents, the requirement is not limited to nightclubs or banquet facilities but to all Group A-2 occupancies. Any restaurant with an occupant load greater than 100 would require sprinkler protection as well. This includes fast food facilities with no low lighting or alcohol sales. The similar intent of Condition 3 is addressed in the commentary to Section 903.2.1.1.

Note that as with Group A-1 occupancies, when sprinklers are required they are required throughout the story where the Group A-2 fire area is located and throughout all intervening floors leading to all levels of exit discharge serving the Group A occupancy. See Section 903.2.1.

**903.2.1.3 Group A-3.** An automatic sprinkler system shall be provided for *fire areas* containing Group A-3 occupancies and intervening floors of the building where one of the following conditions exists:

1. The *fire area* exceeds 12,000 square feet (1115 m<sup>2</sup>).
  2. The *fire area* has an *occupant load* of 300 or more.
  3. The *fire area* is located on a floor other than a *level of exit discharge* serving such occupancies.
- ❖ Group A-3 occupancies are assembly occupancies intended for worship, recreation or amusement and other assembly uses not classified elsewhere in Group A, such as churches, museums and libraries. While Group A-3 occupancies could potentially have a high occupant load, they normally do not have the same potential combination of life safety hazards associated with Group A-2 occupancies. As with most assembly occupancies, however, most of the occupants are typically not completely familiar with their surroundings. When any of the three listed conditions are applicable, an automatic sprinkler system is required throughout fire area containing the Group A-3 occupancy, including the entire story where the Group A-3 occupancy is located, and throughout all floors between the Group A occupancy and all exit discharges that serve that occupancy (see commentary, Sections 903.2.1 and 903.2.1.1).

**903.2.1.4 Group A-4.** An automatic sprinkler system shall be provided for *fire areas* containing Group A-4 occupancies and intervening floors of the building where one of the following conditions exists:

1. The *fire area* exceeds 12,000 square feet (1115 m<sup>2</sup>).
2. The *fire area* has an *occupant load* of 300 or more.

3. The fire area is located on a floor other than a level of exit discharge serving such occupancies.

- ❖ Group A-4 occupancies are assembly uses intended for viewing of indoor sporting events and activities such as arenas, skating rinks and swimming pools. The occupant load density may be high depending on the extent and style of seating, such as bleachers or fixed seats, and the potential for standing-room viewing.

When any of the three listed conditions are applicable, an automatic sprinkler system is required throughout the fire area containing the Group A-4 occupancy, including the entire story where the Group A-4 occupancy is located, and throughout all floors between the Group A occupancy and all exit discharges that serve that occupancy (see commentary, Sections 903.2.1 and 903.2.1.1).

**903.2.1.5 Group A-5.** An automatic sprinkler system shall be provided for Group A-5 occupancies in the following areas: concession stands, retail areas, press boxes and other accessory use areas in excess of 1,000 square feet (93 m<sup>2</sup>).

- ❖ Group A-5 occupancies are assembly uses intended for viewing of outdoor activities. This occupancy classification could include amusement park structures, grandstands and open stadiums. A sprinkler system is not required in the open area of Group A-5 occupancies because the buildings would not accumulate smoke and hot gases. A fire in open areas would also be obvious to all spectators.

Enclosed areas such as retail areas, press boxes and concession stands require sprinklers if they are in excess of 1,000 square feet (93 m<sup>2</sup>). The 1,000-square-foot (93 m<sup>2</sup>) accessory use area is not intended to be an aggregate condition but rather per space. Thus, a press box that is 2,500 square feet (232 m<sup>2</sup>) in area would need to be subdivided into areas less than 1,000 square feet (93 m<sup>2</sup>) each in order to be below the threshold for sprinklers. There is no specific requirement for the separation of these spaces. It is assumed, however, that the separation would be a solid barrier of some type but without a required fire-resistance rating.

The provision is meant to mirror that in Section 1029.6.2.3, which exempts press boxes and storage facilities less than 1,000 square feet (93 m<sup>2</sup>) in area from sprinkler requirements in smoke-protected assembly seating areas.

**903.2.1.6 Assembly occupancies on roofs.** Where an occupied roof has an assembly occupancy with an occupant load exceeding 100 for Group A-2 and 300 for other Group A occupancies, all floors between the occupied roof and the level of exit discharge shall be equipped with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

**Exception:** Open parking garages of Type I or Type II construction.

- ❖ Frequently, roof tops are being used and occupied as assembly occupancies. Building owners will provide

an open air roof-top bar or lounge, or other use similar to a Group A-2 occupancy on the roof of a building. A roof does not meet the definition of a fire area. As such, protection of the occupants can be less than what would otherwise be required were the occupancy located on a floor rather than on the roof. In addition, even if a fire occurs within the building itself, it puts these occupants at risk. The provisions requiring sprinklers are based on the type and occupant load of the assembly occupancy located on the roof. The roof occupancy itself is not required to be sprinklered. The reference to Section 903.3.1.2 for NFPA 13R sprinkler systems is included since this use can occur on the roof of multifamily housing facilities.

The exception for open parking garages is consistent with the existing exception for open parking garages under Section 903.2.11.3 for "Buildings 55 feet or more in height." It is becoming more common in urban renewal areas throughout the U.S. that jurisdictions are asking developers to provide additional recreational spaces for their citizens to enjoy within their own communities. Because of the limited space available, it is not uncommon for such recreational spaces to be provided on the roofs of open parking garages. Based on the wording of this section, without the exception Group A-2 recreational spaces greater than 700 square feet in area (based on 7 square feet of area net per occupant) or other Group A occupancies greater than 1,500 square feet in area (based on 15 square feet of area net per occupant) would require the open parking garage below to be sprinklered, possibly with a dry pipe sprinkler system, that is initially a major cost to the project as well as a major on-going maintenance expense. Such an expense would most likely have an adverse effect on developers doing major city urban renewal projects by keeping them from agreeing to provide such amenities for the local jurisdiction.

Additionally, there is considerable data supporting the exception's elimination of automatic sprinkler systems in open parking garages. For example, two reports that evaluated fire behavior in parking garages are:

1. 2006 NFPA Fire Data Report, "Structure and Vehicle Fires in General Vehicle Parking Garages."
2. 2008 Parking Consultants Council Fire Safety Committee Report, "Parking Structure Fire Facts."

These reports provided the following conclusions:

- There was an average of only 660 fires per year in all types of parking garages in the U.S. This represented a mere 0.006 percent of all fires annually.
- There were no fire fatalities in open parking garages constructed of Construction Type I or II and an average of only 2 injuries per year.

- There was no structural damage in 98.7 percent of the fires in parking garages.
- Vehicle fires in parking garages typically do not spread from vehicle to vehicle. Fire spread from vehicle to vehicle occurred in only 7 percent of the incidents.

Automatic sprinkler systems are required in occupancies other than open parking garages to protect the assembly occupancy above the fire and to protect the means of egress. Based on the inherent fire safety provided by open parking garages of Type I or II construction, an automatic sprinkler system is not required when an assembly use is located on the roof.

**903.2.1.7 Multiple fire areas.** An *automatic sprinkler system* shall be provided where multiple fire areas of Group A-1, A-2, A-3 or A-4 occupancies share exit or *exit access* components and the combined *occupant load* of these fire areas is 300 or more.

- ❖ There are two conditions required to trigger the requirements of this section. The first is that exit or exit access components of Group A-1, A-2, A-3 or A-4 fire areas are shared. The second is that the combined occupant load of the fire areas that share these components exceeds 300 persons.

This section addresses the issue of multiple small assembly occupancies placed in a single story building and not triggering a sprinkler system requirement because of the installation of a rated corridor and separation walls. The code now requires that sprinkler systems be added when the convergence of more than 300 persons share an exit. This is consistent with the intent of automatic sprinkler systems being required for life safety and to maintain tenable exiting in a fire event. A fire event that is near an exit is the same whether there are 300 occupants in one room or three rooms with 100 occupants each sharing an exit. This is also consistent with the requirement in the “multitheater complex” for group A-1, which is a requirement for any time two or more theaters are in the same tenancy and does not consider occupant load as a trigger.

This will still allow those single story buildings with multiple tenancies that have separate exits and utilize the fire area separation concept; such as buildings with multiple restaurants with separate entrances and strip-style mall buildings.

**903.2.2 Ambulatory care facilities.** An *automatic sprinkler system* shall be installed throughout the entire floor containing an ambulatory care facility where either of the following conditions exist at any time:

1. Four or more care recipients are incapable of self-preservation, whether rendered incapable by staff or staff has accepted responsibility for care recipients already incapable.
2. One or more care recipients that are incapable of self-preservation are located at other than the level of exit discharge serving such a facility.

In buildings where ambulatory care is provided on levels other than the *level of exit discharge*, an *automatic sprinkler system* shall be installed throughout the entire floor where such care is provided as well as all floors below, and all floors between the level of ambulatory care and the nearest *level of exit discharge*, including the *level of exit discharge*.

- ❖ Ambulatory care facilities are Group B occupancies, which have an enhanced set of requirements that account for the fact that patients may be incapable of self-preservation and require rescue by other occupants or fire personnel. There are several aspects to the enhanced features, including smoke compartments, sprinklers and fire alarms. More specifically, the requirements for sprinklers are based on the presence of four or more care recipients at any given time that are incapable of self-preservation or any number of care recipients that are incapable of self-preservation located on a floor, other than the level of exit discharge, that serves the ambulatory care facility. The sprinkler requirement is limited to the floor area that contains the Group B ambulatory care facility and any floors between the ambulatory care facility and level of exit discharge (see commentary, Section 422 of the IBC).

**903.2.3 Group E.** An *automatic sprinkler system* shall be provided for Group E occupancies as follows:

1. Throughout all Group E *fire areas* greater than 12,000 square feet (1115 m<sup>2</sup>) in area.
2. Throughout every portion of educational buildings below the lowest *level of exit discharge* serving that portion of the building.

**Exception:** An *automatic sprinkler system* is not required in any area below the lowest *level of exit discharge* serving that area where every classroom throughout the building has not fewer than one exterior *exit door* at ground level.

- ❖ Group E occupancies are limited to educational purposes through the 12th grade and day care centers serving children older than 2½ years of age. The 12,000-square-foot (1115 m<sup>2</sup>) fire area threshold for the sprinkler system was established to allow smaller schools and day care centers to be nonsprinklered to minimize the economic impact on these facilities. The 12,000-square-foot (1115 m<sup>2</sup>) threshold is similar to that used for several other occupancies, such as Group M occupancies.

Sprinklers would also be required in portions of the building located below the level of exit discharge serving that occupancy. However, there is an exception that would allow the omission of the automatic sprinkler system for the Group E fire area if there is a direct exit to the exterior from each classroom at ground level. The occupants must be able to go from the classroom directly to the outside without passing through intervening corridors, passageways or interior exit stairways.

**903.2.4 Group F-1.** An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy where one of the following conditions exists:

1. A Group F-1 fire area exceeds 12,000 square feet (1115 m<sup>2</sup>).
  2. A Group F-1 fire area is located more than three stories above grade plane.
  3. The combined area of all Group F-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m<sup>2</sup>).
  4. A Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m<sup>2</sup>).
- ❖ Group F-1 occupancies must meet several different conditions as to when the fire area or occupancy must be sprinklered. The first three conditions are related to the difficulty of manually suppressing a fire involving a large area. Therefore, occupancies of Group F-1 must be protected throughout with an automatic sprinkler system if the fire area is in excess of 12,000 square feet (1115 m<sup>2</sup>), if the total of all fire areas is in excess of 24,000 square feet (2230 m<sup>2</sup>) or if the fire area is located more than three stories above grade plane. This is one of the few locations in the code where the total floor area of the building is aggregated for application of a code requirement. The stipulated conditions for when an automatic sprinkler system is required also apply to Group M (see Section 903.2.7) and S-1 (see Section 903.2.9) occupancies. Condition 4 for sprinklering a Group F-1 occupancy relates to the requirement for Group F-1 occupancies in excess of 2,500 square feet (232 m<sup>2</sup>) that are used for the manufacture of upholstered furniture or mattresses. Note that this requirement is based simply upon the square footage of the Group F-1 occupancy and is not related to fire areas. Upholstered furniture has the potential for rapid growing and high-heat-release fires. This hazard is increased substantially when there are numerous upholstered furniture or mattresses being manufactured. Such fires put the occupants and emergency responders at risk. This requirement exists regardless of whether the upholstered furniture has passed any fire-retardant tests. See the commentary for Section 903.2.7 for more discussion on the subject of upholstered furniture. See the commentary to Section 903.2.9 for discussion of the formal interpretation and applicability to the code and IBC.

The following examples illustrate how the criteria of this section are intended to be applied:

- If a building contains a single fire area of Group F-1 and the fire area is 13,000 square feet (1208 m<sup>2</sup>), an automatic sprinkler system is required throughout the entire building; however, if this fire area is separated into two fire areas and neither is in excess of 12,000 square feet (1115 m<sup>2</sup>), an automatic fire sprinkler system is not required. To be considered separate fire areas, the areas must be separated by fire barriers or horizontal assemblies having a fire-resistance rating as required in Table 707.3.10.
  - If a 30,000-square-foot (2787 m<sup>2</sup>) Group F-1 building was equally divided into separate fire areas of 10,000 square feet (929 m<sup>2</sup>) each, an automatic sprinkler system would still be required throughout the entire building. Because the aggregate area of all fire areas exceeds 24,000 square feet (2230 m<sup>2</sup>), additional compartmentation will not eliminate the need for an automatic sprinkler system. However, the use of a fire wall to separate the structure into two buildings would reduce the aggregate area of each building to less than 24,000 square feet (2230 m<sup>2</sup>) and each fire area to less than 12,000 square feet (1115 m<sup>2</sup>), which would offset the need for an automatic sprinkler system.
- 903.2.4.1 Woodworking operations.** An automatic sprinkler system shall be provided throughout all Group F-1 occupancy fire areas that contain woodworking operations in excess of 2,500 square feet in area (232 m<sup>2</sup>) that generate finely divided combustible waste or use finely divided combustible materials.
- ❖ Because of the potential amount of combustible dust that could be generated during woodworking operations, an automatic sprinkler system is required throughout a fire area when it contains a woodworking operation that exceeds 2,500 square feet (232 m<sup>2</sup>) in area. Facilities where woodworking operations take place, such as cabinet making, are considered Group F-1 occupancies. The intent of the phrase "finely divided combustible waste" is to describe particle concentrations that are in the explosive range (see Chapter 22 for discussion of dust-producing operations).
- The extent of sprinkler coverage is only intended to be for the Group F-1 occupancy involved in the woodworking activity. If the fire area is larger than 2,500 square feet (232 m<sup>2</sup>) but the woodworking area is less than 2,500 square feet (232 m<sup>2</sup>), sprinklers are not required. It is not the intent to require the installation of sprinklers throughout the building but rather in the fire area where the hazard may be present.
- 903.2.5 Group H.** Automatic sprinkler systems shall be provided in high-hazard occupancies as required in Sections 903.2.5.1 through 903.2.5.3.
- ❖ Group H occupancies are those intended for the manufacturing, processing or storage of hazardous materials that constitute a physical or health hazard. To be considered a Group H occupancy, the amount of hazardous materials is assumed to be in excess of the maximum allowable quantities permitted by Tables 5003.1.1(1) and 5003.1.1(2).
- 903.2.5.1 General.** An automatic sprinkler system shall be installed in Group H occupancies.
- ❖ This section requires an automatic sprinkler system in all Group H occupancies. Even though in some

instances the hazard associated with the occupancy may be one that is not a fire hazard, an automatic sprinkler system is still required to minimize the potential for fire spreading to the high-hazard use; that is, the sprinklers protect the high-hazard area from fire outside the area. This section does not prohibit the use of an alternative automatic fire-extinguishing system in accordance with Section 904. When a water-based system is not compatible with the hazardous materials involved and thus creates a dangerous condition, an alternative fire-extinguishing system should be used. For example, combustible metals, such as magnesium and titanium, have a serious record of involvement with fire and are typically not compatible with water (see commentary, Chapter 59).

Where control areas are used to regulate the quantity of hazardous material within a building, the building is not considered a Group H occupancy. Unless a building would be required by some other code provision to be protected with sprinklers, control areas can be used to control the allowable quantities of hazardous materials in a building so as to not warrant a Group H classification and its mandatory sprinkler requirements.

**903.2.5.2 Group H-5 occupancies.** An automatic sprinkler system shall be installed throughout buildings containing Group H-5 occupancies. The design of the sprinkler system shall be not less than that required under the *International Building Code* for the occupancy hazard classifications in accordance with Table 903.2.5.2.

Where the design area of the sprinkler system consists of a corridor protected by one row of sprinklers, the maximum number of sprinklers required to be calculated is 13.

❖ Group H-5 occupancies are structures that are typically used as semiconductor fabrication facilities and comparable research laboratory facilities that use hazardous production materials (HPM). Many of the materials used in semiconductor fabrication present unique hazards. Many of the materials are toxic, while some are corrosive, water reactive or pyrophoric. Fire protection for these facilities is aimed at preventing incidents from escalating and producing secondary threats beyond a fire, such as the release of corrosive or toxic materials. Because of the nature of Group H-5 facilities, the overall amount of hazardous materials can far exceed the maximum allowable quantities given in Tables 5003.1.1(1) and 5003.1.1(2). Although the amount of HPM material is restricted in fabrication areas, the quantities of HPM in storage rooms normally will be in excess of those allowed by the tables. Additional requirements for Group H-5 facilities are located in Chapter 27 of the code and Section 415.11 of the IBC.

This section also specifies the sprinkler design criteria, based on NFPA 13, for various areas in a Group H-5 occupancy (see commentary, Table 903.2.5.2). When the corridor design area sprinkler option is used, a maximum of 13 sprinklers must be

calculated. This exceeds the requirements of NFPA 13 for typical egress corridors, which require a maximum of either five or seven calculated sprinklers, depending on the extent of protected openings in the corridor. The increased number of calculated corridor sprinklers is based on the additional hazard associated with the movement of hazardous materials in corridors of Group H-5 facilities.

**TABLE 903.2.5.2  
GROUP H-5 SPRINKLER DESIGN CRITERIA**

LOCATION	OCCUPANCY HAZARD CLASSIFICATION
Fabrication areas	Ordinary Hazard Group 2
Service corridors	Ordinary Hazard Group 2
Storage rooms without dispensing	Ordinary Hazard Group 2
Storage rooms with dispensing	Extra Hazard Group 2
Corridors	Ordinary Hazard Group 2

❖ Table 903.2.5.2 designates the appropriate occupancy hazard classification for the various areas within a Group H-5 facility. The listed occupancy hazard classifications correspond to specific sprinkler system design criteria in NFPA 13. Ordinary Hazard Group 2 occupancies, for example, require a minimum design density of 0.20 gpm/ft<sup>2</sup> (8.1 L/min/m<sup>2</sup>) with a minimum design area of 1,500 square feet (139 m<sup>2</sup>). An Extra Hazard Group 2 occupancy, in turn, requires a minimum design density of 0.40 gpm/ft<sup>2</sup> (16.3 L/min/m<sup>2</sup>) with a minimum operating area of 2,500 square feet (232 m<sup>2</sup>). The increased overall sprinkler demand for Extra Hazard Group 2 occupancies is based on the potential use and handling of substantial amounts of hazardous materials, such as flammable or combustible liquids.

**903.2.5.3 Pyroxylin plastics.** An automatic sprinkler system shall be provided in buildings, or portions thereof, where cellulose nitrate film or pyroxylin plastics are manufactured, stored or handled in quantities exceeding 100 pounds (45 kg).

❖ Cellulose nitrate (pyroxylin) plastics pose unusual and substantial fire risks. Pyroxylin plastics are the most dangerous and unstable of all plastic compounds. The chemically bound oxygen in their structure permits them to burn vigorously in the absence of atmospheric oxygen. Although these compounds produce approximately the same amount of energy as paper when they burn, pyroxylin plastics burn at a rate as much as 15 times greater than comparable common combustibles. When burning, these materials release highly flammable and toxic combustion byproducts. Consequently, cellulose nitrate fires are very difficult to control. Although this section specifies a sprinkler threshold quantity of 100 pounds (45.4 kg), the need for additional fire protection should be considered for pyroxylin plastics in any amount.

Although the code includes cellulose nitrate “film” in its requirements, cellulose nitrate motion picture film has not been used in the United States since the 1950s. All motion picture film produced since that

time is what is typically called “safety film.” Consequently, the only application for this section relative to motion picture film is where it may be used in laboratories or storage vaults that are dedicated to film restoration and archives. The protection of these facilities is addressed in Sections 306.2 and 6504.2.

**903.2.6 Group I.** An *automatic sprinkler system* shall be provided throughout buildings with a Group I *fire area*.

**Exceptions:**

1. An *automatic sprinkler system* installed in accordance with Section 903.3.1.2 shall be permitted in Group I-1 Condition 1 facilities.
2. An *automatic sprinkler system* is not required where Group I-4 day care facilities are at the *level of exit discharge* and where every room where care is provided has not fewer than one exterior *exit door*.
3. In buildings where Group I-4 day care is provided on levels other than the *level of exit discharge*, an *automatic sprinkler system* in accordance with Section 903.3.1.1 shall be installed on the entire floor where care is provided, all floors between the level of care and the *level of exit discharge* and all floors below the level of exit discharge other than areas classified as an open parking garage.

❖ The Group I occupancy is divided into four individual occupancy classifications based on the degree of detention, supervision and physical mobility of the occupants. The evacuation difficulties associated with the building occupants creates the need to incorporate a defend-in-place philosophy of fire protection in occupancies of Group I. For this reason, all such occupancies are to be protected with an automatic sprinkler system. Note that this section is applicable to the entire building that contains a Group I occupancy.

Of particular note, this section encompasses all Group I-3 occupancies where more than five persons are detained (see Section 308.5 of the IBC). There has been considerable controversy concerning the use of automatic sprinklers in detention and correctional occupancies. Special design considerations can be taken into account to alleviate the perceived problems with sprinklers in sleeping units. Sprinklers that reduce the likelihood of vandalism as well as the potential to hang oneself are commercially available. Knowledgeable designers can incorporate certain design features to increase reliability and decrease the likelihood of damage to the system.

Group I-4 occupancies would include either adult-only care facilities or occupancies that provide personal care for more than five children, 2½ years of age or younger, on a less than 24-hour basis. Because the degree of assistance and the time needed for egress cannot be gauged, an automatic sprinkler system is required.

There are three exceptions to this section. Exception 1 permits Group I-1 Condition 1 occupancies to be protected throughout with an NFPA 13R system

instead of a NFPA 13 system. This is the lower risk condition for Group I-1 occupancies. Group I-1 Condition 2 occupancies would be required to use an NFPA 13 system.

Exception 2 exempts sprinkler systems completely if the day care center is at the level of exit discharge and every room has at least one exterior exit door. Note that day cares to which this section applies are considered by Section 308.6.1 of the IBC to be Group E occupancies. An automatic sprinkler system would not be required unless dictated by the requirements in Section 903.2.2 (see commentary, Section 308.6.1 of the IBC).

Exception 3 is also related to day cares that are still classified as Group I-4 by nature of the location in the building. In that case, an NFPA 13 system would be required on the floor where the center is located and all floors between and including the level of exit discharge. This is less stringent than the main requirement in Section 903.2.6 that requires the entire building to be sprinklered. As defined in Section 202, a Group I-4 child care facility located at the level of exit discharge and accommodating no more than 100 children, with each child care room having an exit directly to the exterior, would be classified as a Group E occupancy. See also IBC Section 308.6.1.

**903.2.7 Group M.** An *automatic sprinkler system* shall be provided throughout buildings containing a Group M occupancy where one of the following conditions exists:

1. A Group M *fire area* exceeds 12,000 square feet (1115 m<sup>2</sup>).
2. A Group M *fire area* is located more than three stories above grade plane.
3. The combined area of all Group M *fire areas* on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m<sup>2</sup>).
4. A Group M occupancy used for the display and sale of upholstered furniture or mattresses exceeds 5,000 square feet (464 m<sup>2</sup>).

❖ The sprinkler threshold requirements for Group M occupancies are identical to those of Group F-1 and S-1 occupancies (see commentary, Section 903.2.4). The one exception is that Group M occupancies are provided with an increased area for display of upholstered furniture and mattresses of 5,000 square feet (464 m<sup>2</sup>) versus 2,500 square feet (232 m<sup>2</sup>) required for Group F-1 and S-1 occupancies. As noted in the commentary for Group F-1 occupancies, upholstered furniture and mattresses have the potential for rapidly growing and high-heat-release fires. This hazard is increased substantially when there are numerous upholstered furniture items or mattresses on display. Such fires put the occupants and emergency responders at risk. This requirement exists regardless of whether the upholstered furniture has passed any fire-retardant tests.

The code does not specifically address what constitutes upholstered furniture, but by simple dictionary

definition, upholstered furniture has seats covered with padding, springs, webbing and fabric or leather covers. The code does not make any distinction between levels of padding and upholstery provided on furniture, which was intentional. The proponent's reason statement for code change F135-07/08 stated, in part, that "the American Home Furnishings Alliance (AHFA) and the National Home Furnishings Association (NHFA) have examined proposals for exempting vendors of certain constructions of furniture and concluded that such exemptions would be impractical for local code officials to enforce. This is the case because the internal construction of furniture cannot be established reliably without deconstructing it."

Note that, as with Group F-1 occupancies, the criteria is written such that any Group M occupancy, not the fire area, over 5,000 square feet (464 m<sup>2</sup>) used for the display and sale of upholstered furniture and mattresses shall be sprinklered throughout. This is regardless of the quantity of upholstered furniture and mattresses actually available for purchase. The reason these requirements were placed into the IBC and the code was based on a large fire in Charleston, South Carolina that killed nine fire fighters. The facility was a combination furniture showroom and associated storage area. The building did not provide an automatic sprinkler system. See the commentary to Section 903.2.9 for discussion of a formal interpretation dealing with Group S-1 occupancies and applicability to the code and IBC.

Automatic sprinkler systems for mercantile occupancies are typically designed for an Ordinary Hazard Group 2 classification in accordance with NFPA 13. If high-piled storage (see Section 903.2.7.1) is anticipated; additional levels of fire protection may be required. Also, some merchandise in mercantile occupancies, such as aerosols, rubber tires, paints and certain plastic commodities, even at limited storage heights, are considered beyond the standard Class I through IV commodity classification assumed for mercantile occupancies in NFPA 13 and may warrant additional fire protection.

**903.2.7.1 High-piled storage.** An *automatic sprinkler system* shall be provided as required in Chapter 32 in all buildings of Group M where storage of merchandise is in high-piled or rack storage arrays.

- ❖ Regardless of the size of the Group M fire area, an automatic sprinkler system may be required in a high-piled storage area. High-piled storage includes piled, palletized, bin box, shelf or rack storage of Class I through IV combustibles to a height greater than 12 feet (3658 mm) and certain high-hazard commodities greater than 6 feet (1829 mm). Chapter 23 provides a package of requirements that may include sprinkler protection depending upon the size of the high-piled storage area. The design standard for the sprinkler protection of high-piled storage is NFPA 13. NFPA 13 addresses the many different types and configurations of high-piled storage.

**903.2.8 Group R.** An *automatic sprinkler system* installed in accordance with Section 903.3 shall be provided throughout all buildings with a Group R fire area.

- ❖ This section requires sprinklers in any building that contains a Group R fire area. This includes uses, such as hotels, apartment buildings, group homes and dormitories. There are no minimum criteria and no exceptions.

It should be noted that buildings constructed under the *International Residential Code*<sup>®</sup> (IRC<sup>®</sup>) are not included in Group R and would not, therefore, be subject to these particular requirements. The 2009 IRC required sprinklers in all new townhouses and, beginning January 1, 2011, all one- and two-family dwellings. The IRC is a stand-alone code for the construction of detached one- and two-family dwellings and multiple single-family dwellings (townhouses) no more than three stories in height with a separate means of egress and addresses the requirements for sprinklers in a different way. That is, all of the provisions for new construction that affect those buildings are to be covered exclusively by the IRC and are not to be covered by another *International Code*. Buildings that do not fall within the scope of the IRC would be classified in Group R and be subject to these provisions. This is stated clearly in IFC Committee Interpretation No. 29-03.

With respect to life safety, the need for a sprinkler system is dependent on the occupants' proximity to the fire and the ability to respond to a fire emergency. Group R occupancies could contain occupants who may require assistance to evacuate, such as infants, those with a disability or who may simply be asleep. While the presence of a sprinkler system cannot always protect occupants in residential buildings who are aware of the ignition and either do not respond or respond inappropriately, it can prevent fatalities outside of the area of fire origin regardless of the occupants' response. Section 903.3.2 requires quick-response or residential sprinklers in all Group R occupancies. Full-scale fire tests have demonstrated the ability of quick-response and residential sprinklers to maintain tenability from flaming fires in the room of fire origin.

Where a different occupancy is located in a building with a residential occupancy, the provisions of this section still apply and the entire building is required to be provided with an automatic sprinkler system regardless of the type of mixed-use condition considered. This is consistent with the mixed-use provisions in Chapter 5 of the IBC. The type of sprinkler system permitted in the different types of Group R occupancies is further clarified in Section 903.2.8.1 through 903.2.8.4.

**903.2.8.1 Group R-3.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.3 shall be permitted in Group R-3 occupancies.

- ❖ R-3 occupancies are essentially one- and two-family dwellings that fall outside the scope of the IRC, thus

an NFPA 13D system is appropriate. It should be noted there is no restriction on the use of NFPA 13 or NFPA 13R systems.

**[F] 903.2.8.2 Group R-4 Condition 1.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.3 shall be permitted in Group R-4 Condition 1 occupancies.

❖ Group R-4 Condition 1 is the lesser of the risk categories for Group R-4 occupants. The occupants are more capable of evacuating without assistance; therefore, they are treated no different than a Group R-3 occupancy.

**[F] 903.2.8.3 Group R-4 Condition 2.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.2 shall be permitted in Group R-4 Condition 2 occupancies. Attics shall be protected in accordance with Section 903.2.8.3.1 or 903.2.8.3.2.

❖ In Group R-4 Condition 2 occupancies the occupants need more assistance evacuating a building; therefore, a more robust sprinkler system is required. An NFPA 13R system is required. It should be noted that there are some concerns with NFPA 13R systems not adequately addressing attic spaces as typically NFPA 13R systems focus primarily on the main habitable portion of the building. Specific compliance conditions are provided in Sections 903.2.8.3.1 and 908.2.8.3.2.

**[F] 903.2.8.3.1 Attics used for living purposes, storage or fuel-fired equipment.** Attics used for living purposes, storage or fuel-fired equipment shall be protected throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.2.

❖ This section clarifies that, if the attic is used for living purposes or there are fuel-fired equipment and storage in these areas, full coverage in accordance with NFPA 13R is required.

**[F] 903.2.8.3.2 Attics not used for living purposes, storage or fuel-fired equipment.** Attics not used for living purposes, storage or fuel-fired equipment shall be protected in accordance with one of the following:

1. Attics protected throughout by a heat detector system arranged to activate the building fire alarm system in accordance with Section 907.2.10.
  2. Attics constructed of noncombustible materials.
  3. Attics constructed of fire-retardant-treated wood framing complying with Section 2303.2 of the *International Building Code*.
  4. The *automatic sprinkler system* shall be extended to provide protection throughout the attic space.
- ❖ In attics where people are not expected and storage or fuel-fired equipment is not located, some protection is required on top of what NFPA 13R would require. Four different options of protection are provided. The first is simply to provide more warning time to the occupants if a fire should occur in the attic via a heat detector that activates the fire alarm system. The second is simply to reduce the risk of fire by requiring noncombustible construction materials. The

third, similar to the second, is reducing the fire hazard by using fire-retardant-treated wood. This will slow the growth of a fire should one occur or prevent the start of a fire. The final option is simply to provide sprinkler protection to the attic. If a sprinkler system is provided in the attic, issues such as freezing temperatures need to be addressed.

**[F] 903.2.8.4 Care facilities.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.3 shall be permitted in care facilities with five or fewer individuals in a single-family dwelling.

❖ This section is similar to Sections 903.2.8.1 and 903.2.8.2 and allows the use of an NFPA 13D system in place of an NFPA 13 or 13R system. In this case, it is specific to smaller care facilities with five or fewer residents. Again, while not technically a single-family dwelling, they are very similar in nature based on the type and actual use of the building.

**903.2.9 Group S-1.** An *automatic sprinkler system* shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:

1. A Group S-1 *fire area* exceeds 12,000 square feet (1115 m<sup>2</sup>).
2. A Group S-1 *fire area* is located more than three stories above grade plane.
3. The combined area of all Group S-1 *fire areas* on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m<sup>2</sup>).
4. A Group S-1 *fire area* used for the storage of commercial motor vehicles where the *fire area* exceeds 5,000 square feet (464 m<sup>2</sup>).
5. A Group S-1 occupancy used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m<sup>2</sup>).

❖ An automatic sprinkler system must be provided throughout all buildings where the fire area containing a Group S-1 occupancy exceeds 12,000 square feet (1115 m<sup>2</sup>); is more than three stories above grade plane; is a combined fire area, including all floors and mezzanines, exceeding 24,000 square feet (2230 m<sup>2</sup>); or is used for the storage of commercial motor vehicles and exceeds 5,000 square feet (464 m<sup>2</sup>). See the commentary for the definition of "Commercial motor vehicle" in Chapter 2.

The first three sprinkler threshold requirements for Group S-1 occupancies are identical to those of Groups F-1 and M (see commentary, Sections 903.2.4 and 903.2.7). Group S-1 occupancies, such as warehouses and self-storage buildings, are assumed to be used for the storage of combustible materials. While high-piled storage does not change the Group S-1 occupancy classification, sprinkler protection, if required, may have to comply with the additional requirements of Chapter 32. High-piled stock or rack storage in any occupancy must comply with the code and the IBC. The fifth sprinkler threshold is the same as for Group F-1 except that, in this case,

upholstered furniture and mattresses are being stored and not manufactured. Group M has a similar threshold, but is required for larger occupancies containing such items with an area of 5,000 square feet (464 m<sup>2</sup>) versus what is required for Groups S-1 and F-1 occupancies of 2,500 square feet (232 m<sup>2</sup>). See the commentary for Group M and Group F-1 occupancies for more discussion on this issue. Again, it is important to note that the threshold is based upon the square footage of the occupancy and not upon the size of the fire area. A formal interpretation (IFC Interpretation 20-14) has been issued on this section. The formal interpretation addresses self storage warehouses specifically and whether such a facility between 2,500 and 1,2000 square feet would require an automatic sprinkler system. This is based on the fact that upholstered furniture may be stored in such units. The response provided noted that a sprinkler system would be required based on the fact the requirements are focused on the square footage of the occupancy and are not based on fire area or the amount of upholstered furniture or mattresses present.

**903.2.9.1 Repair garages.** An *automatic sprinkler system* shall be provided throughout all buildings used as repair garages in accordance with Section 406.8 of the *International Building Code*, as shown:

1. Buildings having two or more stories above grade plane, including *basements*, with a *fire area* containing a repair garage exceeding 10,000 square feet (929 m<sup>2</sup>).
  2. Buildings not more than one story above grade plane, with a *fire area* containing a repair garage exceeding 12,000 square feet (1115 m<sup>2</sup>).
  3. Buildings with repair garages servicing vehicles parked in *basements*.
  4. A Group S-1 *fire area* used for the repair of commercial motor vehicles where the *fire area* exceeds 5,000 square feet (464 m<sup>2</sup>).
- ❖ Automatic sprinklers may be required in repair garages, depending on the quantity of combustibles present, their location and floor area. In addition, any Group S-1 fire area intended for the repair of commercial motor vehicles that exceeds 5,000 square feet (464 m<sup>2</sup>) would require sprinklers. This is the same criteria as Group S-1 occupancies and Group S-2 enclosed parking garages storing commercial motor vehicles. Repair garages may contain significant quantities of flammable liquids and other combustible materials. These occupancies are typically considered Ordinary Hazard Group 2 occupancies as defined in NFPA 13. Portions of repair garages used for parts cleaning using flammable or combustible liquids may require automatic sprinkler protection. If quantities of hazardous materials exceed the limitations in Chapter 50 for maximum allowable quantities per control area, the repair garage would be reclassified as a Group H occupancy. Note that the term “Commercial motor vehicles” is specially defined in Chapter 2.

**903.2.9.2 Bulk storage of tires.** Buildings and structures where the area for the storage of tires exceeds 20,000 cubic feet (566 m<sup>3</sup>) shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ This section specifies when an automatic sprinkler system is required for the bulk storage of tires based on the volume of the storage area as opposed to a specific number of tires. Even in fully sprinklered buildings, tire fires pose significant problems to fire departments. Tire fires produce thick smoke and are difficult to extinguish by sprinklers alone. NFPA 13 contains specific fire protection requirements for the storage of rubber tires.

Whether the volume of tires is divided into different fire areas or not is irrelevant to the application of this section. If the total for all areas where tires are stored is great enough that the resultant storage volume exceeds 20,000 cubic feet (566 m<sup>3</sup>), the building must be sprinklered throughout. See the commentary to Section 202 definition of “Tires, bulk storage of” for further information.

**903.2.10 Group S-2 enclosed parking garages.** An *automatic sprinkler system* shall be provided throughout buildings classified as enclosed parking garages in accordance with Section 406.6 of the *International Building Code* where either of the following conditions exists:

1. Where the *fire area* of the enclosed parking garage exceeds 12,000 square feet (1115 m<sup>2</sup>).
2. Where the enclosed parking garage is located beneath other groups.

**Exception:** Enclosed parking garages located beneath Group R-3 occupancies.

❖ Fire records have shown that fires in parking structures typically fully involve only a single automobile with minor damage to adjacent vehicles. An enclosed parking garage, however, does not allow the dissipation of smoke and hot gases as readily as an open parking structure, which is also considered a Group S-2 occupancy. If the enclosed parking garage has a fire area greater than 12,000 square feet (1115 m<sup>2</sup>) or is located beneath another occupancy group, the enclosed parking garage must be protected with an automatic sprinkler system. This requirement that the enclosed parking garage located beneath other occupancy groups is required to be sprinklered is based on the potential for a fire to develop undetected, which would endanger the occupants of the other occupancy. The 12,000 square foot (1115 m<sup>2</sup>) threshold is similar to other occupancies such as Groups M and S-1.

It should be noted that while open parking garages are considered a Group S-2 occupancy, they are not required by the provisions of this section to be equipped with an automatic sprinkler system.

The exception exempts enclosed garages in buildings where the garages are located below a Group R-3 occupancy. The exception is essentially moot since the code requires all buildings with a Group R occupancy to be sprinklered throughout. Because the entire

building with the residential occupancy is required to be sprinklered according to Sections 903.2.8, the garage would be sprinklered as well. It should be noted that if the Group R-3 was protected with an NFPA 13D system that the enclosed parking garage would not require sprinklers.

**903.2.10.1 Commercial parking garages.** An *automatic sprinkler system* shall be provided throughout buildings used for storage of commercial motor vehicles where the *fire area* exceeds 5,000 square feet (464 m<sup>2</sup>).

❖ Because of the larger-sized vehicles involved in commercial parking structures, those housing commercial motor vehicles, as defined in Section 202, a more stringent sprinkler threshold is required. Bus garages may also be located adjacent to passenger terminals (Group A-3) that have a substantial occupant load. Commercial parking requires only a single vehicle in order to be classified as commercial parking.

The criterion for sprinkler protection is based on the size of the fire area and not the size of the commercial parking. If the commercial parking involves only 1,000 square feet (93 m<sup>2</sup>) but the fire area exceeds 5,000 square feet (464 m<sup>2</sup>), sprinkler protection is required.

**903.2.11 Specific buildings areas and hazards.** In all occupancies other than Group U, an *automatic sprinkler system* shall be installed for building design or hazards in the locations set forth in Sections 903.2.11.1 through 903.2.11.6.

❖ Sections 903.2.11.1 through 903.2.11.2 specify certain conditions under which an automatic sprinkler system is required, even in otherwise nonsprinklered buildings. As indicated, the listed conditions in the noted sections are applicable to all occupancies except Group U. Most structures that qualify as Group U do not typically have the type of conditions stipulated in Sections 903.2.11.1 through 903.2.11.1.3.

**903.2.11.1 Stories without openings.** An *automatic sprinkler system* shall be installed throughout all stories, including *basements*, of all buildings where the floor area exceeds 1,500 square feet (139.4 m<sup>2</sup>) and where there is not provided not fewer than one of the following types of *exterior wall* openings:

1. Openings below grade that lead directly to ground level by an exterior *stairway* complying with Section 1009 or an outside ramp complying with Section 1010. Openings shall be located in each 50 linear feet (15 240 mm), or fraction thereof, of *exterior wall* in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm).
2. Openings entirely above the adjoining ground level totaling not less than 20 square feet (1.86 m<sup>2</sup>) in each 50 linear feet (15 240 mm), or fraction thereof, of *exterior wall* in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm). The height of the bottom of the clear

opening shall not exceed 44 inches (1118 mm) measured from the floor.

❖ Because of both the lack of openings in exterior walls for access by the fire department for fire fighting and rescue and the problems associated with venting the products of combustion during fire suppression operations, all stories which includes any basements of buildings that do not have adequate openings as defined in this section must be equipped with an automatic sprinkler system. This section applies to stories without sufficient exterior openings where the floor area exceeds 1,500 square feet (139 m<sup>2</sup>) and where the building is not otherwise required to be fully sprinklered. The requirement for an automatic sprinkler system in this section applies only to the affected area and does not mandate sprinkler protection throughout the entire building.

Stories without openings, as defined in this section, are stories that do not have at least 20 square feet (1.9 m<sup>2</sup>) of opening leading directly to ground level in each 50 lineal feet (15 240 mm) or fraction thereof on at least one side. Since exterior doors will provide openings of 20 square feet (1.9 m<sup>2</sup>), or slightly less in some occupancies, exterior stairways and ramps in each 50 lineal feet (15 240 mm) are considered acceptable.

This section specifically states that the required openings be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm). If the openings in the exterior wall are located without regard to the location of the adjacent openings, it is possible that segments of the exterior wall will not have the required access to the interior of the building for fire-fighting purposes. Any arrangement of required stairways, ramps or openings that results in a portion of the wall 50 feet (15 240 mm) or more in length with no openings to the exterior does not meet the intent of the code that access be provided in each 50 lineal feet (15 240 mm) (see Commentary Figure 903.2.11.1).

There is a further restriction on openings that are entirely above grade. More specifically, to support fire fighting operations, the openings need to be accessible and usable. Therefore, Item 2 specifies that the maximum sill height be 44 inches (1117.6 mm) above the floor. This height is consistent with the height provided for emergency escape and rescue windows in Section 1030.3.

One application of this section has been addressed in the *International Code Interpretations* and deals with automotive service shops that have below-grade service areas where employees perform oil changes and other minor maintenance services. The below-grade areas are typically open to the grade-level service bays via openings providing access to the underside of the vehicles without requiring the vehicle to be lifted into the air. Inasmuch as the below-grade space has no openings directly to the exterior, the question was asked if it would be regulated as a windowless story and thus be required to be equipped with an automatic

fire suppression system in accordance with Section 903.2.11.1.

The answer to that question is no. Due to the openness between the adjacent service levels, the below-grade area would be more appropriately regulated similar to a mezzanine rather than a story. A mezzanine is not regulated as a separate story but rather as part of the same story that it serves. Therefore, if the below-grade service level is in compliance with the applicable provisions of Section 505 of the IBC, the windowless story provisions of Section 903.2.11.1 would be evaluated based on the exterior wall openings of the main level and not the service mezzanine below. The direct interconnections provided between the two adjacent floor levels by multiple service openings provide access to the lower service area for fire-fighting and rescue operations. As such, it would not be regulated as a windowless story.

The requirement to sprinkler the basement is independent of mixed-use conditions. Whether the basement is separated or nonseparated is irrelevant to the need for sprinkler protection, nor does the requirement to provide sprinklers in the basement imply that sprinklers must be provided elsewhere. This requirement is applicable to the basement or any story without openings irrespective of other code provisions.

These provisions are also not based upon the size of a fire area but rather upon the size of the basement. Thus, subdividing the basement into multiple fire areas would have no effect on the requirement. However, one benefit of the multiple fire areas could be that each fire area could have a separate limited area sprinkler system with less than 20 sprinklers.

**903.2.11.1.1 Opening dimensions and access.** Openings shall have a minimum dimension of not less than 30 inches (762 mm). Such openings shall be accessible to the fire department from the exterior and shall not be obstructed in a

manner such that fire fighting or rescue cannot be accomplished from the exterior.

- ❖ To qualify, an opening must not be less than 30 inches (762 mm) in least dimension and must be accessible to the fire department from the exterior. The minimum opening dimension gives fire department personnel access to the interior of the story or basement for fire-fighting and rescue operations and provides openings that are large enough to vent the products of combustion.

**903.2.11.1.2 Openings on one side only.** Where openings in a story are provided on only one side and the opposite wall of such story is more than 75 feet (22 860 mm) from such openings, the story shall be equipped throughout with an *approved automatic sprinkler system* or openings as specified above shall be provided on not fewer than two sides of the story.

- ❖ If openings are provided on only one side, an automatic sprinkler system would still be required if the opposite wall of the story is more than 75 feet (22 860 mm) from existing openings. An alternative to providing the automatic sprinkler system would be to design openings on at least two sides of the exterior of the building. As long as the story being considered is not a basement, the openings on two sides can be greater than 75 feet (22 860 mm) from any portion of the floor. In basements, if any portion is more than 75 feet (22 860 mm) from the openings, the entire basement must be equipped with an automatic sprinkler system, as indicated in Section 903.2.11.1.3. Providing openings on more than one wall allows cross ventilation to vent the products of combustion [see Commentary Figures 903.2.11.1.2(1-4)].

**903.2.11.1.3 Basements.** Where any portion of a *basement* is located more than 75 feet (22 860 mm) from openings required by Section 903.2.11.1, or where walls, partitions or other obstructions are installed that restrict the application of water from hose streams, the *basement* shall be equipped throughout with an *approved automatic sprinkler system*.

- ❖ The 75-foot (22 860 mm) distance is intended to be measured in the line of travel—not in a straight line perpendicular to the wall. Where obstructions, such as walls or other partitions, are present in a basement, the walls and partitions enclosing any room or space must have openings that provide an equivalent degree of fire department access to that provided by the openings prescribed in Section 903.2.11.1 for exterior walls. When obstructions, such as walls or partitions are installed in the basement, the ability to apply hose streams through these openings and reach the basement area is reduced or eliminated. The configuration and clear-opening requirements become useless when an interior wall or other obstruction is placed inside the basement. In that case, it is reasonable to require automatic fire sprinklers to provide adequate protection in the basement. If an equivalent degree of fire department access to all portions of the floor area is not provided, the basement would require an automatic sprinkler system.

**903.2.11.2 Rubbish and linen chutes.** An *automatic sprinkler system* shall be installed at the top of rubbish and linen chutes and in their terminal rooms. Chutes shall have additional sprinkler heads installed at alternate floors and at the lowest intake. Where a rubbish chute extends through a building more than one floor below the lowest intake, the extension shall have sprinklers installed that are recessed from the drop area of the chute and protected from freezing in accordance with Section 903.3.1.1. Such sprinklers shall be installed at alternate floors beginning with the second level below the last intake and ending with the floor above the discharge. Chute sprinklers shall be accessible for servicing.

❖ Gravity rubbish (waste) and linen chutes can present a significant hazard to building occupants if they are not properly installed and protected. Generally, these systems are installed in high-occupancy buildings where the occupants will be sleeping or are incapable of self-rescue such as in Group I, R-1 and R-2 occupancies. Secondly, for occupant convenience, openings to the chutes are commonly provided in areas accessible to the public and, in older buildings, the chute opening may be located in an exit access corridor. In comparison to other building shafts, gravity rubbish and linen chutes always contain fuel. As bags of waste debris or linen fall through the chute, they can deposit fluids such as waste cooking oil which adheres to the shaft surface. This waste material and other debris provide fuel that can support and accelerate vertical fire spread. The greatest accumulation of fuel will be in the termination room; however, a significant amount of fuel that covers the interior surface area of the chute will be found in the sections of chutes closest to the collection or termination room. Therefore, it is important that the automatic sprinklers be properly placed and protected so they are available in the event of a fire in the termination room and to protect waste compaction equipment where such equipment is installed.

Installation of gravity chutes for rubbish or linen requires compliance with the IBC, Chapter 6 of NFPA 82 and the code. Under the IBC and NFPA 82, Chapter 6, permanent rubbish and linen chutes are constructed inside of a fire-resistance-rated shaft assembly with a minimum 1-hour fire-resistance rating in buildings less than four stories in height; in buildings four or more stories in height, the fire-resistance rating is increased to 2 hours by Section 713.4 of the IBC. The design of the shaft system and its openings must also comply with the requirements in Sections 713.11 and 713.13 of the IBC, which requires the termination room receiving the discharged material to be separated from the building by a fire-resistance rating equivalent to that of the shaft that it serves.

Section 713.13.6 of the IBC requires the installation of an automatic sprinkler system in rubbish and linen chutes to comply with the requirements of Section 903.2.11.2. Section 903.2.11.2 correlates with the requirements in Chapter 21 of NFPA 13. Chapter 22 of NFPA 13 contains the special occupancy requirements for all buildings, including gravity waste and linen

chutes. The provisions align the IBC and the code requirements with those in NFPA 82 and NFPA 13.

A critical term in this section is “extension.” The word was selected to address chutes installed in buildings of pedestal construction or other designs in which the fire-resistant construction shaft and chute pass through a less hazardous occupancy, such as a Group S-2 parking garage, or other floors that do not have access to the shaft. In these areas, chute openings are generally not provided. As a result, this section now contains a specific provision that may impose a requirement for sprinklers in the portion of the chute that serves as an extension beyond the last intake and the termination room or discharge area.

Because objects will be falling through the chute, the code requires the chute sprinklers to be recessed and protected from impact. Sprinklers are not required at every story housing a chute. The code requires automatic sprinklers at the top of the chute and at its termination. In addition, sprinkler heads are required at alternate floors within the chute with a head being installed at the floor level with the lowest intake point into the chute. Previously, these additional sprinkler heads were only required where the shaft extended through three or more floors. These revisions, plus the previously discussed requirements for extensions, may result in additional sprinkler heads within some shafts as compared to the previous requirements.

Sprinklers in chutes that are in locations subject to freezing require freeze protection in accordance with the requirements of Section 903.3.1.1 and, therefore, the NFPA 13 standard. This can be accomplished using a dry-pendant sprinkler or constructing a dry-pipe sprinkler system.

**903.2.11.3 Buildings 55 feet or more in height.** An *automatic sprinkler system* shall be installed throughout buildings that have one or more stories with an *occupant load* of 30 or more located 55 feet (16 764 mm) or more above the lowest level of fire department vehicle access, measured to the finished floor.

**Exceptions:**

1. Open parking structures.
2. Occupancies in Group F-2.

❖ Because of the difficulties associated with manual suppression of a fire in mid-rise buildings in excess of 55 feet (16 764 mm) above the lowest level of fire department vehicle access, an automatic sprinkler system is required throughout the building regardless of occupancy. Buildings that qualify for a sprinkler system under this section are not necessarily high-rise buildings as defined in Section 202 and are focused also on those with occupants located on the upper floors. These provisions apply only to buildings with occupied floors with an occupant load of 30 or more located on stories 55 feet (16 764 mm) or greater from fire department vehicle access. The 55 feet (16 764 mm) is measured to the finished floor (see Commentary Figure 903.2.11.3).

The listed exceptions are occupancies that, based on height only, do not require an automatic sprinkler system. Open parking structures are also exempt from the high-rise provisions of Section 403 of the IBC. Although an automatic sprinkler system is not required in open parking structures, a sprinkler system may still be needed, depending on the building construction type and the area and number of parking tiers (see Table 406.3.5 of the IBC).

**903.2.11.4 Ducts conveying hazardous exhausts.** Where required by the *International Mechanical Code*, automatic sprinklers shall be provided in ducts conveying hazardous exhaust or flammable or combustible materials.

**Exception:** Ducts where the largest cross-sectional diameter of the duct is less than 10 inches (254 mm).

❖ Section 510 of the IMC addresses the requirements for hazardous exhaust systems. To protect against the spread of fire within a hazardous exhaust system and to prevent a duct fire from involving the building, an automatic sprinkler system must be installed to protect the exhaust duct system. Where materials conveyed in the ducts are not compatible with water, alternative extinguishing agents should be used. The fire suppression requirement is intended to apply to exhaust systems having an actual fire hazard. An automatic sprinkler system in the duct would be of little value for an exhaust system that conveys only nonflammable or noncombustible materials, fumes, vapors or gases.

The exception recognizes the reduced hazard associated with smaller ducts and the impracticality of installing sprinkler protection. Another exception in the IMC indicates that laboratory hoods that meet specific provisions of the IMC are not required to be suppressed. Because the IMC is more specific in this

regard, it should be consulted for the proper application of the exception.

**903.2.11.5 Commercial cooking operations.** An *automatic sprinkler system* shall be installed in commercial kitchen exhaust hood and duct systems where an *automatic sprinkler system* is used to comply with Section 904.

❖ An automatic suppression system is required for commercial kitchen exhaust hood and duct systems where required by Section 609 or by the IMC to have a Type I hood. Type I hoods are required for commercial cooking equipment that produces grease-laden vapors or smoke. Section 904.12 recognizes that alternative extinguishing systems other than an automatic sprinkler system may be used. Where an automatic sprinkler system is used for commercial cooking operations, it must comply with the requirements identified in Section 904.11.4.

**903.2.11.6 Other required suppression systems.** In addition to the requirements of Section 903.2, the provisions indicated in Table 903.2.11.6 require the installation of a fire suppression system for certain buildings and areas.

❖ In addition to Section 903.2, requirements for automatic fire suppression systems are also found elsewhere in the code as indicated in Table 903.2.11.6.

**TABLE 903.2.11.6.** See page 9-26.

❖ Table 903.2.11.6 identifies other sections of the code that require an automatic fire suppression system based on the specific occupancy or use because of the unique hazards of such use or occupancy. The table does not identify the various sections of the code that contain design alternatives based on the use of an automatic fire suppression system, typically an automatic sprinkler system.

For SI: 1 foot = 304.8 mm.

6504.2	Pyroxylin plastic storage and manufacturing

For SI: 1 cubic foot = 0.023 m<sup>3</sup>.

**903.2.12 During construction.** *Automatic sprinkler systems* required during construction, *alteration* and demolition operations shall be provided in accordance with Section 3313.

❖ Chapter 14 of the code and Chapter 33 of the IBC address fire safety requirements during construction, alteration or demolition work. Working sprinkler systems should remain operative at all times unless it is absolutely necessary to shut down the system because of the proposed work. All sprinkler system impairments should be rectified as quickly as possible unless specific prior approval has been obtained from the fire code official. Buildings with a required sprinkler system should not be occupied unless the sprinkler system has been installed and tested consistent with Section 901.5.1. If the system must be placed out of service, the requirements of Section 901.7 are necessary to address the temporary impairment to the fire protection system.

**903.3 Installation requirements.** *Automatic sprinkler systems* shall be designed and installed in accordance with Sections 903.3.1 through 903.3.8.

❖ Specific design, installation and testing criteria are given for automatic sprinkler systems in the sections and subsections that follow, as well as an indication of the applicability of a nationally recognized standard in the area. The information required to complete a thorough review of an automatic sprinkler system is listed in Commentary Figure 903.3.

**1. Information required on shop drawings includes:**

- Name of owner and occupant
- Location, including street address
- Point of compass
- Graphic indication of scale
- Ceiling construction
- Full-height cross section
- Location of fire walls
- Location of partitions
- Occupancy of each area or room
- Location and size of blind spaces and closets
- Any questionable small enclosures in which no sprinklers are to be installed
- Size of city main in street, pressure and whether dead end or circulation and, if dead end, direction and distance to nearest circulating main, city main test results
- Other source of water supply, with pressure or elevation
- Make, type and orifice size of sprinkler
- Temperature rating and location of high-temperature sprinklers
- Limitations on extended coverage sprinklers or other special sprinkler types
- Number of sprinklers on each riser and on each system by floors and total area by each system on each floor
- Make, type, model and size of alarm or dry pipe valve
- Make, type, model and size of preaction or deluge valve
- Type and location of alarm bells
- Backflow prevention method and details
- Total number of sprinklers on each dry pipe system or preaction deluge system
- Approximate capacity in gallons or each dry pipe system
- Setting for pressure-reducing valves
- Pipe size, type, and schedule of wall thickness
- Cutting lengths of pipe (or center-to-center dimensions)
- Type of fittings, riser nipples and size, and all welds and bends
- Type and location of hangers, inserts and sleeves
- Calculations of loads and details for sway bracing
- All control valves, checks, drain pipes, flushing, and test pipes
- Size and location of standpipe risers and hose outlets
- Small hand-hose equipment
- Underground pipe size, length, location, weight, material, point of connection to city main; the type of valves, meters and valve pits; and the depth that top of the pipe is laid below grade
- Size and location of hydrants along with hose-houses
- Size and location of fire department connections
- When the equipment is to be installed as an addition to an old group of sprinklers without additional feed from the yard system, enough of the old system shall be indicated on the plans to show the total number of sprinklers to be supplied and to make all connections clear
- Information to be provided on the hydraulic nameplate
- Name, address and phone number of contractor and sprinkler designer
- Hydraulic reference points shall be shown by a number and/or letter designation and shall correspond with comparable reference points shown on the hydraulic calculation sheets
- System design criteria showing the minimum rate of water application (density), the design area of water application and the water required for hose streams both inside and outside
- Actual calculated requirements showing the total quantity of water and the pressure required at a common reference point for each system
- Elevation data showing elevations of sprinklers, junction points and supply or reference points
- Protected wall openings if room design method is used

**2. Information required on calculations includes:**

- Location
  - Name of owner and occupant
  - Building identification
  - Description of hazard
  - Name and address of contractor and designer
  - Name of approving agency
- 3. System design requirements include:**
- Design area of water application
  - Minimum rate of water application (density)
  - Area of sprinkler coverage
  - Hazard or commodity classification
  - Building height
  - Storage height
  - Storage method
  - Total water requirements, as calculated, including allowance for hose demand water supply information and allowance for in-rack sprinklers
  - Location and elevation static and residual test gauge with relation to the riser reference point
  - Size and location of hydrants used for flow test data
  - Flow location
  - Static pressure, psi
  - Residual pressure, psi
  - Flow, gpm
  - Date
  - Time
  - Test conducted by whom
  - Sketch to accompany gridded system calculations to indicate flow quantities and directions for lines with sprinklers operated in the remote area

**4. Additional information necessary for complete review includes:**

- Sprinkler description and discharge constant (K-value)
- Hydraulic reference points
- Flow, gpm
- Pipe diameter (actual internal diameter)
- Pipe length
- Equivalent pipe length for fittings and components
- Friction loss in psi per foot of pipe
- Total friction loss between reference points
- Elevation difference between reference points
- Required pressure in psi at each reference point
- Velocity pressures and normal pressure if included in calculations
- Notes to indicate starting points, reference to other sheets or clarification of data
- Information on antifreeze solution (type and quantity)
- Water treatment system information including reason for treatment and program details

**5. Included with the submittal must be a graph sheet showing water supply curves and system requirements including:**

- Hose demand plotted on semilogarithmic graph paper so as to present a graphic summary of the complete hydraulic calculations
- Sprinkler system demand including in-rack sprinklers (if applicable)

**Figure 903.3**  
**SAMPLE SPRINKLER SYSTEM DRAWING AND DATA SUBMITTALS**

**903.3.1 Standards.** Sprinkler systems shall be designed and installed in accordance with Section 903.3.1.1, unless otherwise permitted by Sections 903.3.1.2 and 903.3.1.3 and other chapters of this code, as applicable.

❖ Automatic sprinkler systems are to be installed to comply with the code and NFPA 13, 13R or 13D. As provided for in Section 102.7.1, where differences occur between the code and NFPA 13, 13R or 13D, the code applies. The fire code official also has the authority to approve the type of sprinkler system to be installed. See Commentary Figure 903.3.1 for typical design parameters for each type of sprinkler system.

This section also provides a pointer to other sections of the code that might provide more specific or detailed sprinkler requirements such as those found in Chapters 23 and 24 of the code.

**903.3.1.1 NFPA 13 sprinkler systems.** Where the provisions of this code require that a building or portion thereof be equipped throughout with an *automatic sprinkler system* in accordance with this section, sprinklers shall be installed throughout in accordance with NFPA 13 except as provided in Sections 903.3.1.1.1 and 903.3.1.1.2.

❖ NFPA 13 contains the minimum requirements for the design and installation of automatic water sprinkler systems and exposure protection sprinkler systems. The requirements contained in the standard include the character and adequacy of the water supply and the selection of sprinklers, piping, valves and all of the materials and accessories. The standard does not include detailed requirements for installation of private fire service mains and their appurtenances; installation of fire pumps or construction and installation of gravity and pressure tanks and towers.

NFPA 13 defines seven classifications or types of water sprinkler systems: wet pipe (see Commentary Figure 903.3.1.1); dry pipe; preaction or deluge; combined dry pipe and preaction; antifreeze systems; sprinkler systems that are designed for a special purpose and outside sprinklers for exposure protection. While numerous variables must be considered in selecting the proper type of sprinkler system, the wet-pipe sprinkler system is recognized as the most effective and efficient. The wet-pipe system is also the

most reliable type of sprinkler system, because water under pressure is available at the sprinkler. Therefore, wet-pipe sprinkler systems are recommended wherever possible.

The extent of coverage and distribution of sprinklers is based on the NFPA 13 standard. Numerous conditions exist in the standard where sprinklers are specifically required and also where they may or may not be located. Once it is determined that the sprinkler system is to be in accordance with NFPA 13, that standard must be reviewed for installation details. For example, exterior spaces such as combustible canopies are required to be equipped with sprinklers according to Section 8.15.7 of NFPA 13 where the canopy extends for a distance of 4 feet (1219 mm) or more. A 3-foot (914 mm) combustible canopy would not require sprinklers nor would a 6-foot (1829 mm) canopy constructed of noncombustible materials, provided there is no combustible storage under the canopy.

Because installation is required to be in accordance with NFPA 13, if the standard allows for the omission of sprinklers in any location, then the building is still considered as being sprinklered throughout. For example, Section 8.15.8.1.1 of NFPA 13 allows sprinklers to be omitted from bathrooms in dwelling units in hotels and motels. If sprinklers are not provided in the bathrooms due to the conditions stipulated in NFPA 13, the building would still be considered as sprinklered throughout in accordance with the code, NFPA 13 and the IBC.

Exceptions for the use of NFPA 13R and 13D systems are addressed throughout the code when exceptions based upon the use of sprinklers are provided. More specifically, if the use of these other standards is appropriate, it will be noted within the exception. For a building to be considered “equipped throughout” with an NFPA 13 sprinkler system, complete protection must be provided in accordance with the referenced standard, subject to the exempt locations indicated in Section 903.3.1.1.1. See Commentary Figure 904.2.1 for examples of requirements modified through the use of sprinkler systems.

	NFPA 13	NFPA 13R	NFPA 13D
Extent of protection	Equip throughout (Section 903.3.1.1)	Occupied spaces (Section 903.3.1.2)	Occupied spaces (Section 903.3.1.3)
Scope	All occupancies	Low-rise residential	One- and two-family dwellings
Sprinkler design	Density/area concept	4-head design	2-head design
Sprinklers	All types	Residential only	Residential only
Duration	30 minutes (minimum)	30 minutes	10 minutes
Advantages	Property and life protection	Life safety/tenability	Life safety/tenability

**Figure 903.3.1**  
**NFPA 13, NFPA 13R, NFPA 13D SYSTEMS**

**903.3.1.1.1 Exempt locations.** Automatic sprinklers shall not be required in the following rooms or areas where such rooms or areas are protected with an *approved* automatic fire detection system in accordance with Section 907.2 that will respond to visible or invisible particles of combustion. Sprinklers shall not be omitted from a room merely because it is damp, of fire-resistance-rated construction or contains electrical equipment.

1. A room where the application of water, or flame and water, constitutes a serious life or fire hazard.
2. A room or space where sprinklers are considered undesirable because of the nature of the contents, where *approved* by the *fire code official*.
3. Generator and transformer rooms separated from the remainder of the building by walls and floor/ceiling or roof/ceiling assemblies having a *fire-resistance rating* of not less than 2 hours.
4. Rooms or areas that are of noncombustible construction with wholly noncombustible contents.
5. Fire service access elevator machine rooms and machinery spaces.
6. Machine rooms, machinery spaces, control rooms and control spaces associated with occupant evacuation elevators designed in accordance with Section 3008 of the *International Building Code*.

❖ This section allows the omission of sprinkler protection in certain locations if an approved automatic fire detection system is installed. Buildings in compliance with one of the five listed conditions would still be considered fully sprinklered throughout in compliance with the code and NFPA 13 and thus would be eligible for all applicable code alternatives, exceptions or reductions. Elimination of the sprinkler system in a sensitive area is subject to the approval of the fire code official.

Condition 1 addresses restrictions where the application of water could create a hazardous condition. For example, sprinkler protection is to be avoided where it is not compatible with certain stored materials (i.e., some water-reactive hazardous materials such as calcium carbide). Combustible metals, such as magnesium and aluminum, may burn so intensely that the use of water to attempt fire control will only intensify the reaction.

It is not the intent of Condition 2 to omit sprinklers solely because of a potential for water damage. A desire to not sprinkler a certain area (such as a computer room or operating room) does not fall within the limitations of the exception unless there is something unique about the space that would result in water being incompatible. A computer room can be adequately protected using an automatic sprinkler system or an alternative gaseous suppression agent system or a combination of these systems. The intent of Condition 2 is to consider whether or not the contents would react adversely to the application of water. It is important to note that the fire code official

must approve the use of this item. Note also that with respect to computer rooms, NFPA 75—*Protection of Information Technology Equipment* (not a referenced standard), recognizes automatic sprinklers as the primary fire protection of computer rooms.

Condition 3 recognizes the low fuel load and low occupancy hazards associated with generator and transformer rooms and, therefore, allows the omission of sprinkler protection if the rooms are separated from adjacent areas by 2-hour fire-resistance-rated construction. This condition assumes the room is not used for any combustible storage. This condition is similar to Section 8.15.11.3 of NFPA 13, which exempts electrical equipment rooms from sprinkler protection, provided the room is dedicated to the use of dry-type electrical equipment, is constructed as a 2-hour fire-resistance-rated enclosure and is not used for combustible storage.

Condition 4 requires the construction of the room or area, as well as the contents, to be noncombustible. An example would be an area in an unprotected steel frame building (Type IIB construction) used for steel or concrete block storage. Neither involves any significant combustible packaging or sources of ignition, and few combustibles are present (see Commentary Figure 903.3.1).

Condition 5 addresses the concern for elevator machine rooms and machinery spaces associated with fire service access elevators as required for buildings with occupied floors greater than 120 feet (36.58 m) from the lowest level of fire department access by Sections 403.6.1 and 3007 of the IBC. These elevators need to work during fire situations and their operation cannot be threatened by the activation of a sprinkler in a machine room or space that may affect the operation of the elevator. Fire service access elevators are required to be continuously monitored at the fire command center in accordance with Section 3007.7 of the IBC.

Condition 6, similar to Condition 5, exempts sprinklers from the machine rooms and machinery spaces, control rooms and control spaces for occupant evacuation elevators. Like fire service access elevators, these elevators need to work during fire situations and their operation cannot be threatened by the activation of a sprinkler in a machine room or machinery spaces. Such elevators are required to be monitored at the fire command center in accordance with Section 3008.7 of the IBC.

**903.3.1.1.2 Bathrooms.** In Group R occupancies, other than Group R-4 occupancies, sprinklers shall not be required in bathrooms that do not exceed 55 square feet (5 m<sup>2</sup>) in area and are located within individual *dwelling units* or *sleeping units*, provided that walls and ceilings, including the walls and ceilings behind a shower enclosure or tub, are of noncombustible or limited-combustible materials with a 15-minute thermal barrier rating.

❖ This provision was added to the code to reinstate an exception of NFPA 13 that had been in existence

since 1976 but deleted for all but dwelling units in motels and hotels (NFPA Section 8.15.8.1.1) from the 2013 edition of NFPA 13.

Although reinstating the small bathroom exception will have a limited impact on new construction because many modern bathrooms exceed the 55-square-foot area limit in the exception to accommodate wheelchair access, the more important consequence will be removing an unnecessary cost increase for building owners who choose to retrofit existing properties with small bathrooms that were built before it was common to provide wheelchair access. Codes and standards should not erect any unnecessary barriers to retrofitting sprinklers into existing properties, such as existing high-rise buildings.

In the 1976 edition of the Life Safety Code (NFPA 101), to encourage cost-effective fire protection systems for apartment buildings, Section 11-3.8.3.4.1 provided an exception to permit bathrooms that did not exceed 55-square-foot within individual dwelling units to omit sprinklers when the apartment building was sprinklered in accordance with NFPA 13. The basis of the 55-square-foot area is that this area accommodates a “typical” small bathroom that contains a standard tub, a toilet and a sink and nothing more. This exception was later duplicated from NFPA 101 into the 1991 edition of NFPA 13 with the understanding that the next edition of NFPA 101 (1994) could delete the exception, since NFPA 13 would have it covered. NFPA 101-1994 then, as planned, deleted the exception.

The history of apartment unit bathroom fires is statistically minimal. According to the recent NFPA *Home Structure Fire Report*, January 2009, Table 9B, “Reported Apartment Structure Fires by Area of Origin 2003-2006 Annual Averages”, out of 113,000 fires/year, only 1600 (1 percent) are in bathrooms. Given that there are more than 35 years of experience with the bathroom sprinkler exception being in place (since it was put into NFPA 101 in 1976), it would certainly be reasonable to expect anecdotal or statistical experience to indicate the existence of a problem, if there were one.

**903.3.1.2 NFPA 13R sprinkler systems.** *Automatic sprinkler systems* in Group R occupancies up to and including four stories in height in buildings not exceeding 60 feet (18 288 mm) in height above grade plane shall be permitted to be installed throughout in accordance with NFPA 13R.

The number of stories of Group R occupancies constructed in accordance with Sections 510.2 and 510.4 of the *International Building Code* shall be measured from the horizontal assembly creating separate buildings.

❖ NFPA 13R contains design and installation requirements for a sprinkler system to aid in the detection and control of fires in low-rise (four stories or less) residential occupancies.

Sprinkler systems designed in accordance with NFPA 13R are intended to prevent flashover (total

involvement) in the room of fire origin and to improve the chance for occupants to escape or be evacuated. The design criteria in NFPA 13R are similar to those in NFPA 13 except that sprinklers may be omitted from areas in which fatal fires in residential occupancies do not typically originate (bathrooms, closets, attics, porches, garages and concealed spaces).

A common question is whether a mixed occupancy building which contains a Group R occupancy could still use NFPA 13R for the design. If one of the mixed-use occupancies would require a sprinkler system throughout the building in accordance with NFPA 13, then a 13R system would not be allowed. If, however, the only reason a sprinkler system is being installed is because there is a Group R fire area, then a NFPA 13R system would be an appropriate design choice. The areas that are not classified as Group R would require protection in accordance with NFPA 13.

It must be noted that although the building would be considered sprinklered throughout in accordance with NFPA 13R, not all of the code sprinkler alternatives could be applied. Any alternative that requires the installation of an NFPA 13 system would not be applicable if a portion of the building utilizes an NFPA 13R system.

The code provisions that allow for an increase in building height according to Section 504.3 of the IBC do not compound this section. NFPA 13R is applicable to buildings that are up to four stories in height and 60 feet in height above grade plane. If the design of a residential building intends to take advantage of the sprinkler height increase so that the building is five stories or more, the sprinkler system must be an NFPA 13 system. Because this section limits the height to four stories, four stories is the maximum height for a building that can utilize an NFPA 13R system. This is consistent with the scoping provisions in the NFPA 13R standard.

The limitation of four stories in height is to be measured with respect to the established grade plane, which is consistent with IFC Interpretation No. 43-03. As such, a basement would not be considered a story above grade for purposes of determining the applicability of this section.

The second paragraph recognizes the application of the requirements of Sections 510.2 and 510.4 of the IBC which are essentially exceptions to the height and area requirements. This exception is based on providing a horizontal fire separation similar to the concept of a fire wall to create separate buildings. This establishes that the height in stories can be measured from the horizontal assembly instead of from grade plane. The height in feet would still be limited to being measured from grade plane. Such buildings are often referred to as “pedestal buildings.”

**903.3.1.2.1 Balconies and decks.** Sprinkler protection shall be provided for exterior balconies, decks and ground floor patios of *dwelling units* and *sleeping units* where the building is of Type V construction, provided there is a roof or deck above. Sidewall sprinklers that are used to protect such areas

shall be permitted to be located such that their deflectors are within 1 inch (25 mm) to 6 inches (152 mm) below the structural members and a maximum distance of 14 inches (356 mm) below the deck of the exterior balconies and decks that are constructed of open wood joist construction.

❖ Balconies, decks and patios in buildings of Type V construction and used for Group R occupancies are required to have sprinkler protection when there is a roof or deck above. This is in addition to the requirements of NFPA 13R, which primarily addresses the life safety of occupants and not property protection. The intent is to address hazards such as grilling and similar activities. Since NFPA 13R does not require such coverage, there is potential that a fire on a balcony could grow much too large for the system within the building to handle. The concern is that a potential exterior balcony fire could spread to unprotected floor/ceiling assemblies and attic spaces and result in major property damage. Section 308.1.4 specifically addresses restrictions on open flame cooking devices used on combustible balconies.

Regardless of whether the exterior walking surface is attached to the building and called a balcony or is a freestanding structure such as a deck or patio the concern for fire ignition in the area adjacent to the exterior wall is the same. Sidewall sprinklers should be selected based on the area of coverage and climate. If the potential for freezing exists, a dry sidewall sprinkler should be used. Where the overhanging deck or balcony is extensive, an extended coverage sprinkler should be selected.

**903.3.1.2.2 Open-ended corridors.** Sprinkler protection shall be provided in *open-ended corridors* and associated *exterior stairways* and *ramps* as specified in Section 1027.6, Exception 3.

❖ This section is simply emphasizing the fact that, since there is no separation from the exterior exit stairways, sprinklers would be required when using an NFPA 13R system. Section 1027.6, Exception 3 allows the separation between the open-ended corridor and exterior exit stairway to be omitted, but only where several conditions are met. The primary condition is that the corridor be sprinklered. A definition of “Open-ended corridor” is provided in Chapter 2. See Commentary Figure 903.3.1.2.2 for an example of an open-ended corridor.

**903.3.1.3 NFPA 13D sprinkler systems.** *Automatic sprinkler systems* installed in one- and two-family dwellings; Group R-3; Group R-4 Condition 1 and townhouses shall be permitted to be installed throughout in accordance with NFPA 13D.

❖ NFPA 13D contains design and installation requirements for a sprinkler system to aid in the detection and control of fires in one- and two-family dwellings, mobile homes and townhouses. This section also specifically allows the use of an NFPA 13D system for occupancies classified as Group R-3 and Group R-4 Condition 1. Group R-3 are one- and two-family

dwellings that fall outside the scope of the IRC and also those buildings housing small congregate living facilities and boarding houses. These facilities operate very similar to a single-family home and the level of the ability of the occupants is such that little assistance is needed for self-evacuation. This is consistent with the NFPA 13D requirements and is also consistent with FHA court cases based on nondiscrimination for group homes.

Similar to NFPA 13R, sprinkler systems designed in accordance with NFPA 13D are intended to prevent flashover (total involvement) in the room of fire origin and to improve the chance for occupants to escape or be evacuated. Although the allowable omission of sprinklers in certain areas of the dwelling unit in NFPA 13D is similar to that in NFPA 13R, the water supply requirements are less restrictive. NFPA 13D uses a two-head sprinkler design with a 10-minute duration requirement, while NFPA 13R uses a four-head sprinkler design with a 30-minute duration requirement. The decreased water supply requirement emphasizes the main intent of NFPA 13D to control the fire and maintain tenability during evacuation of the residence.

**903.3.2 Quick-response and residential sprinklers.** Where *automatic sprinkler systems* are required by this code, quick-response or residential automatic sprinklers shall be installed

**Figure 903.3.1.2.2  
OPEN-ENDED CORRIDOR**

in all of the following areas in accordance with Section 903.3.1 and their listings:

1. Throughout all spaces within a smoke compartment containing care recipient *sleeping units* in Group I-2 in accordance with the *International Building Code*.
  2. Throughout all spaces within a smoke compartment containing treatment rooms in ambulatory care facilities.
  3. *Dwelling units* and *sleeping units* in Group I-1 and R occupancies.
  4. Light-hazard occupancies as defined in NFPA 13.
- ❖ Quick-response and residential sprinklers are similar in nature. They use a lighter material for the operating mechanism, thus reducing the heat lag in the element. The faster the heat can be absorbed, the sooner the sprinkler will begin to discharge water. Quick-response sprinklers have shown that they operate up to 25 percent faster than traditional sprinklers and create conditions in the room of origin that significantly increase the tenability of the environment. In tests performed by Factory Mutual (FM) for the Federal Emergency Management Agency (FEMA), the gas temperature in the room of origin was 550°F (288°C) with quick-response sprinklers, while it was 1,470°F (799°C) for conventional sprinklers at the time of sprinkler activation. More importantly, while the carbon monoxide (CO) level was 1,860 ppm for conventional sprinklers, the CO level when tested with quick-response sprinklers was only around 350 ppm. Comparatively, the National Institute of Occupational Safety and Health (NIOSH) considers the IDLH (immediately dangerous to life and health) level of CO to be 1,200 ppm. Thus, quick-response sprinklers have been shown to add significantly to the life safety effects of standard sprinkler systems.

Condition 1 requires the use of approved quick-response or residential sprinklers in smoke compartments containing care recipient sleeping units in Group I-2 occupancies. Even though properly operating standard sprinklers are effective, the extent of fire growth and smoke production that can occur before sprinkler activation creates the need for early warning to enable faster response by care providers and initiation of egress that is critical in occupancies containing persons incapable of self-preservation. The faster response time associated with quick-response or residential sprinklers increases the probability that the sprinklers will actuate before the care recipient's life would be threatened by a fire in his or her room.

Condition 2 requires the use of approved quick-response or residential sprinklers in smoke compartments containing treatment rooms in ambulatory care facilities. The justification is the same as that for Condition 1. When there is a potential for care recipients to be incapable of self-preservation, the use of residential sprinkler or quick-response sprinklers are critical.

Because of the kind of occupants sleeping in Group

R and I-1 occupancies, as indicated in Condition 3, a faster responding type of sprinkler is desirable. Similar to the first condition, because occupants will be sleeping, the use of quick-response sprinklers creates additional safety by reducing sprinkler response time, thereby increasing the time available for egress and allowing for the time necessary for occupants to wake up and recognize the emergency event.

Condition 4 recognizes light-hazard occupancies in accordance with NFPA 13. These could include restaurants, schools, office buildings, places of religious worship and similar occupancies where the fire load and potential heat release of combustible contents are low.

**903.3.3 Obstructed locations.** Automatic sprinklers shall be installed with due regard to obstructions that will delay activation or obstruct the water distribution pattern. Automatic sprinklers shall be installed in or under covered kiosks, displays, booths, concession stands or equipment that exceeds 4 feet (1219 mm) in width. Not less than a 3-foot (914 mm) clearance shall be maintained between automatic sprinklers and the top of piles of *combustible fibers*.

**Exception:** Kitchen equipment under exhaust hoods protected with a fire-extinguishing system in accordance with Section 904.

❖ To provide adequate sprinkler coverage, sprinkler protection must be extended under any obstruction that exceeds 4 feet (1219 mm) in width. Large air ducts are another common obstruction where sprinklers are routinely extended beneath the duct. The 3-foot (914 mm) storage clearance requirement for combustible fibers is caused by their potential high heat release. Most storage conditions require only a minimum 18-inch (457 mm) storage clearance to combustibles, depending on the type of sprinklers used and their actual storage conditions.

The exception recognizes that an alternative extinguishing system is permitted for commercial cooking systems in place of sprinkler protection for exhaust hoods that may be more than 4 feet (1219 mm) wide.

The application of this section is more critical to the ongoing use of the space. The obstruction conditions, therefore, should have already been addressed during plan review and installation inspection. This section gives the fire official and building owner adequate information to avoid the most typical obstruction-related issues in terms of proper sprinkler coverage.

**903.3.4 Actuation.** *Automatic sprinkler systems* shall be automatically actuated unless specifically provided for in this code.

❖ The intent of this section is to eliminate the need for occupant intervention during a fire. As such, it is assumed that it will not be necessary for a person to manually open a valve or perform some other physical activity in order to allow the sprinkler system to activate.

Wet-pipe and dry-pipe sprinkler systems, for exam-

ple, are essentially fail-safe systems in the sense that, if the system is in proper operating condition, it will operate once a sprinkler fuses. Dry systems have an inherent time lag for water to reach the sprinkler; therefore, the response is not as fast as for a wet-pipe system. Other types of sprinkler systems, such as preaction and deluge, rely on the actuation of a detection system to operate the sprinkler valve.

**903.3.5 Water supplies.** Water supplies for *automatic sprinkler systems* shall comply with this section and the standards referenced in Section 903.3.1. The potable water supply shall be protected against backflow in accordance with the requirements of this section and the *International Plumbing Code*. For connections to public waterworks systems, the water supply test used for design of fire protection systems shall be adjusted to account for seasonal and daily pressure fluctuations based on information from the water supply authority and as approved by the *fire code official*.

❖ To be effective, all sprinkler systems must have an adequate supply of water. The criteria for an acceptable water supply are contained in the standards referenced in Section 903.3.1. For example, NFPA 13 contains criteria for different types of water supplies as well as the methods to determine the pressure, flow capabilities and capacity necessary to get the intended performance from a sprinkler system. An acceptable water supply could consist of a reliable municipal supply, a gravity tank or a fire pump with a pressure tank or a combination of these.

This section also establishes the requirements for protecting the potable water system against a nonpotable source, such as stagnant water retained within the sprinkler piping. As stated in Section 608.16.4 of the IPC, an approved double check valve device or reduced pressure principle backflow preventer is required.

The other issue addressed by this section is fluctuations in water pressure. Information on pressure fluctuation is necessary to not only ensure that the minimum required pressure will be available for the automatic sprinkler system, but also to ensure that high pressures do not exceed the limitations of the sprinkler system. If the water pressure on a sprinkler system exceeds 100 psi, changes in the hanging methods are required. Also, if a fire pump is provided, it might be possible to exceed 175 psi, which is typically considered the maximum working pressure for a sprinkler system. These are just additional reasons why it is critical to account for pressure fluctuations in the water supply. Obviously, fire flows can be affected by this, as well as other water-based fire protection systems, such as standpipes, which require a minimum 100 psi at the roof of high-rise buildings and such may not be available due to pressure fluctuations. With regards to gathering of data, this requirement is simply intended to make sure that pressure fluctuations are addressed in accordance with the water supply authority to the extent that such informa-

tion is available. Further authority is provided to the fire code official to accept other documentation.

**903.3.5.1 Domestic services.** Where the domestic service provides the water supply for the *automatic sprinkler system*, the supply shall be in accordance with this section.

❖ This section establishes the scope of domestic services for residential combination services. Essentially, compliance with Section 903.3.5 is required.

**903.3.5.2 Residential combination services.** A single combination water supply shall be allowed provided that the domestic demand is added to the sprinkler demand as required by NFPA 13R.

❖ NFPA 13R permits a common supply main to a building to serve both the sprinkler system and domestic services if the domestic demand is added to the sprinkler demand. NFPA 13R systems do not provide the same level of property protection as NFPA 13 systems.

**903.3.6 Hose threads.** Fire hose threads and fittings used in connection with *automatic sprinkler systems* shall be as prescribed by the *fire code official*.

❖ The threads on connections and fittings that the fire department will use to connect a hose must be compatible with the fire department threads.

Design documents must specify the type of thread to be used in order to be compatible with the local fire department equipment after consultation and coordination with the fire code official. The criteria typically apply to fire department connections for sprinkler and standpipe systems, standpipe hose connections, yard hydrants and wall hydrants.

The majority of fire departments in the United States use the American National Fire Hose Connection Screw Thread also commonly known as the national standard thread (NST) and NS. NFPA 1963 gives the screw thread dimensions and the thread size of threaded connections, with nominal sizes ranging from  $\frac{3}{4}$  inch (19 mm) to 6 inches (152 mm) for the NS thread. Although efforts to standardize fire hose threads began after the Boston conflagration in 1872, there are still many different screw threads, some of which give the appearance of compatibility with the NH thread. While NFPA 1963 may be used as a guide, the code does not require that any particular standard be used. Rather, it is important that the fire code official be consulted for the appropriate thread selection. The intent is that the threads match those of the local department identically so that adapters are not required within the fire department's own district.

**903.3.7 Fire department connections.** Fire department connections for *automatic sprinkler systems* shall be installed in accordance with Section 912.

❖ Section 912, to which this section points, provides a comprehensive set of requirements for fire department connections (FDCs), reducing the opportunity

for any of its requirements to be overlooked. See the commentary to Section 912.

**903.3.8 Limited area sprinkler systems.** Limited area sprinkler systems shall be in accordance with the standards listed in Section 903.3.1 except as provided in Sections 903.3.8.1 through 903.3.8.5.

❖ The use of limited area sprinkler systems is restricted to cases in which the code requires a limited number of sprinklers to protect a specific hazard or area and not a complete automatic sprinkler system. For example, limited area sprinkler systems may be used to protect areas including, but not limited to, stages; storage and workshop areas; painting rooms; trash rooms and chutes; furnace rooms; kitchens and hazardous exhaust systems and incidental uses as regulated in Section 1105.3 of the code and Section 509 of the IBC.

**903.3.8.1 Number of sprinklers.** Limited area sprinkler systems shall not exceed six sprinklers in any single fire area.

❖ In the 2015 edition of the code, the number of sprinklers allowed on a limited area sprinkler system in a fire area has been reduced to only six. In previous editions, up to 19 sprinklers were allowed. This reduced number will limit the type of applications for such systems. In the past, 19 sprinklers may have been able to address an entire building, depending on the system design, more easily allowing the use of the domestic water supply.

**903.3.8.2 Occupancy hazard classification.** Only areas classified by NFPA 13 as Light Hazard or Ordinary Hazard Group 1 shall be permitted to be protected by limited area sprinkler systems.

❖ The use of limited area systems is restricted to only the two lowest hazard occupancy classifications in accordance with NFPA 13. Such systems are fairly limited and can only contain six sprinklers per fire area; because of this, the types of hazards should be limited.

**903.3.8.3 Piping arrangement.** Where a limited area sprinkler system is installed in a building with an automatic wet standpipe system, sprinklers shall be supplied by the standpipe system. Where a limited area sprinkler system is installed in a building without an automatic wet standpipe system, water shall be permitted to be supplied by the plumbing system provided that the plumbing system is capable of simultaneously supplying domestic and sprinkler demands.

❖ Two options are provided for how water to the limited area sprinkler system is to be supplied. If the building contains automatic wet standpipes, then the system must be supplied by the standpipe system. If there is no standpipe system available, connection to the domestic water supply is permitted. The water supply must be analyzed to determine if it is sufficient to supply simultaneously both domestic usage and the sprinkler system demand. This will mean looking at peak water use throughout the day. See Section 903.3.5 and the IPC.

**903.3.8.4 Supervision.** Control valves shall not be installed between the water supply and sprinklers unless the valves are of an *approved* indicating type that are supervised or secured in the open position.

❖ No shutoff valves are permitted in the sprinkler system piping unless the valves are specifically approved and are either supervised or secured in the open position. These restrictions increase the likelihood that the sprinkler system will be operational should a fire occur. Valve supervision or securing a valve in the open position are considered equally reliable by this section.

**903.3.8.5 Calculations.** Hydraulic calculations in accordance with NFPA 13 shall be provided to demonstrate that the available water flow and pressure are adequate to supply all sprinklers installed in any single *fire area* with discharge densities corresponding to the hazard classification.

❖ Hydraulic calculations are required to be in accordance with NFPA 13 to demonstrate that the water system is adequate to supply the sprinkler demand in any particular fire area.

**903.4 Sprinkler system supervision and alarms.** Valves controlling the water supply for *automatic sprinkler systems*, pumps, tanks, water levels and temperatures, critical air pressures and waterflow switches on all sprinkler systems shall be electrically supervised by a *listed* fire alarm control unit.

**Exceptions:**

1. *Automatic sprinkler systems* protecting one- and two-family *dwellings*.
  2. Limited area sprinkler systems in accordance with Section 903.3.8.
  3. *Automatic sprinkler systems* installed in accordance with NFPA 13R where a common supply main is used to supply both domestic water and the *automatic sprinkler system*, and a separate shutoff valve for the *automatic sprinkler system* is not provided.
  4. Jockey pump control valves that are sealed or locked in the open position.
  5. Control valves to commercial kitchen hoods, paint spray booths or dip tanks that are sealed or locked in the open position.
  6. Valves controlling the fuel supply to fire pump engines that are sealed or locked in the open position.
  7. Trim valves to pressure switches in dry, preaction and deluge sprinkler systems that are sealed or locked in the open position.
- ❖ The reliability data on automatic sprinkler systems clearly indicate that a closed valve is the leading cause of sprinkler system failure. There are also a number of other critical elements that contribute to successful sprinkler system operation, including, but not limited to, pumps, water tanks and air pressure maintenance devices; therefore, this section requires that the various critical elements that contribute to an

available water supply and to the function of the sprinkler system be electrically supervised.

Automatic sprinkler systems in one- and two-family dwellings are typically designed to comply with NFPA 13D, which does not require electrical supervision (see Exception 1).

Limited area sprinkler systems are generally supervised by their connection to the domestic water service, although the use of a supervised indicating valve is permitted. Compliance with Section 903.3.8 means that the alarm provisions of this section are not applicable to limited area systems. Consequently, limited area sprinkler systems do not require local alarms or supervision. Again, electrical supervision is required only if a control valve is installed between the riser control valve and the sprinkler system piping.

Similar to limited area sprinkler systems, electrical supervision is not required for NFPA 13R residential combination services when a shutoff valve is not installed (see Exception 3). NFPA 13R sprinkler systems are supervised in that the only way to shut off the sprinkler system is to also shut off the domestic water supply.

The valves discussed in Exceptions 4 through 7 can be sealed or locked in the open position because they do not control the sprinkler system water supply.

**903.4.1 Monitoring.** Alarm, supervisory and trouble signals shall be distinctly different and shall be automatically transmitted to an *approved* supervising station or, where *approved* by the *fire code official*, shall sound an audible signal at a constantly attended location.

**Exceptions:**

1. Underground key or hub valves in roadway boxes provided by the municipality or public utility are not required to be monitored.
  2. Backflow prevention device test valves located in limited area sprinkler system supply piping shall be locked in the open position. In occupancies required to be equipped with a fire alarm system, the backflow preventer valves shall be electrically supervised by a tamper switch installed in accordance with NFPA 72 and separately annunciated.
- ❖ Automatic sprinkler systems must be supervised as a means of determining that the system is operational. A valve supervisory switch operating as a normally open or normally closed switch is usually used. NFPA 72 does not permit valve supervisory switches to be connected to the same zone circuit as the waterflow switch unless it is specifically arranged to actuate a signal that is distinctive from the circuit trouble condition signal.
- Required sprinkler systems are to be monitored by an approved supervising service to comply with NFPA 72. Types of supervising stations recognized in NFPA 72 include central stations, remote supervising stations or proprietary supervising stations.
- A central station is an independent off-site facility

operated and maintained by personnel whose primary business is to furnish, maintain, record and supervise a signaling system. A proprietary system is similar to a central station system; however, a proprietary system is typically an on-site facility monitoring a number of buildings on the same site for the same owner. A remote station system has an alarm signal that is transmitted to a remote location acceptable to the authority having jurisdiction and that is attended 24 hours a day. The receiving equipment is usually located at a fire station, police station, regional emergency communications center or telephone answering service. An alternative use to the three previous supervising methods is an audible signal that can be transmitted to a constantly attended location approved by the fire code official.

Exception 1 recognizes that underground key or hub valves in roadway boxes are not normally supervised or required to be supervised by this section or NFPA 13.

Exception 2 acknowledges that local water utilities and environmental authorities in many instances require, by local ordinances, that backflow prevention devices be installed in limited-area sprinkler system piping. To make the testing and maintenance of backflow prevention devices easier, test valves are installed on each side of the device. These valves are typically indicating-type valves and can function as shutoff valves for the sprinkler system and, therefore, require some level of supervision.

Because these infrequently used valves may be the only feature of protection requiring supervision in occupancies not otherwise required to be equipped with a fire alarm system, Exception 2 permits these valves to be locked in the open position; however, if the occupancy is protected by a fire alarm system, these valves must be equipped with approved valve supervisory devices connected to the fire alarm control panel on a separate (supervisory) zone so that the supervisory signal is transmitted to the designated receiving station. Installation and testing of backflow preventers in sprinkler systems are regulated in Sections 312.10 (testing) and 608.16.4 (devices) of the IPC.

**903.4.2 Alarms.** An approved audible device, located on the exterior of the building in an *approved* location, shall be connected to each *automatic sprinkler system*. Such sprinkler waterflow alarm devices shall be activated by water flow equivalent to the flow of a single sprinkler of the smallest orifice size installed in the system. Where a fire alarm system is installed, actuation of the *automatic sprinkler system* shall actuate the building fire alarm system.

❖ The audible alarm, sometimes referred to as the “outside ringer” or “water-motor gong,” sounds when the sprinkler system has activated. The alarm device may be electrically operated or it may be a true water-motor gong operated by a paddle-wheel-type attachment to the sprinkler system riser that responds to the flow of water in the piping. Though no longer the

alarm device of choice, water-motor gongs do have the advantage of not being subject to power failures within or outside the protected building (see Sections 6.9 and 8.17 of NFPA 13 for further information on these devices). The alarm must be installed on the exterior of the building in a location approved by the fire code official. This location is often in close proximity to the fire department connection (FDC), serving a collateral function of helping the responding fire apparatus engineer more promptly locate the FDC.

The alarm is not intended to be an evacuation alarm. The requirement is also not intended to be an indirect requirement for a fire alarm system. Unless a fire alarm system is required by some other code provision, only the exterior alarm device is required. However, when a fire alarm system is installed, the sprinkler system must be interconnected with the fire alarm system so that when the sprinkler system actuates, it sounds the evacuation alarms required for the fire alarm system.

The primary purpose of the exterior alarm is to notify people outside the building that the sprinkler system is in operation. Originally, it was to act as a supplemental alert so that passersby could notify the fire department of the condition. However, because the code now requires electronic supervision of sprinkler systems, that function is mostly moot. The exterior notification now primarily serves the function of alerting the arriving fire department of which building or sprinkler system is in operation before staging fire-fighting activities for the building.

**903.4.3 Floor control valves.** *Approved* supervised indicating control valves shall be provided at the point of connection to the riser on each floor in high-rise buildings.

- ❖ In high-rise buildings, sprinkler control valves with supervisory initiating devices must be installed at the point of connection to the riser on each floor. Sprinkler control valves on each floor are intended to permit servicing activated systems without impairing the water supply to large portions of the building.

**903.5 Testing and maintenance.** Sprinkler systems shall be tested and maintained in accordance with Section 901.

- ❖ Section 901 contains requirements for the testing and maintenance of sprinkler systems. Acceptance tests are necessary to verify that the system performs as intended by design and by the code. Periodic testing and maintenance are essential to verify that the level of protection designed into the building will be operational whenever a fire occurs. Water-based extinguishing systems must be tested and maintained as required by NFPA 25.

The time schedule for testing and maintenance is included in the various standards referenced in Section 901 and listed in Table 901.6.1. Such maintenance includes annual visual inspection of seismic bracing, periodic lubrication of valves and quarterly testing of water flow alarm devices. An ongoing program for such maintenance and testing should be

established and reports prepared and maintained as noted in Section 901.6.2.

**903.6 Where required in existing buildings and structures.** An *automatic sprinkler system* shall be provided in existing buildings and structures where required in Chapter 11.

- ❖ Chapter 11 of this code, specifically Section 1103.5, requires sprinklers for existing buildings used for the manufacture and storage of pyroxylin plastics, in certain Group A-2 occupancies and in existing Group I-2 occupancies. See the commentary for Sections 1103.5.1 through 1103.5.4 for more detail on the retroactive sprinkler requirements.

## SECTION 904 ALTERNATIVE AUTOMATIC FIRE-EXTINGUISHING SYSTEMS

**904.1 General.** Automatic fire-extinguishing systems, other than *automatic sprinkler systems*, shall be designed, installed, inspected, tested and maintained in accordance with the provisions of this section and the applicable referenced standards.

- ❖ Section 904 covers alternative fire-extinguishing systems that use extinguishing agents other than water. Alternative automatic fire-extinguishing systems include wet-chemical, dry-chemical, foam, carbon dioxide, halon and clean-agent suppression systems. In addition to the provisions of Section 904, the indicated referenced standards include specific installation, maintenance and testing requirements for all systems.

**904.1.1 Certification of service personnel for fire-extinguishing equipment.** Service personnel providing or conducting maintenance on automatic fire-extinguishing systems, other than *automatic sprinkler systems*, shall possess a valid certificate issued by an *approved* governmental agency, or other *approved* organization for the type of system and work performed.

- ❖ Maintenance of fire protection systems and devices are minimum Chapter 9 requirements. Fire protection systems, like other technologies, have advanced new designs which require a clear understanding of their construction and maintenance. To ensure that systems and devices are properly maintained, the code now requires individuals performing these activities be certified. Certification must be issued by an approved organization or governmental agency.

These provisions align the code with NFPA standards governing the design, construction, inspection and maintenance of alternative automatic fire-extinguishing systems and portable fire extinguishers. The personnel qualification requirements specified by the applicable NFPA standards for the various alternative automatic fire-extinguishing systems are summarized in Commentary Figure 904.1.1.

Several organizations offer certifications that will

confirm to code officials that individuals are qualified to perform maintenance on alternative automatic fire extinguishing systems and portable fire extinguishers. The International Code Council® (ICC®), in conjunction with the National Association of Fire Equipment Distributors, offers certifications to individuals who service and inspect portable fire extinguishers and pre-engineered alternative fire-extinguishing systems protecting commercial kitchen hoods or industrial equipment such as spray booths. The National Institute for Certification in Engineering Technologies (NICET) offers four progressive levels of certification for individuals who design, erect and inspect special hazard suppression systems. Special hazard suppression systems include all of the various systems recognized in Section 904 and Commentary Figure 904.1.1. Finally, most manufacturers of these systems offer corporate certifications to individuals who will design, install and inspect them. Such certifications are beneficial to code officials because they confirm the individuals are qualified to install or maintain fire protection equipment produced by a specific manufacturer.

**904.2 Where permitted.** Automatic fire-extinguishing systems installed as an alternative to the required *automatic sprinkler systems* of Section 903 shall be *approved* by the *fire code official*.

❖ One of the main considerations in selecting an extinguishing agent should be the compatibility of the agent with the hazard. The fire code official is responsible for approving an alternative extinguishing agent. The approval should be based on the compatibility of the agent with the hazard and the potential effectiveness of the agent to suppress a fire involving the hazards present.

**904.2.1 Restriction on using automatic sprinkler system exceptions or reductions.** Automatic fire-extinguishing systems shall not be considered alternatives for the purposes of exceptions or reductions allowed for *automatic sprinkler systems* or by other requirements of this code.

❖ Although Section 904.2 allows the use of alternative fire extinguishing systems with specific approval, this section prohibits the use of such systems to allow reductions or exceptions allowed for automatic sprinkler systems throughout the IBC. Therefore, the building will not be considered as equipped throughout with an automatic sprinkler system when using systems such as automatic water mist or other alternative systems (see Commentary Figure 904.2.1).

**904.2.2 Commercial hood and duct systems.** Each required commercial kitchen exhaust hood and duct system required by Section 609 to have a Type I hood shall be protected with an *approved* automatic fire-extinguishing system installed in accordance with this code.

❖ This section requires an effective suppression system to combat fire on the cooking surfaces of grease-producing appliances and within the hood and exhaust system of a commercial kitchen installation. Type I hoods, including the duct system, must be protected with an approved automatic fire-extinguishing system because they are used for handling grease-laden vapors or smoke, whereas Type II hoods handle fumes, steam, heat and odors. Type I hoods are typically required for commercial food heat-processing equipment, such as deep fryers, griddles, charbroilers, broilers and open burner stoves and ranges. For additional guidance on the requirements for Type I

NFPA STANDARD NUMBER & EDITION	SUBJECT	SECTION	PERSONNEL QUALIFICATION REQUIREMENT
12, 2011	Carbon dioxide	4.4.1.1	Specifications for carbon dioxide fire-extinguishing systems shall be prepared under the supervision of a person fully experienced and qualified in the design of carbon dioxide extinguishing systems and with the advice of the authority having jurisdiction.
12A, 2009	Halon 1301	5.1.2.1	Plans and calculations shall be submitted for approval to the authority having jurisdiction before installation begins. Their preparation shall be entrusted only to persons fully experienced and qualified in the design of Halon 1301 extinguishing systems.
17, 2013	Dry chemical	1.6	Only trained persons shall be considered competent to design or layout, install and service dry-chemical systems.
17A, 2013	Wet chemical	1.7	Only trained persons shall be considered competent to design or lay out, install, and service wet chemical systems.
2001, 2012	Clean agent	7.6.1	All persons who could be expected to inspect, test, maintain, or operate fire-extinguishing systems shall be thoroughly trained and kept thoroughly trained in the functions the persons are expected to perform.

- a. Section numbers refer to sections in the code.
- b. Section numbers in Chapters 9 and 10 apply to both the IFC and the code.
- c. Sprinkler protection must be extended to the affected areas.
- d. For additional balcony requirements, see Section 903.3.1.2.1.

**FIGURE 904.2.1  
SELECTED EXAMPLES OF REQUIREMENTS MODIFIED THROUGH USE OF AUTOMATIC SPRINKLER SYSTEMS**

and II hoods, see the commentary to Section 507 of the IMC.

**904.3 Installation.** Automatic fire-extinguishing systems shall be installed in accordance with this section.

- ❖ The installation of automatic fire-extinguishing systems must comply with the requirements of Sections 904.3.1 through 904.3.5 in addition to the installation criteria contained in the referenced standard for the proposed type of alternative extinguishing system.

**904.3.1 Electrical wiring.** Electrical wiring shall be in accordance with NFPA 70.

- ❖ NFPA 70 regulates the design and installation of electrical systems and equipment. All electrical work must also be in compliance with any specific electrical classifications and conditions contained in the referenced standards for each type of system.

Section 605 of the code and Chapter 27 of the IBC contain provisions that also reference NFPA 70. Those sections also contain additional information that must be applied when addressing electrical issues.

**904.3.2 Actuation.** Automatic fire-extinguishing systems shall be automatically actuated and provided with a manual means of actuation in accordance with Section 904.11.1. Where more than one hazard could be simultaneously involved in fire due to their proximity, all hazards shall be protected by a single system designed to protect all hazards that could become involved.

**Exception:** Multiple systems shall be permitted to be installed if they are designed to operate simultaneously.

- ❖ Section 904.3.2 requires alternative fire-extinguishing systems to be designed for automatic activation. Activation commonly occurs when a heat-, fire- or smoke-detection system operates. In Type I commercial kitchen hoods, Section 904.12 requires a manual and automatic means of activating the fire-extinguishing system. Designing a fire-extinguishing system to only operate upon manual actuation is prohibited by the IBC and many of the NFPA fire protection system standards.

The requirements for fire-extinguishing system actuation correlate with the requirements of NFPA 17 and NFPA 17A. The requirement prescribes that when a hazard is protected by two or more fire-extinguishing systems, all of the systems must be designed to operate simultaneously. The reason for the revision is that a typical alternative automatic fire-extinguishing system has a limited amount of fire-extinguishing agent. The amount of agent that is available is based on the area or volume of the hazard and the fire behavior of the fuel. Because the amount of agent is limited, the simultaneous operation of all the fire-extinguishing systems ensures that enough agent is applied to extinguish the fire and prevent its spread from the area of origin.

It is fairly common for a single hazard to be protected by two or more alternative automatic fire-extinguishing systems. For example, protection of a spray

booth used for the application of flammable finishes using dry chemical commonly requires two or three alternative automatic fire-extinguishing systems. The reason is that many dry-chemical and all wet-chemical systems are preengineered systems. Utilizing listed nozzles, preengineered systems are designed and constructed based on the manufacturer's installation requirements. Because these systems are assembled using listed nozzles and extinguishing agents, one system may not be able to protect the spraying space and exhaust plenum. As a result, two or more systems may be required as a provision of an extinguishing system's listing to protect certain hazards.

Another example is commercial kitchen cooking operations. Consider a flat grill broiler and a deep-fat fryer located beneath the same Type I hood. It is quite common for each of these commercial cooking appliances to be protected by separate automatic fire-extinguishing systems. Based on the revision to Section 904.3.2, both extinguishing systems must simultaneously operate in the event a fire involves either of the example appliances (see commentary, Section 904.12.1).

**904.3.3 System interlocking.** Automatic equipment interlocks with fuel shutoffs, ventilation controls, door closers, window shutters, conveyor openings, smoke and heat vents and other features necessary for proper operation of the fire-extinguishing system shall be provided as required by the design and installation standard utilized for the hazard.

- ❖ Shutting off fuel supplies will eliminate potential ignition sources in the protected area. Automatic door and window closers and dampers for forced-air ventilation systems are intended to maintain the desired concentration level of the extinguishing agent in the protected area. See the commentary for Section 904.12.2 for information on system interconnections in commercial cooking fire-extinguishing systems.

**904.3.4 Alarms and warning signs.** Where alarms are required to indicate the operation of automatic fire-extinguishing systems, distinctive audible, visible alarms and warning signs shall be provided to warn of pending agent discharge. Where exposure to automatic-extinguishing agents poses a hazard to persons and a delay is required to ensure the evacuation of occupants before agent discharge, a separate warning signal shall be provided to alert occupants once agent discharge has begun. Audible signals shall be in accordance with Section 907.5.2.

- ❖ Safeguards are necessary to prevent injury or death to personnel in areas where the atmosphere will be made hazardous by oxygen depletion due to agent discharge in a confined space. The "where alarms are required" phrase is referring to requirements that will be found in the referenced installation standards indicated in Sections 904.5 through 904.12, as applicable. Predischage alarms that will operate on fire detection system activation must be installed within and at entrances to the affected areas.

Where required by the appropriate installation stan-

ard(s), an extinguishing agent discharge delay feature shall also be provided to allow evacuation of personnel prior to agent discharge. Warning and instructional signs are also to be posted, preferably at the entrances to and within the protected area. See Section 4.5.6.1 of NFPA 12 for additional information on carbon dioxide system alarms, Section 4.3.5 of NFPA 12A for additional information on Halon system alarms and Section 4.3.5 of NFPA 2001 for additional information on clean agent system alarms.

**904.3.5 Monitoring.** Where a building fire alarm system is installed, automatic fire-extinguishing systems shall be monitored by the building fire alarm system in accordance with NFPA 72.

❖ Automatic fire-extinguishing systems need not be electrically supervised unless the building is equipped with a fire alarm system. This section recognizes the fact that a fire alarm system is not required in all buildings. However, because most alternative fire-extinguishing systems require the space to be evacuated before the system is discharged, they are equipped with evacuation alarms. Interconnection of the fire-extinguishing system evacuation alarm with the building evacuation alarm results in an increased level of hazard notification for the occupants in addition to the electrical supervision of the fire-extinguishing system.

**904.4 Inspection and testing.** Automatic fire-extinguishing systems shall be inspected and tested in accordance with the provisions of this section prior to acceptance.

❖ The completed installation must be tested and inspected to determine that the system has been installed in compliance with the code and will function as required. Full-scale acceptance tests must be conducted as required by the applicable referenced standard.

**904.4.1 Inspection.** Prior to conducting final acceptance tests, all of the following items shall be inspected:

1. Hazard specification for consistency with design hazard.
2. Type, location and spacing of automatic- and manual-initiating devices.
3. Size, placement and position of nozzles or discharge orifices.
4. Location and identification of audible and visible alarm devices.
5. Identification of devices with proper designations.
6. Operating instructions.

❖ This section identifies those items that need to be verified or visually inspected prior to the final acceptance tests. All equipment should be listed, approved and installed in accordance with the manufacturer's recommendations

**904.4.2 Alarm testing.** Notification appliances, connections to fire alarm systems and connections to *approved* supervising stations shall be tested in accordance with this section and Section 907 to verify proper operation.

❖ Components of fire-extinguishing systems related to alarm devices and their supervision must be tested before the system is approved. Alarm devices must be tested to satisfy the requirements of NFPA 72.

**904.4.2.1 Audible and visible signals.** The audibility and visibility of notification appliances signaling agent discharge or system operation, where required, shall be verified.

❖ This section requires verification upon completion of the system installation of the audibility and visibility of notification appliances in the area affected by the extinguishing agent discharge of the alternative automatic fire-extinguishing system.

**904.4.3 Monitor testing.** Connections to protected premises and supervising station fire alarm systems shall be tested to verify proper identification and retransmission of alarms from automatic fire-extinguishing systems.

❖ Where monitoring of fire-extinguishing systems is required, such as by Section 904.3.5, all connections related to the supervision of the system must be tested to verify they are in proper working order.

**904.5 Wet-chemical systems.** Wet-chemical extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 17A and their listing. Records of inspections and testing shall be maintained.

❖ NFPA 17A contains minimum requirements for the design, installation, operation, testing and maintenance of wet-chemical preengineered extinguishing systems. Equipment that is typically protected with wet-chemical extinguishing systems includes restaurant, commercial and institutional hoods; plenums; ducts and associated cooking equipment. Strict compliance with the manufacturer's installation instructions is vital for a viable installation.

Wet-chemical solutions used in extinguishing systems are relatively harmless and there is usually no lasting significant effect on a person's skin, respiratory system or clothing. These solutions may produce a mild, temporary irritation but the symptoms will usually disappear when contact is eliminated.

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing, it is more difficult to determine if the systems will be effective when activated and when future inspection and testing is necessary.

**904.5.1 System test.** Systems shall be inspected and tested for proper operation at six-month intervals. Tests shall include a check of the detection system, alarms and releasing devices, including manual stations and other associated equipment. Extinguishing system units shall be weighed and the required amount of agent verified. Stored pressure-type

units shall be checked for the required pressure. The cartridge of cartridge-operated units shall be weighed and replaced at intervals indicated by the manufacturer.

- ❖ This section specifies the frequency for inspection and testing of wet-chemical extinguishing systems. The system and its essential components must be inspected and checked every six months to determine that the system is in full operating condition.

**904.5.2 Fusible link maintenance.** Fixed temperature-sensing elements shall be maintained to ensure proper operation of the system.

- ❖ Wet-chemical extinguishing systems are commonly used to protect commercial cooking equipment. The fusible metal alloy sensing elements are subject to the accumulation of grease or other contaminants that could affect the operation of the fusible link. The sensing elements must be inspected routinely and replaced as needed.

**904.6 Dry-chemical systems.** Dry-chemical extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 17 and their listing. Records of inspections and testing shall be maintained.

- ❖ NFPA 17 contains the minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of dry-chemical extinguishing systems.

The fire code official has the authority to approve the type of dry-chemical extinguishing system to be used. NFPA 17 identifies three types of dry-chemical extinguishing systems: total flooding, local application and hand hose-line systems. Only total flooding and local application systems are considered automatic extinguishing systems.

The types of hazards and equipment that can be protected with dry-chemical extinguishing systems include: flammable and combustible liquids and combustible gases; combustible solids, which melt when involved in a fire; electrical hazards, such as transformers or oil circuit breakers; textile operations subject to flash surface fires; ordinary combustibles such as wood, paper or cloth and restaurant and commercial hoods, ducts and associated cooking appliance hazards, such as deep fat fryers and some plastics, depending on the type of material and configuration.

Total flooding dry-chemical extinguishing systems are used only where there is a permanent enclosure about the hazard that is adequate to enable the required concentration to be built up. The total area of uncloseable openings must not exceed 15 percent of the total area of the sides, top and bottom of the enclosure. Consideration must be given to eliminating the probable sources of re-ignition within the enclosure because the extinguishing action of dry-chemical systems is transient.

Local application of dry-chemical extinguishing systems is to be used for extinguishing fires where the hazard is not enclosed or where the enclosure does not conform to the requirements for total flood-

ing systems. Local application systems have successfully protected hazards involving flammable or combustible liquids, gases and shallow solids, such as paint deposits.

NFPA 17 also discusses preengineered dry-chemical systems consisting of components designed to be installed in accordance with pretested limitations as tested and labeled by a testing agency. Preengineered systems must be installed within the limitations that have been established by the testing agency and may include total flooding, local application or a combination of both types of systems.

The type of dry chemical used in the extinguishing system is a function of the hazard to be protected. The type of dry chemical used in a system should not be changed unless it has been proven changeable by a testing laboratory, is recommended by the manufacturer of the equipment and is acceptable to the fire code official for the hazard being protected. Additional guidance on the use of various dry-chemical agents can be found in NFPA 17.

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing, it is more difficult to determine if the systems will be effective when activated and when future inspection and testing is necessary.

**904.6.1 System test.** Systems shall be inspected and tested for proper operation at six-month intervals. Tests shall include a check of the detection system, alarms and releasing devices, including manual stations and other associated equipment. Extinguishing system units shall be weighed, and the required amount of agent verified. Stored pressure-type units shall be checked for the required pressure. The cartridge of cartridge-operated units shall be weighed and replaced at intervals indicated by the manufacturer.

- ❖ This section specifies the frequency for inspection and testing of dry-chemical extinguishing systems. The system and its essential components must be inspected and checked every six months to determine that the system is in full operating condition.

**904.6.2 Fusible link maintenance.** Fixed temperature-sensing elements shall be maintained to ensure proper operation of the system.

- ❖ Dry-chemical extinguishing systems are commonly used to protect commercial cooking systems and other hazardous use conditions. In these applications the fusible metal alloy sensing elements are subject to the accumulation of grease or other contaminants that could affect the operation of the fusible link. The sensing elements must be inspected routinely and replaced as needed.

**904.7 Foam systems.** Foam-extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 11 and NFPA 16 and their listing. Records of inspections and testing shall be maintained.

- ❖ NFPA 11 covers the characteristics of foam-producing materials used for fire protection and the requirements for design, installation, operation, testing and maintenance of equipment and systems, including those used in combination with other fire-extinguishing agents. The minimum requirements are covered for flammable and combustible liquid hazards in local areas within buildings, storage tanks and indoor and outdoor processing areas.

Low-expansion foam is defined as an aggregation of air-filled bubbles resulting from the mechanical expansion of a foam solution by air with a foam-to-solution volume ratio of less than 20:1. It is most often used to protect flammable and combustible liquid hazards. Also, low-expansion foam may be used for heat radiation protection. Combined-agent systems involve the application of low-expansion foam to a hazard simultaneously or sequentially with dry-chemical powder.

NFPA 11 gives minimum requirements for the installation, design, operation, testing and maintenance of medium- and high-expansion foam systems. Medium-expansion foam is defined as an aggregation of air-filled bubbles resulting from the mechanical expansion of a foam solution by air or other gases with a foam-to-solution volume ratio of 20:1 to 200:1. High-expansion foam has a foam-to-solution volume ratio of 200:1 to approximately 1,000:1.

Medium-expansion foam may be used on solid fuel and liquid fuel fires where some degree of in-depth coverage is necessary (for example, for the total flooding of small, enclosed or partially enclosed volumes, such as engine test cells, transformer rooms, etc.). High-expansion foam is most suitable for filling volumes in which fires exit at various levels. For example, high-expansion foam can be used effectively against high-rack storage fires in enclosures such as in underground passages, where it may be dangerous to send personnel to control fires involving liquefied natural gas (LNG) and liquefied petroleum gas (LP-gas), and to provide vapor dispersion control for LNG and ammonia spills. High-expansion foam is particularly suited for indoor fires in confined spaces, since it is highly susceptible to wind and lack-of-confinement effects.

NFPA 16 contains the minimum requirements for open-head deluge-type foam-water sprinkler systems and foam-water spray systems. The systems are especially applicable to the protection of most flammable liquid hazards and have been used successfully to protect aircraft hangars and truck loading racks.

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing it is more difficult to determine if the systems will be effective when acti-

vated and when future inspection and testing is necessary.

**904.7.1 System test.** Foam-extinguishing systems shall be inspected and tested at intervals in accordance with NFPA 25.

- ❖ Although Section 904.7.1 references NFPA 25 as the standard for the inspection and testing of foam-extinguishing systems, NFPA 25 is limited to water-based extinguishing systems. NFPA 25 technically addresses only foam-water sprinkler systems as specified in NFPA 16. NFPA 11 should be consulted for inspection and testing intervals for low-, medium- and high-expansion foam systems.

As with other alternative fire-extinguishing systems, the inspection and testing of foam systems is necessary to determine that the system is fully operational. In addition to general maintenance of equipment, the condition of the foam concentrate and its storage tanks or containers should be inspected at least once a year to verify adequate quality. The desired concentration of the foam concentrate in a stagnant storage situation may deteriorate over time.

**904.8 Carbon dioxide systems.** Carbon dioxide extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 12 and their listing. Records of inspections and testing shall be maintained.

- ❖ NFPA 12 provides minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of carbon dioxide extinguishing systems.

Carbon dioxide extinguishing systems are useful in extinguishing fires in specific hazards or equipment in occupancies where an inert electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents, such as dry-chemical residue, presents a problem. Carbon dioxide systems have satisfactorily protected the following: flammable liquids; electrical hazards, such as transformers, oil switches, rotating equipment and electronic equipment; engines using gasoline and other flammable liquid fuels; ordinary combustibles, such as paper, wood and textiles and hazardous solids.

The fire code official has the authority to approve the type of carbon dioxide system to be installed. NFPA 12 defines four types of carbon dioxide systems: total flooding, local application, hand hose lines and standpipe and mobile supply systems. Only total flooding and local application systems are automatic suppression systems.

Total-flooding systems may be used where there is a permanent enclosure around the hazard that is adequate to allow the required concentration to be built up and maintained for the required period of time, which varies for different hazards. Examples of hazards that have been successfully protected by total flooding systems include rooms, vaults,

enclosed machines, ducts, ovens and containers and their contents.

Local application systems may be used for extinguishing surface fires in flammable liquids, gases and shallow solids where the hazard is not enclosed or the enclosure does not conform to the requirements for a total-flooding system. Examples of hazards that have been successfully protected by local application systems include dip tanks, quench tanks, spray booths, oil-filled electric transformers and vapor vents.

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing it is more difficult to determine if the systems will be effective when activated and when future inspection and testing is necessary.

**904.8.1 System test.** Systems shall be inspected and tested for proper operation at 12-month intervals.

- ❖ To determine adequate operation, carbon dioxide systems must be inspected and tested at least once a year.

**904.8.2 High-pressure cylinders.** High-pressure cylinders shall be weighed and the date of the last hydrostatic test shall be verified at six-month intervals. Where a container shows a loss in original content of more than 10 percent, the cylinder shall be refilled or replaced.

- ❖ Because of the potential of unobserved leaking high-pressure cylinders, they need to be weighed semi-annually to verify the concentration level is always within at least 10 percent of the original content.

**904.8.3 Low-pressure containers.** The liquid-level gauges of low-pressure containers shall be observed at one-week intervals. Where a container shows a content loss of more than 10 percent, the container shall be refilled to maintain the minimum gas requirements.

- ❖ A weekly visual observation of the liquid level gauges of low-pressure containers is required to verify that there has been no significant leakage.

**904.8.4 System hoses.** System hoses shall be examined at 12-month intervals for damage. Damaged hoses shall be replaced or tested. At five-year intervals, all hoses shall be tested.

- ❖ The maintenance of system hoses is essential to ensuring the reliability of their use in an emergency. Although system hoses need to be visually checked on an annual basis only, a complete pressure test as indicated in Section 904.8.4.1 must be performed every five years.

**904.8.4.1 Test procedure.** Hoses shall be tested at not less than 2,500 pounds per square inch (psi) (17 238 kPa) for high-pressure systems and at not less than 900 psi (6206 kPa) for low-pressure systems.

- ❖ Every five years, system hoses for both high-pressure/low-pressure systems must be pressure tested to verify they are still in proper operating condition. The test typically involves filling the hose with water.

The hose is then pressurized at the desired test pressure for at least 1 minute to observe any potential distortions or leakage in the hose. All hose assemblies that do not pass the test should be marked, destroyed and replaced with new hose assemblies. Hose assemblies that pass the test should be marked, dated and returned to service.

**904.8.5 Auxiliary equipment.** Auxiliary and supplementary components, such as switches, door and window releases, interconnected valves, damper releases and supplementary alarms, shall be manually operated at 12-month intervals to ensure that such components are in proper operating condition.

- ❖ The effectiveness of the carbon dioxide extinguishing system is also dependent upon the operation of its auxiliary components. These components must also be manually operated at least once a year.

**904.9 Halon systems.** Halogenated extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 12A and their listing. Records of inspections and testing shall be maintained.

- ❖ NFPA 12A contains minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of Halon 1301 extinguishing systems. Halon 1301 fire-extinguishing systems are useful in specific hazards, equipment or occupancies where an electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents presents a problem.

Halon 1301 systems have satisfactorily protected gaseous and liquid flammable materials; electrical hazards, such as transformers, oil switches and rotating equipment; engines using gasoline and other flammable fuels; ordinary combustibles, such as paper, wood and textiles and hazardous solids. Halon 1301 systems have also satisfactorily protected electronic computers, data processing equipment and control rooms.

The fire code official has the authority to approve the type of halogenated extinguishing system to be installed. NFPA 12A defines two types of halogenated extinguishing systems: total flooding and local application. Total-flooding systems may be used where there is a fixed enclosure around the hazard that is adequate to enable the required halon concentration to be built up and maintained for the required period of time to enable the effective extinguishing of the fire. Total-flooding systems may provide fire protection for rooms, vaults, enclosed machines, ovens, containers, storage tanks and bins.

Local application systems are used where there is not a fixed enclosure around the hazard or where the fixed enclosure around the hazard is not adequate to enable an extinguishing concentration to be built up and maintained in the space. Hazards that may be successfully protected by local application systems include dip tanks, quench tanks, spray booths, oil-filled electric transformers and vapor vents.

Two other considerations in selecting the proper

extinguishing system are ambient temperature and the personnel hazards associated with the agent. The ambient temperature of the enclosure for a total-flooding system must be above 70°F (21°C) for halon 1301 systems. Special consideration must also be given to the use of halon systems when the temperatures are in excess of 900°F (482°C) because halon will readily decompose at such temperatures and the products of decomposition can be extremely irritating if inhaled, even in small amounts.

Halon 1301 total-flooding systems must not be used in concentrations greater than 10 percent in normally occupied areas. Where personnel cannot vacate the area within 1 minute, Halon 1301 total-flooding systems must not be used in normally occupied areas with concentrations greater than 7 percent. Halon 1301 total-flooding systems may be used with concentrations of up to 15 percent if the area is not normally occupied and the area can be evacuated within 30 seconds.

Therefore, the supply of halon is limited and new supplies of halogenated extinguishing agents will not be available in the future. Existing supplies of halon can, however, continue to be used in existing, undischarged systems or to recharge discharged systems. This newfound need for halon supplies has given rise to new industries geared to the ranking, recycling and reclamation of existing halon supplies. Alternative “clean agent” extinguishing agents have been developed to replace halogenated agents (see Section 904.10).

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing it is more difficult to determine if the systems will be effective when activated and when future inspection and testing is necessary.

**904.9.1 System test.** Systems shall be inspected and tested for proper operation at 12-month intervals.

- ❖ To determine proper operation, Halon systems must be inspected and tested at least once a year.

**904.9.2 Containers.** The extinguishing agent quantity and pressure of containers shall be checked at six-month intervals. Where a container shows a loss in original weight of more than 5 percent or a loss in original pressure (adjusted for temperature) of more than 10 percent, the container shall be refilled or replaced. The weight and pressure of the container shall be recorded on a tag attached to the container.

- ❖ Because of the potential for unobserved leakage of the Halon containers, they must be checked at least semi-annually to verify the original weight and pressure are within the designated tolerances. When necessary, containers must be refilled or replaced when the desired levels are not maintained. The containers

should also be checked for evidence of corrosion or mechanical damage.

**904.9.3 System hoses.** System hoses shall be examined at 12-month intervals for damage. Damaged hoses shall be replaced or tested. At five-year intervals, all hoses shall be tested.

- ❖ Maintenance of system hoses is essential to ensuring the reliability of their use in an emergency. System hoses need to be visually checked annually. A complete pressure test as indicated in Section 904.9.3.1 must be performed every five years.

**904.9.3.1 Test procedure.** For Halon 1301 systems, hoses shall be tested at not less than 1,500 psi (10 343 kPa) for 600 psi (4137 kPa) charging pressure systems and not less than 900 psi (6206 kPa) for 360 psi (2482 kPa) charging pressure systems. For Halon 1211 hand-hose line systems, hoses shall be tested at 2,500 psi (17 238 kPa) for high-pressure systems and 900 psi (6206 kPa) for low-pressure systems.

- ❖ Every five years, system hoses must be pressure tested to verify they are still in proper operating condition. This section specifies the test pressure for the various types of Halon systems. The pressure test is intended to check for any potential distortion or leaking in the hose (see commentary, Section 904.8.4.1).

**904.9.4 Auxiliary equipment.** Auxiliary and supplementary components, such as switches, door and window releases, interconnected valves, damper releases and supplementary alarms, shall be manually operated at 12-month intervals to ensure such components are in proper operating condition.

- ❖ The effectiveness of halogenated extinguishing systems is also dependent upon the operation of its auxiliary components. These components must be manually operated at least once a year.

**904.10 Clean-agent systems.** Clean-agent fire-extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 2001 and their listing. Records of inspections and testing shall be maintained.

- ❖ NFPA 2001 contains minimum requirements for the design, installation, testing, inspection and operation of clean-agent fire-extinguishing systems. A clean agent is an electrically nonconducting suppression agent that is volatile or gaseous at discharge and does not leave a residue on evaporation. Clean-agent fire-extinguishing systems are installed in locations that are enclosed and have openings in the protected area that can be sealed on activation of the alarm to provide effective clean-agent concentrations. A clean-agent fire-extinguishing system should not be installed in locations that cannot be sealed unless testing has shown that adequate concentrations can be developed and maintained.

The two categories of clean agents are halocarbon compounds and inert gas agents. Halocarbon compounds include bromine, carbon, chlorine, fluorine,

hydrogen and iodine. Halocarbon compounds suppress fire by a combination of breaking the chemical chain reaction of the fire, reducing the oxygen supporting the fire and reducing the ambient temperature of the fire origin to reduce the propagation of the fire. Inert gas agents contain primary components consisting of helium, neon, argon or a combination of these. Inert gases work by reducing the oxygen concentration around the fire origin to a level that does not support combustion.

Clean-agent fire-extinguishing systems were developed in response to the demise of halon as an acceptable fire-extinguishing agent because of its harmful effect on the environment. Although the original hope for a halon substitute was that these new clean agents could be directly and proportionally substituted for halon agents in existing systems (drop in replacements), research has shown that clean agents are less efficient in extinguishing fires than are the halons they were intended to replace and require approximately 60 percent more agent by weight and volume in storage to do the same job. Additionally, the physical and chemical characteristics of clean agents differ sufficiently from halon to require different nozzles in addition to the need for larger storage vessels. Existing piping systems should be salvaged for use with clean agents only if they are carefully evaluated and determined to be hydraulically compatible with the flow characteristics of the new agent.

This section also relies on strict adherence to the system manufacturer's design and installation instructions for code compliance. As with many of the alternative fire suppression systems covered in this chapter, clean-agent systems are, for the most part, subjected by their manufacturers to a testing and listing program conducted by an approved testing agency. In such testing and listing programs, the clean agent is listed for use with specific equipment and equipment is listed for use with specific clean agents. The resultant listings include reference to the manufacturer's installation manuals, thereby giving the fire code official another valuable resource for reviewing and approving clean-agent systems.

Although clean agents have found a limited market for local application uses, such as a replacement for Halon 1211 in portable fire extinguishers, their primary application is in total-flooding systems and they are available in both engineered and preengineered configurations.

Engineered clean-agent systems are specifically designed for protection of a particular hazard, whereas preengineered systems are designed to operate within predetermined limitations up to the noted maximums, thus allowing broader applicability to a variety of hazard applications.

Total flooding systems are used where there is a fixed enclosure around the hazard that is adequate to enable the required clean-agent concentration to

build up and be maintained within the space long enough to extinguish the fire. Such applications can include vaults, ovens, containers, tanks, computer rooms, paint lockers or enclosed machinery. In selecting the clean agent to be used in a given application, careful consideration must be given to whether the protected area is a normally occupied space, because different agents have different levels of concentration at which they may be a health hazard to occupants of the area.

The fire code official has the authority to approve the type of clean-agent system to be installed and should become familiar with the unique characteristics and hazards of clean-agent extinguishing systems using all available resources on the subject.

This section also specifically requires that records be maintained of inspections and testing to increase the effectiveness of such systems. Without records of such inspections and testing it is more difficult to determine if the systems will be effective when activated and when future inspection and testing is necessary.

**904.10.1 System test.** Systems shall be inspected and tested for proper operation at 12-month intervals.

❖ To determine proper operation, all clean-agent systems must be inspected and tested at least once a year.

**904.10.2 Containers.** The extinguishing agent quantity and pressure of the containers shall be checked at six-month intervals. Where a container shows a loss in original weight of more than 5 percent or a loss in original pressure, adjusted for temperature, of more than 10 percent, the container shall be refilled or replaced. The weight and pressure of the container shall be recorded on a tag attached to the container.

❖ Because of the potential for unobserved leakage of the clean-agent containers, they must be checked at least semi-annually to verify the original weight and pressure are within the designated tolerances. When necessary, containers must be refilled or replaced when the desired levels are not maintained.

**904.10.3 System hoses.** System hoses shall be examined at 12-month intervals for damage. Damaged hoses shall be replaced or tested. All hoses shall be tested at five-year intervals.

❖ The maintenance of system hoses is essential to ensuring their reliability in an emergency. System hoses must be visually checked annually. A complete pressure test must be performed every five years.

**904.11 Automatic water mist systems.** *Automatic water mist systems* shall be permitted in applications that are consistent with the applicable listing or approvals and shall comply with Sections 904.11.1 through 904.11.3.

❖ This section provides the ability to use automatic water mist systems in specific applications. These installations are required to be consistent with the list-

**Figure 904.11**  
**WATER MIST NOZZLE DISCHARGE**

ings or approvals to which such systems have been tested. See Commentary Figure 904.11.

**904.11.1 Design and installation requirements.** *Automatic water mist systems* shall be designed and installed in accordance with Sections 904.11.1.1 through 904.11.1.4.

❖ The subsections to follow provide the various installation and design requirements related to water mist systems. This relates to the systems themselves and the provisions for a reliable water supply.

**904.11.1.1 General.** *Automatic water mist systems* shall be designed and installed in accordance with NFPA 750 and the manufacturer's instructions.

❖ This section simply provides reference to the subsections with the detailed requirements related to the design and installation of water mist systems.

**904.11.1.2 Actuation.** *Automatic water mist systems* shall be automatically actuated.

❖ If a water mist system is used, it is required to be automatically activated.

**904.11.1.3 Water supply protection.** Connections to a potable water supply shall be protected against backflow in accordance with the *International Plumbing Code*.

❖ The water supply quality is more critical with automatic water mist systems than automatic sprinkler systems. Backflow prevention is required, as it would be for water supply for automatic sprinkler systems.

**904.11.1.4 Secondary water supply.** Where a secondary water supply is required for an *automatic sprinkler system*, an *automatic water mist system* shall be provided with an *approved* secondary water supply.

❖ Since these systems work to protect buildings and spaces in a fashion similar to a sprinkler system and

possibly as an alternative to automatic sprinkler systems, the water supply must be appropriate. If an automatic sprinkler system is required to have a secondary water supply in accordance with Section 403.3.3 of the IBC, then the water mist system must also provide an approved secondary water supply.

**904.11.2 Water mist system supervision and alarms.** Supervision and alarms shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.

❖ This section plays a similar role to an automatic sprinkler system with regard to supervision and alarms. It is critical to make sure valves are open. In addition, an alarm to notify of an activation must be provided as it is for a sprinkler system. Note that this is not intended to be an occupant notification system. See the commentary for Section 903.4.

**904.11.2.1 Monitoring.** Monitoring shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.1.

❖ See the commentary to Sections 903.4.1 and 904.11.2.

**904.11.2.2 Alarms.** Alarms shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.2.

❖ Again, this is not intended as occupant notification but instead is simply to alert someone that the system has activated. See commentary for Sections 903.4.2 and 904.11.2.

**904.11.2.3 Floor control valves.** Floor control valves shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.3.

❖ See the commentary to Section 903.4.3.

**904.11.3 Testing and maintenance.** *Automatic water mist systems* shall be tested and maintained in accordance with Section 901.6.

❖ Testing and maintenance is critical to the long term viability of automatic water mist systems. See the commentary to Section 901.6.

**904.12 Commercial cooking systems.** The automatic fire-extinguishing system for commercial cooking systems shall be of a type recognized for protection of commercial cooking equipment and exhaust systems of the type and arrangement protected. Preengineered automatic dry- and wet-chemical extinguishing systems shall be tested in accordance with UL 300 and *listed* and *labeled* for the intended application. Other types of automatic fire-extinguishing systems shall be *listed* and *labeled* for specific use as protection for commercial cooking operations. The system shall be installed in accordance with this code, its listing and the manufacturer's installation instructions. Automatic fire-extinguishing systems of the following types shall be installed in accordance with the referenced standard indicated, as follows:

1. Carbon dioxide extinguishing systems, NFPA 12.
2. *Automatic sprinkler systems*, NFPA 13.

3. Foam-water sprinkler system or foam-water spray systems, NFPA 16.
4. Dry-chemical extinguishing systems, NFPA 17.
5. Wet-chemical extinguishing systems, NFPA 17A.

**Exception:** Factory-built commercial cooking recirculating systems that are tested in accordance with UL 710B and *listed, labeled* and installed in accordance with Section 304.1 of the *International Mechanical Code*.

- ❖ The history of commercial kitchen exhaust systems shows that the mixture of flammable grease and effluents carried by such systems and the potential for the cooking equipment to act as an ignition source contribute to a higher level of hazard for kitchen exhaust systems than is normally found in many other exhaust systems. Furthermore, fire in a grease exhaust duct can produce temperatures of 2,000°F (1093°C) or more and heat radiating from the duct can ignite nearby combustibles. As a result, the code requires exhaust systems serving grease-producing equipment to include fire suppression to protect the cooking surfaces, hood, filters and exhaust duct to confine a fire to the hood and duct system, thus reducing the likelihood of it spreading to the structure.

In addition to the general requirements of this section, five industry standards are referenced for the installation of fire-extinguishing systems protecting commercial food heat-processing equipment and kitchen exhaust systems. Design professionals should specify and design fire-extinguishing systems to comply with these referenced standards. Only the installation of fire-extinguishing systems is regulated by these references. Where preengineered automatic dry- and wet-chemical extinguishing systems are installed, they must be listed and labeled for the specific cooking operation and tested in accordance with UL 300. Design and construction requirements for the specific types of fire-extinguishing systems are found in the respective sections of the referenced standards.

Regulatory requirements for the approval and installation of fire-extinguishing systems are the same as the approval required for all mechanical equipment and appliances. This section, therefore, requires extinguishing systems to be listed and labeled by an approved agency and installed in accordance with their listing and the manufacturer's installation instructions.

The exception allows factory-built commercial cooking recirculating systems to be installed if they have been tested and listed in accordance with UL 710B. It is important that they be installed in accordance with the manufacturer's installation instructions so that the listing requirements are met. An improper installation could result in hazardous vapors being discharged back into the kitchen.

Commercial cooking recirculating systems consist of an electric cooking appliance and an integral or matched packaged hood assembly. The hood assembly consists of a fan, collection hood, grease

filter, fire damper, fire-extinguishing system and air filter, such as an electrostatic precipitator. These systems are tested for fire safety and emissions. The grease vapor (condensable particulate matter) in the effluent at the system discharge is not allowed to exceed a concentration of 5.0 mg/m<sup>3</sup>. Recirculating systems are not used with fuel-fired appliances because the filtering systems do not remove combustion products. Kitchens require ventilation in accordance with Chapter 4 of the IMC.

Although the provisions in Section 904.12 address many of the specifics for commercial kitchens, additional information regarding commercial cooking suppression systems is located in Sections 904.2 and 904.3. This information is supplemental to that and should be considered together in developing the design for commercial cooking suppression systems.

A question that is often asked about this section is whether it requires existing commercial cooking preengineered fire extinguishing systems to comply with UL 300. Generally, neither this section nor the retroactivity provisions contained in the referenced NFPA standards indicate that retroactive application is intended. The application of this section is subject to the applicability provisions of Section 102.1 of the code. As such, where an existing, previously approved, listed preengineered fire extinguishing system installed for the protection of commercial cooking operations has been, and continues to be, maintained in accordance with the manufacturer's installation and maintenance requirements and the applicable NFPA standard referenced on the extinguishing system unit and continues to comply with Sections 609.3.4, 901.4 and 901.6, no change to the system would be required. In the event, however, that a system can no longer comply with the provisions noted above, or if the changes described in Section 904.12.6.1 have taken place, it would then need to be brought into compliance with the applicable provisions of Section 904.12 and the referenced standards. Note that some extinguishing system manufacturers no longer provide service support, either directly or through their authorized agents, for certain older-model systems (e.g., replacement parts, etc.). Continuing manufacturer maintenance and service support of existing systems would be a key element in the determination of whether a system continues to meet the above requirements and should be investigated on a case-by-case basis with the respective system manufacturer (see Section 904.12.6.2).

Another question that is often asked is whether the requirements of this section apply to grease-producing appliances installed in a mobile commercial vending cart or catering truck. This section is not a "where required" section but, rather, contains "how-to" criteria once it is determined that a hood and a commercial kitchen hood and duct fire suppression system is required. Where a hood and duct fire suppression system is required depends on the type of cooking

operation being conducted and the type of hood that is required to be installed, as indicated in Section 609.2 of the code. That section is specific in requiring a Type I hood above all commercial cooking appliances as they are defined in Chapter 2. That definition limits the term to only appliances used in a commercial food service establishment and goes on to define such establishments as "...any building or portion thereof used for the preparation and serving of food." Accordingly, a typical food vendor's cart, catering truck with on-board cooking, or any other mobile or temporary food concessions, would not be included in that definition and as such, would be outside the scope of Section 101.2 of the IMC, or Section 609.2 or this section of the code.

**904.12.1 Manual system operation.** A manual actuation device shall be located at or near a *means of egress* from the cooking area not less than 10 feet (3048 mm) and not more than 20 feet (6096 mm) from the kitchen exhaust system. The manual actuation device shall be installed not more than 48 inches (1200 mm) nor less than 42 inches (1067 mm) above the floor and shall clearly identify the hazard protected. The manual actuation shall require a maximum force of 40 pounds (178 N) and a maximum movement of 14 inches (356 mm) to actuate the fire suppression system.

**Exception:** *Automatic sprinkler systems* shall not be required to be equipped with manual actuation means.

- ❖ The manual device, usually a pull station, mechanically activates the suppression system. The typical system uses a mechanical circuit of cables under tension to hold the system in the armed (cocked) mode. Melting of a fusible link or actuation of a manual pull station causes the cable to lose tension, which, in turn, starts the discharge of the suppression agent. The manual actuation device must be readily and easily usable by the building occupants; therefore, the device must not require excessive force or range of movement to cause actuation.

In order to allow the actuation device to be used most effectively, the specified mounting height is intended to be consistent with the NFPA 17A standards and be handicapped accessible. This includes the requirement to identify the actuation device with the hazard protected. Where multiple kitchen appliances are provided, properly identifying which device relates to which appliance is very important. Required signage should be readily visible in the hazard area and capable of conveying information quickly and concisely.

Manual actuation is not required for automatic sprinkler systems because the typical system design will employ closed heads and wet system piping. A manual actuation valve would serve no purpose because sprinkler heads are already supplied with pressurized water and will discharge water only when the individual fusible elements open the heads.

**904.12.2 System interconnection.** The actuation of the fire extinguishing system shall automatically shut down the fuel or electrical power supply to the cooking equipment. The fuel and electrical supply reset shall be manual.

- ❖ The actuation of any fire suppression system must automatically shut off all sources of fuel or power to all cooking equipment located beneath the exhaust hood protected by the suppression system. This requirement is intended to shut off all heat sources that could reignite or intensify a fire. Shutting off a fuel and power supply to cooking appliances will eliminate an ignition source and allow the cooking surfaces to cool down. This shutdown is accomplished with mechanical or electrical interconnections between the suppression system and a shutoff valve or switch located on the fuel or electrical supply.

Common fuel shutoff valves include mechanical-type gas valves and electrical solenoid-type gas valves. Contactor-type switches or shunt-trip circuit breakers can be used for electrically heated appliances. The fuel or electric source must not be automatically restored after the suppression system has been actuated.

Chemical-type fire-extinguishing systems discharge for only a limited time and can discharge only once before recharge and reset; therefore, precautions must be taken to prevent a fire from reigniting. After a fire is detected and the initial suppressant discharge begins, the fuel and power supply will be locked out, thereby preventing the operation of the appliances until all systems are again ready for operation. Fuel and power supply shutoff must be manually restored by resetting a mechanical linkage or holding (latching)-type circuit.

**904.12.3 Carbon dioxide systems.** Where carbon dioxide systems are used, there shall be a nozzle at the top of the ventilating duct. Additional nozzles that are symmetrically arranged to give uniform distribution shall be installed within vertical ducts exceeding 20 feet (6096 mm) and horizontal ducts exceeding 50 feet (15 240 mm). Dampers shall be installed at either the top or the bottom of the duct and shall be arranged to operate automatically upon activation of the fire-extinguishing system. Where the damper is installed at the top of the duct, the top nozzle shall be immediately below the damper. Automatic carbon dioxide fire-extinguishing systems shall be sufficiently sized to protect all hazards venting through a common duct simultaneously.

- ❖ This section states specific design requirements for nozzle locations, dampers and ducts for carbon dioxide extinguishing systems that may be used to protect commercial cooking systems. These requirements are intended to supersede similar, more general provisions in NFPA 12. Because carbon dioxide (CO<sub>2</sub>) is a gaseous suppressant, dampers are required in the ductwork to define the atmosphere where the fire event would be. A specific concentration of CO<sub>2</sub> is

necessary and dampers are required to define and contain the suppressant. The discharge cools exposed surfaces in addition to depriving the fire of oxygen. Although not mentioned specifically in this section, the applicable provisions of NFPA 12 should also be applied because the system is a CO<sub>2</sub> system as referenced in Section 904.8.

**904.12.3.1 Ventilation system.** Commercial-type cooking equipment protected by an automatic carbon dioxide extinguishing system shall be arranged to shut off the ventilation system upon activation.

- ❖ Shutting down the ventilation system upon activation of the CO<sub>2</sub> extinguishing system maintains the desired concentration of carbon dioxide to suppress the fire. Leakage of gas from the protected area should be kept to a minimum. Where leakage is anticipated, additional quantities of carbon dioxide must be provided to compensate for any losses.

**904.12.4 Special provisions for automatic sprinkler systems.** *Automatic sprinkler systems* protecting commercial-type cooking equipment shall be supplied from a separate, readily accessible, indicating-type control valve that is identified.

- ❖ This section requires a separate control valve in the water line to the sprinklers protecting the cooking and ventilating system. The additional valve allows the flexibility to shut off the system for repairs or for cleanups after sprinkler discharge without taking the entire system out of service.

**904.12.4.1 Listed sprinklers.** Sprinklers used for the protection of fryers shall be tested in accordance with UL 199E, *listed* for that application and installed in accordance with their listing.

- ❖ Sprinklers specifically listed for such use must be used when protecting deep-fat fryers. These specially listed sprinklers use finer water droplets than standard spray sprinklers. The water spray lowers the temperature below a point where the fire can sustain itself and reduces the possibility of expanding the fire. UL 199E addresses these special sprinklers and includes performance tests for deep-fat fryer extinguishment and also deep-fat fryer cooking temperature splash. The selection of inappropriate sprinklers for deep-fat fryer protection can increase the hazards during water application rather than suppressing the fire.

**904.12.5 Portable fire extinguishers for commercial cooking equipment.** Portable fire extinguishers shall be provided within a 30-foot (9144 mm) distance of travel from commercial-type cooking equipment. Cooking equipment involving solid fuels or vegetable or animal oils and fats shall be protected by a Class K rated portable extinguisher in accordance with Section 904.12.5.1 or 904.12.5.2, as applicable.

- ❖ To combat a fire in its incipient stage, access to a manual means of extinguishment is critical. Although a 30-foot (9144 mm) maximum travel distance is specified, the location of the extinguisher should be a

safe distance from the cooking equipment so that it will not become involved in the fire. Only Class K-rated extinguishers that have been tested on commercial cooking appliances can be used.

**904.12.5.1 Portable fire extinguishers for solid fuel cooking appliances.** Solid fuel cooking appliances, whether or not under a hood, with fireboxes 5 cubic feet (0.14 m<sup>3</sup>) or less in volume shall have a minimum 2.5-gallon (9 L) or two 1.5-gallon (6 L) Class K wet-chemical portable fire extinguishers located in accordance with Section 904.12.5.

- ❖ The fuels used in solid fuel-fired cooking appliances present significantly more potential burning surface area than the flat surface of a grill or deep fat fryer. This surface area is also often shielded by other solid fuel elements. As a result, a large extinguisher or two moderate-sized extinguishers are required. The 2<sup>1</sup>/<sub>2</sub>-gallon (9 L) extinguisher roughly equates to a 2A rating. The K-rating is necessary rather than using a water-based agent because the discharge from water-based extinguishers is usually in the form of a straight stream rather than a less concentrated, flooding type of coverage. A straight stream can dislodge the burning solid fuel material and possibly spread the burning coals to other areas where they could pose both a secondary fire risk, as well as a life safety hazard. The same travel distance to an extinguisher is required for solid fuel extinguishers as for deep fat fryer extinguishers so that manual suppression can be provided if necessary in a reasonable time. See the commentary to Section 904.12.5.2 for further discussion of Class K extinguishers.

**904.12.5.2 Class K portable fire extinguishers for deep fat fryers.** Where hazard areas include deep fat fryers, listed Class K portable fire extinguishers shall be provided as follows:

1. For up to four fryers having a maximum cooking medium capacity of 80 pounds (36.3 kg) each: one Class K portable fire extinguisher of a minimum 1.5-gallon (6 L) capacity.
2. For every additional group of four fryers having a maximum cooking medium capacity of 80 pounds (36.3 kg) each: one additional Class K portable fire extinguisher of a minimum 1.5-gallon (6 L) capacity shall be provided.
3. For individual fryers exceeding 6 square feet (0.55 m<sup>2</sup>) in surface area: Class K portable fire extinguishers shall be installed in accordance with the extinguisher manufacturer's recommendations.

- ❖ In recent years, commercial cooking operations have begun to use improved, more efficient deep fat fryer-type cooking appliances and more healthful, unsaturated cooking oils that require a much higher cooking temperature than the former saturated oils. The Class K extinguishing agent and extinguishers were developed to deal with this new hazard. Class K extinguishers use a wet-chemical, potassium acetate-based agent that has proven to be more effective in

fighting these fires and provides a cooling effect for the deep fat fryer hazard. Though primarily intended for cooking fires, many Class K extinguishers can also be effectively used on Class A, B and C hazards.

Class K fire extinguishers do not have letter ratings similar to other types of extinguishers. The capacity of the Class K extinguisher becomes the effective rating. Based on the extinguishing capability of a moderate sized Class K extinguisher the maximum quantity of typical fat frying medium can be determined. This quantity is determined by weight based on the typical deep fat fryer. A fryer capacity of 80 pounds (36 kg) can provide a surface area between 4½ to 6 square feet (0.42 to 0.56 m<sup>2</sup>), depending on the manufacturer. When the surface area exceeds 6 square feet (0.56 m<sup>2</sup>), guidelines for Class K extinguishers are no longer applicable. Consequently, for the larger surface area fryers the size of Class K extinguisher should be based on the manufacturer's recommendations. Although not specifically indicated in the code text, the understanding is that if the weight capacity of the fryer exceeds 80 pounds (36 kg) but the surface area is less than 6 square feet (0.56 m<sup>2</sup>), the manufacturer's recommendations should be applied for those conditions as well.

**904.12.6 Operations and maintenance.** Automatic fire-extinguishing systems protecting commercial cooking systems shall be maintained in accordance with Sections 904.12.6.1 through 904.12.6.3.

- ❖ Most fires in commercial kitchens involve the cooking appliance and exhaust system in some way. Proper operation of the system in accordance with the IMC, as well as routine maintenance can reduce the hazards related to the collection and removal of smoke and grease-laden vapors.

**904.12.6.1 Existing automatic fire-extinguishing systems.** Where changes in the cooking media, positioning of cooking equipment or replacement of cooking equipment occur in existing commercial cooking systems, the automatic fire-extinguishing system shall be required to comply with the applicable provisions of Sections 904.12 through 904.12.4.

- ❖ The provisions of Section 904.12 have long required new commercial cooking system preengineered fire extinguishing systems to be tested in accordance with UL 300 and listed and labeled for that use. The question has often arisen, however, as to whether or how those provisions should be applied to existing systems. This section provides guidance and adds clarity as to when existing automatic fire extinguishing systems protecting commercial cooking operations need to be modified, upgraded or replaced to meet UL 300 requirements. These provisions are thought to be consistent with provisions adopted by some states and local jurisdictions on this topic.

**904.12.6.2 Extinguishing system service.** Automatic fire-extinguishing systems shall be serviced at least every six

months and after activation of the system. Inspection shall be by qualified individuals, and a certificate of inspection shall be forwarded to the *fire code official* upon completion.

- ❖ Range hood fire-extinguishing systems must be inspected and serviced at regular intervals to determine that they are ready to perform the intended function. Obviously, service is required after the suppression system discharges. The extent of service and maintenance depends on the type of fire-extinguishing system installed. The NFPA standard corresponding to the installed extinguishing agent should be consulted for additional service requirements (see commentary, Section 904.12).

**904.12.6.3 Fusible link and sprinkler head replacement.** Fusible links and automatic sprinkler heads shall be replaced at least annually, and other protection devices shall be serviced or replaced in accordance with the manufacturer's instructions.

**Exception:** Frangible bulbs are not required to be replaced annually.

- ❖ Because of the potential accumulation of grease or other contaminants that could adversely affect proper operation, fusible links and automatic sprinkler heads must be replaced at least annually. The sensing elements of the fusible link devices as well as the sprinkler heads must be routinely visually inspected and replaced as needed, at least annually.

The exception allows frangible bulb-type sprinklers to not be replaced as long as the annual examination shows no accumulation of grease or other contaminants.

**904.13 Domestic cooking systems in Group I-2 Condition 1.** In Group I-2 Condition 1 occupancies where cooking facilities are installed in accordance with Section 407.2.6 of the *International Building Code*, the domestic cooking hood provided over the cooktop or range shall be equipped with an automatic fire-extinguishing system of a type recognized for protection of domestic cooking equipment. Preengineered automatic extinguishing systems shall be tested in accordance with UL 300A and listed and labeled for the intended application. The system shall be installed in accordance with this code, its listing and the manufacturer's instructions.

- ❖ As nursing homes move away from institutional models, it is critical to have a functioning kitchen that can serve as the "hearth of the home." Instead of a large, centralized, institutional kitchen where all meals are prepared and delivered to a central dining room or the resident's room, the new "household model" nursing home uses decentralized kitchens and small dining areas to create the feeling and focus of home. For persons with dementia, it is particularly important to have spaces that look familiar, like the kitchen in their former home, to increase their understanding and ability to function at their highest level. This section addresses the fire protection system needs for these

kitchens. Note that these occupancies already contain quick response sprinklers. This section provides the requirements for the hood fire extinguishing system needed for the cooking hood located over the cook top or range. That system is required to be in compliance with UL 300A.

**904.13.1 Manual system operation and interconnection.** Manual actuation and system interconnection for the hood suppression system shall be in accordance with Sections 904.12.1 and 904.12.2, respectively.

- ❖ To manually activate such systems, the requirements of Sections 904.12.1 and 904.12.2 would apply. This provides for the location of the manual shut down and also directs what equipment and power needs to automatically shut down. See the commentary to Sections 904.12.1 and 904.12.2.

**904.13.2 Portable fire extinguishers for domestic cooking equipment in Group I-2 Condition 1.** A portable fire extinguisher complying with Section 906 shall be installed within a 30-foot (9144 mm) distance of travel from domestic cooking appliances.

- ❖ This requirement for a portable fire extinguisher relates to the added safety of allowing a residential-type kitchen in nursing homes. This provides another line of defense and the location is focused on the distance from the cooking appliances.

## SECTION 905 STANDPIPE SYSTEMS

**905.1 General.** Standpipe systems shall be provided in new buildings and structures in accordance with Sections 905.2 through 905.10. In buildings used for *high-piled combustible storage*, fire protection shall be in accordance with Chapter 32.

- ❖ Standpipe systems are required in buildings to provide a quick, convenient water source for fire department use where hose lines would otherwise be impractical, such as in high-rise buildings. Standpipe systems can also be used prior to deployment of hose lines from fire department apparatus. The requirements for standpipes are based on practical requirements of typical fire-fighting operations and the nationally recognized standard NFPA 14.

The threads on connections to which the fire department may connect a hose must be compatible with the fire department hose threads (see commentary, Section 903.3.6). Chapter 32 requires a Class I standpipe system in exit passageways of buildings used for high-piled storage. Note that if a building containing high-piled storage does not contain an exit passageway then standpipes would not be required. High-piled storage involves the solid piled, bin box, palletized or rack storage of Class I through IV commodities over 12 feet (3658 mm) high. High-hazard commodities stored higher than 6 feet (1829 mm) are also considered high piled.

**905.2 Installation standard.** Standpipe systems shall be installed in accordance with this section and NFPA 14. Fire department connections for standpipe systems shall be in accordance with Section 912.

- ❖ This section requires the installation of standpipe systems to comply with the applicable provisions of NFPA 14 in addition to Section 905. NFPA 14 contains the minimum requirements for the installation of standpipe and hose systems for buildings and structures. The standard addresses additional requirements not addressed in the code, such as pressure limitations, minimum flow rates, piping specifications, hose connection details, valves, fittings, hangers and the testing and inspection of standpipes. The periodic inspection, testing and maintenance of standpipe systems must comply with NFPA 25.

Section 905 and NFPA 14 recognize three classes of standpipe systems: Class I, II or III. The type of system required depends on building height, building area, type of occupancy and the extent of automatic sprinkler protection. Section 905 also recognizes five types of standpipe systems: automatic dry, automatic wet, manual dry, manual wet and semiautomatic dry. The use of each type of system is limited to the building conditions and locations identified in Section 905.3. The classes and types of standpipe systems are defined in Section 202.

Section 912, to which this section points, provides a comprehensive set of requirements for FDCs reducing the opportunity for any of its requirements to be overlooked. See the commentary for Section 912.

**905.3 Required Installations.** Standpipe systems shall be installed where required by Sections 905.3.1 through 905.3.8. Standpipe systems are allowed to be combined with *automatic sprinkler systems*.

**Exception:** Standpipe systems are not required in Group R-3 occupancies.

- ❖ Standpipe systems are installed in buildings based on the occupancy, fire department accessibility and special conditions that may require manual fire suppression exceeding the capacity of a fire extinguisher. Standpipe systems are most commonly required for buildings that exceed the height threshold requirement in Section 905.3.1 or due to features of a specific occupancy or the building, such as covered and open mall buildings, stages and underground buildings.

This section also states that a standpipe system does not have to be separate from an installed sprinkler system. It is common practice in multistory buildings for the standpipe system risers to also serve as risers for the automatic sprinkler systems.

In these instances, precautions need to be taken so that the operation of one system will not interfere with the operation of the other system. Therefore, control valves for the sprinkler system must be installed where the sprinklers are connected to the standpipe riser at each floor level. This allows the

standpipe system to remain operational, even if the sprinkler system is shut off at the floor control valve.

The exception recognizes that standpipe systems in Group R-3 occupancies would be of minimal value to the fire department and would send the wrong message to the occupants of a dwelling unit. In the case of multiple single-family dwellings, each dwelling unit has a separate entrance and is separated from the other units by 1-hour fire partitions. These conditions permit ready access to fires and also provide for a degree of fire containment through compartmentation, which is not always present in other occupancies.

**905.3.1 Height.** Class III standpipe systems shall be installed throughout buildings where the floor level of the highest story is located more than 30 feet (9144 mm) above the lowest level of the fire department vehicle access, or where the floor level of the lowest story is located more than 30 feet (9144 mm) below the highest level of fire department vehicle access.

**Exceptions:**

1. Class I standpipes are allowed in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2.
2. Class I manual standpipes are allowed in open parking garages where the highest floor is located not more than 150 feet (45 720 mm) above the lowest level of fire department vehicle access.
3. Class I manual dry standpipes are allowed in open parking garages that are subject to freezing temperatures, provided that the hose connections are located as required for Class II standpipes in accordance with Section 905.5.

4. Class I standpipes are allowed in *basements* equipped throughout with an *automatic sprinkler system*.
5. In determining the lowest level of fire department vehicle access, it shall not be required to consider either of the following:
  - 5.1. Recessed loading docks for four vehicles or less.
  - 5.2. Conditions where topography makes access from the fire department vehicle to the building impractical or impossible.

❖ Given the available manpower on the fire department vehicle, standard fire-fighting operations and standard hose sizes, a 30-foot (9144 mm) vertical distance is generally considered the maximum height to which a typical fire department engine company can practically and readily extend its hose lines. Thus, the maximum vertical travel (height) threshold is based on the time it would take a typical fire department engine (pumper) company to manually suppress a fire. The standpipe connection reduces the time needed for the fire department to extend hose lines up or down stairways to advance and apply water to the fire. For this use, a minimum Class III standpipe system is required.

With respect to the height of the building, the threshold is measured from the level at which the fire department can gain access to the building directly from its vehicle and begin vertical movement. Floor levels above grade are measured from the lowest level of fire department vehicle access to the highest floor level above [see Commentary Figure 905.3.1(1)]. If a building contains floor levels below

the level of fire department vehicle access, the measurement is made from the highest level of fire department vehicle access to the lowest floor level. In cases where a building has more than one level of fire department vehicle access, the most restrictive measurement is used because it is not known at which level the fire department will access the building. In other words, the vertical distance is to be measured from the more restrictive level of fire department vehicle access to the level of the highest (or lowest, if below) floor [see Commentary Figure 905.3.1(2)].

The threshold based on the height of the building is independent of the occupancy of the building, the area of the building or the presence of an automatic sprinkler system. This is based on the universal need to be able to provide a water supply for fire suppression in any building and on the limitations of the physical effort necessary to extend hose lines vertically.

Before discussing the exceptions it is important to understand the differences between the different classes and operational characteristics of standpipes. More detailed information is included in Section 202 for the definitions of the different classes and types of standpipes.

Standpipes can be dry or wet, manual, automatic or semiautomatic. Automatic systems can be either wet or dry. Manual systems can be either wet or dry. A semiautomatic system is always in association with a dry system.

The code is written such that it could be assumed the default is an automatic wet system. This is, however, not the case. The requirement is left to the design standard, NFPA 14. Section 5.4.1.1 of NFPA 14 indicates that Class I standpipes can be manual if

the building is not high-rise. Section 5.4.1.4 of the standard indicates that a Class I standpipe must be wet except where the pipe is subject to freezing. Thus, where a Class I standpipe is installed, possibly as a part of Exception 1, the system can be manual wet if the building is not a high rise. This is consistent with IFC Committee Interpretation No. 33-03. As long as the building is not high rise, it can be provided with a Class I standpipe system that is manual wet.

Class II and III standpipes are required to be automatic-wet or semiautomatic wet except where the piping is subject to freezing according to Section 5.4.2 of NFPA 14. They cannot be manual. Only Class I standpipes can be manual and only be used under the conditions noted in this code. Note that other sections of the code may specify whether the system must be automatic or not. If the requirement is not noted elsewhere in the code, then the decision to use an automatic or manual system is left to the designer.

Exception 1 recognizes the fact that with a fully operational automatic sprinkler system, the time that the fire department has to extend hoses within the building is substantially increased and that the amount of effort required is greatly reduced. Consequently, a single Class I connection can be provided. The second, 1½-inch (38 mm) connection is allowed to be omitted. NFPA 14 also has a similar provision but is more restrictive as it only eliminates the hose station and additionally requires a 2½ inch by 1½ inch (65 mm by 40 mm) reducer and a cap attached with a chain (Section 7.3.4.1 of NFPA 14). In accordance with Section 102.7, the code would take precedence and the reducer and cap would not be required.

Exception 2 identifies one of the issues relative to open parking garages. This exception allows for the garage, when not more than 150 feet (45 720 mm) in height above the lowest level of fire department access, to have a wet standpipe but without additional operating pressure until the fire department connects and begins pumping into the system. This makes sense since normal operations typically do not begin until after the fire department is on the scene and has made its initial assessments. This is generally considered to be the maximum safe height for pumpers to overcome the hydrostatic head presented by 150 feet (45 720 mm) of water. Careful considerations should be made since not all fire departments have equipment capable of this type of pumping capacity.

Exception 3 is similar to the prior exception but with the added provision that the standpipe can be dry if subject to freezing, regardless of height. Because the standpipe will be without water and dependent upon the fire department to provide both water and pressure, standpipe outlets must be spaced more frequently, as noted in Section 905.5 for Class II standpipes so that fire fighters can connect and begin operations quicker. The exception does not require Class II outlets; only that the spacing be consistent with the requirement for Class II.

Exception 4 is similar to Exception 1 but only addresses sprinklers in the basement. Thus it is possible to use this exception if only the basement is protected by automatic sprinklers. However, Class I connections can only be provided in the basements—not on the upper floors. The exception cannot be used for stories above grade unless the entire building is sprinklered and, therefore, compliant with Exception 1.

Exception 5 provides additional information about what must be considered when determining building height with respect to the level of fire department vehicle access. The first item is a practical one that excludes loading docks of a limited size. The second item notes that although it may be possible to have a fire department vehicle arrive adjacent to the building at a low level, it may not be possible for the fire department to access the building from that level. An example of this condition would be where a road surface is located below a building constructed on a bluff. Although the fire department vehicles can approach from the lower road, fire department personnel cannot access the building from that lower level. Thus, the standpipe requirement would not be based on the road below the bluff.

**905.3.2 Group A.** Class I automatic wet standpipes shall be provided in nonsprinklered Group A buildings having an *occupant load* exceeding 1,000 persons.

**Exceptions:**

1. Open-air-seating spaces without enclosed spaces.

2. Class I automatic dry and semiautomatic dry standpipes or manual wet standpipes are allowed in buildings that are not high-rise buildings.

❖ The main concern in assembly occupancies with a high occupant load is evacuation. Many occupants may not be familiar with either their surroundings or the egress arrangement in the building. This section also assumes the building is not sprinklered; therefore, control and suppression of the fire is left to the fire department.

Exception 1 exempts open-air seating without enclosed spaces, such as grandstands and bleachers. In such occupancies, a buildup of smoke and hot gases is not possible because these structures are open to the atmosphere.

Exception 2 states that in lieu of a Class I automatic wet standpipe, automatic-dry and semiautomatic dry Class I standpipes are permitted in buildings that are not considered to be a high rise.

**905.3.3 Covered and open mall buildings.** Covered mall and open mall buildings shall be equipped throughout with a standpipe system where required by Section 905.3.1. Mall buildings not required to be equipped with a standpipe system by Section 905.3.1 shall be equipped with Class I hose connections connected to the *automatic sprinkler system* sized to deliver water at 250 gallons per minute (946.4 L/min) at the most hydraulically remote hose connection while concurrently supplying the automatic sprinkler system demand. The standpipe system shall be designed not to exceed a 50 pounds per square inch (psi) (345 kPa) residual pressure loss with a flow of 250 gallons per minute (946.4 L/min) from the fire department connection to the hydraulically most remote hose connection. Hose connections shall be provided at each of the following locations:

1. Within the mall at the entrance to each exit passageway or corridor.
2. At each floor-level landing within *interior exit stairways* opening directly on the mall.
3. At exterior public entrances to the mall of a covered mall building
4. At public entrances at the perimeter line of an open mall building.
5. At other locations as necessary so that the distance to reach all portions of a tenant space does not exceed 200 feet (60 960 mm) from a hose connection.

❖ Covered and open mall buildings are only required to have a standpipe system if Section 905.3.1 requires such features. If standpipes are not required due to building height, Class I hose connections that are connected to the automatic sprinkler system are still required. Also, to ensure that both the sprinkler system and hose connections will function at an acceptable level, the system must be sized for both the sprinkler demand and the hose connection demand. This section specifies a minimum flow rate and a

maximum pressure loss to the most remote hose connection so that the fire department can gain full use of the hose connection during a fire. Hose connections are required when a standpipe system is not at key locations, such as entrances to exit passageways and at entrances to the covered or open mall. Note that these locations are essentially the same locations required for Class I hose connections in Section 905.4, except that this section also requires that the distance of all portions of tenant spaces does not exceed 200 feet (60 960 mm) from a hose connection.

**905.3.4 Stages.** Stages greater than 1,000 square feet (93 m<sup>2</sup>) in area shall be equipped with a Class III wet standpipe system with 1½-inch and 2½-inch (38 mm and 64 mm) hose connections on each side of the stage.

**Exception:** Where the building or area is equipped throughout with an *automatic sprinkler system*, a 1½-inch (38 mm) hose connection shall be installed in accordance with NFPA 13 or in accordance with NFPA 14 for Class II or III standpipes.

- ❖ Because of the potentially large fuel load and three-dimensional aspect of the fire hazard associated with stages greater than 1,000 square feet (93 m<sup>2</sup>) in area, Class III standpipes are required on each side of these large stages. The standpipes must be equipped with a 1½-inch (38 mm) hose connection and a 2½-inch (64 mm) hose connection. The 1½-inch (38 mm) connection is for the hose requirement in Section 905.3.4.1. The 2½-inch (64 mm) connection is to provide greater flexibility for the fire department in its fire-fighting operations.

Stages, as used in this section, are those stages defined in Section 410.2 of the IBC, which include overhead hanging curtains, drops, scenery or stage effects other than lighting and sound. These were traditionally referred to as “legitimate stages.” It is not an appropriate application of this section to require standpipes for elevated areas in banquet rooms, or theatrical platforms where the higher fuel loads associated with a legitimate stage do not exist.

The exception recognizes the benefit of the building or area being sprinklered. If so, then only a single 1½-inch (38 mm) connection is required. This hose connection is intended to be used by the fire department and apply less water from the hose due to the suppression activity of the sprinkler system. Hose threads must be compatible with those of the fire department as required in Section 903.3.6.

In a fully sprinklered building it is acceptable to supply the hose connections through the same standpipe as the sprinklers. This is reflected in the reference to both NFPA 13, which acknowledges this concept, and NFPA 14, which contains similar provisions. If the provisions of NFPA 14 are used, although the standpipe must be wet and Class II in its installation, the design of the water supply and interconnection of systems can be in accordance with the

requirements for Class II as well as for Class III standpipes.

**905.3.4.1 Hose and cabinet.** The 1½-inch (38 mm) hose connections shall be equipped with sufficient lengths of 1½-inch (38 mm) hose to provide fire protection for the stage area. Hose connections shall be equipped with an *approved* adjustable fog nozzle and be mounted in a cabinet or on a rack.

- ❖ The 1½-inch (38 mm) standpipe hose installed for stages greater than 1,000 square feet (93 m<sup>2</sup>) in area is intended for use by stage personnel who have been trained to use it. The length of hose provided is a function of the size and configuration of the stage. This includes by definition the entire performance area and adjacent backstage and support areas not fire separated from the performance area. The effective reach of the fire stream from the fog nozzle is a function of the available water supply, and in particular, the pressure. Fog nozzles typically require 100 pounds per square inch (psi) (690 kPa) for optimum performance.

**905.3.5 Underground buildings.** Underground buildings shall be equipped throughout with a Class I automatic wet or manual wet standpipe system.

- ❖ Underground buildings present unique hazards to life safety because of their isolation and inaccessibility. Additional fire protection and fire fighting measures for the fire department are required to compensate for the lack of exterior access for fire suppression and rescue operations (see Section 405 of the IBC).

**905.3.6 Helistops and heliports.** Buildings with a rooftop *helistop* or *heliport* shall be equipped with a Class I or III standpipe system extended to the roof level on which the *helistop* or *heliport* is located in accordance with Section 2007.5.

- ❖ Buildings containing rooftop helistops or heliports are required to be equipped with a Class I or III standpipe. A heliport is a distinct hazard that will involve flammable fuels. In the event of an emergency, rapid deployment of hand hose lines will be necessary to attack a resulting fire, effectuate rescue and to protect exposures and the remainder of the building.

The requirement results in a standpipe system throughout the building, not just a connection at the roof level. This is critical in fire-fighting operations because many times the connection below the rooftop level may be needed just to gain access onto the roof. If the only connection is on the roof, it is of no use if the fire fighters cannot get to it.

Additionally, a heliport includes fueling operations. It is entirely possible for a spill to not only affect the rooftop, but also floors below as the liquid fuel spreads. The standpipe system will again be utilized in these situations.

Section 2007.5 requires a 2½-inch (64 mm) standpipe outlet to be within 150 feet (45 675 mm) of all portions of the heliport or helistop area and be either Class I or III.

**905.3.7 Marinas and boatyards.** Standpipes in marinas and boatyards shall comply with Chapter 36.

❖ Section 3604.2 contains the specifics as to when standpipes are required at marinas. Marinas and boatyards have unique challenges for fire fighting. Although there is water readily available, it is not easily or effectively capable of being applied to a fire at such a facility. A fire in such facilities can spread from structure to structure and from vessel to vessel with no effective way to attack and control it. Section 3604.2 references NFPA 303 for the standpipe requirements and additionally requires that no point on the marina pier or float system exceed 150 feet (45 675 mm) from a standpipe hose connection (see commentary, Section 3604.2).

**905.3.8 Rooftop gardens and landscaped roofs.** Buildings or structures that have rooftop gardens or landscaped roofs and that are equipped with a standpipe system shall have the standpipe system extended to the roof level on which the rooftop garden or landscaped roof is located.

❖ This section requires that if the building is equipped with a standpipe system, whether or not such systems are required, it must be extended to a roof containing a garden or that is landscaped. These requirements relate to the requirements in Section 317 that address the increased fuel load being added to roofs.

**905.4 Location of Class I standpipe hose connections.** Class I standpipe hose connections shall be provided in all of the following locations:

1. In every required *interior exit stairway*, a hose connection shall be provided for each story above and below grade plane. Hose connections shall be located at an intermediate landing between stories, unless otherwise *approved by the fire code official*.
2. On each side of the wall adjacent to the *exit* opening of a horizontal *exit*.

**Exception:** Where floor areas adjacent to a horizontal *exit* are reachable from an *interior exit stairway* hose connection by a 30-foot (9144 mm) hose stream from a nozzle attached to 100 feet (30 480 mm) of hose, a hose connection shall not be required at the horizontal *exit*.

3. In every *exit* passageway, at the entrance from the exit passageway to other areas of a building.

**Exception:** Where floor areas adjacent to an exit passageway are reachable from an *interior exit stairway* hose connection by a 30-foot (9144 mm) hose stream from a nozzle attached to 100 feet (30 480 mm) of hose, a hose connection shall not be required at the entrance from the exit passageway to other areas of the building.

4. In covered mall buildings, adjacent to each exterior public entrance to the mall and adjacent to each entrance from an *exit* passageway or *exit corridor* to the mall. In open mall buildings, adjacent to each public entrance to the mall at the perimeter line and adjacent

to each entrance from an exit passageway or exit corridor to the mall.

5. Where the roof has a slope less than four units vertical in 12 units horizontal (33.3-percent slope), a hose connection shall be located to serve the roof or at the highest landing of an *interior exit stairway* with access to the roof provided in accordance with Section 1011.12.
6. Where the most remote portion of a nonsprinklered floor or story is more than 150 feet (45 720 mm) from a hose connection or the most remote portion of a sprinklered floor or story is more than 200 feet (60 960 mm) from a hose connection, the *fire code official* is authorized to require that additional hose connections be provided in *approved* locations.

❖ Hose connections are required for the fire department to make use of the standpipe system. Since the fire department will typically access the building using the stairways, and most fire departments do not permit entry to the fire floor without an operating hose line, a hose connection must be installed for each floor level of each required enclosed stairway.

Item 1 also specifies that the hose connections are to be located at intermediate landings between stories. This reduces congestion at the stairway door and may reduce the hose lay distance. The hose connections, however, are still permitted at each story instead of at the intermediate landing if this arrangement is approved by the fire code official.

Because horizontal exits are also primary entrances to the fire floor, Item 2 states that hose connections must also be provided at each horizontal exit. The construction of the fire separation assembly used as the horizontal exit will protect the fire fighters while they are connecting to the standpipe system. The hose connections are to be located on each side of the horizontal exit to enable fire fighters to be in a protected area, regardless of the location of the fire. The exception acknowledges that there may already be a hose connection in close proximity to the horizontal exit if there is a stairway adjacent to the horizontal exit. The intent is to allow fewer standpipe outlets if the area can be adequately covered by the standpipes in stairways since those are the standpipes typically used by the fire department.

Item 3 states that an exit passageway in a building required to have a standpipe system is typically used as an extension of a required exit stairway. This allows use of the exit passageway for fire-fighting staging operations in the same way as an exit stair. The exception acknowledges that there may already be a hose connection in close proximity to the exit passageway. If there is a stairway containing a hose connection in close proximity to the exit passageway that can meet the 30-foot hose stream from a nozzle attached to 100 feet of hose then an additional standpipe is not required. The intent is to allow fewer standpipe outlets if the area can be adequately covered by the standpipes in stairways since those are the standpipes typically used by the fire department.

In covered and open mall buildings, Item 4 requires hose connections at each entrance to an exit passageway or exit corridor. In addition, covered mall buildings would be required to have connections at each exterior public entrance. Open malls would require connections at the public entrance perimeter line. These locations allow fire personnel to have a support line as soon as they enter the building.

Item 5 is consistent with NFPA 14 regarding the installation of Class I standpipe hose connections on the roofs of buildings. This requirement requires only one standpipe to extend to the roof level or highest landing of the stair serving the roof. This coordinates with Section 1011.12 which only requires one stairway to extend to the roof.

Hose connections in each exit stairway result in hose connections being located based on the travel distances permitted in Table 1017.2, which recognizes that most fire departments carry standpipe hose packs with 150 feet (45 720 mm) of hose or possibly with 100 feet (30 480 mm) of hose and an additional 50-foot (15 240 mm) section that could be easily connected.

With the typical travel distance permitted in non-sprinklered buildings of 200 feet (60 960 mm), reasonable coverage is provided when the effective reach of a fire stream is considered. Depending on the arrangement of the floor, however, all areas may not be effectively protected. Although this situation could easily be corrected by locating additional hose connections on the floor, such connections may rarely be used because of the difficulty in identifying their location during a fire and the fact that most fire departments require an operational hose line before they enter the fire floor. Because longer travel distances are allowed in sprinklered buildings, the problem is increased, but the need for prompt manual suppression is reduced by the presence of the sprinkler system. Item 6 gives the fire code official the authority to require additional hose connections if needed.

**905.4.1 Protection.** Risers and laterals of Class I standpipe systems not located within an *interior exit stairway* shall be protected by a degree of *fire resistance* equal to that required for vertical enclosures in the building in which they are located.

**Exception:** In buildings equipped throughout with an *approved automatic sprinkler system*, laterals that are not located within an *interior exit stairway* are not required to be enclosed within fire-resistance-rated construction.

- ❖ To minimize the potential for damage to the standpipe systems from a fire, the risers and laterals (i.e., the horizontal segments of standpipe system piping) must be located in an enclosure having the same fire-resistance rating as required for a vertical or shaft enclosure within the building. The required fire-resistance rating for the enclosure can be determined as detailed in Section 713.4 of the IBC.

The exception states that the enclosure for laterals is not required if the building is equipped throughout with an approved automatic sprinkler system. The

potential for damage to the standpipe system is minimized by the protection provided by the sprinkler system. The automatic sprinkler system may be either an NFPA 13 or 13R system, depending on what was permitted for the building occupancy.

If the interior exit stairway is not required to have a rated enclosure, such as in an open parking garage, the laterals are similarly not required to be in an enclosure. The protection afforded the vertical riser in the stairway must be the same as that afforded the laterals. If the stairway is not required by other sections of the code to be located in a rated enclosure then the laterals are not required to be in rated protection either.

**905.4.2 Interconnection.** In buildings where more than one standpipe is provided, the standpipes shall be interconnected in accordance with NFPA 14.

- ❖ In cases where there are multiple Class I standpipe risers, the risers must be supplied from and interconnected to a common supply line. The required fire department connection must serve all of the sprinklers or standpipes in the building.

**905.5 Location of Class II standpipe hose connections.** Class II standpipe hose connections shall be accessible and shall be located so that all portions of the building are within 30 feet (9144 mm) of a nozzle attached to 100 feet (30 480 mm) of hose.

- ❖ Sections 905.5.1 through 905.5.3 specify the requirements for Class II standpipe hose connections. Class II standpipe systems are primarily intended for use by the building occupants.

This section for Class II standpipes does not specifically require hose stations and uses the term hose connection with a location based upon 100 feet (30 480 mm) of hose. However, the definition of Class II and III standpipes and Section 7.3.3.1 of NFPA 14 specifically require hose stations. Section 905.2 specifically references NFPA 14.

Although NFPA 14 requires a hose station, the decision as to whether a hose station is required may be one that is affected by the policies and procedures of the local fire department. It should be remembered that Class II hose connections and hose stations are intended for occupant use and not necessarily for fire department use. The fire department typically uses the Class I connection that is compatible with 2<sup>1</sup>/<sub>2</sub>-inch (64 mm) hose.

**905.5.1 Groups A-1 and A-2.** In Group A-1 and A-2 occupancies with *occupant loads* of more than 1,000, hose connections shall be located on each side of any stage, on each side of the rear of the auditorium, on each side of the balcony and on each tier of dressing rooms.

- ❖ Because of the high occupant load density in Group A-1 and A-2 occupancies, providing additional means for controlling fires in their initial stage is important to enable prompt evacuation of the building. This section is independent of the Class I standpipe requirement for stages based on square footage as indicated in Section 905.3.4.

**905.5.2 Protection.** Fire-resistance-rated protection of risers and laterals of Class II standpipe systems is not required.

- ❖ Class II standpipe systems are normally not located in exit stairways; standpipe hose connections are located near the protected area to allow quick access. Therefore, it is likely that neither the risers nor the laterals would be located in any enclosure.

**905.5.3 Class II system 1-inch hose.** A minimum 1-inch (25 mm) hose shall be allowed to be used for hose stations in light-hazard occupancies where investigated and *listed* for this service and where *approved* by the *fire code official*.

- ❖ This section permits the use of 1-inch (25 mm) listed noncollapsible hose as an alternative to 1½-inch (38 mm) hose, subject to the approval of the fire code official. This alternative is limited to light-hazard occupancies, such as office buildings and certain assembly occupancies that tend to have lower fuel loads, since a smaller hose can discharge less water.

**905.6 Location of Class III standpipe hose connections.** Class III standpipe systems shall have hose connections located as required for Class I standpipes in Section 905.4 and shall have Class II hose connections as required in Section 905.5.

- ❖ Class III standpipe systems that have both a 2½-inch (64 mm) hose connection and a 1½-inch (38 mm) hose connection must comply with the applicable requirements of Sections 905.4, 905.5 and 905.6. Thus, it is necessary to review and comply with all applicable provisions.

**905.6.1 Protection.** Risers and laterals of Class III standpipe systems shall be protected as required for Class I systems in accordance with Section 905.4.1.

- ❖ Because Class III standpipe systems are intended for use by fire-suppression personnel, they must be located in construction that has a fire-resistance rating equivalent to that of the vertical or shaft enclosure requirements of the building (see commentary, Section 905.4.1).

**905.6.2 Interconnection.** In buildings where more than one Class III standpipe is provided, the standpipes shall be interconnected in accordance with NFPA 14.

- ❖ As indicated in Section 905.4.2 for Class I standpipe systems, multiple standpipe risers must be interconnected with a common supply line. An indicating valve is typically installed at the base of each riser so that individual risers can be taken out of service without affecting the water supply or the operation of other standpipe risers.

**905.7 Cabinets.** Cabinets containing fire-fighting equipment, such as standpipes, fire hose, fire extinguishers or fire department valves, shall not be blocked from use or obscured from view.

- ❖ This section does not require that cabinets be provided to contain fire protection equipment. However, if they

are provided, cabinets must be readily visible and accessible at all times. Sections 905.7.1 and 905.7.2 contain additional criteria for the construction and identification of the cabinets. Where cabinets are located in fire-resistance-rated assemblies, the integrity of the assembly must be maintained. Cabinet design for hose connections, control valves or other devices that require manual operation should be such that there is sufficient clearance between the cabinet body and the device to allow grasping of the device (quite likely with a gloved hand) and prompt operation of it.

**905.7.1 Cabinet equipment identification.** Cabinets shall be identified in an *approved* manner by a permanently attached sign with letters not less than 2 inches (51 mm) high in a color that contrasts with the background color, indicating the equipment contained therein.

**Exceptions:**

1. Doors not large enough to accommodate a written sign shall be marked with a permanently attached pictogram of the equipment contained therein.
2. Doors that have either an *approved* visual identification clear glass panel or a complete glass door panel are not required to be marked.

- ❖ This section specifies the minimum criteria to make the signs readily visible. Different color combinations may be approved by the fire code official if the color contrast between the letters and the background is vivid enough to make the sign visible at an approved distance. The exceptions address alternatives to letter signage if the cabinet is still conspicuously identified or the contents are readily visible.

**905.7.2 Locking cabinet doors.** Cabinets shall be unlocked.

**Exceptions:**

1. Visual identification panels of glass or other *approved* transparent frangible material that is easily broken and allows access.
2. *Approved* locking arrangements.
3. Group I-3 occupancies.

- ❖ Ready access to all fire-fighting equipment in the cabinet is essential. The exceptions, however, recognize the need to lock cabinets for security reasons and to prevent theft or vandalism (see also the commentary, Section 906.8).

**905.8 Dry standpipes.** Dry standpipes shall not be installed.

**Exception:** Where subject to freezing and in accordance with NFPA 14.

- ❖ Wet standpipe systems are preferred because they tend to be the most reliable type of standpipe system; therefore, dry standpipes are prohibited unless subject to freezing. For example, Class I manual standpipe systems, which do not have a permanent water supply, are permitted in open parking structures. This recognizes that open parking structures are not

heated and that most fires are limited to the vehicle of origin. The use of any dry standpipe system instead of a wet standpipe should take into consideration the added response time and its effect on the occupancy characteristics of the building.

**905.9 Valve supervision.** Valves controlling water supplies shall be supervised in the open position so that a change in the normal position of the valve will generate a supervisory signal at the supervising station required by Section 903.4. Where a fire alarm system is provided, a signal shall be transmitted to the control unit.

**Exceptions:**

1. Valves to underground key or hub valves in roadway boxes provided by the municipality or public utility do not require supervision.
  2. Valves locked in the normal position and inspected as provided in this code in buildings not equipped with a fire alarm system.
- ❖ As with sprinkler systems, water control valves for standpipe systems must be electrically supervised as a means of determining that the system is operational (see commentary, Section 903.4).

Exception 1 recognizes that underground key or hub valves in roadway boxes are not normally supervised or need to be supervised whether the building contains a standpipe system or an automatic sprinkler system.

Exception 2 does not require the control valves for the standpipes to be electrically monitored if they are locked in the normal position and a fire alarm system is not installed in the building. When a fire alarm system is installed, the control valves for the standpipes must be electrically monitored and tied into the supervision required for the fire alarm system.

**905.10 During construction.** Standpipe systems required during construction and demolition operations shall be provided in accordance with Section 3313.

- ❖ As stated in Section 3313, at least one standpipe is required during construction of buildings four stories or more in height or during demolition of standpipe-equipped buildings. Standpipe systems must be accessible and operable during construction and demolition operations to assist in any potential fire (see commentary, Sections 3313.1 and 3313.2 of the code and Sections 3311.1 and 3311.2 of the IBC).

**905.11 Existing buildings.** Where required in Chapter 11, existing structures shall be equipped with standpipes installed in accordance with Section 905.

- ❖ This section simply refers to Chapter 11 which addresses all requirements that apply to existing buildings (see commentary, Section 1103.6).

**SECTION 906  
PORTABLE FIRE EXTINGUISHERS**

**906.1 Where required.** Portable fire extinguishers shall be installed in all of the following locations:

1. In new and existing Group A, B, E, F, H, I, M, R-1, R-2, R-4 and S occupancies.

**Exception:** In Group R-2 occupancies, portable fire extinguishers shall be required only in locations specified in Items 2 through 6 where each *dwelling unit* is provided with a portable fire extinguisher having a minimum rating of 1-A:10-B:C.

2. Within 30 feet (9144 mm) of commercial cooking equipment.
3. In areas where flammable or *combustible liquids* are stored, used or dispensed.
4. On each floor of structures under construction, except Group R-3 occupancies, in accordance with Section 3315.1.
5. Where required by the sections indicated in Table 906.1.
6. Special-hazard areas, including but not limited to laboratories, computer rooms and generator rooms, where required by the *fire code official*.

- ❖ Portable fire extinguishers (PFEs) are required in certain instances to give the occupants the means to suppress a fire in its incipient stage. The capability for manual fire suppression can contribute to the protection of the occupants, especially if there are evacuation difficulties associated with the occupancy or the specific hazard in the area. To be effective, personnel must be properly trained in the use of portable fire extinguishers.

Because of the high-hazard nature of building contents, portable fire extinguishers are required in occupancies in Group H.

Portable fire extinguishers are required in occupancies in Groups A, B, E, F, I, M, R-1, R-2, R-4 and S because of the need to control the fire in its early stages and because evacuation can be slowed by the density of the occupant load, the capability of the occupants to evacuate or the overall fuel load in the building. Because the IBC references the code for fire extinguisher requirements in new buildings, the code is applicable to new buildings.

Portable fire extinguishers are required in areas containing special hazards such as commercial cooking equipment and specific hazardous operations as indicated in Table 906.1. Because of the potentially extreme fire hazard associated with such areas or occupancy conditions, prompt extinguishment of the fire is critical.

Portable fire extinguishers are required in all buildings under construction, except in occupancies in Group R-3. The extinguishers are intended for use by construction personnel to suppress a fire in its incipient stages.

Portable fire extinguishers are also required in laboratories, computer rooms and other work spaces in which fire hazards may exist based on the use of the space. Many of these will be addressed by the required occupancy group criteria or by the specific hazard provisions of Table 906.1. Laboratories, for example, may not be considered Group H, but still use limited amounts of hazardous materials that would make manual means of fire extinguishment desirable.

The exception to Item 1 permits smaller PFEs in dwelling units of Group R-2 occupancies instead of larger PFEs in the common areas. Under the revised exception, the installation of 1-A:10-B:C PFEs within individual dwelling units that allows apartment owners to eliminate their installation in common areas such as corridors, laundry rooms and swimming pool areas. PFEs in these areas are susceptible to vandalism or theft. Another issue is that larger PFEs are more difficult for the infirm and elderly to safely deploy and operate. Note that the exception does not waive the ongoing maintenance requirement for PFEs within the dwelling units.

For the period of 2003 through 2007, NFPA reported that approximately 38,000 fires occurred annually in apartment buildings. Sixty percent of these fires occurred inside of dwelling units versus 14 percent that occur in common areas covered by Items 3 and 6 of Section 906.1. It is more logical to place PFEs inside of dwelling units versus common areas because it locates the extinguisher in an area where statistically most fires occur. If the occupant cannot control the fire using the PFE, he or she can escape and allow the automatic sprinkler system to operate and control the fire. This exception improves the safety of Group R-2 residents because it does not require them to leave a dwelling involved in a fire, find a PFE and then return to the fire-involved dwelling unit to attempt incipient fire attack.

Including this requirement in the code alerts designers and building officials that the extinguishers are required. This will allow designers to plan for thicker walls where recessed cabinets may be used or to design locations where the extinguishers will not project into or obstruct the egress or circulation path.

**TABLE 906.1.** See next column.

- ❖ Table 906.1 lists those sections of the code that represent specific occupancy conditions requiring portable fire extinguishers for incipient fire control. Wherever the code requires a fire extinguisher because of one of the listed occupancy conditions, it may identify the required rating of the extinguisher that is compatible with the hazard involved in addition to referencing Section 906.

**TABLE 906.1**  
**ADDITIONAL REQUIRED PORTABLE FIRE EXTINGUISHERS**

SECTION	SUBJECT
303.5	Asphalt kettles
307.5	Open burning
308.1.3	Open flames—torches
309.4	Powered industrial trucks
2005.2	Aircraft towing vehicles
2005.3	Aircraft welding apparatus
2005.4	Aircraft fuel-servicing tank vehicles
2005.5	Aircraft hydrant fuel-servicing vehicles
2005.6	Aircraft fuel-dispensing stations
2007.7	Heliports and helistops
2108.4	Dry cleaning plants
2305.5	Motor fuel-dispensing facilities
2310.6.4	Marine motor fuel-dispensing facilities
2311.6	Repair garages
2404.4.1	Spray-finishing operations
2405.4.2	Dip-tank operations
2406.4.2	Powder-coating areas
2804.3	Lumberyards/woodworking facilities
2808.8	Recycling facilities
2809.5	Exterior lumber storage
2903.5	Organic-coating areas
3006.3	Industrial ovens
3104.12	Tents and membrane structures
3206.10	High-piled storage
3315.1	Buildings under construction or demolition
3317.3	Roofing operations
3408.2	Tire rebuilding/storage
3504.2.6	Welding and other hot work
3604.4	Marinas
3703.6	Combustible fibers
5703.2.1	Flammable and combustible liquids, general
5704.3.3.1	Indoor storage of flammable and combustible liquids
5704.3.7.5.2	Liquid storage rooms for flammable and combustible liquids
5705.4.9	Solvent distillation units
5706.2.7	Farms and construction sites—flammable and combustible liquids storage
5706.4.10.1	Bulk plants and terminals for flammable and combustible liquids
5706.5.4.5	Commercial, industrial, governmental or manufacturing establishments—fuel dispensing
5706.6.4	Tank vehicles for flammable and combustible liquids
5906.5.7	Flammable solids
6108.2	LP-gas

**906.2 General requirements.** Portable fire extinguishers shall be selected, installed and maintained in accordance with this section and NFPA 10.

**Exceptions:**

1. The distance of travel to reach an extinguisher shall not apply to the spectator seating portions of Group A-5 occupancies.
  2. Thirty-day inspections shall not be required and maintenance shall be allowed to be once every 3 years for dry-chemical or halogenated agent portable fire extinguishers that are supervised by a *listed* and *approved* electronic monitoring device, provided that all of the following conditions are met:
    - 2.1. Electronic monitoring shall confirm that extinguishers are properly positioned, properly charged and unobstructed.
    - 2.2. Loss of power or circuit continuity to the electronic monitoring device shall initiate a trouble signal.
    - 2.3. The extinguishers shall be installed inside of a building or cabinet in a noncorrosive environment.
    - 2.4. Electronic monitoring devices and supervisory circuits shall be tested every 3 years when extinguisher maintenance is performed.
    - 2.5. A written log of required hydrostatic test dates for extinguishers shall be maintained by the *owner* to verify that hydrostatic tests are conducted at the frequency required by NFPA 10.
  3. In Group I-3, portable fire extinguishers shall be permitted to be located at staff locations.
- ❖ NFPA 10 contains minimum requirements for the selection, installation and maintenance of portable fire extinguishers. Portable fire extinguishers are investigated and rated in conformance to NFPA 10 and listed under a variety of standards. Portable fire extinguishers must be labeled and rated for use on fires of the type, severity and hazard class protected. NFPA 10 notes that more frequent inspections may be necessary where conditions warrant. For existing installations, a history of recent fires, vandalism, physical abuse and theft should be considered in determining if more frequent inspections are needed. For both existing and new facilities, determining the frequency of inspections should consider the environmental conditions in which the extinguisher will be located, including corrosiveness and temperature variations; and, the possibility of obstructions that may place the extinguisher out of reach in case of an emergency.
- Exception 1 recognizes the openness to the atmosphere associated with Group A-5 occupancies. A fire in open areas is more obvious to all spectators. Group A-5 occupancies also do not accumulate

smoke and hot gases because they are not enclosed spaces. These reasons, in addition to the large and expansive layout within seating areas, make it reasonable and practical not to apply the distance of travel to a PFE criteria in Group A-5. Revised distance of travel allowances would need to be approved by the fire code official. Group A-5 occupancies also tend to be more subject to the corrosive conditions of an outdoor environment, and may include freeze/thaw cycles that can be detrimental to fire extinguishers.

Exception 2 acknowledges a 30-day inspection interval similar to NFPA 10. An electronic monitoring device can determine whether or not the fire extinguisher is still present and whether or not its contents are still at the proper charge. The use of such devices, being relatively new, is allowed if it is limited to dry-chemical and halogenated agents with the additional safeguards noted in the list. Where inspection intervals may be at more frequent intervals, as discussed above, the use of electronic monitoring may have even greater benefit and is acknowledged as such in NFPA 10. The log, noted in the exception, can be a written log or a printout of the electronic log maintained by the electronic monitoring device. This exception provides the building owner with an alternative to the contract inspections popularly used.

Exception 3 recognizes that portable fire extinguishers located throughout the facility are at times tampered with, removed or used for weapons by inmates in a detention or correctional setting. This exception would protect the extinguishers from damage or removal by inmates while still making them available to staff and employees for use in an emergency situation.

**906.2.1 Certification of service personnel for portable fire extinguishers.** Service personnel providing or conducting maintenance on portable fire extinguishers shall possess a valid certificate issued by an *approved* governmental agency, or other *approved* organization for the type of work performed.

❖ Maintenance of fire protection systems and devices are minimum Chapter 9 requirements. Fire protection systems, like other technologies, have advanced new designs which require a clear understanding of their construction and maintenance. To ensure that systems and devices are properly maintained, the code now requires individuals performing these activities be certified. Certification must be issued by an approved organization or governmental agency.

These provisions align the code with NFPA standards governing the inspection and maintenance of portable fire extinguishers.

Qualifications for individuals who service portable fire extinguishers are established in the 2010 edition of NFPA 10. Section 7.1.2.1 of NFPA 10 requires individuals inspecting and servicing portable fire extinguishers be trained and certified to reliably perform these activities.

**906.3 Size and distribution.** The size and distribution of portable fire extinguishers shall be in accordance with Sections 906.3.1 through 906.3.4.

❖ Proper selection and distribution of portable fire extinguishers is essential to having adequate protection for the building structure and the occupancy conditions within. This section introduces the sections that provide those requirements. Determination of the desired type of portable fire extinguisher depends on the character of the fire anticipated, building occupancy, specific hazards and ambient temperature conditions [see commentary, Tables 906.3(1) and 906.3(2)].

**906.3.1 Class A fire hazards.** Portable fire extinguishers for occupancies that involve primarily Class A fire hazards, the minimum sizes and distribution shall comply with Table 906.3(1).

❖ Class A fires generally involve materials considered to be “ordinary combustibles,” such as wood, cloth, paper, rubber and most plastics [see commentary, Table 906.3(1)].

**TABLE 906.3(1)  
FIRE EXTINGUISHERS FOR CLASS A FIRE HAZARDS**

	LIGHT (Low) HAZARD OCCUPANCY	ORDINARY (Moderate) HAZARD OCCUPANCY	EXTRA (High) HAZARD OCCUPANCY
Minimum rated single extinguisher	2-A <sup>c</sup>	2-A	4-A <sup>a</sup>
Maximum floor area per unit of A	3,000 square feet	1,500 square feet	1,000 square feet
Maximum floor area for extinguisher <sup>b</sup>	11,250 square feet	11,250 square feet	11,250 square feet
Maximum distance of travel to extinguisher	75 feet	75 feet	75 feet

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon = 3.785 L.  
 a. Two 2½-gallon water-type extinguishers shall be deemed the equivalent of one 4-A rated extinguisher.  
 b. Annex E.3.3 of NFPA 10 provides more details concerning application of the maximum floor area criteria.  
 c. Two water-type extinguishers each with a 1-A rating shall be deemed the equivalent of one 2-A rated extinguisher for Light (Low) Hazard Occupancies.

❖ Table 906.3(1), which parallels Table 6.2.1.1 of NFPA 10, establishes the minimum number and rating of fire extinguishers for Class A fires in any particular occupancy. The occupancy classifications are further defined in NFPA 10. The maximum area that a single fire extinguisher can protect is determined based on the rating of the fire extinguisher. The distance of travel limitation of 75 feet (22 860 mm) is intended to be the actual walking distance along a normal path of travel to the extinguisher. For this reason, it is necessary to select fire extinguishers that comply with both the distribution criteria and travel distance limitation for a specific occupancy classification.

**906.3.2 Class B fire hazards.** Portable fire extinguishers for occupancies involving flammable or *combustible liquids* with depths of less than or equal to 0.25-inch (6.4 mm) shall be selected and placed in accordance with Table 906.3(2).

Portable fire extinguishers for occupancies involving flammable or *combustible liquids* with a depth of greater than 0.25-inch (6.4 mm) shall be selected and placed in accordance with NFPA 10.

❖ Class B fires involve flammable and combustible liquids, oil-based paints, alcohols, solvents, flammable gases and similar materials. Selection of these extinguishers is made based on the depth of the liquid that could become involved in a fire. If the depth is ¼-inch (6.35 mm) or less, selection is made using Table 906.3(2). Class B extinguishers for greater liquid depth, characterized in NFPA 10 as “appreciable depth,” must be selected and installed in accordance with Section 6.3.2 of NFPA 10 [see commentary, Table 906.3(2)].

**TABLE 906.3(2)  
FLAMMABLE OR COMBUSTIBLE LIQUIDS WITH  
DEPTHS OF LESS THAN OR EQUAL TO 0.25-INCH<sup>a</sup>**

TYPE OF HAZARD	BASIC MINIMUM EXTINGUISHER RATING	MAXIMUM DISTANCE OF TRAVEL TO EXTINGUISHERS (feet)
Light (Low)	5-B	30
	10-B	50
Ordinary (Moderate)	10-B	30
	20-B	50
Extra (High)	40-B	30
	80-B	50

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.  
 a. For requirements on water-soluble flammable liquids and alternative sizing criteria, see Section 5.5 of NFPA 10.

❖ Fires involving flammable or combustible liquids present a severe hazard challenge regardless of occupancy. Table 906.3(2), which parallels Table 6.3.1.1 of NFPA 10, prescribes the minimum portable fire extinguisher requirements where flammable or combustible liquids are limited in depth [0.25 inch (6 mm) or less]. As can be seen in the table, the size of the extinguisher is directly related to the distance of travel to the extinguisher for each given occupancy classification. These fire extinguisher provisions are independent of whether other fixed automatic fire-extinguishing systems are installed. For occupancy conditions involving flammable or combustible liquids in potential depths greater than 0.25 inch (6 mm), the selection and spacing criteria of NFPA 10 must be used in addition to any applicable requirements in Chapter 57 and NFPA 30.

**906.3.3 Class C fire hazards.** Portable fire extinguishers for Class C fire hazards shall be selected and placed on the basis of the anticipated Class A or B hazard.

❖ Class C fires involve energized electrical equipment where the electrical nonconductivity of the extinguish-

ing agent is critical. The need for this class of extinguisher is simply based on the presence of the hazard in an occupancy and no numerical rating is required.

**906.3.4 Class D fire hazards.** Portable fire extinguishers for occupancies involving combustible metals shall be selected and placed in accordance with NFPA 10.

❖ Class D fires are fires involving flammable solids, the bulk of which are combustible metals, including, but not limited to magnesium, potassium, sodium and titanium. Most Class D extinguishers will have a special low velocity nozzle or discharge wand to gently apply the agent in large volumes to avoid disrupting any finely divided burning materials. Extinguishing agents are also available in bulk and can be applied with a scoop or shovel. While Class D extinguishers are often referred to as “dry chemical” fire extinguishers, they are more properly called “dry powder” fire extinguishers because their mechanism of extinguishment is by a smothering action rather than by chemical reaction with the combustion process.

There are several Class D fire-extinguisher agents available, some will handle multiple types of metal fires, others will not. Sodium carbonate-based extinguishers are used to control sodium, potassium, and sodium-potassium alloy fires but have limited use on other metals. This material smothers and forms a crust. Sodium chloride-based extinguishers contain sodium chloride salt and a thermoplastic additive. The plastic melts to form an oxygen-excluding crust over the metal, and the salt dissipates heat. This powder is useful on most alkali metals including magnesium, titanium, aluminum, sodium, potassium, and zirconium. Graphite based-extinguishers contain dry graphite powder that smothers burning metals. Unlike sodium chloride powder extinguishers, the graphite powder fire extinguishers can be used on very hot burning metal fires, such as lithium, but the powder will not stick to and extinguish flowing or vertical lithium fires. The graphite powder acts as a heat sink as well as smothering the metal fire. See the commentary to Section 5906.5.7 for a discussion of extinguishing flammable solid fires.

**906.4 Cooking grease fires.** Fire extinguishers provided for the protection of cooking grease fires shall be of an *approved* type compatible with the automatic fire-extinguishing system agent and in accordance with Section 904.12.5.

❖ The combination of high-efficiency cooking appliances and hotter burning cooking media creates a potentially severe fire hazard. Although commercial cooking systems must have an approved exhaust hood and be protected by an approved automatic fire-extinguishing system, a manual means of extinguishment is desirable to attack a fire in its incipient stage.

As indicated in Section 904.12.5, a Class K-rated portable fire extinguisher must be located within 30

feet (9144 mm) of travel distance of commercial-type cooking equipment. Class K-rated extinguishers have been specifically tested on commercial cooking appliances using vegetable or animal oils or fats. These portable fire extinguishers are usually of sodium bicarbonate or potassium bicarbonate dry-chemical type.

**906.5 Conspicuous location.** Portable fire extinguishers shall be located in conspicuous locations where they will be readily accessible and immediately available for use. These locations shall be along normal paths of travel, unless the *fire code official* determines that the hazard posed indicates the need for placement away from normal paths of travel.

❖ Fire extinguishers must be located in readily accessible locations along normal egress paths. This increases the occupants familiarity with the location of the fire extinguishers. When considering location, the most frequent occupants should be considered. These are the occupants who would become most familiar with the fire-extinguisher placement. For most buildings, it is the employees who are most familiar with their surroundings; therefore, a good understanding of employee operations is important for proper extinguisher placement.

**906.6 Unobstructed and unobscured.** Portable fire extinguishers shall not be obstructed or obscured from view. In rooms or areas in which visual obstruction cannot be completely avoided, means shall be provided to indicate the locations of extinguishers.

❖ Portable fire extinguishers must be located where they are readily visible at all times. If visual obstruction cannot be avoided, the location of the extinguishers must be marked by an approved means of identification. This could include additional signage, lights, arrows or other means approved by the fire code official. Unobstructed does not necessarily mean visible from all angles within the space. Often, columns or furnishings may obscure the extinguisher from one direction or another. These are not by themselves obstructions. The intent is that the extinguisher is not hidden but rather can be readily found. If the extinguisher is placed in the wall behind a door, it is clearly obstructed since it cannot be easily viewed. An extinguisher on a wall that is visible from most of the space would be considered unobstructed.

**906.7 Hangers and brackets.** Hand-held portable fire extinguishers, not housed in cabinets, shall be installed on the hangers or brackets supplied. Hangers or brackets shall be securely anchored to the mounting surface in accordance with the manufacturer’s installation instructions.

❖ Portable fire extinguishers not housed in cabinets are usually mounted on walls or columns using securely fastened hangers. Brackets must be used where the fire extinguishers need to be protected from impact or other potential physical damage.

**906.8 Cabinets.** Cabinets used to house portable fire extinguishers shall not be locked.

**Exceptions:**

1. Where portable fire extinguishers subject to malicious use or damage are provided with a means of ready access.
  2. In Group I-3 occupancies and in mental health areas in Group I-2 occupancies, access to portable fire extinguishers shall be permitted to be locked or to be located in staff locations provided the staff has keys.
- ❖ Cabinets housing fire extinguishers must not be locked in order to provide quick access in an emergency. Exception 1, however, allows the cabinets to be locked in occupancies where vandalism, theft or other malicious behavior is possible. Exception 2 also permits cabinets housing fire extinguishers to be locked or to be located in staff locations in Group I-3 occupancies and mental health areas in Group I-2 occupancies. Occupants in Group I-3 areas of jails, prisons or similar restrained occupancies should not have access to fire extinguishers because they could possibly be used as a weapon or be subject to vandalism. Staff adequately trained in the use of fire extinguishers are assumed to have ready access to the keys for the cabinets at all times

**906.9 Extinguisher installation.** The installation of portable fire extinguishers shall be in accordance with Sections 906.9.1 through 906.9.3.

- ❖ This section introduces the installation criteria for portable fire extinguishers based on the weight of the unit.

**906.9.1 Extinguishers weighing 40 pounds or less.** Portable fire extinguishers having a gross weight not exceeding 40 pounds (18 kg) shall be installed so that their tops are not more than 5 feet (1524 mm) above the floor.

- ❖ Due to the varying height and physical strength levels of persons who might be called upon to operate a portable fire extinguisher, the mounting height of the extinguisher must be commensurate with its weight so that it may be easily retrieved by anyone from its mounting location and placed into use.

**906.9.2 Extinguishers weighing more than 40 pounds.** Hand-held portable fire extinguishers having a gross weight exceeding 40 pounds (18 kg) shall be installed so that their tops are not more than 3.5 feet (1067 mm) above the floor.

- ❖ See the commentary to Section 906.9.1.

**906.9.3 Floor clearance.** The clearance between the floor and the bottom of installed hand-held portable fire extinguishers shall be not less than 4 inches (102 mm).

- ❖ The clearance between the floor and the bottom of installed hand-held extinguishers must not be less than 4 inches (102 mm) to facilitate cleaning beneath the unit and reduce the likelihood of the extinguisher becoming dislodged during cleaning operations (floor mopping, sweeping, etc.).

**906.10 Wheeled units.** Wheeled fire extinguishers shall be conspicuously located in a designated location.

- ❖ Wheeled fire extinguishers consist of a large-capacity (up to several hundred pounds of agent) fire extinguisher assembly (either stored-pressure or pressure transfer type) equipped with a carriage and wheels and discharge hose. They are constructed so that one able-bodied person could move the unit to the fire area and begin extinguishment unassisted. Wheeled fire extinguishers are capable of delivering greater flow rates and stream range for various extinguishing agents than hand-held portable fire extinguishers. Wheeled fire extinguishers are generally more effective in high-hazard areas and, as with any extinguisher, must be readily available and stored in an approved location. The wheeled fire extinguisher should be located a safe distance from the hazard area so that it will not become involved in the fire or access to it compromised by a fire. These units are typically found at airport fueling ramps, refineries, bulk plants and similar locations where high-challenge fires may be encountered. The extinguishing agents available in wheeled units include carbon dioxide, dry chemical, dry powder and foam.

## SECTION 907 FIRE ALARM AND DETECTION SYSTEMS

**907.1 General.** This section covers the application, installation, performance and maintenance of fire alarm systems and their components in new and existing buildings and structures. The requirements of Section 907.2 are applicable to new buildings and structures. The requirements of Section 907.9 are applicable to existing buildings and structures.

- ❖ Fire alarm systems, which typically include manual fire alarm systems and automatic fire detection systems, must be installed in accordance with Section 907 and NFPA 72. As indicated in this section, only Section 907.9 is intended to be applicable to existing buildings and structures.

Manual fire alarm systems are installed in buildings to limit fire casualties and property losses. Fire alarm systems do this by promptly notifying the occupants of the building of an emergency, which increases the time available for evacuation. Similarly, when fire alarm systems are supervised, the fire department will be promptly notified and its response time relative to the onset of the fire will be reduced.

Automatic fire detection systems are required under certain conditions to increase the likelihood that a fire is detected and occupants are given an early warning. The detection system is a system of devices and associated hardware that activates the alarm system. The automatic detecting devices are to be smoke detectors, unless a condition exists that calls for the use of a different type of detector.

**907.1.1 Construction documents.** *Construction documents* for fire alarm systems shall be of sufficient clarity to indicate

the location, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code, the *International Building Code* and relevant laws, ordinances, rules and regulations, as determined by the *fire code official*.

❖ Construction documents for fire alarm systems must be submitted for review to determine compliance with the code, the IBC and NFPA 72. All of the information required by this section may not be available during the design stage and initial permit process. Later submission of more detailed shop drawings may be required in accordance with Section 907.1.2. These provisions are intended to reflect the minimum scope of information needed to determine code compliance. When the work can be briefly described on the application form, the fire code official may utilize judgment in determining the need for more detailed documents.

**907.1.2 Fire alarm shop drawings.** Shop drawings for fire alarm systems shall be submitted for review and approval prior to system installation, and shall include, but not be limited to, all of the following where applicable to the system being installed:

1. A floor plan that indicates the use of all rooms.
  2. Locations of alarm-initiating devices.
  3. Locations of alarm notification appliances, including candela ratings for visible alarm notification appliances.
  4. Design minimum audibility level for occupant notification.
  5. Location of fire alarm control unit, transponders and notification power supplies.
  6. Annunciators.
  7. Power connection.
  8. Battery calculations.
  9. Conductor type and sizes.
  10. Voltage drop calculations.
  11. Manufacturers' data sheets indicating model numbers and listing information for equipment, devices and materials.
  12. Details of ceiling height and construction.
  13. The interface of fire safety control functions.
  14. Classification of the supervising station.
- ❖ Since the fire protection contractor(s) may not have been selected at the time a permit is issued for construction of a building, detailed shop drawings for fire alarm systems may not be available. Because they provide the information necessary to determine code compliance, as specified in this section, they must be submitted and approved by the fire code official before the contractor can begin installing the system.

**907.1.3 Equipment.** Systems and components shall be *listed* and *approved* for the purpose for which they are installed.

❖ The components of the fire alarm system must be approved for use in the planned system. NFPA 72 requires all devices, combinations of devices, appliances and equipment to be labeled for their proposed use. The testing agency will test the components for use in various types of systems and stipulate the use of the component on the label. Evidence of listing and labeling of the system components must be submitted with the shop drawings. In some instances, the entire system may be labeled.

At least one major testing agency, Underwriters Laboratories, Inc. (UL), has a program in which alarm installation and service companies are issued a certificate and become listed by the agency as being qualified to design, install and maintain local, auxiliary, remote station or proprietary fire alarm systems. The listed companies may then issue a certificate showing that the system is in compliance with Section 907. Terms of the company certification by UL include the company being responsible for keeping accurate system documentation, including as-built record drawings, acceptance test records and complete maintenance records on a given system. The company is also responsible for the required periodic inspection and testing of the system under contract with the owner. A similar program has been available for many years for central station alarm service, whereas the UL program is relatively new to the industry. Even though this company and system listing program is not required by the code or NFPA 72, it can be a valuable tool for the fire code official in determining compliance with the referenced standard.

Another issue that must be considered is the compatibility of the system components as required by NFPA 72. The labeling of system components discussed above should include any compatibility restrictions for components. Compatibility is primarily an issue of the ability of smoke detectors and fire alarm control panels (FACPs) to function properly when interconnected and affects the two-wire type of smoke detectors, which obtain their operating power over the same pair of wires used to transmit signals to the FACP (the control unit initiating device circuits). Laboratories will test for component compatibility either by actual testing or by reviewing the circuit parameters of both the detector and the FACP. Generally, if both the two-wire detector and the FACP are of the same brand, there should not be a compatibility problem. Nevertheless, the fire code official must be satisfied that the components are listed as being compatible. Failure to comply with the compatibility requirements of NFPA 72 can lead to system malfunction or failure when it may be needed the most.

**907.2 Where required—new buildings and structures.** An *approved* fire alarm system installed in accordance with the provisions of this code and NFPA 72 shall be provided in new buildings and structures in accordance with Sections 907.2.1 through 907.2.23 and provide occupant notification in accordance with Section 907.5, unless other requirements are provided by another section of this code.

Not fewer than one manual fire alarm box shall be provided in an *approved* location to initiate a fire alarm signal for fire alarm systems employing automatic fire detectors or waterflow detection devices. Where other sections of this code allow elimination of fire alarm boxes due to sprinklers, a single fire alarm box shall be installed.

**Exceptions:**

1. The manual fire alarm box is not required for fire alarm systems dedicated to elevator recall control and supervisory service.
2. The manual fire alarm box is not required for Group R-2 occupancies unless required by the *fire code official* to provide a means for fire watch personnel to initiate an alarm during a sprinkler system impairment event. Where provided, the manual fire alarm box shall not be located in an area that is accessible to the public.

❖ This section specifies the occupancies or conditions in new buildings or structures that require some form of fire alarm system. The fire alarm system is either a manual fire alarm system (manual fire alarm boxes) or an automatic smoke detection system. These systems must, upon activation, provide occupant notification throughout the area protected by the system unless other alternative provisions are allowed by this section.

Manual fire alarm systems must be installed in certain occupancies depending on the number of occupants, capabilities of the occupants and height of the building. An automatic smoke detection system must be installed in those occupancies and conditions where the need to detect the fire is essential to evacuation or protection of the occupants. The requirements for automatic smoke detection are generally based on the evacuation needs of the occupants and whether the occupancy includes sleeping accommodations.

Fire alarm systems must be installed in accordance with the code and NFPA 72. NFPA 72 identifies the minimum performance, location, mounting, testing and maintenance requirements for fire alarm systems. Smoke detectors must be used, except when ambient conditions would prohibit their use. In that case other detection methods may be used. The manufacturer's literature will identify the limitations on the use of smoke detectors, including environmental conditions such as humidity, temperature and airflow.

Only certain occupancies are required to have either a manual fire alarm or automatic fire detection system installed (see Commentary Figure 907.2). The need for either system is generally determined

by the number of occupants, the height of the building or the ability of the occupants for self-preservation.

Note that generally the fire alarm requirements are based upon occupancy and not on fire area. Commentary Figure 907.2 contains the conditions that require when either system must be installed in a building. The extent that an alarm system must be installed in a building once it has been determined that such a system is required is based on several factors. One, if it is the only occupancy in the building, then it would be required throughout the building. Two, if the building is a mixed occupancy, it can either be separated or nonseparated. If the occupancy is separated in accordance with Section 508.4 of the IBC, then the alarm system is only required within that separated portion of the building. If the building is considered a nonseparated, mixed occupancy building, then Section 508.3.1 of the IBC states that the code apply to each portion of the building based upon the occupancy classification of that space and the most restrictive provisions of Chapter 9 shall apply to the building or portion thereof in which the nonseparated occupancies are located. Therefore, if you had a Group A occupancy in a nonseparated mixed occupancy (containing other occupancies such as Group B and M) where the Group A occupancy exceeds an occupant load of 300, then the entire nonseparated mixed occupancy would require the alarm system. Note that Section 508.3.1 focuses on each space to determine occupancy and requirements. Once the occupant load is determined, then any requirements, such as fire alarms, would be required throughout.

The code does not address whether or not a non-separated mixed occupancy has a completely independent means of egress such as in a strip mall. Additionally, in a building containing primarily Group A occupancies, the code does not clearly address whether such occupancies within a building should be looked at as an aggregate or individual space. This issue has been clarified in the 2012 edition of the code through the use of the fire area concept for Group A occupancies, but only for the basic manual fire alarm requirements in Section 907.2.1. The emergency voice/alarm communication requirements in Section 907.2.1.1 still simply provide a criteria of 1000 or more occupants in a Group A occupancy. A building with multiple Group A occupancies without using the concept of separation of egress paths would need to be reviewed in aggregate. Fire area separation could not be used to provide separation of occupancies in this case.

Commentary Figure 907.2 contains the threshold requirements for when a manual fire alarm system or an automatic fire detection system is required based on the occupancy group. It is important to remember that although the requirement for manual pull stations may not apply (e.g., sprinklered buildings), alarm and occupant notification may still be required. Sections 907.2.11 through 907.2.23 contain additional require-

ments for fire alarm systems depending on special occupancy conditions such as atriums, high-rise buildings or covered mall buildings.

The single manual fire alarm box required by this section is needed to provide a means of manually activating a fire alarm system that only contains automatic devices such as sprinkler waterflow switches or smoke detectors. Its primary use is for alarm system maintenance technicians to be able to manually activate the fire alarm system in the event of a fire during the time the system or portions of the system is down for maintenance. Note that this requirement is not subject to any of the exceptions in Sections 907.2.1

through 907.2.23 that might waive the need for manual fire alarm boxes in certain buildings.

Exception 1 recognizes the specialized nature of fire alarm systems installed only for emergency elevator control and supervision.

Exception 2 waives the single manual fire alarm box but gives the fire code official authority to require it in sprinklered buildings for use by fire watch personnel or sprinkler maintenance personnel to be able to manually activate the fire alarm system in the event of a fire during the time the sprinkler system is down for maintenance.

MANUAL FIRE ALARM SYSTEM	
Occupancy Group(s)	Threshold
Assembly (A-1, A-2, A-3, A-4, A-5)	All with an occupant load of > 300 (907.2.1)
Business (B)	Total Group B occupant load of > 500; or, > 100 above/below level of exit discharge; or, in Group B fire areas containing an ambulatory care facility (907.2.2)
Educational (E)	> 50 occupants (several exceptions for manual fire alarm box placement) (907.2.3)
Factory (F-1, F-2)	> 2 stories with occupant load of > 500 above/below lowest level of exit discharge (exception for sprinklers) (907.2.4)
High hazard (H)	Group H-5 and in occupancies for manufacture of organic coatings. (907.2.5)
Institutional (I-1, I-2, I-3, I-4)	All (exceptions for I-1 and I-2 manual fire alarm box placement and private mode signaling) (907.2.6)
Mercantile (M)	Total Group M occupant load of > 500; or, occupant load of >100 above/below level of exit discharge (907.2.7)
Hotels (R-1)	All (exceptions for < 2 stories with sleeping units having exit directly to exterior; sprinklers) (907.2.8.1)
Multi-family (R-2)	If units > 3 stories above lowest level of exit discharge; or, > 1 story below highest level of exit discharge; or, > 16 units (exceptions for < 2 stories with sleeping units having exit directly to exterior; sprinklers) open ended corridors/no corridor (907.2.9.1)
Residential care/assisted living (R-4)	All (exceptions for sprinklers, manual fire alarm boxes at staff locations, direct exit to exterior, less than 2 stories) (907.2.10.1)
AUTOMATIC SMOKE DETECTION SYSTEM	
Business (B) Ambulatory care facilities	Facility plus public use areas outside of it including public corridors and elevator lobbies (exception for sprinklers) (907.2.2.1)
High hazard (H)	Highly toxic gases, organic peroxides, oxidizers (907.2.5)
Institutional (I-1, I-2, I-3)	All, in specific areas by occupancy (907.2.6.1, 907.2.6.2, 907.2.6.3.3)
Hotels (R-1)	All, in interior corridors (exception for buildings without interior corridors and with sleeping units having exit directly to exterior) (907.2.8.2)
Residential care/assisted living (R-4)	All, in corridors, waiting areas open to corridors, nonsleeping area habitable spaces and kitchens (exceptions for sprinklers and sleeping units having exit directly to exterior) (907.2.10.2)
College and university buildings (R-2 dormitories)	Common spaces; laundry, mechanical and storage rooms; interior corridors. No interior corridors and each unit has direct exit access or exit.

**Figure 907.2**  
**SUMMARY OF MANUAL FIRE ALARM AND AUTOMATIC SMOKE DETECTION SYSTEM THRESHOLDS**

**907.2.1 Group A.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group A occupancies where the occupant load due to the assembly occupancy is 300 or more. Group A occupancies not separated from one another in accordance with Section 707.3.10 of the *International Building Code* shall be considered as a single occupancy for the purposes of applying this section. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

**Exception:** Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

- ❖ Group A occupancies are typically occupied by a significant number of people who are not completely familiar with their surroundings. The provisions of this section address three separate situations regarding the application of the alarm requirements for Group A occupancies. The three situations addressed by the provisions are: (1) where an assembly occupancy and another occupancy are involved, (2) where multiple assembly areas exist in a building, and (3) where the assembly use occurs in and is a part of a Group E occupancy.

In situations where an assembly area and another occupancy are involved, the code specifies that it is the occupant load “due to the assembly occupancy” that would need to be 300 or more before the manual alarm system is required. For example, if the building is constructed with an assembly occupancy, such as a restaurant, with an occupant load of 250 and an adjacent office area with an occupant load of 100, the assembly space would not require an alarm system because the occupant load “due to the assembly occupancy” is less than 300. This is really simply a clarification of the way the provisions were intended to be applied. This would be the intended way to apply the provision whether the building was constructed using the accessory-, separated-, or nonseparated-occupancy requirements of Chapter 5 of the IBC.

In buildings that contain multiple assembly areas, the second portion of the code text requires that the aggregate occupant load of the assembly areas is used unless the spaces are separated as required for fire areas in Section 707.3.10 of the IBC. Consider two examples to address this portion of the requirements. In a multitheater complex, the auditoriums are generally not separated from each other by the 2-hour fire-resistance rating that Table 707.3.10 of the IBC would require; therefore, the aggregate occupant load of all of the assembly spaces would be combined to determine if the occupant load was 300 or more. If it was, then the manual alarm would be required in all of the assembly spaces. As another

example, consider a strip mall shopping center with a restaurant at one end of the building with an occupant load of 200 and a different restaurant with an occupant load of 150 at the other end of the building. Even though these are two completely separate establishments and have an amount of retail occupancy between them, the occupant load of the assembly areas does exceed 300. Therefore, unless a 2-hour fire-resistance-rated separation complying with Section 707.3.10 of the IBC is provided somewhere between the two restaurants to separate them into different fire areas, a manual fire alarm would be required in the Group A occupancies. If a complying separation is provided at some point in the building, then each assembly space can be reviewed independently and would not require the installation of the alarm system. Be aware that the separation of assembly spaces or the need to aggregate the occupant loads from them could occur not only on the same floor within a building but also to assembly uses located on different stories.

The exception allows the omission of manual fire alarm boxes in buildings equipped throughout with an automatic sprinkler system if activation of the sprinkler system will activate the building evacuation alarms associated with the manual fire alarm system.

This section also permits assembly-type areas in Group E occupancies to comply with Section 907.2.3 instead of the requirements of this section. A typical high school, for example, contains many areas used for assembly purposes such as a gymnasium, cafeteria, auditorium or library; however, they all exist to serve as an educational facility as their main function. The exception does not eliminate the fire alarm system and occupant notification system, but rather permits them to be initiated automatically by the sprinkler waterflow switch(es) instead of by the manual fire alarm boxes. It also reduces the possibility of mischievous or malicious false alarms being turned on by manual fire alarm boxes in venues where large numbers of people congregate.

**907.2.1.1 System initiation in Group A occupancies with an occupant load of 1,000 or more.** Activation of the fire alarm in Group A occupancies with an *occupant load* of 1,000 or more shall initiate a signal using an emergency voice/alarm communications system in accordance with Section 907.5.2.2.

**Exception:** Where *approved*, the prerecorded announcement is allowed to be manually deactivated for a period of time, not to exceed 3 minutes, for the sole purpose of allowing a live voice announcement from an *approved*, constantly attended location.

- ❖ In order to afford authorized personnel the ability to selectively evacuate or manage occupant relocation in large assembly venues, this section requires the fire alarm system to operate through an emergency voice/alarm communications system. The exception allows the automatic alarm signals to be overridden for live voice instructions if the live voice instructions

do not exceed 3 minutes. The location from which the live voice announcement originates must be constantly attended and approved by the fire code official (see also commentary, Section 907.5.2.2). In terms of the applicability of this section, it is not as specific as Section 907.2.1. More specifically, the concept of fire areas does not apply. Credit is not given to reduce the occupant load through the use of the fire area concept (see commentary, Section 907.2).

**907.2.1.2 Emergency voice/alarm communication system captions.** Stadiums, arenas and grandstands required to caption audible public announcements shall be in accordance with Section 907.5.2.2.4.

❖ A 2008 U.S. Federal Court case prompted a change to the code and the IBC. The court ruled that persons with hearing impairments who attend events at stadiums, grandstands and arenas require a means of equivalent communications in lieu of the public address system. Providing occupant notification in these structures is challenging because of the building area and the number and diversity of occupants. Provisions were added in the code to require captioned messages in these buildings and grandstands when public address (PA) systems are prescribed by the accessibility requirements.

IBC Section 1108.2.7.3 sets forth requirements for audible PA systems in stadiums, arenas and grandstands. It requires that equivalent text information be provided to the audience and that the delivery time for these messages be the same as those broadcast from the PA system. These requirements apply to pre-recorded and real-time messages. Section 1108.2.7.3 of the IBC also requires captioning of messages in stadiums, arenas and grandstands that have more than 15,000 fixed seats.

Because messages being broadcast can include instructions to building or site occupants explaining the actions they need to take in the event of an emergency, the requirements of NFPA 72 are applicable for captioning systems. Such a system falls within the scope of Chapter 24 of NFPA 72, entitled “Emergency Communication Systems.” NFPA 72 defines an emergency communications system (ECS) as a system designed for life safety that indicates the existence of an emergency and communicates the appropriate response and action. The ECS is required to be classified as either a one- or two-way path system. It can be within a building or over a wide area or can be targeted to a particular group of recipients. The messages that will be broadcast are based on an emergency response plan developed during a risk analysis by the project stakeholders and is approved by the fire code official.

The NFPA 72 ECS requirements are based on in-building or wide-area occupant notification. Wide-area systems could include the entire area of a jurisdiction. For a stadium, arena or grandstand captioning, NFPA 72 defines these as mass notification systems (MNS). In the context of the NFPA 72 requirements, this particular code change requires a

one-way MNS where instructions are broadcast by personnel authorized to distribute messages. This could include firefighters during a fire event; the system could be used by law enforcement officers during a domestic terrorism incident or a weather event like a tornado warning.

The design of the compliant MNS in Chapter 24 of NFPA 72 is not prescriptive—a MNS is a performance-based design. Accordingly, fire code officials should require their design to be sealed by a registered professional engineer. Chapter 24 of the standard requires the preparation of a risk analysis based on the nature and anticipated risks of the facility. The risk analysis is part of the design brief, which will serve as the basis of the system design and is a required design document. NFPA 72 requires the following elements included in the risk analysis:

- The number of persons within the building, area, space, campus or region;
- The character of the occupancy, such as unique hazards and the rate at which the hazard can develop;
- The anticipated threats, including natural, technological and intentional events;
- The reliability and performance of the MNS;
- Security of the MNS and its components;
- How the building or staff implement the risk analysis, including the use of the MNS; and
- How emergency services, such as the fire service and law enforcement agencies, can employ the MNS.

In a stadium or arena, the captioning system is required to be a component of the emergency voice/communication alarm system (EV/ACS). Such a system is required by Section 907.2.1.1 in Group A occupancies with an occupant load of 1,000 or more.

The requirement in Section 907.5.2.2.4 specifies the captioning system would be connected to the EV/ACS. The fire alarm control unit will require a listed interface unit capable of displaying text messages. Textual visible appliances are allowed by NFPA 72 when used in conjunction with audible, visual or both types of notification appliances. In the public mode, textual visible appliances are located to ensure readability by the building occupants. Such a system can display messages using televisions or light-emitting diode (LED) marquee signs.

The design concept of MNS is relatively new in the design community. Captioning systems might utilize components that are not listed for fire alarm service so the design will be required to comply with Chapter 241 of NFPA 72 for textual visible notification appliances. Emergency textual messages take precedence over any nonemergency text messages. Under NFPA 72, these devices require a primary and secondary power supply. If the devices are not monitored for integrity or loss of communications by an autonomous control or a fire alarm control unit, the appliance

must clearly display its status. The size of characters displayed must comply with the requirements in NFPA 72. The NFPA 72 size, character and font requirements are based on the location of the display in relation to the height and distance from the persons viewing it.

**907.2.2 Group B.** A manual fire alarm system shall be installed in Group B occupancies where one of the following conditions exists:

1. The combined Group B *occupant load* of all floors is 500 or more.
2. The Group B *occupant load* is more than 100 persons above or below the lowest *level of exit discharge*.
3. The *fire area* contains an ambulatory care facility.

**Exception:** Manual fire alarm boxes are not required where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

❖ Group B occupancies generally involve individuals or groups of people in separate office areas. As a result, the occupants are not necessarily aware of what is going on in other parts of the building. Group B buildings with large occupant loads, even in single-story buildings, or where a substantial number of occupants are above or below the level of exit discharge, increase the difficulty of alerting the occupants of a fire. This is especially true in nonsprinklered buildings with given occupant load thresholds. Group B occupancies include a specific use called ambulatory care facilities which present a higher level of life hazard than the typical Group B occupancy. The fact that the care recipients of such facilities may be rendered incapable of self-preservation for limited periods of time makes the need for a fire alarm system critical. Section 907.2.2 requires a manual alarm system any time a fire area contains a ambulatory care facility. See the commentary to Section 202, definition of “Ambulatory care facility” and Section 907.2.2.1.

The exception does not eliminate the fire alarm system, but rather permits it to be initiated automatically by the sprinkler waterflow switch(es) instead of by the manual fire alarm boxes.

**907.2.2.1 Ambulatory care facilities.** *Fire areas* containing ambulatory care facilities shall be provided with an electronically supervised automatic smoke detection system installed within the ambulatory care facility and in public use areas outside of tenant spaces, including public *corridors* and elevator lobbies.

**Exception:** Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 provided the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

❖ Years ago, few surgical procedures were performed outside of a hospital. Today, complex outpatient sur-

geries conducted outside of a hospital are commonplace. They are performed in facilities often called “day surgery centers” or “ambulatory surgical centers” because patients are able to walk in and walk out the same day. Procedures render care recipients temporarily incapable of self-preservation by application of nerve blocks, sedation or anesthesia; however, they do typically recover quickly.

The IBC identifies health care Group I occupancies as including a 24-hour stay. Without a 24-hour stay, these surgery centers were classified as Group B, which allowed the care providers to render an unlimited number of people incapable of self-preservation with no more protection than a business office. Since these types of facilities contain distinctly different hazards to life safety than other Group B occupancies, they are now required to have a higher level of life safety and fire protection as evidenced by the requirements of this section, as well as Section 903.2.2 and the construction provisions of the code.

This section more specifically states that any time a fire area contains an ambulatory care facility, the fire area should be provided with a supervised smoke detection system in the ambulatory care facility and in public use areas outside of tenant spaces. Therefore, in a medical office building, for example, the ambulatory care facility contained within would have a full coverage system. The other offices in the building would not require smoke detection in the individual tenant spaces but instead in the public areas, such as lobby or lounge areas.

The exception does not eliminate the fire alarm system, but rather permits it to be initiated automatically by the sprinkler water flow switch(es) instead of by manual fire alarm boxes.

**907.2.3 Group E.** A manual fire alarm system that initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When *automatic sprinkler systems* or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

**Exceptions:**

1. A manual fire alarm system is not required in Group E occupancies with an *occupant load* of 50 or less.
2. Emergency voice/alarm communication systems meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall not be required in Group E occupancies with occupant loads of 100 or less, provided that activation of the manual fire alarm system initiates an *approved* occupant notification signal in accordance with Section 907.5.
3. Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:
  - 3.1. Interior *corridors* are protected by smoke detectors.

- 3.2. Auditoriums, cafeterias, gymnasiums and similar areas are protected by *heat detectors* or other *approved* detection devices.
- 3.3. Shops and laboratories involving dusts or vapors are protected by *heat detectors* or other *approved* detection devices.
- 4. Manual fire alarm boxes shall not be required in Group E occupancies where all of the following apply:
  - 4.1. The building is equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.
  - 4.2. The emergency voice/alarm communication system will activate on sprinkler water flow.
  - 4.3. Manual activation is provided from a normally occupied location.

❖ Section 404.2.3 addresses the development and implementation of lockdown plans. These requirements were developed to ensure that the level of life safety inside of the building is not reduced or compromised during a lockdown. In order for a building to safely function in a lockdown condition, the code requires a means of communication between the established central location and each secured area. Section 404.3.3.1 does not prescribe the means of communication, which could include the use of text messages to cell phones/mobile devices, e-mail messages or the use of preestablished audio or visual signals. The provisions in Section 404.2.3 are not specific to Group E occupancies—they are applicable to all occupancies that develop and implement lockdown plans.
