- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 2403 PROTECTION OF OPERATIONS

**2403.1 General.** Operations covered by this chapter shall be protected as required by Sections 2403.2 through 2403.4.4.

- ❖ This section states that the general protection requirements that apply to all processes (spraying, dipping and powder coating) are contained in this section. The regulation and mitigation of hazards common to all processes described in Section 2401.1 are set forth here.

**2403.2 Sources of ignition.** Protection against sources of ignition shall be provided in accordance with Sections 2403.2.1 through 2403.2.8.

- ❖ Protection against sources of ignition is one of the most critical aspects of fire prevention in flammable finish operations. Flammable finish materials are finely divided or atomized during spraying operations, making them much more volatile and subject to ignition. Controlling sources of ignition is a preventive measure in a hazardous area where vapors can exist and potential ignition sources are readily available in the operations (ovens, electrical outlets, etc.).

**2403.2.1 Electrical wiring and equipment.** Electrical wiring and equipment shall comply with this chapter and NFPA 70.

- ❖ In order to control the ignition and personnel hazards of electrical wiring and equipment, they must meet the requirements of NFPA 70. Those requirements are found in Article 516 of NFPA 70 for areas in and around the spraying equipment, which places restrictions on the use of portable electric lamps. The classification of an area is based on the amount of flammable vapors, combustible mists, residues, dust or deposits present.

**2403.2.1.1 Flammable vapor areas.** Electrical wiring and equipment in flammable vapor areas shall be of an explosion-proof type *approved* for use in such hazardous locations. Such areas shall be considered to be Class I, Division 1 or Class II, Division 1 hazardous locations in accordance with NFPA 70.

❖ The areas where flammable vapors [defined as flammable constituents in air that exceed 25 percent of the lower flammable limit (LFL)] are present must meet the requirements for Class I, Division 1 hazardous locations. The areas where combustible residues (such as dusts or deposits) are present must meet the requirements for the Class II, Division 1 (for dusts and residue) electrical classification. This is a very critical aspect of prevention of sources of ignition. Based on the definition of “Flammable vapor area,” the fire code official is authorized to define the extent of the flammable vapor area in any specific case. Otherwise, the areas described in that definition, such as the interior of spray booths, are used for electrical classification. See Commentary Figures 2403.2.1.1(1) and 2403.2.1.1(2) for examples of locations classified according to NFPA 70, Section 516.

**2403.2.1.2 Areas subject to deposits of residues.** Electrical equipment, flammable vapor areas or drying operations that are subject to splashing or dripping of liquids shall be specifically *approved* for locations containing deposits of readily ignitable residue and explosive vapors.

**Exceptions:**

1. This provision shall not apply to wiring in rigid conduit, threaded boxes or fittings not containing taps, splices or terminal connections.

2. This provision shall not apply to electrostatic equipment allowed by Section 2407.

In resin application areas, electrical wiring and equipment that is subject to deposits of combustible residues shall be *listed* for such exposure and shall be installed as required for hazardous (classified) locations. Electrical wiring and equipment not subject to deposits of combustible residues shall be installed as required for ordinary hazard locations.

❖ It is critical that only specifically approved electrical equipment be allowed in spraying spaces where deposits of combustible residues may readily accumulate. This section limits the use of electrical equipment in the above-mentioned area subject to deposit of residue for two primary reasons:

1. Sparks from such equipment could cause ignition of flammable vapors or overspray residue.
2. Buildup of combustible overspray or splashed residue accumulating on the surfaces of electrical equipment subject to heating may cause equipment to overheat and ignite. See Commentary Figures 2403.2.1.1(1) and 2403.2.1.1(2) for examples of electrically classified locations.

Taps, splices or terminal connections (similar to those of connections within flammable liquid transfer systems) are the areas where accidents are most likely to occur. By removing risks associated with such fittings and installing rigid conduit to protect against splashing or dripping of liquids, the hazards associated with such electrical equipment are

## FLAMMABLE FINISHES

reduced substantially. Because the electrostatic equipment is part of many flammable-finish processes, Section 2407 requires that the equipment be approved. "Approved" is defined in Chapter 2 as "accepted by the fire code official" (see the commentary to this definition).

**2403.2.1.3 Areas adjacent to spray booths.** Electrical wiring and equipment located outside of, but within 5 feet (1524 mm) horizontally and 3 feet (914 mm) vertically of openings in a spray booth or a spray room, shall be *approved* for Class I, Division 2 or Class II, Division 2 hazardous locations, whichever is applicable.

❖ Class I, Division 2, and Class II, Division 2 typically apply to areas where accumulation of flammable vapors and combustible dust are prevented through ventilation and dust collection systems. However, flammable vapors and combustible dusts may be present in these areas if the ventilation system fails.

**2403.2.1.4 Areas subject to overspray deposits.** Electrical equipment in flammable vapor areas located such that deposits of combustible residues could readily accumulate thereon

shall be specifically *approved* for locations containing deposits of readily ignitable residue and *explosive* vapors in accordance with NFPA 70.

### Exceptions:

1. Wiring in rigid conduit.
2. Boxes or fittings not containing taps, splices or terminal connections.
3. Equipment allowed by Sections 2404 and 2407 and Chapter 30.

❖ Hazards associated with overspray deposit are similar to areas subject to deposits of residues specified in Section 2403.2.1.2 (see commentary, Section 2403.2.1.2). Exception 1 allows the use of rigid conduit to protect against splashing or dripping of liquids, which substantially reduces the hazards associated with electrical equipment.

Exception 2 acknowledges that where boxes do not contain taps, splices or terminal connections (similar to those of connections within flammable liquid transfer systems), the hazards associated with such electrical equipment are reduced substantially.

Exception 3 exempts equipment allowed by the code (approved or listed) for hazardous uses, such as equipment allowed by Sections 2404 and 2407 and Chapter 30 because those items are designed to protect against ignition or explosion hazards.

**2403.2.2 Open flames and sparks.** Open flames and spark-producing devices shall not be located in flammable vapor areas and shall not be located within 20 feet (6096 mm) of such areas unless separated by a permanent partition.

**Exception:** Drying and baking apparatus complying with Section 2404.6.1.2.

❖ For obvious prevention reasons, open flames and spark-producing devices are not allowed in areas considered as flammable vapor areas and areas that could contain flammable vapors should the ventilation system fail. Open flames are prohibited where flammable or combustible liquids are stored, dispensed or applied. Heaters and all types of open-flame appliances are prohibited in and within 20 feet (6096 mm) of spray spaces and vapor areas, such as dip tanks and spray-finishing areas.

The exception recognizes that there are additional safety requirements in Section 2404.6.1.2 and Chapter 30 that reduce the probability of an ignition associated with open flames and sparks from drying and baking apparatus.

**2403.2.3 Hot surfaces.** Heated surfaces having a temperature sufficient to ignite vapors shall not be located in flammable vapor areas. Space-heating appliances, steam pipes or hot surfaces in a flammable vapor area shall be located such that they are not subject to accumulation of deposits of combustible residues.

**Exception:** Drying apparatus complying with Section 2404.6.1.2.

❖ Where practical, auxiliary heating appliances (regardless of them being tested or listed) should not be installed inside a spray booth, room or area. Heating equipment and appliances approved for use only in Class I, Division 1 (flammable spray); or Class II, Division 1 (powder coating) hazardous locations are to be installed in spray booths, rooms or areas. Even the hot surfaces of indirect heating appliances can ignite combustible dusts or flammable or combustible vapors produced by spray or resin application operations.

The exception, as mentioned previously, notes that there are additional safety requirements in Section 2404.6.1.2 and Chapter 30 that prevent or reduce the probability of an ignition associated with open flames and sparks.

**2403.2.4 Equipment enclosures.** Equipment or apparatus that is capable of producing sparks or particles of hot metal that would fall into a flammable vapor area shall be totally enclosed.

❖ Equipment in areas considered as vapor areas and areas that could contain flammable vapors and com-

combustible residue such as dusts or deposits is restricted. The same reasoning as for open flames required by Section 2403.2.2 applies. An example of this equipment is a metal grinding machine that produces sparks. Also see Section 2403.2.7 for welding requirements and signage.

**2403.2.5 Grounding.** Metal parts of spray booths, exhaust ducts and piping systems conveying Class I or II liquids shall be electrically grounded in accordance with NFPA 70. Metallic parts located in resin application areas, including but not limited to exhaust ducts, ventilation fans, spray application equipment, workpieces and piping, shall be electrically grounded.

❖ Static electricity is one of the most insidious and most common of all ignition sources. According to D.R. Scarborough in 2003, static sparks are the most common ignition sources involving spray-finishing operations. Additionally, humans are conductors of electricity, meaning that operators must also be considered when grounding systems are determined. NFPA 77 provides additional guidance on mitigating static electricity.

**2403.2.6 Smoking prohibited.** Smoking shall be prohibited in flammable vapor areas and hazardous materials storage rooms associated with flammable finish processes. “No Smoking” signs complying with Section 310 shall be conspicuously posted in such areas.

❖ Smoking is a significant ignition source and is therefore prohibited where flammable or combustible liquids or combustible dusts are stored, dispensed or applied. “No smoking” signs must be conspicuously located throughout the work area. Designated smoking areas should be located well outside the spray-finishing area and preferably in a separate room. The requirements of Sections 5003.7.1 and 5706.4.8 can also apply in facilities where flammable finish processes occur (see also commentary, Section 310).

**2403.2.7 Welding warning signs.** Welding, cutting and similar spark-producing operations shall not be conducted in or adjacent to flammable vapor areas or dipping or coating operations unless precautions have been taken to provide safety. Conspicuous signs with the following warning shall be posted in the vicinity of flammable vapor areas, dipping operations and paint storage rooms:

NO WELDING  
THE USE OF WELDING OR CUTTING  
EQUIPMENT IN OR NEAR THIS AREA  
IS DANGEROUS BECAUSE OF FIRE  
AND EXPLOSION HAZARDS. WELDING  
AND CUTTING SHALL BE DONE ONLY  
UNDER THE SUPERVISION OF THE  
PERSON IN CHARGE.

❖ For obvious reasons, open flames and spark-producing devices are not allowed in areas considered as flammable vapor areas (and areas that could potentially contain flammable vapors should the prevention

system components, such as ventilation, fail). Open flames are prohibited where flammable or combustible liquids are stored, dispensed or applied. Although no specific separation distance between the welding area and spraying space is required, the 20 feet (6096 mm) beyond the spraying space or to a permanent partition as also mentioned in Section 2403.2.2 may be a good general separation guideline for these incompatible operations. Because welding and cutting processes can typically be found in buildings that house flammable-finish processes, they create a potentially hazardous environment, especially for personnel unaware of such hazards. As with other hazardous conditions, such as smoking, warning signs and placards must be posted to give appropriate notice to warn personnel of the hazards of welding near spraying spaces.

**2403.2.8 Powered industrial trucks.** Powered industrial trucks used in electrically classified areas shall be *listed* for such use.

- ❖ Similar language is used in Section 5003.7.3. Again, because these types of industrial trucks are powered by an electrical motor or internal combustion engine, the ignition of flammable vapors or combustible dusts is likely unless they are listed for such use (see also commentary, Sections 309 and 5003.7.3).

**2403.3 Storage, use and handling of flammable and combustible liquids.** The storage, use and handling of flammable and *combustible liquids* shall be in accordance with this section and Chapter 57.

- ❖ Provisions of Chapter 57 and this section govern the storage and handling of flammable and combustible liquids for flammable finishes. As mentioned previously, Section 2403 applies to all flammable-finishing operations within the scope of this chapter; therefore, Section 2403.3 applies to flammable-finish operations that use flammable and combustible liquids.

**2403.3.1 Use.** Containers supplying spray nozzles shall be of a closed type or provided with metal covers that are kept closed. Containers not resting on floors shall be on noncombustible supports or suspended by wire cables. Containers supplying spray nozzles by gravity flow shall not exceed 10 gallons (37.9 L) in capacity.

- ❖ Requirements in this section are intended to prevent spills or the release of flammable vapors from flammable liquid containers. Tight-fitting metal lids or covers must be installed on all containers during use. Only those containers used to supply spray apparatus should be in the spraying space or spray-finishing enclosure during spray-finishing operations. Containers supplying spray apparatus must rest on a floor or noncombustible stand when in use or be suspended from the ceiling by wire cables. Gravity dispensing of flammable liquids to spray nozzles is permitted for quantities not exceeding 10 gallons (38 L) to control the size of an uncontrolled gravity-fed leak.

**2403.3.2 Valves.** Containers and piping to which a hose or flexible connection is attached shall be provided with a shut-off valve at the connection. Such valves shall be kept shut when hoses are not in use.

- ❖ Shutoff valves must be installed at the juncture between flexible hoses or tubing and fixed piping used to dispense flammable liquids to spray-finishing apparatus to allow prompt stoppage of liquid flow if a hose or tubing failure occurs. Shutoff valves must be closed when spray apparatus is not in use.

**2403.3.3 Pumped liquid supplies.** Where flammable or *combustible liquids* are supplied to spray nozzles by positive displacement pumps, pump discharge lines shall be provided with an *approved* relief valve discharging to pump suction or a safe detached location.

- ❖ In order to prevent excess flows or line ruptures from positive-pressure pumps, pressure relief valves or other devices must be installed on the discharge side of positive-displacement pumps supplying flammable liquids to spray apparatus. These devices must operate before the discharge pressure exceeds the safe operating pressure of the connected valves, piping and equipment. Any discharge from the devices must be controlled to prevent ignition or environmental damage.

**2403.3.4 Liquid transfer.** Where a flammable mixture is transferred from one portable container to another, a bond shall be provided between the two containers. Not less than one container shall be grounded. Piping systems for Class I and II liquids shall be permanently grounded.

- ❖ The uncontrolled discharge of static electricity is a common ignition source during flammable liquid transfer. Proper bonding and grounding precautions must be followed for the safe discharge of static charges produced during flammable liquid transfer. See Section 5705.2 for general flammable and combustible liquid transfer requirements.

**2403.3.5 Class I liquids as solvents.** Class I liquids used as solvents shall be used in spray gun and equipment cleaning machines that have been *listed* and *approved* for such purpose or shall be used in spray booths or spray rooms in accordance with Sections 2403.3.5.1 and 2403.3.5.2.

- ❖ Another hazardous aspect of spray finishing is the use of solvents to clean spray guns and related equipment. When spray booths require cleaning, the use of solvents may often pose a greater hazard than the normally used spray-finishing material. Usually an integral part of the labeling process, manufacturer's installation, operation and maintenance instructions must be carefully followed. The type of solvent to be used in any given machine must be as recommended by the machine manufacturer.

**2403.3.5.1 Listed devices.** Cleaning machines for spray guns and equipment shall not be located in areas open to the public and shall be separated from ignition sources in accordance

with their listings or by a distance of 3 feet (914 mm), whichever is greater. The quantity of solvent used in a machine shall not exceed the design capacity of the machine.

❖ Cleaning machines for spray guns and equipment are commonly used in the industry. See Commentary Figure 2403.3.5.1 for an illustration of a spray gun cleaning machine. Such machines use solvents powerful enough to dissolve paint residues in the thin tubing and small orifices of the spray equipment. They are similar to the automotive parts cleaners that have been in widespread use since the early 1970s, and consist of a metal sink-like bowl set on a base unit that houses a storage container for retrieval of spent solvent after the cleaning process. The solvent is circulated in the machine by a pneumatic pump. Vapors are captured in the sink bowl and are vented to the outdoors, either directly or, where located inside a spray booth, by directing vapors to the spray booth operating exhaust system inlets (see Section 2403.3.5.2). A safety interlock prevents the solvent pump from operating if the exhaust system fails. Installation of such machines must be restricted to areas not accessible to the general public to avoid exposure to the potential hazards of the cleaning operations and prevent the inadvertent introduction of ignition sources to the cleaning area.

**2403.3.5.2 Within spray booths and spray rooms.** When solvents are used for cleaning spray nozzles and auxiliary

equipment within spray booths and spray rooms, the ventilating equipment shall be operated during cleaning.

❖ The safety systems that are an integral part of operating spray booths and spray rooms can be used when solvents are used for equipment cleaning. These systems help, as they would during application of flammable finishes, in reducing the chances of ignition or the severity of a fire, should an ignition occur.

**2403.3.6 Class II and III liquids.** Solvents used outside of spray booths, spray rooms or *listed* and *approved* spray gun and equipment cleaning machines shall be restricted to Class II and III liquids.

❖ Cleaning spray equipment inside a spray booth or room designed to accommodate the hazards of spray painting and equipment maintenance should be the primary choice of operators. The code recognizes that this is not always a feasible option and thus allows for cleaning spray equipment outside an approved spray booth or room, or a labeled spray gun and equipment cleaning machine, provided that the cleaning solvents used are limited to combustible liquids having a flashpoint greater than 100°F (38°C).

**2403.4 Operations and maintenance.** Flammable vapor areas, exhaust fan blades and exhaust ducts shall be kept free from the accumulation of deposits of combustible residues. Where excessive residue accumulates in such areas, spraying

Figure 2403.3.5.1  
SPRAY GUN CLEANING MACHINE

## FLAMMABLE FINISHES

operations shall be discontinued until conditions are corrected.

❖ A regular cleaning schedule should be adopted for spraying spaces and spray-finishing enclosures. Accumulations of spray residue in interior spray booths or rooms or on exhaust duct surfaces should be removed at least daily or more frequently when accumulations become excessive. Any time overspray residue accumulations become excessive, the operator must suspend spray operations until the spray booth or area is thoroughly and properly cleaned. Water-wash nozzles, strainers and eliminator packs must be checked or cleaned daily or at the end of each shift, and tank sludge removed and discarded in a safe manner. Interior surfaces of ductwork and fan blades should be inspected regularly for accumulations of overspray residue caused by fouled nozzles, strainers or eliminator packs. The use of soap-based, water-soluble coatings makes it easier to strip surfaces using high-pressure water spray without greatly increasing the fire hazard. Determination of whether the accumulation of residue has become excessive in a particular location must be made by the fire code official on a case-by-case basis.

**2403.4.1 Tools.** Scrapers, spuds and other tools used for cleaning purposes shall be constructed of nonsparking materials.

❖ Because of the potential ignition problem that exists, the cleaning tools need to be of the nonsparking type. The term “nonsparking” is somewhat inaccurate. Tools made of brass and similar nonsparking materials do produce sparks but the sparks have ignition energies too low to ignite flammable vapors. Nonetheless, such tools should be used carefully to avoid producing sufficient frictional heat to cause an ignition.

**2403.4.2 Residue.** Residues removed during cleaning and debris contaminated with residue shall be immediately removed from the premises and properly disposed.

❖ Paint and solvent residue, cleaning rags and used protective coverings may be susceptible to spontaneous ignition. Residue and cleaning debris must be removed from the building and stored in approved containers located well away from the building. Removing residue and cleaning debris on a regular schedule, such as at the end of each work shift, are highly recommended.

**2403.4.3 Waste cans.** *Approved* metal waste cans equipped with self-closing lids shall be provided wherever rags or waste are impregnated with finishing material. Such rags and waste shall be deposited therein immediately after being utilized. The contents of waste cans shall be properly disposed of not less than once daily and at the end of each shift.

❖ Waste cans (sometimes called “oily rag cans”) used for storing materials that might auto-ignite as a result of the spontaneous combustion process must be tested and listed for that use by a recognized testing

laboratory or agency and must bear a label showing that they have been tested and including the name of the testing agency (see Section 304.3.1). Such containers are most commonly round and generally available in sizes ranging from 5 to 40 gallons (19 to 152 L). They are equipped with a manual or foot treadle-operated lid that opens to a maximum angle of 60 degrees (1 rad) and closes by gravity. These containers are designed to prevent continuing combustion of the contents if ignition occurs.

The container design includes features that keep the can body from coming into contact with combustible surfaces of walls or floors. Daily disposal of container contents reduces the amount of time that oily materials will lie dormant, generating internal heat that can lead to ignition. UL 32 provides further information on the construction, testing and listing of these containers (see the commentary to the Section 202 definition of “Listed”). Note that the general requirements of the daily removal and disposal of the contents of such waste cans found in Section 304.3.1 is superseded by the more specific disposal requirements of this section.

**2403.4.4 Solvent recycling.** Solvent distillation equipment used to recycle and clean dirty solvents shall comply with Section 5705.4.

❖ Section 5705.4 includes detailed requirements for solvent distillation processes and equipment, such as labeling, unit capacity, location and prohibited processes. Note that the terms “solvent distillation unit,” “appliance” and “equipment” are used interchangeably in the code.

## SECTION 2404 SPRAY FINISHING

**2404.1 General.** The application of flammable or *combustible liquids* by means of spray apparatus in continuous or intermittent processes shall be in accordance with the requirements of Sections 2403 and 2404.2 through 2404.9.4.

❖ This section establishes the applicability of the general requirements of Section 2403 to spraying operations, in addition to the provisions of Sections 2404.2 through 2404.9.4.

**2404.2 Location of spray-finishing operations.** Spray-finishing operations conducted in buildings used for Group A, E, I or R occupancies shall be located in a spray room protected with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 and separated vertically and horizontally from other areas in accordance with the *International Building Code*. In other occupancies, spray-finishing operations shall be conducted in a spray room, spray booth or spraying space *approved* for such use.

### Exceptions:

1. Automobile undercoating spray operations and spray-on automotive lining operations conducted in areas with *approved* natural or mechanical ventilation shall be exempt from the provisions of Section

2404 when *approved* and where utilizing Class IIIA or IIIB *combustible liquids*.

2. In buildings other than Group A, E, I or R occupancies, *approved* limited spraying space in accordance with Section 2404.9.
  3. Resin application areas used for manufacturing of reinforced plastics complying with Section 2409 shall not be required to be located in a spray room, spray booth or spraying space.
- ❖ In the listed occupancy groups, separating spray-finishing operations from other portions of the building and protecting those portions from spraying-associated hazards are critical for several reasons. Spray-finishing operations are generally too hazardous to be conducted in occupancies with a high life or property exposure. The number of occupants in such buildings and the physical conditions of those occupants vary. People exposed to the danger of a fire involving spray finishing must be able to evacuate or protect themselves promptly and effectively to avoid the risk of serious injury or death. Also, the psychology of people in a Group A, E, I or R occupancy is very different from those in a Group F manufacturing occupancy where spraying operations are usually found. A person walking in a manufacturing environment where flammable-finish processes take place in a large area where spray booths and signs are in plain view, for example, is more aware of the physical dangers associated with these processes than someone in a Group R occupancy who may be merely relaxing with a cigarette. Also note that the protection provided in these occupancies is, in many cases, less than would be found in manufacturing occupancies. Separation and protection in the form of fire-resistance-rated construction and automatic fire suppression must be provided where such operations are to be conducted in the same building.

Note that Section 307.1, Exception 1, of the *International Building Code*® (IBC®) excludes spraying operations from being classified in Group H as long as they comply with IBC Section 416 and the provisions of the fire code. Section 416.2 requires that spray rooms be separated from the rest of the building by 1-hour fire barriers and horizontal assemblies constructed in accordance with IBC Sections 707 and 711, respectively.

Exception 1 recognizes that most automobile undercoating and corrosion-inhibitor application operations use combustible liquids with flash points greater than 140°F (60°C). Precautions must be taken to prevent these materials from being heated above their flash points or ignited in finely divided or atomized form. Ventilation to reduce the accumulation of hazardous vapors and mists must comply with the requirements of Chapter 57 and the *International Mechanical Code*® (IMC®).

Exception 2 recognizes the reduced hazard of limited spray applications in compliance with the special requirements in Section 2404.9, including small job

size, noncontinuous operation and substantial mechanical ventilation requirements.

Exception 3 defers to the specific safeguards applicable to resin application areas used in the manufacture of reinforced plastics in Section 2409.

**2404.3 Design and construction.** Design and construction of spray rooms, spray booths and spray spaces shall be in accordance with Sections 2404.3.1 through 2404.3.3.1.

- ❖ This section establishes the applicability of Sections 2404.3.1 through 2404.3.3.1 to the design and construction of spaces where spray-finishing operations may be carried out.

**2404.3.1 Spray rooms.** Spray rooms shall be constructed and designed in accordance with Section 2404.3.1.1 and the *International Building Code*, and shall comply with Sections 2404.4 through 2404.8.

- ❖ A spray room is a power-ventilated, fully enclosed room used exclusively for the open spraying of flammable and combustible materials. The entire spray room is considered a spraying space. The primary difference between a spray room and a spray booth is that spray booths are partially open.

Spray rooms, as with the other locations for spraying operations, are very highly regulated by the code and the IBC. As such, IBC Section 307.1, Exception 1 excludes spraying operations from being classified in Group H as long as they comply with IBC Section 416 and the provisions of the fire code. IBC Section 416.2 requires that spray rooms be separated from the rest of the building by 1-hour fire barriers and horizontal assemblies constructed in accordance with IBC Sections 707 and 711, respectively.

The occupancy of portions of buildings storing supplies of hazardous materials for these coating operations may be classified as Group H-2 or H-3 because of the presence of flammable or combustible liquids where the quantity of liquid stored exceeds the MAQ per control area listed in Table 5003.1.1(1). However, the occupancy is to be classified as Group F-1 for processes where the quantities do not exceed the MAQ. See also the commentary to the Section 202 definition of “Spray room.”

**2404.3.1.1 Floor.** Combustible floor construction in spray rooms shall be covered by *approved*, noncombustible, non-sparking material, except where combustible coverings, including but not limited to thin paper or plastic and strippable coatings, are utilized over noncombustible materials to facilitate cleaning operations in spray rooms.

- ❖ In spray rooms, noncombustible floors would be the preferred type of floor construction so as not to contribute to the fuel load available to an unwanted fire. However, if the floor is not noncombustible, noncombustible and nonsparking material must be used to cover the floor. Kraft paper and similar coverings are commonly used in spraying spaces to protect against overspray. Such coverings must be removed and discarded when accumulation becomes excessive.

Note that IBC Section 416.2 further requires that

## FLAMMABLE FINISHES

spray room floors be "...waterproofed and drained in an approved manner." Waterproof floors are to be arranged to drain either to the outside of the building, to internal drains or to other suitable places. Properly designed and guarded drains or scuppers of sufficient number and size to dispose of all surplus water likely to be discharged by automatic sprinklers must be provided.

**2404.3.2 Spray booths.** The design and construction of spray booths shall be in accordance with Sections 2404.3.2.1 through 2404.3.2.6, Sections 2404.4 through 2404.8 and NFPA 33.

❖ Sections 2404.3.2.1 through 2404.3.2.6 and 2404.4 through 2404.8 and NFPA 33 contain requirements for controlling hazards associated with spray booths. Much of the hazard prevention and mitigation of flammable-finish fires in a spray booth depend on the proper construction and design of the spray booth. See the commentary to the Section 202 definition of "Spray booth." Note that, by definition, a spray booth is considered to be an appliance.

**2404.3.2.1 Construction.** Spray booths shall be constructed of *approved* noncombustible materials. Aluminum shall not be used. Where walls or ceiling assemblies are constructed of sheet metal, single-skin assemblies shall be no thinner than 0.0478 inch (18 gage) (1.2 mm) and each sheet of double-skin assemblies shall be no thinner than 0.0359 inch (20 gage) (0.9 mm). Structural sections of spray booths are allowed to be sealed with latex-based or similar caulks and sealants.

❖ Even though spray booths are not required to meet the fire-resistance-rated construction requirements of the IBC, the requirements of this section recognize the need to minimize the spread of a fire and prevent a spray booth from contributing to a fire should one start within the booth. Aluminum is not suitable for structurally sound construction of enclosures because of its low melting point; it would be likely to melt in case of a substantial fire within the booth. For a spray booth to maintain its structural integrity in a fire, it should be constructed of steel, masonry or equivalent noncombustible materials. Section 5003.8 also requires hazardous materials storage cabinets to be constructed of 18-gage [0.0478 inch (1.2 mm)] steel. Both booths and cabinets are viewed as equipment used to control and contain spills or fires.

**2404.3.2.2 Surfaces.** The interior surfaces of spray booths shall be smooth; shall be constructed so as to permit the free passage of exhaust air from all parts of the interior, and to facilitate washing and cleaning; and shall be designed to confine residues within the booth. Aluminum shall not be used.

❖ Rough, corrugated or uneven surfaces are difficult to clean. Periodic cleaning of the interior surfaces reduces the fire hazard posed by the accumulation of flammable or combustible coatings. Because flammable or combustible vapors and dusts are typically heavier than air, design considerations should include the passage of exhaust air and proper air cir-

ulation to all parts of the spray booth, especially at or near the floor level. Due to the physical properties of aluminum, it is unsuitable for cleaning and scraping of overspray residue. See the commentary to Section 2404.3.2.1 for further discussion on the use of aluminum in spray-booth construction.

**2404.3.2.3 Floor.** Combustible floor construction in spray booths shall be covered by *approved*, noncombustible, non-sparking material, except where combustible coverings, including but not limited to thin paper or plastic and strippable coatings, are utilized over noncombustible materials to facilitate cleaning operations in spray booths.

❖ The spray-booth floor requirements in this section parallel those for spray rooms in Section 2404.3.1.1 (see commentary, Section 2404.3.1.1).

**2404.3.2.4 Means of egress.** *Means of egress* shall be provided in accordance with Chapter 10.

**Exception:** *Means of egress* doors from premanufactured spray booths shall be not less than 30 inches (762 mm) in width by 80 inches (2032 mm) in height.

❖ As with any room or space within a building from which occupants may need to egress, spray booths must comply with the exiting requirements of Chapter 10. See Section 1015, which establishes the minimum number of exits from rooms and spaces within a building, based on occupant load.

In typical spray booths, only a single egress door will be required. A premanufactured spray booth is considered to be an appliance or equipment and not a true separate room or space. Spray booths will also be occupied only by authorized personnel who are familiar with that environment. Accordingly, for booth design and listing purposes the exception specifically allows the egress door to be slightly smaller than the generally applicable minimum required width of 32 inches (813 mm) for means-of-egress doors specified in Section 1010.1.1. This is consistent with the door width exceptions for residential and Group I-3 occupancies in that section, which are based on familiarity with the occupancy in Group R and the controlled environment of Group I-3.

**2404.3.2.5 Clear space.** Spray booths shall be installed so that all parts of the booth are readily accessible for cleaning. A clear space of not less than 3 feet (914 mm) shall be maintained on all sides of the spray booth. This clear space shall be kept free of any storage or combustible construction.

### Exceptions:

1. This requirement shall not prohibit locating a spray booth closer than 3 feet (914 mm) to or directly against an interior partition, wall or floor/ceiling assembly that has a *fire-resistance rating* of not less than 1 hour, provided the spray booth can be adequately maintained and cleaned.
2. This requirement shall not prohibit locating a spray booth closer than 3 feet (914 mm) to an exterior wall or a roof assembly, provided the wall or roof is con-

structed of noncombustible material and the spray booth can be adequately maintained and cleaned.

- ❖ Spray booths are viewed as equipment where accessibility is essential to cleaning and maintenance. This section is also included for housekeeping reasons, and to keep combustible debris and materials away from the spray booth to reduce the chances of an ignition on its exterior from a fire that might occur within the booth. This clearance also serves to prevent heat from a fire within a booth from being transferred to adjacent combustible material. It also will prevent a fire near a booth (from combustible storage, for example) from acting as an ignition source for the booth (see Commentary Figure 2404.3.2.5).

Under Exception 1, if the construction materials of an interior partition further inhibit the spread of a fire and if there are proper means of cleaning the spray booth, the intent of the section is considered met. This exception, however, still does not allow any storage within 3 feet (914 mm) of the spray booth. Note that the 1-hour partition, wall or floor/ceiling assembly is a generic description of an assembly and not a specific type of assembly (e.g., fire wall, fire barrier, fire partition, etc.) with a specific assigned purpose. As such, no continuity requirements apply for such assemblies as would be applicable to assemblies with a specific required fire protection function and their designation as a specific type of assembly.

Exception 2 recognizes that if an exterior wall or roof assembly is of noncombustible construction, it will not contribute to the fuel load or spread of the fire to other interior parts of the building. This meets the intent of this section as long as there are proper means of cleaning the spray booth. This exception

still does not allow any storage within 3 feet (914 mm) of the spray booth.

**2404.3.2.6 Size.** The aggregate area of spray booths in a building shall not exceed the lesser of 10 percent of the area of any floor of a building or the basic area allowed for a Group H-2 occupancy without area increases, as set forth in the *International Building Code*. The area of an individual spray booth in a building shall not exceed the lesser of the aggregate size limit or 1,500 square feet (139 m<sup>2</sup>).

**Exception:** One individual booth not exceeding 500 square feet (46 m<sup>2</sup>).

- ❖ The intent of limiting the size of a spray booth is to compartmentalize or provide passive fire protection. This limits the size of a fire and the processes to a more manageable condition. Section 2404.2 requires spraying operations to be conducted in an approved spray booth, spraying space or spray room. As stated in this section, the size of an approved spray booth is limited to the lesser of 1,500 square feet (139 m<sup>2</sup>) or 10 percent of the area of any floor of a building or the basic area allowed for a Group H-2 occupancy without area increases, as set forth in the IBC. If the area limits for an approved spray booth are exceeded, then the operation must be conducted in a spray room in accordance with Section 2404.3.1. The term “spray room” is defined in Section 202.

The exception references the first paragraph of the section. In businesses where the building is small [typically less than 5,000 square feet (465 m<sup>2</sup>)], it may be impractical to design for a spray booth that is less than 10 percent of the overall building area. In case of a fire, smaller buildings are easier to control from a passive fire protection standpoint than larger operations.

## FLAMMABLE FINISHES

**2404.3.3 Spraying spaces.** Spraying spaces shall be designed and constructed in accordance with the *International Building Code*, and Section 2404.3.3.1 and Sections 2404.4 through 2404.8 of this code.

❖ Because spraying spaces are not enclosed, the occupancy classification of the room in which the spraying space is located depends on whether the MAQs of hazardous materials per control area are exceeded. The occupancy of buildings or portions of buildings housing these coating operations is typically classified as Group H-2 [because flammable liquids are typically in open system use or under pressure greater than 15 pounds per square inch (psi) (103 kPa)] where the aggregate quantity of flammable/combustible liquids or dusts stored or used in a single control area exceeds the MAQ per control area listed in Table 5003.1.1(1). However, the occupancy is to be classified as Group F-1 or as a mixed use (such as Group F-1/S-1) for processes where the quantities do not exceed the MAQ per control area.

**2404.3.3.1 Floor.** Combustible floor construction in spraying spaces shall be covered by *approved*, noncombustible, non-sparking material, except where combustible coverings, such as thin paper or plastic and strippable coatings, are utilized over noncombustible materials to facilitate cleaning operations in spraying spaces.

❖ The spray-booth floor requirements in this section parallel those for spray rooms in Section 2404.3.1.1 and spray booths in Section 2404.3.2.3 (see commentary, Section 2404.3.1.1).

**2404.4 Fire protection.** Spray booths and spray rooms shall be protected by an *approved* automatic fire-extinguishing system complying with Chapter 9. Protection shall also extend to exhaust plenums, exhaust ducts and both sides of dry filters when such filters are used.

❖ Automatic sprinkler protection is the preferred method of protection for spray booths and spray rooms where the building is otherwise sprinklered. In nonsprinklered buildings that contain spray booths and spray rooms, alternative automatic fire-extinguishing systems, such as clean agents, carbon dioxide, dry chemical, etc., are allowed to be installed when approved by the fire code official. See the commentary to Section 904 for further discussion of specific types of alternative fire-extinguishing systems. Fire protection systems, equipment and devices must be installed and maintained in accordance with Chapter 9. Because the flammable-finish operations are subject to accumulation of residue, failure of the system as a result of poor maintenance is more likely in these areas than in most other types of facilities.

**2404.4.1 Fire extinguishers.** Portable fire extinguishers complying with Section 906 shall be provided for spraying areas in accordance with the requirements for an extra (high) hazard occupancy.

❖ Portable fire extinguishers for fighting incipient fires must be installed for ready access by the spray-booth, spray-room or spraying-space operator. Addi-

tionally, they should be selected on the basis of extra-hazard criteria contained in NFPA 10 to provide sufficient extinguishing agents and discharge time for the hazard to be protected. Because a spraying-space fire would involve ordinary combustibles as well as flammable/combustible liquids and dusts, the selection of a fire extinguisher will include Class A and B ratings.

Section 906 and NFPA 10 require no less than a 4-A:40-B:C extinguisher when the maximum travel distance to the extinguisher does not exceed 30 feet (9144 mm). A 4-A:40-B:C extinguisher is also acceptable when the maximum travel distance does not exceed 50 feet (15 240 mm) (see Commentary Figure 2404.4.1). Employees who are expected to fight incipient fires should receive instruction in the operation of the installed fire protection equipment.

**2404.5 Housekeeping, maintenance and storage of hazardous materials.** Housekeeping, maintenance, storage and use of hazardous materials shall be in accordance with Sections 2403.3, 2403.4, 2404.5.1 and 2404.5.2.

❖ This section establishes the applicability of the requirements of Sections 2403.3, 2403.4, 2404.5.1 and 2404.5.2 for controlling hazards associated with housekeeping, maintenance and the storage of hazardous materials.

**2404.5.1 Different coatings.** Spray booths, spray rooms and spraying spaces shall not be alternately utilized for different types of coating materials where the combination of materials is conducive to spontaneous ignition, unless all deposits of one material are removed from the booth, room or space and exhaust ducts prior to spraying with a different material.

❖ Spray operations involving potentially reactive coating materials must be confined to separate spray booths or purged after use. Using the same spray booth for separate operations involving materials that react with each other may produce a reaction

between the overspray residues of such materials once they are captured by the filters. Therefore, the entire system, including the ducts/filters, must be purged.

Spontaneous ignition, also known as autoignition or self-ignition, is defined by Burklin and Purington as “ignition due to chemical reaction or bacterial action in which there is slow oxidation of organic compounds until the material ignites; usually there is sufficient air for oxidation but insufficient ventilation to carry heat away as it is generated.” A detailed treatment of the subject appears in the NFPA *Fire Protection Handbook*.

The One Meridian Plaza office building fire in 1991 was allegedly started by the spontaneous ignition of oil-soaked rags that were improperly stored during a remodeling operation. This high-rise building in the heart of Philadelphia, Pennsylvania, was so seriously damaged in the fire that it was razed in 1999. A listed container for the storage of the oily rags as required by Section 2403.4.3 (see commentary, Section 2403.4.3) was not used. The fire code official should determine the kinds of oils or solvents used and research their potential for spontaneous ignition (see commentary, Section 304.3.2).

**2404.5.2 Protection of sprinklers.** Automatic sprinklers installed in flammable vapor areas shall be protected from the accumulation of residue from spraying operations in an *approved* manner. Bags used as a protective covering shall be 0.003-inch-thick (0.076 mm) polyethylene or cellophane or shall be thin paper. Automatic sprinklers contaminated by overspray particles shall be replaced with new automatic sprinklers.

❖ Automatic sprinkler heads must be protected from accumulations of spray residue to reduce the likelihood of residue build-up, which could insulate the fusible element and lead to failure of the head to respond in a timely manner in case of fire. Protective lightweight paper or plastic bags is allowed to be installed over sprinkler heads but must be replaced at regular intervals or when they become heavily coated. A regular inspection of the sprinkler heads in flammable-vapor areas should be undertaken by spray process operators to identify and replace any sprinklers that may have become coated with residue.

**2404.6 Sources of ignition.** Control of sources of ignition shall be in accordance with Section 2403.2 and Sections 2404.6.1 through 2404.6.2.4.

❖ This section establishes the applicability of the requirements of Sections 2403.2, 2404.6.1 and 2404.6.2.4 for controlling ignition hazards.

**2404.6.1 Drying operations.** Spray booths and spray rooms shall not be alternately used for the purpose of drying by arrangements or methods that could cause an increase in the surface temperature of the spray booth or spray room except in accordance with Sections 2404.6.1.1 and 2404.6.1.2. Except as specifically provided in this section, drying or baking units utilizing a heating system having open flames or

that are capable of producing sparks shall not be installed in a flammable vapor areas.

❖ Drying apparatus that causes significant heating of the workpiece or spray-booth surface may ignite finishing vapors or overspray residue located inside the spray booth. Separate drying apparatus or enclosures free of overspray residue should be installed when a drying apparatus is used.

Introduction of additional sources of ignition, including drying and baking units that do not meet the requirements of Section 2404.6.1.2, is not permitted in spraying areas.

**2404.6.1.1 Spraying procedure.** The spraying procedure shall use low-volume spray application.

❖ This section would apply only to smaller applications/processes where smaller amounts of flammable finishes are used. This is intended for spray booths and spray rooms that are used only occasionally for spraying and drying operations.

**2404.6.1.2 Drying apparatus.** Fixed drying apparatus shall comply with this chapter and the applicable provisions of Chapter 30. When recirculation ventilation is provided in accordance with Section 2404.7.2, the heating system shall not be within the recirculation air path.

❖ The practice of drying finished work pieces in the same enclosure where spray finishing is in progress is common in the automobile refinishing industry. This practice must be confined to spray-finishing enclosures designed for this purpose in compliance with the requirements of this section. Although the recirculated air should not be flammable (less than 25-percent LFL or dust residue is removed) as required by Section 2404.7.2, the heating system should be positioned to avoid possible ignition as a result of any malfunctions or unforeseen incidents.

Although this section appears to require fixed drying apparatus, the section is intended to require both fixed and portable infrared apparatus. This is further evident in Section 2404.6.1.2.2, in which the additional requirements for portable infrared apparatus are given.

**2404.6.1.2.1 Interlocks.** The spraying apparatus, drying apparatus and ventilating system for the spray booth or spray room shall be equipped with interlocks arranged to accomplish all of the following:

1. Prevent operation of the spraying apparatus while drying operations are in progress.
2. Where the drying apparatus is located in the spray booth or spray room, prevent operation of the drying apparatus until a timed purge of spray vapors from the spray booth or spray room is complete. This purge time shall be based upon completing at least four air changes of spray booth or spray room volume or for a period of not less than 3 minutes, whichever is greater.
3. Have the ventilating system maintain a safe atmosphere within the spray booth or spray room during the drying

## FLAMMABLE FINISHES

process and automatically shut off drying apparatus in the event of a failure of the ventilating system.

4. Shut off the drying apparatus automatically if the air temperature within the booth exceeds 200°F (93°C).
- ❖ This section prescribes requirements for the safe use of infrared drying units in spray-finishing enclosures used for automobile refinishing and other similar applications. The interlocks listed in this section are required to reduce the likelihood that a potential source of ignition (drying apparatus) and the fuel (flammable vapors) are not present in the spray booth or spray room simultaneously. Also, the hazard of the ease with which heated flammable vapors are ignited is further mitigated by controlling the temperature of the room. Without these features, and the greater of four air changes or a 3-minute purge for the spraying space, right conditions for ignition of vapors or residue could easily develop.

**2404.6.1.2.2 Portable infrared apparatus.** Where a portable infrared drying apparatus is used, electrical wiring and portable infrared drying equipment shall comply with NFPA 70. Electrical equipment located within 18 inches (457 mm) of floor level shall be *approved* for Class I, Division 2 hazardous locations. Metallic parts of drying apparatus shall be electrically bonded and grounded. During spraying operations, portable drying apparatus and electrical connections and wiring thereto shall not be located within spray booths, spray rooms or other areas where spray residue would be deposited thereon.

- ❖ In addition to the drying apparatus requirements stated throughout Section 2404.6.1, portable infrared apparatus is required to meet the provisions of this section. These requirements, such as bonding and grounding of apparatus, are intended to prevent the ignition of vapors in the transport of the apparatus.

**2404.6.2 Illumination.** Where spraying spaces, spray rooms or spray booths are illuminated through glass panels or other transparent materials, only fixed luminaires shall be utilized as a source of illumination.

- ❖ Fixed lighting units (luminaires) can be designed to minimize the possibility of ignition caused by the accidental heating of vapors above their autoignition temperature. Radiant heat from the source of illumination on the flammable finishes may cause ignition.

**2404.6.2.1 Glass panels.** Panels for luminaires or for observation shall be of heat-treated glass, wired glass or hammered wire glass and shall be sealed to confine vapors, mists, residues, dusts and deposits to the flammable vapor area. Panels for luminaires shall be separated from the luminaire to prevent the surface temperature of the panel from exceeding 200°F (93°C).

- ❖ The surface of incandescent bulbs, halogen lamps and other light fixtures (luminaires) often exceeds the ignition temperature of common flammable and combustible liquids. Separation of light fixtures (luminaires) from the glazing will help reduce the surface temperature on the unexposed side of the glass.

Glass panels must be designed, arranged and protected to ease cleaning and prevent breakage.

**2404.6.2.2 Exterior luminaires.** Luminaires attached to the walls or ceilings of a flammable vapor area, but outside of any classified area and separated from the flammable vapor areas by vapor-tight glass panels, shall be suitable for use in ordinary hazard locations. Such luminaires shall be serviced from outside the flammable vapor areas.

- ❖ Safety features, such as ventilation and separation using vapor-tight glass panels, allow for the use of ordinary light fixtures (luminaires) that are not electrically classified for hazardous locations. To maintain the integrity of the separation (that is, vapor-tight glass panels and installation outside of the classified area), these light fixtures (luminaires) must be serviced from outside the spraying area.

**2404.6.2.3 Integral luminaires.** Luminaires that are an integral part of the walls or ceiling of a flammable vapor area are allowed to be separated from the flammable vapor area by glass panels that are an integral part of the luminaire. Such luminaires shall be *listed* for use in Class I, Division 2 or Class II, Division 2 locations, whichever is applicable, and also shall be suitable for accumulations of deposits of combustible residues. Such luminaires are allowed to be serviced from inside the flammable vapor area.

- ❖ Light fixtures (luminaires) with construction that includes a glass panel for separation and that are installed within the construction of the wall or ceiling flammable-vapor area must be Class I, Division 2 because flammable vapors are present. Class II, Division 2 light fixtures are required where combustible residue, such as dust, is present.

**2404.6.2.4 Portable electric lamps.** Portable electric lamps shall not be used in flammable vapor areas during spraying operations. Portable electric lamps used during cleaning or repairing operations shall be of a type *approved* for hazardous locations.

- ❖ Portable electric lamps are unsuitable for use in spraying spaces during spraying operations due to their increased exposure to dropping and other use-related damage. Portable electric lamps vary in type and electrical classification. It would be a difficult judgment call for an operator to determine the appropriate type and location of a portable lamp in spraying spaces. Although portable electric lamps, if approved for hazardous locations, are allowed to be utilized during cleaning or repairing operations, they should be avoided if possible.

**2404.7 Ventilation.** Mechanical ventilation of flammable vapor areas shall be provided in accordance with Section 502.7 of the *International Mechanical Code*.

- ❖ Flammable-vapor areas, as defined in Section 202, include, but are not limited to, the interior of spray booths and spray rooms. The proper design and installation of exhaust ventilation systems in spraying spaces is critical because of the potential production of large amounts of flammable vapors in the processes.

Exhaust systems in spray-finishing areas must also comply with IMC Section 502.7, which regulates hazardous exhaust systems. Additionally, because IMC Section 502.7.3 is identical to this section, compliance with the general section of IMC Section 502, especially Section 502.1.1 (“...the inlet to an exhaust system shall be located in the area of heaviest concentration of contaminants...”), is recommended. The location of heaviest concentration resulting from the physical characteristics of a material (for example, vapor density) or the process (such as atomization of the material) must be considered when inlets to exhaust systems are designed.

**2404.7.1 Operation.** Mechanical ventilation shall be kept in operation at all times while spraying operations are being conducted and for a sufficient time thereafter to allow vapors from drying coated articles and finishing material residue to be exhausted. Spraying equipment shall be interlocked with the ventilation of the flammable vapor areas such that spraying operations cannot be conducted unless the ventilation system is in operation.

❖ Ventilation must be functioning during the spraying operation phase and the drying phase of a process when vapors are generated. The interlock between the ventilation and spraying equipment will reduce the likelihood of human error, such as operator failure to activate the ventilation system prior to the use of the spray equipment. Operating spray equipment without having the exhaust system in operation could allow fugitive flammable vapors to migrate to areas that may contain unprotected ignition sources and ignite. Continuous operation of ventilation systems could also be an integral component of the design of certain alternative fire-extinguishing systems, such as dry chemical systems. Note that this section parallels Section 502.7.3.1 of the IMC.

**2404.7.2 Recirculation.** Air exhausted from spraying operations shall not be recirculated.

**Exceptions:**

1. Air exhausted from spraying operations is allowed to be recirculated as makeup air for unmanned spray operations, provided that all of the following conditions exist:
  - 1.1. The solid particulate has been removed.
  - 1.2. The vapor concentration is less than 25 percent of the LFL.
  - 1.3. *Approved* equipment is used to monitor the vapor concentration.
  - 1.4. When the vapor concentration exceeds 25 percent of the LFL, both of the following shall occur:
    - a. An alarm shall sound.
    - b. Spray operations shall automatically shut down.
  - 1.5. In the event of shutdown of the vapor concentration monitor, 100 percent of the air

volume specified in Section 510 of the *International Mechanical Code* is automatically exhausted.

2. Air exhausted from spraying operations is allowed to be recirculated as makeup air to manned spraying operations where all of the conditions provided in Exception 1 are included in the installation and documents have been prepared to show that the installation does not pose a life safety hazard to personnel inside the spray booth, spraying space or spray room.

❖ The prohibition of recirculation in this section and in IMC Section 502.7.3.2 is specifically directed to the concern that exhaust system makeup air does not add to the fire hazard of the spraying space. The exceptions are fairly specific and focus on the LFL and the monitoring of that limit. The exceptions are based on the environmental community’s concerns about the volume of emissions generated by spray finishing. The permissible exposure limit (PEL) is generally more restrictive than the LFL.

The recirculation of exhausted air containing flammable vapors could help spread the hazard of flash fires from the area of vapor generation to other parts of the building. At best, it would adversely affect only the area of vapor generation in that it could render the exhaust ventilation useless. It may also give the operators of the facility a false sense that the level of ventilation is safe for the system.

Exception 1 lists five conditions that must be met for the recirculation of exhausted air in unmanned spray operations. If solid particulates (dusts) are removed from the exhausted air, the exhausted air is no longer considered a fire hazard because the potential for a dust explosion is eliminated. Flammable vapors are defined in Section 202 as “flammable constituents in air that exceed 25 percent of the LFL.” By reducing the flammable vapor concentrations to less than 25 percent of the LFL, the exhausted air is no longer considered a flammable vapor. To increase the likelihood that the concentrations remain at less than 25 percent of the LFL, flammable vapor detection systems must automatically shut down the operations, set off an alarm and exhaust 100 percent of the air. This would allow for energy conservation in unmanned operations, without compromising the safety features typically associated with such ventilation systems. Exception 2 is applicable to manned operations where additional documentation is needed to reduce the risk to personnel, such as people operating the spray equipment, from an injury or life safety standpoint. This documentation may include a risk analysis of fire and health hazards associated with the operation of this equipment when some portion of the exhausted air is recirculated.

In general, fire safety efforts have received some assistance from the environmental regulations that have placed restrictions on the amount of volatile organic compounds (VOCs) emitted to the atmo-

sphere. This in turn limits the types of materials used and lowers the flammability characteristics through the use of less volatile liquids.

**2404.7.3 Air velocity.** The ventilation system shall be designed, installed and maintained so that the flammable contaminants are diluted in noncontaminated air to maintain concentrations in the exhaust airflow below 25 percent of the contaminant’s lower flammable limit (LFL). In addition, the spray booth shall be provided with mechanical ventilation so that the average air velocity through openings is in accordance with Sections 2404.7.3.1 and 2404.7.3.2.

❖ This section contains performance-based criteria to quantify the amount of exhaust in relation to the control of the contaminant source. In other words, a direct solution is to restrict the concentration of all known contaminants of concern to a specified and acceptable level. That “level” is below 25 percent of the LFL for a particular contaminant. Where the concentration of a flammable contaminant in air is maintained below 25 percent of the LFL for that contaminant, there is insufficient fuel vapor in the gas phase to sustain homogeneous ignition. Managing the contaminant(s) in a diluted state means there is less chance of catastrophic flame propagation, ignition or explosion. The quantity or volume of exhaust required is source specific.

**2404.7.3.1 Open-face or open-front spray booth.** For spray application operations conducted in an open-face or open-front spray booth, the ventilation system shall be designed, installed and maintained so that the average air velocity into the spray booth through all openings is not less than 100 feet per minute (0.51 m/s).

**Exception:** For fixed or automated electrostatic spray application equipment, the average air velocity into the spray booth through all openings shall be not less than 50 feet per minute (0.25 m/s).

❖ To help keep flammable vapors in a designated spraying space and limit the amount of overspray, the code requires that the exhaust system be adequately sized to maintain an average velocity over the open face of the booth or booth cross section of no less than 100 feet per minute (0.51 m/s), which is the minimum velocity to capture particulate spray material. To determine the minimum ventilation/exhaust capacity in cubic feet per minute [cfm (m<sup>3</sup>/s)], multiply the booth width [feet (mm)] by booth height [feet (mm)] by 100 [linear feet per minute (m/s)].

In electrostatic spray application, paint, in the form of either powdered particles or atomized liquid, is initially projected toward a conductive workpiece using normal spraying methods, and is then accelerated toward the workpiece by a powerful electrostatic charge. This process is much more efficient than ordinary spray finishing, using 95 percent of sprayed paint, thus reducing overspray. The exception recognizes this efficiency by allowing the air velocity across

openings to be one-half of that required for ordinary spraying. See the commentary to Section 2407 for further discussion of electrostatic apparatus.

**2404.7.3.2 Enclosed spray booth or spray room with openings for product conveyance.** For spray application operations conducted in an enclosed spray booth or spray room with openings for product conveyance, the ventilation system shall be designed, installed and maintained so that the average air velocity into the spray booth through openings is not less than 100 feet per minute (0.51 m/s).

**Exceptions:**

1. For fixed or automated electrostatic spray application equipment, the average air velocity into the spray booth through all openings shall be not less than 50 feet per minute (0.25 m/s).
2. Where methods are used to reduce cross drafts that can draw vapors and overspray through openings from the spray booth or spray room, the average air velocity into the spray booth or spray room shall be that necessary to capture and confine vapors and overspray to the spray booth or spray room.

❖ To help keep flammable vapors in a designated spraying space and limit the amount of overspray, the code requires that the exhaust system be adequately sized to maintain an average velocity through the openings in the booth of no less than 100 feet per minute (0.51 m/s), which is the minimum velocity to capture particulate spray material.

In electrostatic spray application, paint, in the form of either powdered particles or atomized liquid, is initially projected toward a conductive workpiece using normal spraying methods and is then accelerated toward the workpiece by a powerful electrostatic charge. This process is much more efficient than ordinary spray finishing, using 95 percent of sprayed paint, thus reducing overspray. Exception 1 recognizes this efficiency by allowing the air velocity across openings to be one-half of that required for ordinary spraying.

Competing airflows (cross drafts) in a space in which a spraying operation is located can cause a “reverse air flow” that can draw vapors or overspray out of the spray booth or spray room. Exception 2 provides a performance-oriented exhaust air velocity option where the effect of such cross drafts is reduced or eliminated.

**2404.7.4 Ventilation obstruction.** Articles being sprayed shall be positioned in a manner that does not obstruct collection of overspray.

❖ When ventilation systems for spray operations are designed and installed, the configuration and position of the object being sprayed must be considered because it might disrupt the ventilation pattern in both cross-draft and down-draft ventilation spray booths, thereby compromising the effectiveness of the ventilation system.

**2404.7.5 Independent ducts.** Each spray booth and spray room shall have an independent exhaust duct system discharging to the outside.

**Exceptions:**

1. Multiple spray booths having a combined frontal area of 18 square feet (1.67 m<sup>2</sup>) or less are allowed to have a common exhaust when identical spray finishing material is used in each booth. If more than one fan serves one booth, fans shall be interconnected such that all fans will operate simultaneously.
2. Where treatment of exhaust is necessary for air pollution control or for energy conservation, ducts shall be allowed to be manifolded if all of the following conditions are met:
  - 2.1. The sprayed materials used are compatible and will not react or cause ignition of the residue in the ducts.
  - 2.2. Nitrocellulose-based finishing material shall not be used.
  - 2.3. A filtering system shall be provided to reduce the amount of overspray carried into the duct manifold.
  - 2.4. Automatic sprinkler protection shall be provided at the junction of each booth exhaust with the manifold, in addition to the protection required by this chapter.

❖ This section requires independent duct exhaust of residue from spray-finishing operations. These ducts must be routed directly to the exterior of the building. Similar language is used in IMC Sections 502.7.3.5 and 510.4. Ducts may not penetrate fire-resistance-rated assemblies [see Commentary Figure 2404.7.5(1)].

Exception 1 applies to very small spray booths where the vapor area is very small compared to the area of standard spray booths. Because these individual smaller spray booths are considered as one fire area from a ventilation standpoint, all identical materials are to be used when this exception applies. This will ensure that incompatible materials are not used in booths with a common exhaust system [see Commentary Figure 2404.7.5(2)].

Exception 2 notes that because the exhausted air is at times treated, it can be manifolded. However, special hazards must be avoided to ensure fire protection safety. Incompatible materials must be separated in case of a reaction within the ducts. A similar requirement is found in IMC Section 510.4. Nitrocellulose and nitrocellulose-based products are unstable materials that can easily be ignited, and once ignited, need large quantities of water for suppression. Additionally, nitrocellulose is incompatible with many materials (alkalis, amines, etc.). The cleaning products used in other booths may even ignite the nitrocellulose-based products in a manifolded exhaust system. Therefore, the exhaust of nitrocellulose-based products is considered an exception to this section. See the commentary to Chapter 65 for further information on the hazards of cellulose nitrate (pyroxylin) plastics.

Additional protection, such as filtering and sprinklers at the junction of spray booth exhaust, is also required.

**2404.7.6 Termination point.** The termination point for exhaust ducts discharging to the atmosphere shall be not less than the following distances:

1. Ducts conveying explosive or flammable vapors, fumes or dusts: 30 feet (9144 mm) from the lot line; 10 feet

**Figure 2404.7.5(1)**  
**INDEPENDENT DUCTS FOR SPRAY BOOTHS**

## FLAMMABLE FINISHES

(3048 mm) from openings into the building; 6 feet (1829 mm) from exterior walls and roofs; 30 feet (9144 mm) from combustible walls or openings into the building that are in the direction of the exhaust discharge; 10 feet (3048 mm) above adjoining grade.

2. Other product-conveying outlets: 10 feet (3048 mm) from the lot line; 3 feet (914 mm) from exterior walls and roofs; 10 feet (3048 mm) from openings into the building; 10 feet (3048 mm) above adjoining grade.

❖ This section details the requirements for safe outlets/termination points of exhaust ducts conveying spray-finish operation effluent. This section gives distances that must be maintained, depending on the type of exhaust, and is consistent with the requirement in IMC Section 501.2.1.

Item 1 details the requirements of safe outlets/termination points for exhaust ducts that convey explosive or flammable vapors, fumes or dusts like those exhaust systems that serve operations involving the application of flammable finishes. This section is intended to reduce the exposure from the dangerous vapors in the exhaust. This is done to:

1. Protect other parts of the building.
2. Protect other buildings.
3. Reduce a potential reaction from materials that may be incompatible.
4. Reduce the severity of a fire, in case of an ignition.

Vapors that are considered flammable and flammable finishes, including dusts, have more restrictive outlet/termination requirements than other vapors due to the potential for ignition. To avoid recirculation of flammable vapors, fumes or dusts back into the building, the duct must be designed and located to reduce such exposures. This may be achieved by physically separating the exhaust outlet

from openings in the building, walls and roof, where sources of ignition or incompatible materials may be present [see Commentary Figures 2404.7.6(1) and 2404.7.6(2)].

For health and safety reasons, hazardous exhaust cannot be directed onto adjacent property. Maintaining the required distance allows the hazardous contents of the exhaust to disperse into the atmosphere, thereby minimizing the exposure of an adjoining property to the potential ignition hazard of a burning ember or spark or the hazardous, noxious and objectionable odors emitted from such systems. Wind and wind-induced eddy currents can react with building structural surfaces to create air pressure zones that can diminish exhaust flow or redirect exhaust into nearby building openings, such as fresh air or combustion air intakes and operable windows.

Exhaust systems sometimes incorporate rotating hoods over the discharge opening to prevent high winds from restricting the flow of exhaust gases out of the system. The hoods align themselves with the direction of the wind to allow the unimpeded and sometimes induced discharge from the exhaust outlet. The termination height specified for combustible walls is more restrictive to allow the concentration of explosive or flammable constituents in the exhaust to diminish before landing or accumulating on a combustible wall. The fire code official must consider prevailing wind conditions in locating hazardous exhaust outlets with respect to other building openings.

Item 2 details provisions regarding safe outlets/termination points of other product-conveying ducts, such as those exhausting nonflammable and nonexplosive dusts and waste products. This item requires that the exhaust outlet be located well into the undisturbed wind stream and away from the cavity

and wake (eddy) zones around the building. This counteracts the negative effects of wind-induced conditions and also prevents the reentry of exhaust products into the building through openings and fresh air intakes.

**2404.7.7 Fan motors and belts.** Electric motors driving exhaust fans shall not be placed inside booths or ducts. Fan rotating elements shall be nonferrous or nonsparking or the casing shall consist of, or be lined with, such material. Belts shall not enter the duct or booth unless the belt and pulley within the duct are tightly enclosed.

❖ This requirement in the ventilation section is intended to reduce sources of ignition from spark-producing

elements. This would increase the likelihood that overspray in the booth or duct cannot accumulate on the motor housing, which could ultimately cause the motor to overheat. Products that are subject to sparking should be avoided within spraying spaces. Belts that drive exhaust fans are not permitted in the spraying area unless the belts and pulleys are tightly enclosed to prevent solvents in exhaust air from degrading the belt materials and causing a failure of the ventilation system.

As mentioned in the commentary to Section 2403.4.1, the term “nonsparking” is somewhat inaccurate. Parts made of brass and similar “nonsparking” materials do produce sparks but with ignition

## FLAMMABLE FINISHES

energies too low to ignite flammable vapors. Nevertheless, such parts should be designed carefully to avoid producing sufficient frictional heat to cause an ignition.

**2404.7.8 Filters.** Air intake filters that are part of a wall or ceiling assembly shall be *listed* as Class I or II in accordance with UL 900. Exhaust filters shall be required.

❖ Spray-booth and ventilation system design should effectively enclose spray operations. To prevent exhausting contaminated vapors into the atmosphere and to prevent accumulation of overspray and residue on duct surfaces and at the duct discharge location, filters must be installed ahead of the exhaust ventilation systems from spraying spaces.

UL 900 requirements cover tests to determine combustibility and the amount of smoke generated for air filter units of both washable and throwaway types used for removal of dust and other air-borne particles from air circulated mechanically in equipment and systems. Because the combustibility and smoke generation of an air filter unit once used depends on the chemicals or materials it is impregnated with, the filter test requirements of UL 900 are for the clean condition only. See the commentary to IMC Section 605.2 for further discussion of UL 900 filters.

**2404.7.8.1 Supports.** Supports and holders for filters shall be constructed of noncombustible materials.

❖ This section is intended to minimize the combustible materials in a spray booth. The area near a filter that is used or partially used is very susceptible to ignition.

**2404.7.8.2 Attachment.** Overspray collection filters shall be readily removable and accessible for cleaning or replacement.

❖ Dry-type overspray collectors or filters of paper or fiberglass construction are more efficient than baffle plates. They are frequently used in spray booths containing moderate volumes of work. Replaceable flat or cartridge filters are intended to be discarded once they are significantly loaded with finish residue.

**2404.7.8.3 Maintaining air velocity.** Visible gauges, audible alarms or pressure-activated devices shall be installed to indicate or ensure that the required air velocity is maintained.

❖ Maintaining air velocities is critical in maintaining a safe environment outside the spraying space, as well as proper collection of flammable vapors and dusts within the spraying space. If air velocities that the exhaust system is designed for are not maintained, the spray booth operator must be made aware of this malfunction. To reduce the possibility of a fire or injury caused by human error, an automatic shut-down of the system is recommended when the designed air velocities are not maintained.

**2404.7.8.4 Filter rolls.** Spray booths equipped with a filter roll that is automatically advanced when the air velocity is reduced to less than 100 feet per minute (0.51 m/s) shall be

arranged to shut down the spraying operation if the filter roll fails to advance automatically.

❖ In the case of roll-type filters, fresh filter material is advanced into the air stream when the air velocity is reduced to less than 100 feet per minute (0.51 m/s). The impregnated filter is wound on a take-up reel. When the entire filter roll is consumed, it is discarded and replaced with a fresh roll of filter material. Shutting down the spray booth when the filter cannot automatically advance (either because of system failure or the need for cartridge replacement) ensures that the operator of the spray booth does not fail in his or her task of replacing the filter.

**2404.7.8.5 Filter disposal.** Discarded filter pads shall be immediately removed to a safe, detached location or placed in a noncombustible container with a tight-fitting lid and disposed of properly.

❖ To reduce the possibility of ignition, filters should be disposed of in approved metal containers with tight-fitting, self-closing lids. Waste containers should be removed from the building when full and at the end of each work shift. See also the commentary to Section 2403.4.3 for further discussion of waste disposal.

**2404.7.8.6 Spontaneous ignition.** Spray booths using dry filters shall not be used for spraying materials that are highly susceptible to spontaneous heating and ignition. Filters shall be changed prior to spraying materials that could react with other materials previously collected. An example of a potentially reactive combination includes lacquer when combined with varnishes, stains or primers.

❖ Ventilation system filters must be noncombustible. Once fouled with paint or coating residue, the filters become highly combustible. Moreover, they are more susceptible to spontaneous heating. Dry-type overspray collectors or filters of paper or fiberglass construction are more efficient than baffle plates and are frequently used in spray booths containing moderate volumes of work. Replaceable flat or cartridge filters are intended to be discarded once they are significantly loaded with finish residue. See also the commentary to Section 2404.5.1 for further discussion of spontaneous ignition.

**2404.7.8.7 Waterwash spray booths.** Waterwash spray booths shall be of an *approved* design so as to prevent excessive accumulation of deposits in ducts and residue at duct outlets. Such booths shall be arranged so that air and overspray are drawn through a continuously flowing water curtain before entering an exhaust duct to the building exterior.

❖ Waterwash booths are typically used for high-volume paint and lacquer usage. Many paints and lacquers are susceptible to spontaneous heating and combustion when left in a poorly ventilated or enclosed area. Materials containing linseed oil are especially prone to this type of reaction. Spray-finishing operations involving these materials should be confined to waterwash booths when possible because water is used as the filtration medium instead of dry filters.

**2404.8 Interlocks.** Interlocks for spray application finishes shall be in accordance with Sections 2404.8.1 through 2404.8.2.

- ❖ This section establishes the applicability of the requirements of Sections 2404.8.1 and 2404.8.2 for controlling hazards of spraying operations through the installation of system interlocks.

**2404.8.1 Automated spray application operations.** Where protecting automated spray application operations, automatic fire-extinguishing systems shall be equipped with an *approved* interlock feature that will, upon discharge of the system, automatically stop the spraying operations and workpiece conveyors into and out of the flammable vapor areas. Where the building is equipped with a fire alarm system, discharge of the automatic fire-extinguishing system shall also activate the building alarm notification appliances.

- ❖ An interlock is a practical solution to avoid a fire situation in which the automated system would allow for a “moving fire” as the pieces within the automated assembly move through the spraying space. The interlock would stop the spray application, which would further contribute to the flammable fuel/vapors, and prevent a moving fire from spreading faster and farther than expected. This is especially significant in larger conveyor and multiple spraying-space/spray-booth systems, where fire could spread quickly beyond the designed sprinkler area. The interlock between the suppression system and the alarm system would notify the occupants of a building to evacuate.

**2404.8.1.1 Alarm station.** A manual fire alarm and emergency system shutdown station shall be installed to serve each flammable vapor area. When activated, the station shall accomplish the functions indicated in Section 2404.8.1.

- ❖ In case the operator of a spraying area becomes aware of a fire prior to the actuation of the extinguishing system, or in case there is an emergency not related to a fire where there is a risk to the occupants of the building, a manual fire alarm station is needed. The manual station is to provide the same functions as the automated interlock in Section 2404.8.1, such as stopping the spread of fire and activating occupant notification. Because areas near the spraying space are dangerous, to reduce the risk of injury to an operator who may be attempting to activate the manual alarm, an additional alarm is required adjacent to an exit for the operator to activate while exiting from a hazardous situation.

**2404.8.1.2 Alarm station location.** Not less than one manual fire alarm and emergency system shutdown station shall be readily accessible to operating personnel. Where access to this station is likely to involve exposure to danger, an additional station shall be located adjacent to an *exit* from the area.

- ❖ Manual fire alarm and emergency system shutdown stations, in order to be effective, must be located

within easy reach of spray operation personnel who might be working in the area. The term “readily accessible” can be described as the capability of being quickly reached or approached for the purpose of operation. Ready access means that there are no physical obstructions and that there is no change in elevation to reach the required object or location.

When access to required manual fire alarm and emergency system shutdown stations could be compromised by a flash fire or equipment malfunction, an additional station must be installed near [within 5 feet (1524 mm)] an exit door from the area so that at least one station is available in the path of egress to transmit an alarm in a timely manner. This location also encourages the actuation of the manual fire alarm and emergency system on the fire floor prior to entering the stairway or exiting the building, resulting in the alarm being received from the actual fire floor and not another floor along the path of egress. The installation criteria contained in Section 907.4 for manual fire alarm boxes are applicable to such stations since part of their function is as a fire alarm pull station.

**2404.8.2 Ventilation interlock prohibited.** Air makeup and flammable vapor area exhaust systems shall not be interlocked with the fire alarm system and shall remain in operation during a fire alarm condition.

**Exception:** Where the type of fire-extinguishing system used requires such ventilation to be discontinued, air makeup and exhaust systems shall shut down and dampers shall close.

- ❖ Exhaust ventilation of flammable vapors and smoke during a fire may help reduce the fire severity and increase visibility. Therefore, an interlock system to shut down the spray operations during a fire should not include the safety systems, such as ventilation. In an emergency, the success of the fire-extinguishing system takes precedence over the function of the ventilation system. Therefore, if the ventilation system in any way compromises the fire-extinguishing system, the exception allows these systems to be interlocked to shut down in the event of a fire. Examples of systems that may be compromised if the ventilation system is on are many of the extinguishing systems that are not water based, such as carbon dioxide, halogenated agent, clean agent, etc.

**2404.9 Limited spraying spaces.** Limited spraying spaces shall comply with Sections 2404.9.1 through 2404.9.4.

- ❖ Limited spraying spaces are to accommodate uses that are limited in their frequency and amounts of hazardous materials used. As mentioned previously, this operation is intended more for small touch-up work found in a maintenance shop.

**2404.9.1 Job size.** The aggregate surface area to be sprayed shall not exceed 9 square feet (0.84 m<sup>2</sup>).

- ❖ Limiting the workpiece size limits the amount of flammable vapors that are produced in such an area. This

is again to accommodate small incidental-type spraying processes found in typical manufacturing or mercantile occupancies.

**2404.9.2 Frequency.** Spraying operations shall not be of a continuous nature.

❖ As mentioned previously, the limited spraying setup is to accommodate small incidental-type processes. If the processes are continuous, a spray booth, spray room or spraying space must be used whose requirements are more stringent and are better regulated from a fire prevention and fire protection standpoint.

**2404.9.3 Ventilation.** Positive mechanical ventilation providing a minimum of six complete air changes per hour shall be installed. Such system shall meet the requirements of this code for handling flammable vapor areas. Explosion venting is not required.

❖ Six air changes per hour is the requirement for limited spraying areas; however, if the quantity of hazardous material in the room or control area in which the limited spraying space is located exceeds the MAQ for hazardous materials given in Chapter 50 or 57, both exhaust ventilation requirements in those chapters for flammable vapors and the requirement in this section have to be met. A typical example would be a plating shop where allowable quantities of corrosives and toxics are exceeded (Group H-4) and where the exhaust ventilation at a rate of 1 cfm per square foot [0.00508 m<sup>3</sup>/(s • m<sup>2</sup>)] of floor area is required. If a limited spraying space is located in such a room, the most restrictive requirement has to be met; that is, the greater of 1 cfm per square foot [0.00508 m<sup>3</sup>/(s • m<sup>2</sup>)] or six air changes per hour. The vapor density of the material should be taken into account (whether vapors are heavier or lighter than air) when considering the location of exhaust inlets. Additionally, because IMC Section 502.7.2 is identical to this section, conformance to the general requirements of IMC Section 502, especially Section 502.1.1 (the inlet to an exhaust system shall be located in the area of heaviest concentration of contaminants), is recommended.

**2404.9.4 Electrical wiring.** Electrical wiring within 10 feet (3048 mm) of the floor and 20 feet (6096 mm) horizontally of the limited spraying space shall be designed for Class I, Division 2 locations in accordance with NFPA 70.

❖ Processes in limited spraying spaces may still result in some vapor generation. Because they are generally heavier than air, vapors in spray processes typically accumulate near the floor. These vapors may travel long distances undetected before causing a flash fire. To limit the ignition sources, wiring must be installed to meet Class I, Division 2 requirements within 10 feet (3048 mm) of the floor and 20 feet (6096 mm) horizontally.

## SECTION 2405 DIPPING OPERATIONS

**2405.1 General.** Dip-tank operations shall comply with the requirements of Section 2403 and Sections 2405.2 through 2405.11.

❖ This section establishes the applicability of the requirements of Sections 2403 and 2405 for controlling hazards associated with dip tanks and dipping operations.

**2405.2 Location of dip-tank operations.** Dip-tank operations conducted in buildings used for Group A, I or R occupancies shall be located in a room designed for that purpose, equipped with an *approved automatic sprinkler system* and separated vertically and horizontally from other areas in accordance with the *International Building Code*.

❖ Separation and protection from hazards of other portions of a building housing the occupancy groups listed in this section are critical for several reasons. Dipping and coating processes are too hazardous to be conducted in occupancies with a high life or property exposure. The number of occupants in such buildings and their physical conditions vary. People exposed to the danger of a fire involving dip-tank operations must be able to evacuate or protect themselves promptly and effectively to avoid the risk of serious injury or death. Also, the behavior psychology of people in a Group A, I or R occupancy is very different from those in a Group F manufacturing occupancy. A person walking in a manufacturing facility where dipping operations/processes take place in a large area where the dip tanks and signs are in plain view is more aware of the physical dangers associated with these processes than someone in a Group R occupancy, who would more likely be relaxing and thinking of things other than physical hazards.

The protection designed into these occupancies is, in many cases, less than would be found in manufacturing occupancies. Separation and protection in the form of fire-resistance-rated construction and automatic fire suppression must be provided where dipping operations must be conducted in the same building. Fire barriers, horizontal assemblies or both having a fire-resistance rating of 3 hours are required between Group F-1 and A, or I and R occupancies. Except for Group I-2, this requirement can be reduced in a sprinklered building by 1 hour. If the amounts of hazardous materials exceed the MAQ listed in Chapter 50, the occupancy separation between Group H and A, or I and R occupancies varies depending on what material(s) is involved (see IBC Section 508).

**2405.3 Construction of dip tanks.** Dip tanks shall be constructed in accordance with Sections 2405.3.1 through 2405.3.4.3 and NFPA 34. Dip tanks, including drain boards, shall be constructed of noncombustible material and their

supports shall be of heavy metal, reinforced concrete or masonry.

- ❖ The selection of materials and design of dipping and coating processes must consider the physical properties of the liquid and the processing environment. The corrosivity, density, viscosity, vapor pressure and flash point of the liquid influences the selection of materials and arrangement of processing equipment. Additionally, mechanical hazards, such as impacts and collisions involving conveyor equipment, should be considered. Protected steel or concrete tank supports reduce the likelihood of a collapse in the event of a fire caused by a spill or release. The figure accompanying the definition of “Dip tank” in Chapter 2 shows the arrangement of a typical dip tank, including overflow and emergency release drains.

**2405.3.1 Overflow.** Dip tanks greater than 150 gallons (568 L) in capacity or 10 square feet (0.93 m<sup>2</sup>) in liquid surface area shall be equipped with a trapped overflow pipe leading to an *approved* location outside the building. The bottom of the overflow connection shall be not less than 6 inches (152 mm) below the top of the tank.

- ❖ An overflow drain is required for tanks with capacities greater than 150 gallons (568 L) or having a surface area greater than 10 square feet (0.93 m<sup>2</sup>) to confine spills or uncontrolled releases caused by overflowing or overflowing when parts are immersed. The capacity of overflow drains should exceed the capacity of the tank and discharge through an approved trap and separator or to an approved salvage tank.

**2405.3.2 Bottom drains.** Dip tanks greater than 500 gallons (1893 L) in liquid capacity shall be equipped with bottom drains that are arranged to automatically and manually drain the tank quickly in the event of a fire unless the viscosity of the liquid at normal atmospheric temperature makes this impractical. Manual operation shall be from a safe, accessible location. Where gravity flow is not practicable, automatic pumps shall be provided. Such drains shall be trapped and discharged to a closed, vented salvage tank or to an *approved* outside location.

**Exception:** Dip tanks containing Class IIIB *combustible liquids* where the liquids are not heated above room temperature and the process area is protected by automatic sprinklers.

- ❖ Emergency release drains permit flammable liquids in dip tanks to be safely discharged if a fire occurs. A trap between the drain opening and the separator or salvage tank reduces the likelihood that the fire will flash back into the tank. The arrangement of emergency release drains must permit both automatic and manual operation. Moreover, viscous liquids are exempt from these requirements. These liquids, however, generally have higher flash points and are more difficult to ignite than other, less viscous materials. If a highly viscous combustible liquid is heated for use as a coating material, having a drain remains a good practice. If installed, the drain should be sized for the volume and viscosity of the liquid under normal usage

conditions. When practical, tanks should be arranged to drain by gravity. Pumps must be used if gravity discharge is not practical. When a tank is equipped with a pump, the pump should be installed on the discharge side of the trap. When a pump is installed to aid in emergency release, flammable and combustible liquid piping must comply with Chapter 57. The exception covers Class IIIB combustible liquids, which have a flashpoint above 200°F (93°C). These liquids are not viewed by the code as extremely hazardous, especially when they are not heated above room temperature. For example, Table 5003.1.1(1), Note f allows for unlimited quantities of Class IIIB liquids in storage and use in a sprinklered building.

**2405.3.3 Dipping liquid temperature control.** Protection against the accumulation of vapors, self-ignition and excessively high temperatures shall be provided for dipping liquids that are heated directly or heated by the surfaces of the object being dipped.

- ❖ The evaporation rate of a liquid increases as the liquid temperature increases. By controlling the maximum liquid temperature, in case of a malfunction or unplanned event, the temperature of the liquid will not increase to a point where the exhaust ventilation cannot accommodate the exhaust of the vapors. Moreover, controlling the maximum liquid temperature would prevent the liquid from reaching its self-ignition (or auto-ignition) temperature. The temperature control for the liquid must be specifically designed for the liquid. Self-ignition temperatures of liquids can be found in many references. The *SFPE* (Society of Fire Protection Engineers) *Handbook of Fire Protection Engineering* includes tables listing auto-ignition temperatures for a variety of products. Although it is a more general application, similar temperature control requirements apply when exempt use and storage amounts of heated hazardous materials are exceeded (see Section 5004.8.1).

**2405.3.4 Dip-tank covers.** Dip-tank covers allowed by Section 2405.4.1 shall be capable of manual operation and shall be automatic closing by *approved* automatic-closing devices designed to operate in the event of a fire.

- ❖ Dip-tank covers installed as a method of automatic suppression conforming to Section 2405.4.1 must be capable of manual actuation. Automatic closure must be initiated by a fusible link or another approved heat-sensitive device. Covers that cannot close under the force of gravity must be assisted by hydraulic activators, springs, counterweights or other methods.

**2405.3.4.1 Construction.** Covers shall be constructed of noncombustible material or be of a tin-clad type with enclosing metal applied with locked joints.

- ❖ Dip-tank covers must be constructed of noncombustible material to avoid adding to the fire load, as well as to maintain the integrity of the system as a passive containment fire protection system. Tin-clad covers should be designed the same as metal-clad or tin-clad fire doors (see NFPA 80). Materials used for

## FLAMMABLE FINISHES

automatic-closing mechanisms, such as hydraulic actuators, springs, etc., should also be constructed of noncombustible materials.

**2405.3.4.2 Supports.** Chain or wire rope shall be utilized for cover supports or operating mechanisms.

❖ Devices for holding the cover open must be designed to permit it to close freely and seal tightly. If noncombustible materials are used, a fusible link or another heat-sensitive device must be used to initiate closure.

**2405.3.4.3 Closed covers.** Covers shall be kept closed when tanks are not in use.

❖ Keeping the cover closed when the tank is not in use reduces the release of flammable vapors or the accidental introduction of an ignition source into the vapor area located below the rim of the dip tank.

**2405.4 Fire protection.** Dip-tank operations shall be protected in accordance with Sections 2405.4.1 through 2405.4.2.

❖ This section establishes the applicability of the requirements of Section 2405.4 for controlling and extinguishing fires in dipping operations.

**2405.4.1 Fixed fire-extinguishing equipment.** An approved automatic fire-extinguishing system or dip-tank cover in accordance with Section 2405.3.4 shall be provided for the following dip tanks:

1. Dip tanks less than 150 gallons (568 L) in capacity or 10 square feet (0.93 m<sup>2</sup>) in liquid surface area.
2. Dip tanks containing a liquid with a *flash point* below 110°F (43°C) used in such manner that the liquid temperature could equal or be greater than its *flash point* from artificial or natural causes, and having both a capacity of more than 10 gallons (37.9 L) and a liquid surface area of more than 4 square feet (0.37 m<sup>2</sup>).

❖ This section applies to fire-extinguishing equipment for certain smaller sizes of dip tanks. It offers the option of dip-tank covers instead of a fixed fire-extinguishing system. Tanks equipped with noncombustible automatic-closing covers conforming to Section 2405.3.4 need not be protected by a fire suppression system on the basis that the cover can be closed, thus containing a dip tank fire and further restricting oxygen supply to the fire. Additionally, the suppression system will not be effective in controlling a fire when the cover is in the sloped position because the sprinkler water would simply run off the cover and away from the fire. Automatic sprinkler protection is recommended for plant areas located around dip tanks and other similar equipment. However, the primary protection for the dip tank should be one of the following types of systems listed in order of desirability and effectiveness:

1. Water-spray fixed system (NFPA 15 or 16).
2. Foam-extinguishing system (NFPA 11, 11A or 16).
3. Carbon dioxide system (NFPA 12).

4. Halogenated system (NFPA 12A).

5. Dry-chemical system (NFPA 17).

Water-spray fixed systems are more effective at controlling flammable liquid pool fires, such as those involving dip tanks, because they produce finer water droplets that are more effective at absorbing heat from these rapidly burning, intense fires. Most water droplets are quickly vaporized by the fire and rarely pose a significant danger of boil-over, froth-over or slop-over from penetrating the surface of the flammable or combustible liquid (see NFPA 30 for further information on these phenomena unique to flammable and combustible liquids in tanks). Unless dip-tank covers are installed, fixed fire-extinguishing equipment is required for dip tanks less than 150 gallons (568 L) or 10 square feet (0.93 m<sup>2</sup>). Unless dip-tank covers are installed, dip tanks containing Class I flammable liquids and Class II combustible liquids with flash points below 110°F (43°C) used at ambient temperatures above their flash points; and having capacities greater than 10 gallons (38 L) and exposed surface areas greater than 4 square feet (0.37 m<sup>2</sup>) must be protected in accordance with Section 2405.4.1.1 because of their ease of ignition.

**2405.4.1.1 Fire-extinguishing system.** An approved automatic fire-extinguishing system shall be provided for dip tanks with a 150-gallon (568 L) or more capacity or 10 square feet (0.93 m<sup>2</sup>) or larger in a liquid surface area. Fire-extinguishing system design shall be in accordance with NFPA 34.

❖ Automatic fire suppression must be installed at dip tanks with a capacity greater than 150 gallons (568 L) or larger than 10 square feet (0.93 m<sup>2</sup>) in surface area. See the commentary to Section 2405.4.1 for the preferred type of extinguishing system.

**2405.4.2 Portable fire extinguishers.** Areas in the vicinity of dip tanks shall be provided with portable fire extinguishers complying with Section 906 and suitable for flammable and combustible liquid fires as specified for extra (high) hazard occupancies.

❖ Readily accessible portable fire extinguishers for incipient fire fighting must be installed for use by employees working around dipping and coating processing equipment. Both the size and distribution of portable fire extinguishers must conform to this section, Section 906.1 and the applicable sections of NFPA 10 for extra (high) hazards. Two units of Class B extinguishing capabilities are required for each square foot (m<sup>2</sup>) of dip-tank area if either dry-chemical or carbon dioxide portable extinguishers are installed. Only one unit of Class B rating is required per square foot (m<sup>2</sup>) if aqueous film-forming foam (AFFF) portable extinguishers are provided. For example, a 40-square-foot (4 m<sup>2</sup>) dip tank would require an 80-B-rated dry-chemical or carbon dioxide extinguisher, or a 40-B AFFF extinguisher. The maximum travel distance to the nearest required portable fire extinguisher is 30 feet (9144 mm). Employees who are expected to fight incipient fires should

receive instructions in the operation of installed fire protection equipment. Fire protection systems, equipment and devices must be maintained in accordance with Section 901.6.

**2405.5 Housekeeping, maintenance and storage of hazardous materials.** Housekeeping, maintenance, storage and use of hazardous materials shall be in accordance with Sections 2403.3 and 2403.4.

❖ This section establishes the applicability of the requirements of Sections 2403.3 and 2403.4 for controlling hazards associated with housekeeping, maintenance and the storage of hazardous materials.

**2405.6 Sources of ignition.** Control of sources of ignition shall be in accordance with Section 2403.2.

❖ See the commentary to Section 2403.2.

**2405.7 Ventilation of flammable vapor areas.** Flammable vapor areas shall be provided with mechanical ventilation adequate to prevent the dangerous accumulation of vapors. Required ventilation systems shall be arranged such that the failure of any ventilating fan shall automatically stop the dipping conveyor system.

❖ This section includes performance-based language that requires ventilation to prevent the dangerous accumulation of vapors. Additionally, conveyor systems used with dipping operations need to be interlocked with the ventilation system to avoid continuation of operations in the event of a ventilation system failure. The IMC contains requirements for hazardous exhaust systems and requires independent duct exhaust of vapor releases from dipping and coating processing tanks, reservoirs, trench drains, drain boards, conveyor tunnels and any other space where flammable vapors may be liberated. Ducts are not to penetrate fire-resistance-rated assemblies. The plenum and ductwork must be protected by automatic sprinklers or other approved fire suppression systems installed in accordance with Chapter 9. Only fans and mechanical equipment approved for use in Class I, Division 1 hazardous locations are to be installed in the exhaust air stream, and ductwork must be of materials, thicknesses and construction methods specified in the IMC.

**2405.8 Conveyor interlock.** Dip tanks utilizing a conveyor system shall be arranged such that in the event of a fire, the conveyor system shall automatically cease motion and the required tank bottom drains shall open.

❖ Mechanical or electrical interlocks must interrupt conveyor motion and cause required emergency release drains to open in the event of a fire. Stopping the conveyor prevents newly coated parts from transporting a fire beyond the immediate vicinity of the dipping or coating processing area and its protection systems.

**2405.9 Hardening and tempering tanks.** Hardening and tempering tanks shall comply with Sections 2405.3 through 2405.3.3, 2405.4.2 and 2405.8, but shall be exempt from other provisions of Section 2405.

❖ Requirements of Sections 2405.9.1 through 2405.9.5 apply to oil-quenching tanks used in hardening and tempering processes. Individually, hardening and tempering are usually accomplished by immersing parts in tanks containing certain metal salts heated to temperatures between 1,400°F and 2,350°F (760°C and 1287°C). This process often requires several steps, with parts cooled by oil quenching between steps. Such oil-quenching baths are the subject of these requirements. Animal, vegetable and mineral oils, and various mixtures of each, are used for oil quenching, but mineral oils are most commonly used. Recently, polymers have replaced oils on a small scale in some oil-quenching processes. For most oil-quenching processes, oils have flash points above 300°F (149°C) (Class III-B) and many have flash points exceeding 500°F (260°C). Oil-quenching baths are usually maintained 100°F to 200°F (38°C to 93°C) below their flash points. The same design, construction, operation, maintenance and fire protection requirements applying to dip tanks pertain to hardening and tempering tanks, as do the requirements of Sections 2405.9.1 through 2405.9.5.

**2405.9.1 Location.** Tanks shall be located as far as practical from furnaces and shall not be located on or near combustible floors.

❖ High temperatures produced by hardening and tempering processes require the maintenance of separation between tanks, ignition sources and combustible materials (see Commentary Figure 2405.9.1).

**2405.9.2 Hoods.** Tanks shall be provided with a noncombustible hood and vent or other *approved* venting means, terminating outside of the structure to serve as a vent in case of a fire. Such vent ducts shall be treated as flues and proper clearances shall be maintained from combustible materials.

❖ Though the materials in hardening and tempering baths are usually not considered flammable, the elevated temperatures may represent an ignition source to other combustibles. The contents of oil-quenching tanks used for high flash-point liquids may be difficult to ignite, but once ignited, the rate of heat release is comparable to other flammable and combustible liquids. Hoods over hardening, tempering and oil-quenching tanks will help maintain tenable conditions near the tanks and help control a fire, should it occur, by providing a controlled avenue of vertical spread. Therefore, exhaust hood materials must be noncombustible and separated from combustible structural components.

**FLAMMABLE FINISHES**

**2405.9.3 Alarms.** Tanks shall be equipped with a high-temperature limit switch arranged to sound an alarm when the temperature of the quenching medium reaches 50°F (10°C) below the *flash point*.

- ❖ Thermostats may be used to limit the heat input to the oil bath for temperature maintenance. However, many systems require cooling systems to maintain oil baths within specified temperature limitations. Water leaking from these cooling systems can pose a special hazard from boil-over as the water is converted to steam (see Commentary Figure 2405.9.3).

**2405.9.4 Fire protection.** Hardening and tempering tanks greater than 500 gallons (1893 L) in capacity or 25 square feet (2.3 m<sup>2</sup>) in liquid surface area shall be protected by an *approved* automatic fire-extinguishing system complying with Chapter 9.

- ❖ Tanks larger than 500 gallons (1893 L) in capacity or 25 square feet (2.3 m<sup>2</sup>) in surface area present a sig-

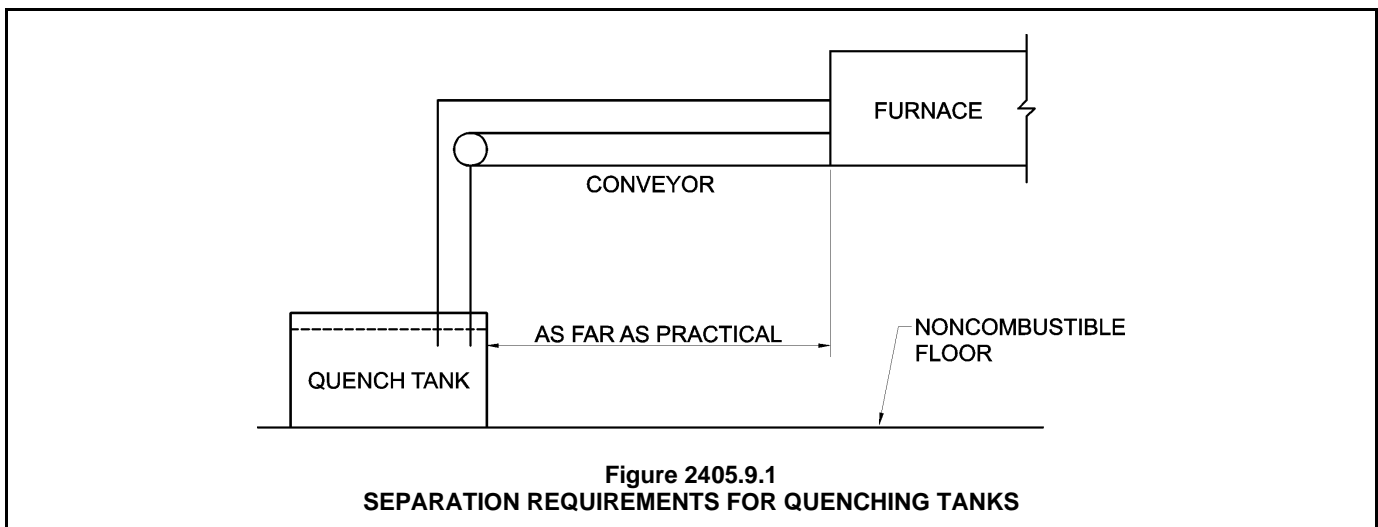

nificant enough hazard as to be required to be protected by an automatic fire-suppression system.

**2405.9.5 Use of air pressure.** Air under pressure shall not be used to fill or agitate oil in tanks.

- ❖ Heated oil can cause air injected below the oil surface to expand, allowing oil to spill from the tank. Air containing moisture can contaminate the oil bath, leading to boil-over.

**2405.10 Flow-coating operations.** Flow-coating operations shall comply with the requirements for dip tanks. The area of the sump and any areas on which paint flows shall be considered to be the area of a dip tank.

- ❖ In flow-coat operations, a liquid coating is applied to the workpiece in a nonatomized stream through fixed or oscillating nozzles. Excess liquid is collected in a trough or sump below the workpiece and recirculated through a reservoir. The principal hazard from flow

coating is the liberation of flammable liquid vapor from the surface of excess liquid. The area of the trough or sump for collecting overspray defines the scope of the hazard. Protection of flow-coat operations must be based on the combined area of the trough or sump and any surfaces in which paint or coating material flows en route to the trough or sump (see Commentary Figure 2405.10). In large operations, drain tunnels extend outside the enclosure. Moving the object through the drain tunnels reduces solvent evaporation. Using the tunnels also improves the film coating on the object. Curtain coating operates on a similar principle, except a trough is filled above the workpiece and allowed to overflow in a thin flat stream. This process is often used to coat flat or slightly curved workpieces.

**2405.10.1 Paint supply.** Paint shall be supplied by a gravity tank not exceeding 10 gallons (38 L) in capacity or by direct low-pressure pumps arranged to shut down automatically in case of a fire by means of *approved* heat-actuated devices.

- ❖ Positive displacement pumps are most commonly used to recirculate paint and coating material from the reservoir to the nozzles. Gravity tanks not exceeding 10 gallons (38 L) in capacity are also permitted. When a pump is used, the pump power supply must be interlocked with heat detectors to shut down if a fire occurs.

**2405.11 Roll-coating operations.** Roll-coating operations shall comply with Section 2405.10. In roll-coating operations utilizing flammable or *combustible liquids*, sparks from static electricity shall be prevented by electrically bonding and grounding all metallic rotating and other parts of machinery and equipment and by the installation of static collectors, or by maintaining a conductive atmosphere such as a high relative humidity.

- ❖ Roll-coating methods apply material to flat work pieces, usually paper, cardboard, cloth or thin metals, using liq-

uid-coated cylinders or rollers. Coating material may be applied to the rollers by rotating them in an open trough or pan or applying liquid to the space between two rollers (see Commentary Figure 2405.11).

**SECTION 2406  
POWDER COATING**

**2406.1 General.** Operations using finely ground particles of protective finishing material applied in dry powder form by a fluidized bed, an electrostatic fluidized bed, powder spray guns or electrostatic powder spray guns shall comply with Sections 2406.2 through 2406.7. In addition, Section 2407 shall apply to fixed electrostatic equipment used in powder coating operations.

- ❖ This section applies to powder-coating operations, which involve the application of finely ground particles of protective finishing material. The finish from powder coating is very strong and more durable than conventional finishes. This is a benefit, from an environmental and fire protection standpoint, because there are no liquid finishes or solvents to produce flammable vapors or VOCs. Additionally, less solid waste is created with this method of finishing. The foremost hazard associated with such application(s) is fire or explosion as a result of the airborne dust. The hazard associated with powder-coating operations is considered less than that of a similar operation using flammable or combustible liquids. The energy required to ignite a cloud of air-suspended coating powder is from 100 to 1,000 times higher than that required to ignite flammable vapors associated with fluid-coating processes. Nevertheless, these operations pose a significant explosion hazard when organic powder is suspended in air, forming dust clouds.

**2406.2 Location.** Powder coating operations shall be conducted in enclosed powder coating rooms, enclosed powder

**Figure 2405.10  
TYPICAL FLOW-COAT SETUP**

## FLAMMABLE FINISHES

coating facilities that are ventilated or ventilated spray booths.

- ❖ This section simply states that powder coating must be conducted within enclosed rooms, spaces or apparatus that are designed for the purpose and constructed in accordance with the applicable provisions of Sections 2406.3 through 2406.7.

**2406.3 Construction of powder coating rooms and booths.** Powder coating rooms shall be constructed of noncombustible materials. Spray booths shall be constructed in accordance with Section 2404.3.2.

**Exception:** *Listed* spray-booth assemblies that are constructed of other materials shall be allowed.

- ❖ The majority of powder-coating operations are conducted in rooms or spray booths designed specifically to accommodate the air-borne dust. Listed spray-booth assemblies should be specifically listed for powder-coating operations to ensure that the differences in medium between flammable spray finish and powder coating are addressed in the protection systems. An example of such differences is the type of electrical classification between powder-coating operations and flammable-finish operations.

The exception allows powder-coating operations to be conducted in spray booths constructed of any

material, provided that the spray booths are listed (see the commentary to Section 202 for the definition of "Listed").

**2406.4 Fire protection.** Areas used for powder coating shall be protected by an *approved* automatic fire-extinguishing system complying with Chapter 9.

- ❖ Although automatic sprinkler protection is the most common method of protection in facilities, other approved automatic fire suppression systems may be installed where approved by the fire code official. Fire protection systems, equipment and devices must be installed in accordance with Chapter 9 and maintained.

**2406.4.1 Additional protection for fixed systems.** Automated powder application equipment shall be protected by the installation of an *approved*, supervised flame detection apparatus that shall react to the presence of flame within 0.5 second and shall accomplish all of the following:

1. Shutting down of energy supplies (electrical and compressed air) to conveyor, ventilation, application, transfer and powder collection equipment.
2. Closing of segregation dampers in associated ductwork to interrupt airflow from application equipment to powder collectors.

**Figure 2405.11**  
**TYPICAL ROLL-COATING SETUP**

3. Activation of an alarm that is audible throughout the powder coating room or booth.

- ❖ Automated powder application may or may not have operators who would take steps to reduce the severity of the fire by shutting down the supply of powder, turning off energy supplies, warning occupants for evacuation, etc. The flame detection system and its associated interlocks are part of the protection system, in case ignition has already occurred. To reduce the severity of a fire or dust cloud explosion, the powder-coating application must be shut down immediately upon fire detection. Because automated powder application equipment may at times be unsupervised, flame detection that automatically can shut down the system is required. Shutting down systems such as conveyors, which can further spread the fire, or an application that further augments the existing fuel load/air-borne dust is critical to reducing the severity of a fire. Further, an audible alarm throughout the powder-coating room or area must notify the occupants to evacuate immediately to avoid injury. For example, injury to occupants of the booth may be avoided or reduced if they evacuate when a small incipient fire is detected before it reaches areas within the booth where dust-cloud explosions are sustainable.

**2406.4.2 Fire extinguishers.** Portable fire extinguishers complying with Section 906 shall be provided for areas used for powder coating in accordance with the requirements for an extra-hazard occupancy.

- ❖ Section 906 gives the requirements for portable fire extinguishers. Areas may be classified as an extra-hazard occupancy in accordance with NFPA 10 because of the higher hazard of powder-coating operations.

**2406.5 Operation and maintenance.** Powder coating areas shall be kept free from the accumulation of powder coating dusts, including horizontal surfaces such as ledges, beams, pipes, hoods, booths and floors.

- ❖ Regularly scheduled cleaning of accumulation of powder on surfaces is an important and often ignored good housekeeping practice. This is especially critical when pieces are bonded to the conveyor. If too much residue is accumulated on the conveyor, the pieces may no longer be bonded. When pieces are preheated, the additional dust accumulation may contribute to air-borne dust and escalate a small fire to a much larger and more severe fire.

**2406.5.1 Cleaning.** Surfaces shall be cleaned in such a manner so as to avoid scattering dusts to other places or creating dust clouds. Vacuum sweeping equipment shall be of a type *approved* for use in hazardous locations.

- ❖ Additional air-borne dust must be avoided during cleaning operations. Any type of dust-agitating process can create a potential for flash fires or dust explosions. Removal of dusts from any horizontal surfaces, such as ledges, beams, pipes, hoods, booths and floors, is important in reducing the excess

dust concentrations within powder-coating areas.

Cleaning should minimize the scattering of dust or creation of a dust cloud that can easily cause a fire or explosion. Vacuum sweeping equipment must be approved for the type of use and be electrically classified in accordance with NFPA 70 (see commentary, Section 2403.2.1).

**2406.6 Sources of ignition.** Control of sources of ignition shall be in accordance with Section 2403.2 and Sections 2406.6.1 through 2406.6.4.

- ❖ This section establishes the applicability of the listed sections to the control of ignition sources in powder-coating operations.

**2406.6.1 Drying, curing and fusion equipment.** Drying, curing and fusion equipment shall comply with Chapter 30.

- ❖ Chapter 30 details the construction, operation, maintenance and fire protection of, as well as the equipment and piping associated with, industrial ovens (see commentary, Chapter 30).

**2406.6.2 Spark-producing metals.** Iron or spark-producing metals shall be prevented from being introduced into the powders being applied by magnetic separators, filter-type separators or by other *approved* means.

- ❖ Iron or spark-producing metals, such as small workpieces or tools, have caused ignitions or explosions of the air-borne combustible dusts in powder-coating operations. Although magnetic or filter-type separators are the simplest and most commonly used systems for reducing such a hazard, other approved means of removing metals are acceptable.

**2406.6.3 Preheated parts.** When parts are heated prior to coating, the temperature of the parts shall not exceed the ignition temperature of the powder to be used.

- ❖ During the heating process and prior to coating, safety controls must be implemented to prevent the ignition of the powder on an overheated piece as a result of a system malfunction (temperature control failures, when a piece is overheated on a conveyor that has stopped, etc.).

**2406.6.4 Grounding and bonding.** Precautions shall be taken to minimize the possibility of ignition by static electrical sparks through static bonding and grounding, where possible, of powder transport, application and recovery equipment.

- ❖ See the commentary to Section 2403.2.5.

**2406.7 Ventilation.** Exhaust ventilation shall be sufficient to maintain the atmosphere below one-half the minimum *explosive* concentration for the material being applied. Nondeposited, air-suspended powders shall be removed through exhaust ducts to the powder recovery system.

- ❖ Powder coating creates explosive atmospheres because of the large surface areas of the particles when dispersed in the air. The explosive limit or concentration, just as with flammable vapors, will depend on the type of material being used. For example, Factory Mutual tested several powder-coating materials and

found a range of lower explosive limit (LEL) of 0.026 to 0.097 ounces per square foot and auto-ignition temperatures between 790°F to 1,039°F (412°C to 559°C). Therefore, ventilation system requirements may vary from one type of coating to another. Also, a collection system is required to collect any unused powder. This requirement is similar to ventilation requirements for flammable vapors in its intent to limit the amount of vapors or dusts to a concentration that would not support ignition. Therefore “one-half the minimum explosive concentration” for powder coating is similar in intent to the “25 percent of the lower flammable limit (LFL).” The safety factor in the combustible dust is 2, while the safety factor for the LFL is 4. This is partly the result of the lower ignitability of a dust compared to a vapor (see commentary, Section 2407.1).

## SECTION 2407 ELECTROSTATIC APPARATUS

**2407.1 General.** Electrostatic apparatus and devices used in connection with paint-spraying and paint-deteating operations shall be of an *approved* type.

- ❖ Electrostatic spraying and paint deteating equipment, as well as electrostatic devices, such as generators, motors, transformers and electrodes, must be acceptable to the fire code official and should bear the label of an independent testing laboratory. Evidence of satisfactory performance is indicated by use or display of the appropriate label or seal of the laboratory. Testing laboratories generally publish directories or lists containing important information about labeled products.

**2407.2 Location and clear space.** A space of not less than twice the sparking distance shall be maintained between goods being painted or deteated and electrodes, electrostatic atomizing heads or conductors. A sign stating the sparking distance shall be conspicuously posted near the assembly.

**Exception:** Portable electrostatic paint-spraying apparatus *listed* for use in Class I, Division I, locations.

- ❖ The equipment manufacturer’s instructions must be consulted to determine the sparking distance of the equipment involved. Once the sparking distance is determined, it must be posted conspicuously in the work area. The sign must be clear, concise and of durable construction.

Maintaining the required separation distance prevents sparks generated by the properly maintained equipment from igniting vapors near the surface of the newly coated workpiece before it dries.

The exception recognizes that portable electrostatic spray guns have been listed by recognized testing laboratories for many years and are in use in commercial/industrial applications throughout the United States. These units are listed for use in Class I, Division I, Group D environments and they do not create an ignition source from potential sparking. Such units are designed to preclude sparking when

the spray gun is moved directly against the object being sprayed. The requirements to install barriers, provide signs or require general isolation of equipment do not improve the safety of this category of equipment and hamper its use by industry.

**2407.3 Construction of equipment.** Electrodes and electrostatic atomizing heads shall be of *approved* construction, rigidly supported in permanent locations and effectively insulated from ground. Insulators shall be nonporous and noncombustible.

**Exception:** Portable electrostatic paint-spraying apparatus *listed* for use in Class I, Division I, locations.

- ❖ Electrostatic atomizing heads are connected to both an air source and flammable coating products. Additionally, this particular piece of equipment is connected to high-voltage electricity. Oxygen, fuel and sources of ignition are readily available. Therefore, special care and consideration must be given in the construction and installation of such equipment. To avoid any sparking of the equipment, electrostatic atomizing heads must be insulated from grounded objects or parts.

The exception recognizes that portable electrostatic spray guns have been listed by recognized testing laboratories for many years and are in use in commercial/industrial applications throughout the United States. These units are listed for use in Class I, Division I, Group D environments and they do not create an ignition source from potential sparking. Such units are designed to preclude sparking when the spray gun is moved directly against the object being sprayed. The requirements to install barriers, provide signs or require general isolation of equipment do not improve the safety of this category of equipment and hamper its use by industry.

**2407.3.1 Barriers.** Booths, fencing, railings or guards shall be placed about the equipment such that either by their location or character, or both, isolation of the process is maintained from plant storage and personnel. Railings, fencing and guards shall be of conductive material, adequately grounded, and not less than 5 feet (1524 mm) from processing equipment.

**Exception:** Portable electrostatic paint-spraying apparatus *listed* for use in Class I, Division I, locations.

- ❖ The required guards prevent materials with an opposite charge from being placed within the range of the electrostatic spraying apparatus. Guards or railings are grounded so that any charge accumulation or deficit on people or materials will be safely neutralized. The separation distance requirement allows the charge dissipation to occur at a safe distance from ignitable vapors.

The exception recognizes that portable, electrostatic spray guns have been listed by recognized testing laboratories for many years and are in use in commercial/industrial applications throughout the United States. These units are listed for use in Class I, Division I, Group D environments and they do not

create an ignition source from potential sparking. Such units are designed to preclude sparking when the spray gun is moved directly against the object being sprayed. The requirements to install barriers, provide signs or require general isolation of equipment do not improve the safety of this category of equipment and hamper its use by industry.

**2407.4 Fire protection.** Areas used for electrostatic spray finishing with fixed equipment shall be protected with an *approved* automatic fire-extinguishing system complying with Chapter 9 and Section 2407.4.1.

❖ Although automatic sprinkler protection is the most common method of protection in facilities, other approved automatic fire suppression systems may be installed if approved by the fire code official. Fire protection systems, equipment and devices must be installed in accordance with Chapter 9 and maintained.

**2407.4.1 Protection for automated liquid electrostatic spray application equipment.** Automated liquid electrostatic spray application equipment shall be protected by the installation of an *approved*, supervised flame detection apparatus that shall, in the event of ignition, react to the presence of flame within 0.5 second and shall accomplish all of the following:

1. Activation of a local alarm in the vicinity of the spraying operation and activation of the building alarm system, if such a system is provided.
2. Shutting down of the coating material delivery system.
3. Termination of all spray application operations.
4. Stopping of conveyors into and out of the flammable vapor areas.
5. Disconnection of power to the high-voltage elements in the flammable vapor areas and disconnection of power to the system.

❖ Automated liquid electrostatic spray application may or may not have operators who would take steps to reduce the severity of the fire, such as shutting down the supply of coating material, warning occupants for evacuation purposes, etc. The flame detection system and its associated interlocks are part of the protection system, in case ignition has already occurred. Systems that are designed to reduce the severity of the accident in the event of a fire need to be initiated automatically. Supervised flame detection systems are required by this section to stop the flow of additional fuel into the system, stop the spread of fire by shutting down the conveyor, activate an alarm for evacuation, terminate spray application operations that would further add to the fuel and disconnect power to the system. The power disconnection referred to in this section is for the spray booth equipment, but does not include power to emergency systems.

**2407.5 Housekeeping, maintenance and storage of hazardous materials.** Housekeeping, maintenance, storage and

use of hazardous materials shall be in accordance with Sections 2403.3, 2403.4 and Sections 2407.5.1 and 2407.5.2.

❖ This section establishes the applicability of the listed sections to hazardous materials in and around electrostatic apparatus and its operations.

**2407.5.1 Maintenance.** Insulators shall be kept clean and dry. Drip plates and screens subject to paint deposits shall be removable and taken to a safe place for cleaning. Grounds and bonding means for the paint-spraying apparatus and all associated equipment shall be periodically cleaned and maintained free of overspray.

❖ Accumulation of dirt, oil, moisture or debris may compromise the effectiveness of insulators. Overspray accumulations are less severe with electrostatic processes but still require attention. Electrostatic spray equipment requires that grounding and bonding means be properly maintained free of overspray so as to preclude the potential injury to employees or the creation of potential fire hazards caused by the stored electric charge of objects.

**2407.5.2 Signs.** Signs shall be posted to provide the following information:

1. Designate the process zone as dangerous with respect to fire and accident.
2. Identify the grounding requirements for all electrically conductive objects in the flammable vapor area, including persons.
3. Restrict access to qualified personnel only.

❖ Signs should warn of the smoking, open-flame, grounding areas and high-voltage equipment hazards. Additionally, signs should warn against entrance of unqualified personnel into these areas to avoid accidents caused by people or employees who are not trained for the surrounding hazards.

**2407.6 Sources of ignition.** Transformers, power packs, control apparatus and all other electrical portions of the equipment, except high-voltage grids and electrostatic atomizing heads and connections, shall be located outside of the flammable vapor areas or shall comply with Section 2403.2.

❖ Devices that are not classified must be located outside the vapor area to prevent ignition of flammable vapors and overspray residue. The vapor area is defined as "that area where flammable vapors exceed 25 percent of the materials LFL." Equipment must be tested and labeled for use in Class I, Division 1, hazardous locations, as defined by Article 516 of NFPA 70, when locating equipment outside the spraying or vapor area is impractical.

**2407.7 Ventilation.** The flammable vapor area shall be ventilated in accordance with Section 2404.7.

❖ See the commentary to Section 2404.2.

**2407.8 Emergency shutdown.** Electrostatic apparatus shall be equipped with automatic controls operating without time delay to disconnect the power supply to the high-voltage

## FLAMMABLE FINISHES

transformer and signal the operator under any of the following conditions:

1. Stoppage of ventilating fans or failure of ventilating equipment from any cause.
  2. Stoppage of the conveyor carrying articles past the high-voltage grid.
  3. Occurrence of a ground or an imminent ground at any point of the high-voltage system.
  4. Reduction of clearance below that required in Section 2407.2.
- ❖ The required interlocks reduce the likelihood of the apparatus igniting flammable vapors in the event of any of the specified conditions. Conditions 1 and 2 may lead to an increase in the concentration of flammable vapors in the atmosphere. Condition 3 may lead to the release of a spark or arc capable of igniting flammable vapors. Additionally, occurrence of Condition 4 could bring those parts of the system capable of producing an ignition into an area containing an ignitable vapor concentration.

**2407.9 Ventilation interlock.** Hand electrostatic equipment shall be interlocked with the ventilation system for the spraying area so that the equipment cannot be operated unless the ventilating system is in operation.

- ❖ The required interlock is intended to prevent the use of hand sprayers without ventilation equipment in operation. Failure to operate exhaust ventilation may lead to the creation of ignitable vapor concentration in the spraying space.

### SECTION 2408 ORGANIC PEROXIDES AND DUAL-COMPONENT COATINGS

**2408.1 General.** Spraying operations involving the use of organic peroxides and other dual-component coatings shall be in accordance with the requirements of Section 2403 and Sections 2408.2 through 2408.5.

- ❖ This section establishes the applicability of Sections 2408.2 through 2408.5, as well as Section 2403 for the regulation of organic peroxides and other dual-component coatings.

**2408.2 Use of organic peroxide coatings.** Spraying operations involving the use of organic peroxides and other dual-component coatings shall be conducted in *approved* sprinklered spray booths complying with Section 2404.3.2.

- ❖ Because of the reactivity of the material, the use of organic peroxide and other dual-component coating systems is limited to spray booths only. For example, organic peroxide coatings cannot be applied in the limited spraying spaces described in Section 2404.1.4. This section is more specific and, therefore, supersedes the more general requirements. Storage of organic peroxides shall comply with Chapter 62.

**2408.3 Equipment.** Spray guns and related handling equipment used with organic peroxides shall be of a type manufactured for such use.

- ❖ This process involves the discharging of two different components through the same spray gun. The sensitivity of the materials used results in a system that is extremely sensitive to shock, friction, temperature, contaminants, etc. The design and installation of the system cannot be taken lightly.

**2408.3.1 Pressure tanks.** Separate pressure vessels and inserts specifically for the application shall be used for the resin and for the organic peroxide, and shall not be interchanged. Organic peroxide pressure tank inserts shall be constructed of stainless steel or polyethylene.

- ❖ Special consideration must be given to the materials used in organic peroxide systems. Materials that do not react with organic peroxides, such as stainless steel or polyethylene, ensure system component integrity.

**2408.4 Housekeeping, maintenance, storage and use of hazardous materials.** Housekeeping, maintenance, storage and use of hazardous materials shall be in accordance with Sections 2403.3 and 2403.4 and Sections 2408.4.1 through 2408.4.7.

- ❖ This section establishes the applicability of the listed sections to hazardous materials in conjunction with organic peroxides and dual-component coatings.

**2408.4.1 Contamination prevention.** Organic peroxide initiators shall not be contaminated with foreign substances.

- ❖ See the commentary to Section 2409.4.3.

**2408.4.2 Spilled material.** Spilled organic peroxides shall be promptly removed so there are no residues. Spilled material absorbed by using a noncombustible absorbent shall be promptly disposed of in accordance with the manufacturer's recommendation.

- ❖ In order to avoid contact with materials and conditions that would cause a reaction, it is good housekeeping practice to promptly clean the spilled organic peroxide. Additionally, to reduce the possibility of a reaction, prompt disposal is recommended. Because the organic peroxides vary in nature and volatility, the manufacturer's recommendations or Material Safety Data Sheets (MSDS) must be followed for disposal.

**2408.4.3 Residue control.** Materials shall not be contaminated by dusts and overspray residues resulting from the sanding or spraying of finishing materials containing organic peroxides.

- ❖ Because of the hazards associated with organic peroxides and the chemical reactions within the system, issues such as contamination control are very important. To avoid a violent reaction with contaminants that may be introduced accidentally to the organic peroxide initiators, careful consideration must be given to the overall system design.

**2408.4.4 Handling.** Handling of organic peroxides shall be conducted in a manner that avoids shock and friction that produces decomposition and violent reaction hazards.

❖ Many organic peroxides are unstable reactive materials that are decomposed by heat, shock or friction. The rate of decomposition varies depending on the material and the condition it is exposed to. Organic peroxides vary in reactions from plain decomposition (without a fire or explosion hazard) to deflagration or detonation. Special handling care must be given to these materials. The manufacturer's information on handling and care (typically, the "Special Precautions" and "Reactivity" sections of the MSDS) should be referred to for proper storage of the product.

**2408.4.5 Mixing.** Organic peroxides shall not be mixed directly with accelerators or promoters.

❖ In order to avoid any unexpected reaction, organic peroxides should not be mixed directly. Dual-coating systems specifically designed and approved for such use must be used.

**2408.4.6 Personnel qualifications.** Personnel working with organic peroxides and dual-component coatings shall be specifically trained to work with these materials.

❖ Because of the sensitive nature of organic peroxides, only trained personnel should work with them. Qualified personnel should be trained in material handling to avoid accidents, as well as procedures (such as system shutdown, notification, evacuation, etc.) in case of an accident. Qualified personnel should also be familiar with the MSDS of the flammable finishes.

**2408.4.7 Storage.** The storage of organic peroxides shall comply with Chapter 62.

❖ Chapter 62 is specific to the storage and use of organic peroxides (see commentary, Chapter 62). The manufacturer's information on handling and care (typically "Special Precautions" and "Reactivity" sections of the MSDS) should be referred to for proper storage of the product.

**2408.5 Sources of ignition.** Only nonsparking tools shall be used in areas where organic peroxides are stored, mixed or applied.

❖ Many organic peroxides are sensitive to heat, shock and friction. Additionally, many of these materials are dissolved in flammable or combustible solvents. Because of the volatility of the material, sources of ignition must be avoided completely. As mentioned in other sections of this chapter, the term "nonsparking" is somewhat inaccurate. Tools made of brass and similar nonsparking materials produce sparks with ignition energies too low to ignite flammable vapors. Nonetheless, such tools should be used carefully to avoid producing sufficient frictional heat to cause an ignition. Smoking is prohibited in organic peroxide coating areas. "No Smoking" signs should be conspicuously located throughout the work area. Desig-

nated smoking areas should be located well outside the organic peroxide and dual-coating areas and storage rooms, preferably in a separate room (see also commentary, Section 310).

## SECTION 2409 INDOOR MANUFACTURING OF REINFORCED PLASTICS

**2409.1 General.** Indoor manufacturing processes involving spray or hand application of reinforced plastics and using more than 5 gallons (19 L) of resin in a 24-hour period shall be in accordance with Sections 2409.2 through 2409.6.1.

❖ The applicability of this section is limited to operations involving the use of more than 5 gallons (19 L) of resin in a 24-hour period. It is intended to allow very limited amounts of resin to be removed from storage containers and applied in the manufacturing process during that period without further regulation other than those applicable to any hazardous material.

**2409.2 Resin application equipment.** Equipment used for spray application of resin shall be installed and used in accordance with Section 2408 and Sections 2409.3 through 2409.6.1.

❖ The equipment used for resin application should be manufactured for that use. Listed equipment is recommended.

**2409.3 Fire protection.** Resin application areas shall be protected by an *automatic sprinkler system*. The sprinkler system design shall be not less than that required for Ordinary Hazard, Group 2, with a minimum design area of 3,000 square feet (279 m<sup>2</sup>). Where the materials or storage arrangements are required by other regulations to be provided with a higher level of sprinkler system protection, the higher level of sprinkler system protection shall be provided.

❖ Similar language and requirements can be found in Sections 5005.1.8 and 5004.5 when storage and use or dispensing of hazardous materials exceed the allowable quantities per control area given in Section 5003. If design density required by other sections results in a higher sprinkler demand, the more stringent requirement applies.

**2409.4 Housekeeping, maintenance, storage and use of hazardous materials.** Housekeeping, maintenance, storage and use of hazardous materials shall be in accordance with Sections 2403.3 and 2403.4 and Sections 2409.4.1 through 2409.4.3.

❖ This section establishes the applicability of the listed sections to hazardous materials in and around the indoor manufacturing of reinforced plastics.

**2409.4.1 Handling of excess catalyzed resin.** A noncombustible, open-top container shall be provided for disposal of excess catalyzed resin. Excess catalyzed resin shall be drained into the container while still in the liquid state. Enough water shall be provided in the container to maintain a

## FLAMMABLE FINISHES

minimum 2-inch (51 mm) water layer over the contained resin.

- ❖ Some catalyzed resin products produce heat as they cure (exothermic reaction). This may be a fire hazard if the container is not open-top. In a confined container, enough heat may be generated to ignite the resin. Additionally, the required water in the container would help cool down the material and the container until the product is cured or safely disposed of.

**2409.4.2 Control of overchop.** In areas where chopper guns are used, exposed wall and floor surfaces shall be covered with paper, polyethylene film or other *approved* material to allow for removal of overchop. Overchop shall be allowed to cure for not less than 4 hours prior to removal.

- ❖ To ease removal of excess materials, coverings are required in the areas where chopper guns are used. Again, the materials are best left until they are cured to reduce the likelihood of any reactions or ignition from the heat produced during curing (exothermic reaction).

**2409.4.2.1 Disposal.** Following removal, used wall and floor covering materials required by Section 2409.4.2 shall be placed in a noncombustible container and removed from the facility.

- ❖ Once the material is cured for 4 hours, immediate disposal is important to reduce further chances of reaction. Additional heat may be produced if the materials are not fully cured. Regular disposal of hazardous materials is an important part of housekeeping in fire prevention.

**2409.4.3 Storage and use of hazardous materials.** Storage and use of organic peroxides shall be in accordance with Section 2408 and Chapter 62. Storage and use of flammable and *combustible liquids* shall be in accordance with Chapter 57. Storage and use of unstable (reactive) materials shall be in accordance with Chapter 66.

- ❖ Because a variety of materials are used in the GFRP process, chapters specific to the materials are referenced. In addition to the referenced chapters, the MSDS, as well as the manufacturer's recommendation for safe practices, should be considered. Although the codes contain information for the general hazardous materials category, the MSDS are specific to the material being used. For example, the reactivity section of an MSDS is specific in the types of materials that may be incompatible with the resin used.

**2409.5 Sources of ignition in resin application areas.** Sources of ignition in resin application areas shall comply with Section 2403.2.

- ❖ As with other flammable finishes, the sources of ignition must be controlled to a manageable level in hazardous environments.

**2409.6 Ventilation.** Mechanical ventilation shall be provided throughout resin application areas in accordance with Section 2404.7. The ventilation rate shall be adequate to maintain the

concentration of flammable vapors in the resin application area at or below 25 percent of the LFL.

**Exception:** Mechanical ventilation is not required for buildings that have 75 percent of the perimeter unenclosed.

- ❖ In many cases, acetone is used for cleanup of resin accumulations. Therefore, the LFL for both resin and the cleaning solvent must be considered when designing the ventilation for the resin application areas. The exception recognizes that natural ventilation is considered adequate if the perimeter of the building is 75 percent open.

**2409.6.1 Local ventilation.** Local ventilation shall be provided inside of workpieces where personnel will be under or inside of the workpiece.

- ❖ Ventilation in areas where personnel are present is required for fire prevention as well as for reduction of health risks.

## SECTION 2410

### FLOOR SURFACING AND FINISHING OPERATIONS

**2410.1 Scope.** Floor surfacing and finishing operations exceeding 350 square feet (33 m<sup>2</sup>) and using Class I or II liquids shall comply with Sections 2410.2 through 2410.5.

- ❖ Floor surfacing and finishing using Class I or II liquids in facilities such as bowling alleys or gymnasiums pose a high risk because of the spread of liquid over large surface areas. The intent of this section is to provide additional protection and hazard reduction for large surface fires resulting from floor surfacing and finishing.

**2410.2 Mechanical system operation.** Heating, ventilation and air-conditioning systems shall not be operated during resurfacing or refinishing operations or within 4 hours of the application of flammable or *combustible liquids*.

- ❖ In order to avoid circulation of potentially flammable vapors into other parts of the building, mechanical systems that are not part of the exhaust system required in Section 2410.3 must be shut down during the application of flammable or combustible liquids and for 4 hours after the last of the flammable or combustible liquids is applied. For example, if a flammable surface is applied and the entire area application takes 2 hours, the number of hours that the mechanical systems must be shut down is 6 (4 hours after the application).

**2410.3 Business operation.** Floor surfacing and finishing operations shall not be conducted while an establishment is open to the public.

- ❖ In case of a fire, the types and numbers of injuries are reduced by allowing surfacing and finishing operations only when the business is not open to the public. This would limit the exposure to fewer people (nighttime employees, etc.).

**2410.4 Ignition sources.** The power shall be shut down to all electrical sources of ignition within the flammable vapor area, unless those devices are classified for use in Class I, Division 1 hazardous locations.

❖ Because floor surfacing and finishing is a temporary process, the protection system is also temporary. Therefore, unlike processes such as spray booths, the building or area is not required to meet electrical requirements for hazardous areas. These systems that cannot meet the hazard conditions at the time of surfacing and finishing must be shut down to reduce the potential for unrated electrical sources to cause ignition of vapors.

**2410.5 Ventilation.** To prevent the accumulation of flammable vapors, mechanical ventilation at a minimum rate of 1 cubic foot per minute per square foot [ $0.00508 \text{ m}^3 / (\text{s} \cdot \text{m}^2)$ ] of area being finished shall be provided. Such exhaust shall be by *approved* temporary or portable means. Vapors shall be exhausted to the exterior of the building.

❖ The air exhausted over the entire surface must be at minimum 1 cfm per square foot [ $0.00508 \text{ m}^3 / (\text{s} \cdot \text{m}^2)$ ], even in the most remote areas or corners where finishing and surfacing take place. Please note that floor surfacing and finishing do not occur often in a building. Because outside companies are typically hired to do such surfacing, protection systems, such as exhaust, are temporary and can, therefore, be portable. To prevent recirculation of exhaust air that may contain flammable vapors, the exhausted air must be discharged to the exterior of the building.

# Chapter 25: Fruit and Crop Ripening

## General Comments

American consumers have become accustomed to having a wide variety of the ripest and most attractive fruits and vegetables available all year. To supply this demand, horticulturists, growers and distributors have devised a means of growing and transporting these commodities to minimize damage and spoilage. Two fruits in greatest demand, tomatoes and bananas, are now shipped hard and green off the vine or tree, minimizing bruising but contributing to poor sales. To make the fruit attractive and edible, it must be ripened. Ethylene, a naturally occurring hormone in many fruit-bearing plants, is used to complete the ripening process after the fruit arrives at the distributor. This material has a wide explosive range and, when inhaled, is a medical anesthetic. Though only small concentrations of the gas are required in the ripening process, explosions have occurred. These incidents are usually attributed to the use of excessive concentrations of gas well above the

lower flammable limit (LFL). Placed in a relatively vapor-tight room filled with ethylene gas at small concentrations—100 to 150 parts per million (ppm) (100 to 500 mg/L)—for varying durations, quantities of fruit are ripened slowly, bringing them to just the right point before transporting them to the local retail market.

## Purpose

Chapter 25 provides guidance that is intended to reduce the likelihood of explosions resulting from improper use or handling of ethylene gas used for crop-ripening and coloring processes. This is accomplished by regulating ethylene gas generation; storage and distribution systems and controlling ignition sources. Design and construction of facilities for this use are regulated by the *International Building Code*® (IBC®) to reduce the impact of potential accidents on people and buildings.

## SECTION 2501 GENERAL

**2501.1 Scope.** Ripening processes where ethylene gas is introduced into a room to promote the ripening of fruits, vegetables and other crops shall comply with this chapter.

**Exception:** Mixtures of ethylene and one or more inert gases in concentrations that prevent the gas from reaching greater than 25 percent of the lower explosive limit (LEL) when released to the atmosphere.

❖ This section establishes that this chapter is applicable to fruit- and crop-ripening processes that use ethylene gas as a ripening agent. While still green, many fruits and vegetables are picked and shipped to their point of distribution. Prior to shipping or upon arrival at the distribution warehouse near the retail market, fruits and vegetables are transferred to containers (trailers) or rooms filled with low concentrations of ethylene gas to facilitate ripening. As they ripen, some fruits and vegetables, including bananas, tomatoes, pears, apples and honeydew melons, produce ethylene gas. If kept in tightly enclosed rooms or containers, gas accumulates, expediting the ripening process as concentrations increase.

This process would be relatively safe, simple and effective except for one problem—ethylene is a highly flammable gas (see Commentary Figure 2501.1). A constituent of liquefied petroleum gas (LP-gas), eth-

ylene is colorless with a sweet odor and taste. It is explosive in sunlight when mixed with chlorine. Moderate concentrations of ethylene in air are a medical anesthetic; thus, care must be taken to prevent inhalation. Atmospheres containing ethylene are classi-

Ignition Temperature <sup>a</sup>	842°F to 914°F
Vapor Density	1.0
Flammable Range	
Lower	2.7 percent
Upper	36 percent
NFPA 704 Hazard Classification	
Health	1
Flammability	4
Reactivity	2
Other	—

For SI: °C = (°F - 32)/1.8.

a. In the *NFPA Fire Protection Guide on Hazardous Materials*, 13th edition, NFPA 325 reports the lower value, while NFPA 49 reports the higher value.

**Figure 2501.1  
FLAMMABILITY CHARACTERISTICS  
AND ETHYLENE HAZARDS**

fied as Class I, Division 1, Group C hazardous locations by NFPA 70. Additionally, ethylene (R-1150) is sometimes used as a refrigerant gas and classified among Group 3 (highly flammable) refrigerants. Explosions involving trucks and warehouses where ethylene gas is used as a fruit-ripening agent are usually attributed to the use of excessive concentrations of gas well above the lower explosive limit (LEL). The exception recognizes the reduced hazard of ethylene-inert gas mixtures when the mixtures keep the ethylene concentration at or below 25 percent of its LEL.

**2501.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. Because of the extremely flammable nature of ethylene gas, an operational permit is required by Section 105.6.20 for ethylene-based ripening processes.

**2501.3 Ethylene generators.** *Approved* ethylene generators shall be operated and maintained in accordance with Section 2506.

❖ Chapter 25 recognizes the use of listed ethylene generators as a means of safely producing ethylene concentrations needed to ripen crops. This section requires that those devices be properly operated and maintained (see commentary, Section 2506.1).

## SECTION 2502 DEFINITIONS

**2502.1 Terms defined in Chapter 2.** Words and terms used in this chapter and defined in Chapter 2 shall have the meanings ascribed to them as defined therein.

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 2503 ETHYLENE GAS

**2503.1 Location.** Ethylene gas shall be discharged only into *approved* rooms or enclosures designed and constructed for this purpose.

❖ Rooms or spaces occupied for the ripening of fruits and crops using ethylene gas must be constructed to

accommodate the process without exposing the rest of the building to process hazards. The design and construction of facilities for this use are regulated by the applicable provisions of the IBC to reduce the impact of potential accidents on people and buildings. In particular, buildings and portions of buildings used for crop-ripening or coloring processes must conform to the requirements of IBC Section 414.

Because ethylene is a flammable gas, the occupancy group classification of the building depends on the quantities of gas present and the use of the control area concept (see IBC Section 414.2). If the amount of gas exceeds the maximum allowable quantity per control area (MAQ) [see IBC Table 307.1(1)], the applicable provisions of IBC Section 415 would also apply. Additionally, Chapter 53 regulates the physical hazards of compressed gases and Chapter 58 regulates the material hazards of flammable gases. Both would apply to ethylene used in fruit-ripening processes as would the general hazardous materials provisions of Chapter 50.

**2503.2 Dispensing.** Valves controlling discharge of ethylene shall provide positive and fail-closed control of flow and shall be set to limit the concentration of gas in air below 1,000 parts per million (ppm).

❖ Although the hazards of using ethylene should be of considerable concern, technological innovation has produced a safe alternative to the old method of distributing ethylene to the ripening rooms. In the past, compressed ethylene gas in cylinders was piped through regulating equipment into rooms. Regulating equipment was calibrated to restrict gas quantity to a volume that would produce concentrations below the lower explosive gas limit; however, excessive concentrations occasionally escaped and uncontrolled ignition sources produced serious explosions.

Ideally, gas sensors should be used to stop gas flow as it approaches the desired level. Manual overrides must be provided to interrupt the gas flow if a danger exists. A 1:1,000 concentration is only 0.1 percent in air. The LFL of ethylene is 2.6 percent. When used properly, this gas poses little hazard.

## SECTION 2504 SOURCES OF IGNITION

**2504.1 Ignition prevention.** Sources of ignition shall be controlled or protected in accordance with this section and Chapter 3.

❖ Lighted smoking materials and other open-flame sources are prohibited in crop-ripening and color-processing rooms. This prohibition should also be extended to the immediate vicinity of the entrance to such rooms. “No Smoking” signs are to be conspicuously posted and stringently enforced (see also commentary, Sections 305, 308 and 310).

**2504.2 Electrical wiring and equipment.** Electrical wiring and equipment, including luminaires, shall be *approved* for

use in Class I, Division 2, Group C hazardous (classified) locations.

- ❖ Atmospheres containing ethylene are classified as Class 1, Division 1, Group C hazardous locations by NFPA 70. All electrical wiring and equipment must be suitably listed and labeled for use in such atmospheres.

**2504.3 Static electricity.** Containers, piping and equipment used to dispense ethylene shall be bonded and grounded to prevent the discharge of static sparks or arcs.

- ❖ Suitable grounds must be provided on all ethylene-handling systems and equipment to permit the dissipation of static electricity, thus preventing the generation of static sparks. Electrically isolated sections of systems and equipment must be independently grounded. NFPA 77 provides valuable guidance on this topic. Grounding and bonding should be in accordance with NFPA 70.

**2504.4 Lighting.** Lighting shall be by *approved* electric lamps or luminaires only.

- ❖ Open-flame lighting is prohibited in crop-ripening rooms and spaces because ethylene gas is flammable. Only approved electrical lighting equipment is allowed and it must comply with the provisions of Section 2504.2 of the code (see commentary, Section 2504.2).

**2504.5 Heating.** Heating shall be by indirect means utilizing low-pressure steam, hot water or warm air.

**Exception:** Electric or fuel-fired heaters *approved* for use in hazardous (classified) locations and that are installed and operated in accordance with the applicable provisions of NFPA 70, the *International Mechanical Code* or the *International Fuel Gas Code*.

- ❖ Wherever practical, heat for crop-ripening and coloring rooms should be indirect (steam, hot water or warm air) to eliminate sparks or open-flame ignition hazards. Piped steam and hot water-heating systems operate at temperatures of 250°F to 430°F (121°C to 221°C) and are considered the most appropriate method when providing indirect heat to ripening rooms.

The exception provides that electric heaters may be used where approved by the fire code official. The type of electric heaters required must be approved and listed for use in Class I, Division 1, Group C electrically classified locations because of the presence of ethylene gas. Such heaters must also be designed to keep all exposed surfaces at temperatures of 800°F (427°C) or below because ethylene gas has an ignition temperature of 842°F (450°C). Fuel-fired heaters using gas or liquid fuel may also be used, provided they are approved and comply with the *International Mechanical Code*® (IMC®) or the *International Fuel Gas Code*® (IFGC®), as applicable. These appliances must also have a sealed combustion chamber to prevent open-flame ignition of the ethylene gas and be installed in accordance with the

manufacturer's instructions. All heaters must be protected from physical damage to prevent fuel spills or heater malfunctions.

## SECTION 2505 COMBUSTIBLE WASTE

**2505.1 Housekeeping.** Empty boxes, cartons, pallets and other combustible waste shall be removed from ripening rooms or enclosures and disposed of at regular intervals in accordance with Chapter 3.

- ❖ Waste accumulation, especially packing materials and crop debris, is to be removed regularly from the premises and disposed of in an approved manner to reduce the volume of nonessential combustible materials susceptible to ignition and contributing to the fire load. Section 304 of the code provides specific regulations for waste disposal (see commentary, Section 304).

## SECTION 2506 ETHYLENE GENERATORS

**2506.1 Ethylene generators.** Ethylene generators shall be *listed* and *labeled* by an *approved* testing laboratory, *approved* by the *fire code official* and used only in *approved* rooms in accordance with the ethylene generator manufacturer's instructions. The listing evaluation shall include documentation that the concentration of ethylene gas does not exceed 25 percent of the lower explosive limit (LEL).

- ❖ Several companies produce ethylene generators especially for fruit-ripening processes. These devices convert a liquid similar to ethanol into ethylene gas. This process produces ethylene in concentrations far below the LEL, even in very small compartments, which is an important feature since these generators are portable and could be operating in ripening rooms of different sizes. During a test conducted by an independent testing laboratory and witnessed by representatives of the Los Angeles City Fire Marshal's office, a small [4,000 cubic foot (113 m<sup>3</sup>)] fruit-ripening room was filled with 400 cases of green bananas with the generator set at the maximum setting. During the 8-hour test, the device did not produce a concentration greater than 0.1 percent by volume; the LEL for ethylene is 2.6 percent by volume. While this may not be a worst-case scenario, it certainly suggests a significant safety margin—a factor of 26. This section mandates that ethylene generators be listed and labeled by a third-party testing laboratory. The basic standard used in the investigation and listing of these devices is UL 499, which, while it covers the most significant electrical hazards of ethylene generators, does not evaluate the flammable vapor-air mixtures produced when the devices are operated in closed rooms. This section is intended to fill that gap by requiring that the listing evaluation attests to the safety of the devices by documenting in the report results that the maximum ethylene concentration capable of being generated by the device does not

## FRUIT AND CROP RIPENING

exceed 25 percent of the LEL. This section also requires adherence to the ethylene generator manufacturer's instructions, which are considered part of the listing.

**2506.2 Ethylene generator rooms.** Ethylene generators shall be used in rooms having a volume of not less than 1,000 cubic feet (28 m<sup>3</sup>). Rooms shall have air circulation to ensure even distribution of ethylene gas and shall be free from sparks, open flames or other ignition sources.

- ❖ Because ethylene generators are portable, the level of hazard associated with their use in closed rooms can change each time one is moved to a new ripening room. The intent of this section is to reduce the hazard potential by requiring that ethylene generators be used only in ripening rooms having a minimum volume of 1,000 cubic feet (28 m<sup>3</sup>) [10 feet by 10 feet by 10 feet (3048 mm by 3048 mm by 3048 mm)], that are free from ignition hazards and have air circulation to distribute the ethylene gas evenly throughout the space to avoid the potential for pockets of gas having concentrations approaching or exceeding 25 percent of the LEL.

### SECTION 2507 WARNING SIGNS

**2507.1 Where required.** *Approved* warning signs indicating the danger involved and necessary precautions shall be posted on all doors and entrances to the premises.

- ❖ Given the flammability and the anesthetic quality of ethylene gas, it poses potential dangers to personnel who might accidentally enter a ripening room, building or area unaware of the hazards. As with other hazardous materials, warning signs and placards must be posted to give appropriate notice to warn personnel of the hazards of the ripening process and discourage entry by unauthorized and unprotected people. Warning signs must comply with Sections 5003.5 and 5003.5.1 and include NFPA 704 hazard warning system markings to warn of fire- and health-related hazards of these materials (see commentary, Sections 5003.5 and 5003.5.1).

### Bibliography

The following resource material was used in the preparation of the commentary for this chapter of the code:

“Ethylene Gas Generator—Fruit Ripening.” *Field Service Bulletin F-2-81*. Long Grove, IL: Kemper Group of Insurance Companies, 1981.

# Chapter 26: Fumigation and Insecticidal Fogging

## General Comments

Fumigation is the use of toxic pesticide chemicals to kill insects, rodents and other vermin. In addition, agricultural fumigation is used to kill plant and animal parasites, weed seeds and various types of fungi that adversely affect agricultural products.

Fumigants are available as liquids that will vaporize readily at ambient temperatures, solids that can release a toxic gas on reacting with water or acid or gases. Fumigants and insecticidal fogging agents pose little hazard if properly applied; however, the inherent toxicity of all these agents and the potential flammability of some makes special precautions necessary when they are used. Requirements of this chapter are intended to protect both the public and fire fighters from hazards associated with these products.

The use of fumigants poses the following two distinct hazards to both fire fighters and the general public: some fumigants are flammable or burn under certain circumstances and all fumigants are poisonous or toxic. Compounding these hazards, the fumigation fog may easily be confused with smoke from a fire if it is not properly contained within a building or compartment. Though these concerns seem quite serious, the proper use of fumigants poses little fire hazard. With the exception of allyl alcohol, aluminum phosphide, dichloropropane-dichloropropene mixtures and formaldehyde, most fumigants are relatively difficult to ignite. However, all fumigants are intended to kill something, whether involved in a fire or not. In fact, many of these agents are quite toxic if involved in a fire.

## Special Fire Protection Problems

In particular, aluminum phosphide poses a special fire protection problem. This agent readily decomposes in water to form phosphine ( $\text{PH}_3$ ), a pyrophoric toxic gas. In 1990, M.R. Spencer noted that although the lower flammable limit (LFL) of phosphine is only 1.79 percent, this is more than 10 times the effective concentration for fumigation. However, he also noted that poorly distributed agent and storage canisters can easily produce ignitable concentrations.

The other agents—allyl alcohol, dichloropropane-dichloropropene mixtures and formaldehyde—are either flammable or combustible liquids commonly used in diluted form. However, all flammable or combustible liquids are easier to ignite when finely dispersed in air; therefore, special precautions must be taken to eliminate ignition sources during fumigation and fogging

operations. Commentary Figure 26-1 lists hazard classifications of various common fumigants.

## Information Sources

Understanding and regulating fumigants and insecticidal fogging agents requires specialized knowledge of their hazards beyond the basic classifications of health, flammability and reactivity. Several references provide additional details necessary to apply code requirements. The most helpful of these references is the product's Material Safety Data Sheet (MSDS). A copy of this document is often shipped with a product in transit (see commentary, Section 407 and Chapter 50). Anyone handling or using these products should also have access to this information in compliance with the provisions of the hazard communication requirements of the Occupational Safety and Health Act (OSH Act).

Reference books, such as the *Farm Chemicals Handbook* and the *Crop Protection Chemicals Reference*, are also comprehensive sources for handling and storage information. The former contains a list of common agricultural chemicals based on their use, a list of suppliers or distributors and a chemical dictionary containing each product listed.

Every manufacturer of a pesticide or fumigant also produces a reference known as a label book containing facsimiles of the warning labels for each of its products. This reference is often helpful because U.S. Environmental Protection Agency (EPA) regulations require that labels contain breakdowns of the contents of environmentally hazardous substances and signal words providing clues about their toxicity.

## Storage and Handling

Other code chapters should be consulted for specific storage and handling requirements for certain fumigants. Chapters 50, 57, 60 and 63 prescribe safeguards for the storage and handling of materials based on their specific hazardous properties. Requirements of this chapter apply only to the use of these products as fumigants or insecticidal fogging agents.

## Purpose

Some of these products are also flammable and their involvement in fire may result in serious health or environmental hazards. The key to the safe use of these products is knowledge of the hazards, elimination of ignition sources and isolation of the premises during application.

PRODUCT	DOT CLASSIFICATION	NFPA 704 HAZARD CLASSIFICATION			
		Health	Flammability	Reactivity	Other
Allyl alcohol	Flammable liquid, Poisonous	3	3	0	
Aluminum phosphide	Flammable solid, Poisonous, Water reactive	4	4	2	W
Calcium cyanide	Poison B	3	0	0	
Carbon tetrachloride	ORM-A	3	0	0	
Chloropicrin	Poison B	4	0	3	
Paradichlorobenzene	ORM-A	2	2	0	
Dichloropropane-dichloropropene mixtures	Flammable liquid	3	3	0	
Ethylene dibromide (EDB)	ORM-A	3	0	0	
EDB/chloropicrin mixtures		4	0	3

Phosphine	Poison A, Flammable	4	4	4	

a. This list was compiled from chemicals listed under the heading "Fumigants" in the *Farm Chemicals Handbook*.

b. Other common fumigants include: streptomycin, dibromo-chloropropane, metam ammonium and metan sodium (consult MSDS or these products before issuing permits.)

**Figure 26-1**  
**HAZARDOUS PROPERTIES OF COMMON FUMIGANTS<sup>a, b</sup>**

**SECTION 2601**  
**GENERAL**

**2601.1 Scope.** Fumigation and insecticidal fogging operations within buildings, structures and spaces shall comply with this chapter.

❖ The requirements of this chapter govern fumigation operations using insecticidal fogging agents and other air-borne pesticides used to control insects, rodents, vermin and other similar pests inside buildings, structures and spaces.

**2601.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ Issuing an operational permit as prescribed in Section 105.6.19 gives the fire code official a method for identifying and controlling the hazards of fumigation and insecticidal fogging operations. The process of issuing permits also gives the fire code official a reason or method to advise fire fighters of the potential hazards at fumigation sites. This will allow fire fighters to take special note of the hazards present and will give them the information needed to determine whether the operation is mistaken for a fire.

This chapter states the requirements for approval and special warning signs because of the toxicity and

flammability hazards of fumigants. Upon notification of the hazardous potential, the fire code official should notify the fire department responsible for protecting the work site.

A guard or fire watch must be posted at the work site and must have a means available to report a fire or other emergency. If possible, a means should also be provided for the fire department to contact the guards or fire watches to verify the occurrence of a fire and obtain additional information en route to the scene.

**SECTION 2602**  
**DEFINITIONS**

**2602.1 Definitions.** The following terms are defined in Chapter 2:

**FUMIGANT.**

**FUMIGATION.**

**INSECTICIDAL FOGGING.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chap-

ter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3 or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 2603 FIRE SAFETY REQUIREMENTS

**2603.1 General.** Buildings, structures and spaces in which fumigation and insecticidal fogging operations are conducted shall comply with the fire protection and safety requirements of Sections 2603.2 through 2603.7.

❖ The provisions in Sections 2603.2 through 2603.7 apply to safe fumigation and insecticidal fogging in buildings, structures and spaces.

**2603.2 Sources of ignition.** Fires, open flames and similar sources of ignition shall be eliminated from the space under fumigation or insecticidal fogging. Heating, where needed, shall be of an *approved* type.

❖ Some insecticides and fumigants are flammable. Others that are considered nonflammable may ignite readily when suspended in air or dispersed as a vapor during fogging or fumigation operations. See the commentary to Chapters 22, 50, 57 and 60, and Section 307 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), for further information on the safe storage and handling of dusts and other materials used as pesticides or fogging agents.

**2603.2.1 Electricity.** Electricity in any part of the building, structure or space where operation of switches or electrical devices, equipment or systems could serve as a source of ignition shall be shut off.

**Exception:** Circulating fans that have been specifically designed for utilization in hazardous atmospheres and installed in accordance with NFPA 70.

❖ The structure's electrical service must be disconnected at the main service disconnect during fumigation or insecticidal fogging operations. While not specifically required, a physical means for preventing the inadvertent, premature restoration of power by anyone other than the fumigation supervisor should be provided, such as by locking the service disconnect switch, if possible, or by equivalent means.

The exception allows the use of fans to assist in the distribution of fumigant throughout the building undergoing fumigation. The power supply for circulating fans must be located outside the building undergoing fumigation or the fans may be self-powered, either by battery or an integral internal combustion engine. In any case, fans exposed to the hazardous atmosphere must be appropriately classified when an insecticide or fogging agent is susceptible to ignition during application or use, so as not to become an ignition source.

Equipment and devices used in the presence of flammable liquid vapors must be classified for use in

Class I, Division 1, hazardous locations. When used where a dust explosion hazard exists, the fans must be classified for Class II hazardous locations.

**2603.2.2 Electronic devices.** Electronic devices, including portable equipment and cellular phones, shall be shut off. Telephone lines shall be disconnected from telephones.

❖ This section focuses on the ignition hazard posed to flammable vapor-rich atmospheres by popular personal electronic devices, such as cell phones, MP3 players, computers, etc., and requires that if present, they be shut off. Even though telephones are low-voltage devices, in certain atmospheres, the simple ringing of a telephone can be a source of ignition in a space undergoing fumigation. To avert potential ignition by a telephone, telephone lines must be unplugged from the phone sets.

**2603.2.3 Duration.** Sources of ignition shall be shut off during the fumigation activity and remain shut off until the ventilation required in Section 2603.6 is completed.

❖ This section provides the common-sense precaution regarding ignition sources that they must be secured as required by Sections 2603.2, 2603.2.1 and 2603.2.2 until the fumigation operation is finished and the fumigated space has been ventilated in accordance with Section 2603.6.

**2603.3 Notification.** The *fire code official* and fire chief shall be notified in writing not less than 48 hours before the building, structure or space is to be closed in connection with the utilization of any toxic or flammable fumigant. Notification shall give the location of the enclosed space to be fumigated or fogged, the occupancy, the fumigants or insecticides to be utilized, the person or persons responsible for the operation, and the date and time at which the operation will begin. Written notice of any fumigation or insecticidal fogging operation shall be given to all affected occupants of the building, structure or space in which such operations are to be conducted with sufficient advance notice to allow the occupants to evacuate the building, structure or space. Such notice shall inform the occupants as to the purposes, anticipated duration and hazards associated with the fumigation or insecticidal fogging operation.

❖ Written notice is required at least 48 hours before a structure is closed for fumigation or fogging with flammable or toxic agents. All pesticides must be considered toxic to some degree because they are intended to kill something at some concentration. Occupants of the structure must be given sufficient advance notice to permit evacuation and removal of any belongings or equipment that may be endangered by fumigation or fogging operations. The fire code official should relay the notification information and the nature of the fumigation or fogging operation to the responsible fire service personnel for this location.

Fire fighters must be aware of the nature of hazards to encourage the use of protective gear and precautions when investigating or operating at sites involving structures undergoing fumigation. Fire code

officials may consider the required written notification as a default for permit application under Section 2601.2; however, the fire code official must inspect the premises and equipment to verify compliance with the code before a permit is issued (see commentary, Sections 105.2.2 and 105.6.20).

**2603.3.1 Warning signs.** *Approved* warning signs indicating the danger, type of chemical involved and necessary precautions shall be posted on all doors and entrances to the affected building, structure or space and upon all gangplanks and ladders from the deck, pier or land to a ship. Such notices shall be printed in red ink on a white background. Letters in the headlines shall be not less than 2 inches (51 mm) in height and shall state the date and time of the operation, the name and address of the person, the name of the operator in charge, and a warning stating that the affected building, structure or space shall be vacated not less than 1 hour before the operation begins and shall not be reentered until the danger signs have been removed by the proper authorities.

- ❖ Warning signs and placards must be posted to give notice for evacuation, warn of the hazards of the fumigant or fogging agent and discourage entry by unauthorized and unprotected people. Warning signs must include the name and address of the party responsible for conducting fumigation operations. Both names and hazards associated with the chemical fumigant must appear on the warning signs.

The NFPA 704 hazard warning system is especially useful for warning of the fire-related hazards of these materials. Hazard warning signs also provide useful qualitative information about the relative toxicity of pesticides and fumigants in use at a particular site to warn and assist the fire department (see Commentary Figure 2603.3.1).

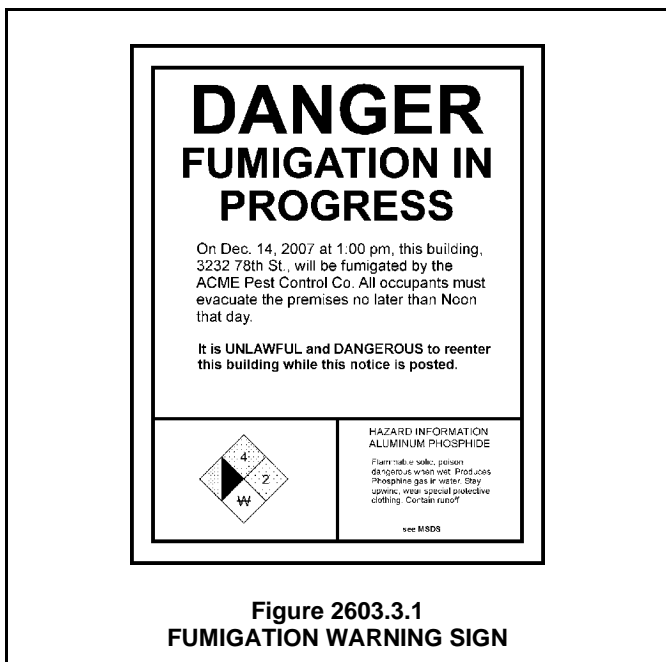

Figure 2603.3.1  
FUMIGATION WARNING SIGN

**2603.3.2 Breathing apparatus.** Persons engaged in the business of fumigation or insecticidal fogging shall maintain and have available *approved* protective breathing apparatus.

- ❖ Respiratory protective equipment must be appropriate for the hazards of the material used. Stored-air self-contained breathing apparatus (SCBA) is not necessarily the only appropriate form of respiratory protection. Canister respirators with suitable filters may provide employees greater flexibility to perform required tasks without posing a danger of exposure or contamination to the employee. Employees required to wear respiratory protective equipment should be fitted for the correct size mask and enrolled in a medical surveillance program. The required protective equipment must be available at all times during the fumigation or fogging process.

**2603.3.3 Watch personnel.** During the period fumigation is in progress, except where fumigation is conducted in a gas-tight vault or tank, a responsible watchperson shall remain on duty at the entrance or entrances to the enclosed fumigated space until after the fumigation is completed and the building, structure or space is properly ventilated and safe for occupancy. Sufficient watchers shall be provided to prevent persons from entering the enclosed space under fumigation without being observed.

- ❖ A minimum of one watch must be posted at each entrance to the structure or space being fumigated. Watch personnel must discourage or prevent entry by unauthorized and unprotected individuals until fumigation is completed; the building, structure or premises has been ventilated; and the building, structure or premises is again ready for occupancy. Watch personnel must also have a means available to report emergencies without leaving their posts unattended. If practical, a means should be provided for the fire department to contact the watch while responding to determine whether a fire exists and, if so, obtain additional information before arrival.

**2603.3.4 Evacuation during fumigation.** Occupants of the building, structure or space to be fumigated, except the personnel conducting the fumigation, shall be evacuated from such building, structure or space prior to commencing fumigation operations.

- ❖ This section reinforces the life safety focus of this chapter by requiring that occupants of areas to be fumigated must leave the area of treatment prior to the commencing of fumigation operations to avoid contact with the toxic fumigant. Obviously, the fumigator's personnel are allowed to remain since they would be protected by appropriate protective clothing and a breathing apparatus. Although it is not explicitly stated, occupants should remain outside of the fumigated area until it has been properly ventilated and cleaned up in accordance with Section 2603.6.

**2603.3.5 Evacuation during insecticidal fogging operations.** Occupants in the building, structure or space to be

fogged, except the personnel conducting the insecticidal fogging operations, shall be evacuated from such building, structure or space prior to commencing fogging operations.

- ❖ This section reinforces the life safety focus of this chapter by requiring that the occupants of the areas to be fogged must leave the area of treatment prior to the commencing of insecticidal fogging operations to avoid contact with the toxic pesticide fog. Obviously, the insecticidal fogger's personnel are allowed to remain since they would be protected by appropriate protective clothing and a breathing apparatus. Although it is not explicitly stated, occupants should remain outside of the fogged area until it has been properly ventilated and cleaned up in accordance with Section 2603.6.

**2603.4 Insecticidal fogging liquids.** Insecticidal fogging liquids with a *flash point* below 100°F (38°C) shall not be utilized.

- ❖ The use of Class I flammable liquids as fumigants is prohibited. Many fumigants that are otherwise non-flammable or only combustible may be easily ignited when dispersed or suspended in air as a vapor or fine mist. This prohibition does not apply to flammable active ingredients in nonflammable concentrations when in a solution with other ingredients.

**2603.5 Sealing of buildings, structures and spaces.** Paper and other similar materials that do not meet the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701 shall not be used to wrap or cover a building, structure or space in excess of that required for the sealing of cracks, casements and similar openings.

- ❖ Fundamental to a successful fumigation operation is achieving the proper concentration of fumigant for the proper length of time to allow the treatment to permeate all portions of the structure, including interstitial spaces and even some building materials to a cellular level. To achieve this level of permeation, the building, structure or space must be made as gas tight as possible. Small holes, cracks and openings can easily be sealed with tape; heavy-weight paper secured with tape or water-soluble or peelable paste; caulking compound; foam plastic sealant; or similar, readily available materials. Larger openings can be sealed using plastic sheets held in place with tacks or staples and sealed with tape; heavy-weight paper secured with tape or water-soluble or peelable paste; or a spray-on vinyl sealant. The use of these and similar readily combustible materials should be limited to small cracks, casements and similar openings.

This section is intended to ensure that more extensive sealing procedures than the simple crack and hole sealing described above, such as wrapping the building or tenting it, be done using materials that are, at a minimum, flame resistant in accordance with one of the test methods of NFPA 701. The use of such materials reduces the susceptibility of the enclosing

membrane to easy ignition that could quickly engulf the entire structure in fire.

**2603.5.1 Maintenance of openings.** All openings to the building, structure or space to be fumigated or fogged shall be kept securely closed during such operation.

- ❖ Because of the "soak time" needed for fumigation operations to be successful, this section requires that the sealing of all openings to the fumigation area be maintained tightly sealed throughout the duration of the fumigation operation. This sealing of openings coupled with the watch person required by Section 2603.3.3 will also help prevent unauthorized personnel from inadvertently wandering into a toxic atmosphere or releasing fumigants to parts of the building not being fumigated. It will also prevent fumigant fog from escaping and being mistaken by a passerby for smoke from a fire which could result in an unwanted report of a fire.

**2603.6 Venting and cleanup.** At the end of the exposure period, fumigators shall safely and properly ventilate the premises and contents; properly dispose of fumigant containers, residues, debris and other materials used for such fumigation; and clear obstructions from gas-fired appliance vents.

- ❖ Following the desired fumigant exposure period, the structure must be completely aired by opening as many doors and windows as possible from the outside. Also at this time, any exterior wrapping and sealing materials should be removed. Complete removal of sealing materials from the gas-fired appliance vent and combustion air intake openings that were sealed during fumigation is especially important to avoid potential backups of products of combustion in the building. Approved ventilators and fans powered from a source, and with their switches accessible from outside the building, should be started as well (see commentary, Section 2603.2.1). Personnel should then withdraw from the immediate vicinity of the fumigated structure and wait a reasonable length of time before entering the building to open more doors and windows to complete the ventilation process.

Throughout the ventilation process, personnel should wear personal breathing protection equipment (respirators). Tests for the presence of gas may be conducted as soon as the fumigator determines that the structure is properly aired. Chemical tests for residual fumigant must be carried out to verify that both the structure and its contents are free of toxic concentrations of fumigant, at which time the building may be reoccupied for normal activities.

Consistent with Section 304, rubbish and debris generated by the fumigation project must be removed from the premises and properly discarded. Because fumigants are hazardous materials, fumigant containers and other materials that might contain flammable or toxic fumigant residues must be disposed of in accordance with the fumigant manufacturer's instructions.

**2603.7 Flammable fumigants restricted.** The use of carbon disulfide and hydrogen cyanide shall be restricted to agricultural fumigation.

❖ While they are very effective fumigants, carbon disulfide (Formula: CS<sub>2</sub>; CAS # 75-15-0) and hydrogen cyanide (Formula: HCN; CAS # 74-90-8) present such severe flammability and toxicity hazards that their use is restricted to agricultural fumigation applications only.

In addition to being toxic (see commentary, Chapter 60), carbon disulfide is a Class IB flammable liquid (see commentary, Chapter 57) having a flash point of -22°F (-30°C), a boiling point of 116°F (47°C) and a flammability range of 1 to 50 percent, thus making any release an extreme fire and deflagration hazard to the extent that its vapors can be ignited by contact with the heated surfaces of steam heating pipes or ordinary incandescent light bulbs. Given these dangers, carbon disulfide is typically used in mixtures with other materials, such as carbon tetrachloride as a fire suppressant, or stabilizing chemicals, such as sulfur dioxide, to mitigate the hazards of use.

The typical agricultural use of carbon disulfide is as a fumigant for treating raw cereal grains in grain bins and silos.

Hydrogen cyanide (also known as formonitrile, hydrocyanic acid or prussic acid) is colorless, possesses a characteristic almond-like aroma and is an insecticide principally used for fumigation of stored agricultural products, especially grains and flour in mills, warehouses and the holds of ships.

In fruit-growing regions of the United States, hydrogen cyanide has also been widely used for destroying scale insects on citrus trees by covering each tree with a gas tent. Hydrogen cyanide can be a Class IA flammable liquid (see commentary, Chapter 57) or a flammable gas (see commentary, Chapter 58). As a liquid, it may also be classified as a Class 2 unstable reactive material (see commentary, Chapter 66), a Class 1 water-reactive material (see commentary, Chapter 67) and a highly toxic material (see commentary, Chapter 60). Hydrogen cyanide may enter the body in toxic amounts by absorption through unbroken skin, inhalation and direct ingestion.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 27: Semiconductor Fabrication Facilities

## General Comments

The invention, development and exploitation of semiconductor technology has changed the world. Without integrated circuits, and the microchips (or “chips”) they are composed of, the world of high technology would not exist. With the benefits of living in a high-tech age come some unique and pressing challenges. The manufacture of microchips is a complex, hazardous and demanding operation involving state-of-the-art design and manufacturing techniques, specially designed processing centers and a highly trained work force. Despite these rigors, the dangers of the processes can neither be avoided nor ignored.

The manufacture of semiconductors and microprocessors has developed into its own industry within the last 25 years. The proliferation of computer technology has resulted in the incredible expansion of the semiconductor manufacturing industry. These sophisticated products require a special processing environment and new rules to match the new technology. Unlike many other hazardous operations, hazards of the production

materials are not manifested in the finished product. Considering the unique and often acute hazards of many materials used in semiconductor processing, this contributes to the relatively good safety record of the industry.

## Purpose

The requirements of this chapter are intended to control hazards associated with the manufacture of semiconductors. Though the finished product possesses no unusual hazards, materials commonly associated with semiconductor manufacturing are often quite hazardous and include flammable liquids; pyrophoric and flammable gases; toxic substances and corrosives. The requirements are concerned with both life safety and property protection. However, the fire code official should recognize that the risk of extraordinary property damage is far more common than the risk of personal injury from fire.

---

## SECTION 2701 GENERAL

**2701.1 Scope.** Semiconductor fabrication facilities and comparable research and development areas classified as Group H-5 shall comply with this chapter and the *International Building Code*. The use, storage and handling of hazardous materials in Group H-5 shall comply with this chapter, other applicable provisions of this code and the *International Building Code*.

❖ Semiconductor facilities are unique facilities that, due to their size, complex layout and the logistics of their operations, have been provided with a unique package of requirements. In some cases these unique requirements will allow the maximum allowable quantities (MAQs) established in Tables 5003.1.1(1) and 5003.1.1(2) to be exceeded. The hazardous material MAQs are essentially replaced by more specific allowances and restrictions in this chapter. In cases where a material hazard is not addressed in this chapter, the applicable requirements found in Chapter 50 and associated material-specific chapters of the code and the *International Building Code*® (IBC®) would still apply regardless of whether the MAQs have been exceeded. Semiconductor fabrication facilities are classified in Occupancy Group H-5 and are to comply with the applicable provisions of IBC Section 415.11.

**2701.2 Application.** The requirements set forth in this chapter are requirements specific only to Group H-5 and shall be applied as exceptions or additions to applicable requirements set forth elsewhere in this code.

❖ Chapter 27 requirements are specific only to Group H-5 occupancies, with the requirements applied as exceptions or additions to requirements addressed elsewhere in the code. Where Chapter 27 contains a specific requirement for a certain condition and a general requirement for the same condition exists elsewhere in the code, the specific Chapter 27 requirements are to be applied. For example, general requirements for spill control and containment for use conditions involving hazardous materials in amounts exceeding MAQs are found in Section 5005.2, with conditions specific to Group H-5 occupancies addressed in Section 2705.2.2. For Group H-5 occupancy conditions, the specific Section 2705.2.2 requirements take precedence over the general requirements addressed in Section 5005.2.

**2701.3 Multiple hazards.** Where a material poses multiple hazards, all hazards shall be addressed in accordance with Section 5001.1.

❖ All hazard classifications of a material are to be considered. For example, glacial acetic acid is classified as both a Class II combustible liquid and a corrosive liquid. Thus, for glacial acetic acid, the requirements

for both Class II combustible liquids and corrosive liquids must be met. This section restates the conditions found in Section 5001.1.

**2701.4 Existing buildings and existing fabrication areas.** Existing buildings and existing *fabrication areas* shall comply with this chapter, except that transportation and handling of HPM in *corridors* and enclosures for stairways and ramps shall be allowed where in compliance with Section 2705.3.2 and the *International Building Code*.

❖ Although the adoption and enforcement of code requirements specifically addressing semiconductor manufacturing and similar research and development operations have been in place for over 20 years, there are still some facilities that predate the adoption of regulations specific to these operations. This section requires modifications to existing facilities to comply with certain provisions of IBC Section 415.11. Additionally, requirements found in Section 2705.3.2 of this code and Section 415.11.3 of the IBC must be met when existing conditions or modifications do not include service corridors and existing exit access corridors that are used to transport hazardous production materials (HPM) to fabrication areas.

**2701.5 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. The process also notifies the fire department of the need for prefire planning for the hazardous property. See the commentary to Section 105.6 for a

general discussion of operations requiring an operational permit; notably Section 105.6.21 for a discussion of specific quantity-based hazardous materials operational permits; and Section 105.6.22 for HPM operational permits.

**SECTION 2702  
DEFINITIONS**

**2702.1 Definitions.** The following terms are defined in Chapter 2:

**CONTINUOUS GAS DETECTION SYSTEM.**

**EMERGENCY CONTROL STATION.**

**FABRICATION AREA.**

**HAZARDOUS PRODUCTION MATERIAL (HPM).**

**HPM ROOM.**

**PASS-THROUGH.**

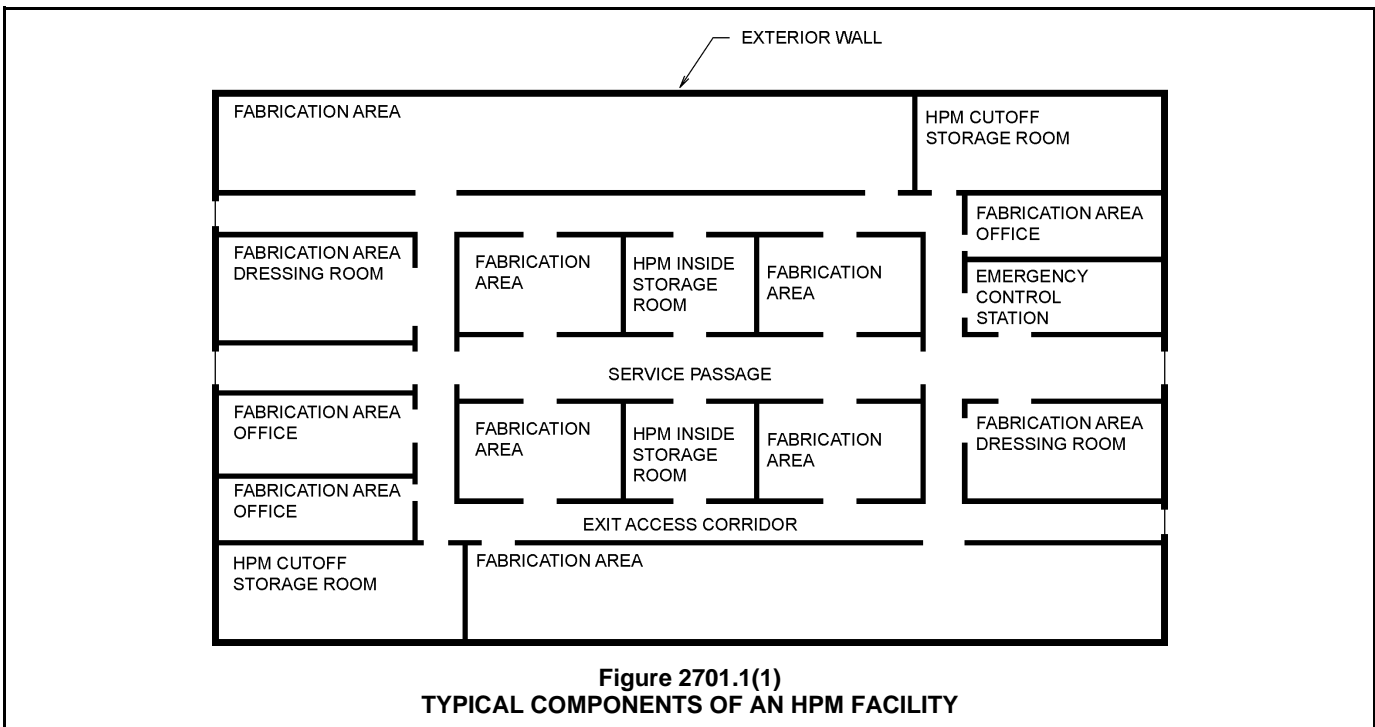

**SEMICONDUCTOR FABRICATION FACILITY.**

**SERVICE CORRIDOR.**

**TOOL.**

**WORKSTATION.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

**Figure 2701.1(1)  
TYPICAL COMPONENTS OF AN HPM FACILITY**

MATERIAL	DESCRIPTION OR USE	NFPA 704 HAZARD CLASSIFICATION			
		Health	Flammability	Reactivity	Other
Acetic acid	Corrosive liquid used for wet etching (metal)	2	2	1	
Acetone	Flammable liquid used for wafer cleaning	1	3	0	
Ammonium fluoride	Corrosive for wet etching (oxide)	3	0	0	
Arsenic trichloride	Diffusion	3	0	1	W
Arsenic trioxide	Diffusion	4	0	0	
Arsine	Poison flammable gas used for epitaxial growth, diffusion and ion implantation	4	4	3	
Boron tribromide	Corrosive liquid used for diffusion	4	0	3	W
Boron trichloride	Nonflammable corrosive gas used for diffusion	4	0	1	W
Chlorine	Poison gas used for dry etching	3	0	0	OXY
Diborane	Highly reactive flammable gas used for diffusion	3	4	3	W
Dichlorosilane	Flammable liquefied gas used for epitaxial growth	4	4	4	
Gallium	Reactive metal used as a semiconductor crystal material	1	0	3	
Gallium arsenide	Reactive metal salt used as a semiconductor crystal material	3	0	0	
Gallium arsenide phosphide	Reactive metal salt used as a semiconductor crystal material	3	0	0	
Germanium	Reactive metal used as a semiconductor crystal material	0	0	3	
Hydrofluoric acid	Highly corrosive liquid or gas used for wet etching (oxide)	4	0	0	
Hydrogen peroxide <sup>a</sup>	Organic peroxide used for wafer cleaning	2	0	1	OXY
Isopropanol	Flammable liquid used for wafer cleaning	1	3	0	
Methanol	Flammable liquid used for wafer cleaning	1	3	0	
Nitric acid	Corrosive liquid used for wet etching (metal)	3	0	0	OXY
Oxygen (liquid)	Oxidizing gas used for oxidation	3	0	0	OXY
Phosphine	Flammable liquefied poison gas used for diffusion and ion implantation	4	4	4	
Phosphoric acid	Corrosive liquid used for wet etching (metal)	2	0	0	
Phosphorus oxychloride	Corrosive liquid used for diffusion	4	0	3	W
Phosphorus pentoxide	Corrosive solid sublimed for use in diffusion	4	0	3	W
Phosphorus tribromide	Corrosive liquid used for diffusion	4	0	3	W
Silane	Pyrophoric gas used for oxidation	2	4	4	
Silicon	Flammable solid (metal) used as a semiconductor crystal material	2	4	2	W
1, 1, 1-Trichloroethane	Mildly flammable solvent (difficult to ignite) used for wafer cleaning	2	1	0	
Tetrachlorosilane	Flammable liquid used for epitaxial growth	3	4	2	W

a. NFPA 704 values for 35 to 52 percent by weight (the most concentration) are listed. The reactivity hazard increases to 3 at concentrations above 52 percent.

**Figure 2701.1(2)**  
**HAZARDOUS PRODUCTION MATERIALS (HPM) USED IN THE MANUFACTURE OF SEMICONDUCTORS**

## SECTION 2703 GENERAL SAFETY PROVISIONS

**2703.1 Emergency control station.** An *emergency control station* shall be provided in accordance with Sections 2703.1.1 through 2703.1.3.

❖ This section introduces the requirements for emergency control stations in HPM facilities.

**2703.1.1 Location.** The *emergency control station* shall be located on the premises at an *approved* location outside the fabrication area.

❖ In order to enhance its operational integrity, the emergency control station must not be located in an area where hazardous materials are stored, used or transported, such as a fabrication area.

**2703.1.2 Staffing.** Trained personnel shall continuously staff the *emergency control station*.

❖ If an emergency control station is to be effective, continuous staffing must be provided. Those personnel must be conversant with the meaning of and proper response protocols for all system signals received in the station, and be able to implement prompt responsive actions.

**2703.1.3 Signals.** The *emergency control station* shall receive signals from emergency equipment and alarm and detection systems. Such emergency equipment and alarm and detection systems shall include, but not be limited to, the following where such equipment or systems are required to be provided either in this chapter or elsewhere in this code:

1. *Automatic sprinkler system* alarm and monitoring systems.
2. Manual fire alarm systems.
3. Emergency alarm systems.
4. Continuous gas detection systems.
5. Smoke detection systems.
6. Emergency power system.
7. Automatic detection and alarm systems for pyrophoric liquids and Class 3 water-reactive liquids required by Section 2705.2.3.4.
8. Exhaust ventilation flow alarm devices for pyrophoric liquids and Class 3 water-reactive liquids cabinet exhaust ventilation systems required by Section 2705.2.3.4.

❖ This section specifies the systems that are to be monitored by an emergency control station. The fire alarm system signals are received at the emergency control station, which must be located in an area approved by the fire code official. See also the commentary to the Section 202 definition of "Emergency control station."

**2703.2 Systems, equipment and processes.** Systems, equipment and processes shall be in accordance with Sections 2703.2.1 through 2703.2.3.2.

❖ This section introduces and establishes the applicability of the provisions of Section 2703.2.1 through

2703.2.3.2 to HPM systems, equipment and processes.

**2703.2.1 Application.** Systems, equipment and processes shall include, but not be limited to, containers, cylinders, tanks, piping, tubing, valves and fittings.

❖ This section clarifies the applicability of Section 2703.2 by defining what is included in the terms "systems," "equipment" and "processes" as they are used in this section.

**2703.2.2 General requirements.** In addition to the requirements in Section 2703.2, systems, equipment and processes shall also comply with Section 5003.2, other applicable provisions of this code, the *International Building Code* and the *International Mechanical Code*.

❖ This section contains a general reference to the IBC and the *International Mechanical Code*® (IMC®), as well as to Section 5003.2 and other sections of the code for regulations pertaining to hazardous materials-related systems, equipment and processes. Except as addressed in Section 2703.2.3, the requirements of the code for things such as containers, cylinders, tanks, piping, tubing, valves and fittings in Group H-5 occupancy facilities are basically the same as they are for other occupancies.

**2703.2.3 Additional requirements for HPM supply piping.** In addition to the requirements in Section 2703.2, HPM supply piping and tubing for HPM gases and liquids shall comply with this section.

❖ This section introduces the additional requirements of Sections 2703.2.3.1 and 2703.2.3.2, which are applicable to HPM supply piping due to the nature of the materials it transports.

**2703.2.3.1 General requirements.** The requirements set forth in Section 5003.2.2.2 shall apply to supply piping and tubing for HPM gases and liquids.

❖ The additional requirements for supply piping and tubing transferring HPM gases or liquids include the general requirements established in Section 5003.2.2.2, as well as more specific requirements for supply piping or tubing containing HPM gases or liquids having a health-hazard ranking of 3 or 4 found in Section 2703.2.3.2.

**2703.2.3.2 Health-hazard ranking 3 or 4 HPM.** Supply piping and tubing for HPM gases and liquids having a health-hazard ranking of 3 or 4 shall be welded throughout, except for connections located within a ventilation enclosure if the material is a gas, or an *approved* method of drainage or containment provided for connections if the material is a liquid.

❖ The primary purpose of the more specific requirements for supply piping or tubing containing a health-hazard ranking of 3 or 4 is to minimize the potential for HPM leakage. The use of mechanical compression-type fittings or other nonwelded joints for these materials is intended to be limited to areas where liquid leaks will be contained or drained, and gas leaks will be contained or exhausted.

**2703.3 Construction requirements.** Construction of semiconductor fabrication facilities shall be in accordance with Sections 2703.3.1 through 2703.3.9.

- ❖ This section contains references to the various construction requirements affecting the components of a semiconductor fabrication facility.

**2703.3.1 Fabrication areas.** Construction and location of fabrication areas shall comply with the *International Building Code*.

- ❖ Semiconductors are manufactured to specific standards. Current high-speed computers require highly sophisticated microprocessors, which rely on extremely fine electrical pathways to transmit the impulses forming the basis for their operation. A single particle of dust that is only a fraction of a micron in diameter may destroy a microprocessor by clogging one of these electronic arteries. Specially designed enclosures called “clean rooms” must be used for fabricating these products to protect the finished product during assembly. Commentary Figure 2703.3.1 illustrates various classifications used to describe the degree of cleanliness in a clean room. Environmental particulates inside the clean room are controlled by filtering all air entering the room through special high-efficiency particulate air (HEPA) filters and constantly replacing the air inside the room.

Fabrication areas are portions of an HPM area where semiconductors are actually produced. The circuit pattern is etched on the surface of the semiconductor crystal material during fabrication. Successive layers of etched semiconductor material are assembled to create integrated circuits or microchips. Fabrication is done in clean rooms, which derive their name from the ability of mechanical ventilation systems to maintain an environment nearly free of airborne particulate contamination. As a result, clean rooms are classified according to the number of particles in a cubic foot of air. For example, in a Class 10 clean room, mechanical ventilation is capable of removing all but 10 particles per cubic foot from the air in the room. The extraordinary precision required in the manufacture of semiconductors demands such cleanliness.

A fire in such an environment represents not only a life and property hazard, but also a serious contamination concern. The monetary value of semiconductors is of secondary concern when compared to the value of lost production time during recovery from a fire or other emergency. Such losses may extend into the millions of dollars from even very small fires. IBC Section 415.11 specifies requirements for the fabrication of areas to control these hazards. The requirements of this chapter are intended to complement and maintain compliance with the requirements of IBC Section 415.11.

**2703.3.2 Pass-throughs in exit access corridors.** Pass-throughs in *exit access corridors* shall be constructed in accordance with the *International Building Code*.

- ❖ Pass-throughs in exit access corridor walls must be constructed to maintain the integrity of any required fire-resistance rating of such walls in an HPM facility. Pass-through doors must also function to maintain that integrity. The IBC contains construction requirements for exit access corridor walls and their opening protectives in Chapter 10 (see also the commentary to the Section 202 definition of “Pass-through”).

**2703.3.3 Liquid storage rooms.** Liquid storage rooms shall comply with Chapter 57 and the *International Building Code*.

- ❖ Liquid storage rooms are used to store closed containers of flammable or combustible liquids used in the HPM processes. Section 5704.3.7 contains detailed requirements for these rooms (see also the commentary to the Section 202 definition of “Liquid storage room”).

**2703.3.4 HPM rooms.** HPM rooms shall comply with the *International Building Code*.

- ❖ Proper storage of hazardous materials can reduce the danger associated with those materials. Section 2704.3 establishes that adequate separation must be provided between materials and limits the quantity of materials stored in HPM rooms. This section requires that the separation of HPM storage rooms must comply with IBC Section 415.11 (see also the commentary to the Section 202 definition of “HPM room”).

Class	Measured Particle Size (Microns)				
	0.1	0.2	0.3	0.5	0.5
1	35	7.5	3	1	—
10	350	7.5	30	10	—
100	—	750	300	100	—
1,000	—	—	—	1,000	7
10,000	—	—	—	10,000	70
100,000	—	—	—	100,000	700

**Figure 2703.3.1  
CLEAN ROOM CLASSIFICATIONS**

**2703.3.5 Gas cabinets.** Gas cabinets shall comply with Section 5003.8.6.

- ❖ To reduce the hazards presented by gases used in the fabrication of semiconductors, Section 5003.8.6 contains specific construction and ventilation requirements for enclosed gas cabinets used for the storage of HPM gases (see also the commentary to the Section 202 definition of “Gas cabinet”).

**2703.3.6 Exhausted enclosures.** Exhausted enclosures shall comply with Section 5003.8.5.

- ❖ To reduce the hazards presented by hazardous materials used in the fabrication of semiconductors, Section 5003.8.5 contains specific construction and ventilation requirements for exhausted enclosures used for the storage of HPM. Whereas gas cabinets must be fully enclosed and equipped with self-closing doors, exhausted enclosures are typically open-fronted and lend themselves to small-scale operations, such as fume hoods found in chemical laboratories (see also the commentary to the Section 202 definition of “Exhausted enclosure”).

**2703.3.7 Gas rooms.** Gas rooms shall comply with Section 5003.8.4.

- ❖ To reduce the hazards presented by hazardous gases used in the fabrication of semiconductors, Section 5003.8.4 contains specific construction and ventilation requirements for gas rooms used for the storage of HPM gases. These rooms are intended to be restricted to the storage of cylinders and tanks of highly toxic and toxic compressed gases. The storage of other hazardous materials, such as flammable and combustible liquids, is not permitted within a gas room. Similar to gas cabinets, the required exhaust ventilation for the gas room must be operated at negative pressures to prevent leakage of hazardous vapors to adjacent areas.

**2703.3.8 Service corridors.** Service corridors shall comply with Section 2705.3 and the *International Building Code*.

- ❖ The likelihood of accidental spillage or contact with HPM is increased during the transportation of such materials. Section 2705.3 regulates materials, handling and transportation in passageways used for purposes other than required means of egress.

**2703.3.9 Cabinets containing pyrophoric liquids or water-reactive Class 3 liquids.** Cabinets in *fabrication areas* containing pyrophoric liquids or Class 3 water-reactive liquids in containers or in amounts greater than  $\frac{1}{2}$  gallon (2 L) shall comply with Section 2705.2.3.4.

- ❖ See the commentary to Section 2705.2.3.4.

**2703.4 Emergency plan.** An emergency plan shall be established as set forth in Section 403.7.1.

- ❖ Thorough planning is essential to evacuate personnel effectively and to combat a fire or other emergency. Risks associated with a structure containing HPM require extraordinary efforts regarding evacuation

and fire control. Specific emergency planning procedures are outlined in Section 403.7.1.

**2703.5 Maintenance of equipment, machinery and processes.** Maintenance of equipment, machinery and processes shall comply with Section 5003.2.6.

- ❖ Fundamental to the safe operation of an HPM facility are the care and maintenance of the equipment used in the various fabrication processes. Section 5003.2.6 contains detailed maintenance requirements.

**2703.6 Security of areas.** Areas shall be secured in accordance with Section 5003.9.2.

- ❖ Public safety requires that HPM facilities be secure against unauthorized entry in accordance with Section 5003.9.2. Such security reduces the likelihood of hazardous material release or fire caused by a malicious act.

**2703.7 Electrical wiring and equipment.** Electrical wiring and equipment in HPM facilities shall comply with Sections 2703.7.1 through 2703.7.3.

- ❖ The safety and integrity of electrical wiring and equipment is a key factor in workplace safety. This section introduces the electrical safety requirements, by area, for HPM facility fabrication areas, workstations and storage rooms.

**2703.7.1 Fabrication areas.** Electrical wiring and equipment in *fabrication areas* shall comply with NFPA 70.

- ❖ NFPA 70 contains requirements for the electrical safety of HPM facilities, including fabrication areas.

**2703.7.2 Workstations.** Electrical equipment and devices within 5 feet (1524 mm) of workstations in which flammable or pyrophoric gases or flammable liquids are used shall comply with NFPA 70 for Class I, Division 2 hazardous locations. Workstations shall not be energized without adequate exhaust ventilation in accordance with Section 2703.14.

**Exception:** Class I, Division 2 hazardous electrical equipment is not required where the air removal from the workstation or dilution will prevent the accumulation of flammable vapors and fumes on a continuous basis.

- ❖ Areas located in and around workstations are considered Class I, Division 2, hazardous locations as defined by Article 500 of NFPA 70. Incidental exposures to flammable fumes or vapors must be considered horizontally possible within 5 feet (1524 mm) of each workstation where flammable liquids or gases are used. Either a mechanical or electrical interlock must be installed to engage the required exhaust ventilation system before HPM enters the workstation. This reduces the likelihood of gas or vapor exposure.

The exception in this section states that, in some cases, it is both possible and reasonable to assume that a hazardous concentration of flammable gas or vapor is unlikely to occur when ventilation is properly engaged. Class I, Division 2, electrical wiring and equipment is not required where automatic exhaust interlocks are installed.

**2703.7.3 Hazardous production material (HPM) rooms, gas rooms and liquid storage rooms.** Electrical wiring and equipment in HPM rooms, gas rooms and liquid storage rooms shall comply with NFPA 70.

❖ Electrical wiring, equipment and devices in HPM cut-off rooms used for the storage of flammable liquids or gases must be classified for hazardous locations, in accordance with NFPA 70. The hazardous location requirements in NFPA 70 contain special protection features to preclude ignition of flammable vapors, liquids, gases or dusts by sparks or electrical arcing.

**2703.8 Corridors and enclosures for stairways and ramps.** Hazardous materials shall not be used or stored in *corridors* or enclosures for stairways and ramps.

❖ Because corridors leading to enclosures for stairways and ramps are critical to the safe egress and life safety of personnel, this section prohibits the storage or use of HPM within them. This is consistent with Sections 1022.1 and 1023.1, which prohibit the use of an exit for any purpose other than the egress function.

**2703.9 Service corridors.** Hazardous materials shall not be used in an open-system use condition in service corridors.

❖ HPM dispensing, or the open use or open transfer of HPM from original shipping containers to secondary containers, must not be performed in service corridors in order to reduce the likelihood of liberating dangerous vapors or fumes that might be difficult to mitigate.

**2703.10 Automatic sprinkler system.** An *approved automatic sprinkler system* shall be provided in accordance with Sections 2703.10.1 through 2703.10.5 and Chapter 9.

❖ Sections 2703.10.1 through 2703.10.5 contain specific sprinkler protection design requirements for the various parts and components of an HPM facility. Section 903.2.5.2 requires automatic sprinkler protection throughout HPM facilities and states specific design criteria for various areas of the facility. Fabrication areas, service corridors and inside HPM storage rooms are considered Ordinary Hazard Group 2 and HPM storage rooms with dispensing are classified as Extra Hazard Group 2, in accordance with NFPA 13.

**2703.10.1 Workstations and tools.** The design of the sprinkler system in the area shall take into consideration the spray pattern and the effect on the equipment.

❖ The design of the sprinkler system must consider obstructions to water penetration of workstations and tools and the potential for collateral damage to equipment from sprinkler discharge that could delay a return to normal operations.

**2703.10.1.1 Combustible workstations.** A sprinkler head shall be installed within each branch exhaust connection or individual plenums of workstations of combustible construction. The sprinkler head in the exhaust connection or plenum shall be located not more than 2 feet (610 mm) from the point

of the duct connection or the connection to the plenum. Where necessary to prevent corrosion, the sprinkler head and connecting piping in the duct shall be coated with *approved* or *listed* corrosion-resistant materials. The sprinkler head shall be accessible for periodic inspection.

**Exceptions:**

1. *Approved* alternative automatic fire-extinguishing systems are allowed. Activation of such systems shall deactivate the related processing equipment.
2. Process equipment that operates at temperatures exceeding 932°F (500°C) and is provided with automatic shutdown capabilities for hazardous materials.
3. Exhaust ducts 10 inches (254 mm) or less in diameter from flammable gas storage cabinets that are part of a workstation.
4. Ducts *listed* or *approved* for use without internal automatic sprinkler protection.

❖ Generally, workstations are constructed of noncombustible materials. Wet benches and machines handling certain corrosives may have substantial nonmetallic components or surfaces. Notwithstanding the requirements of Sections 2703.10.4.1 and 2703.10.4.2, an automatic sprinkler must be installed within 2 feet (610 mm) of where the exhaust duct connects to a workstation of combustible construction. It is reasonable to require the installation of a corrosion-resistant sprinkler, in accordance with NFPA 13, and the application of a corrosion-resistant pipe coating because combustible (nonmetallic) parts are commonly used as a result of corrosion concerns. The duct must be accessible to permit regular periodic inspection and maintenance. (Note: corrosion-resistant sprinklers require periodic replacement despite their ability to withstand severe exposures.)

Many fire protection engineers prefer the use of listed special flow control (also called “on-off”) sprinklers or cycling (on-off) sprinkler systems to minimize the effects of water damage from automatic sprinklers. Others prefer preaction systems as a backup to an alternative fire suppression system, including clean agent or carbon dioxide systems.

Exception 1 allows the installation of an alternative, automatic fire-extinguishing system, in accordance with Section 904, instead of automatic sprinklers. The activation of the alternative system must deactivate or deenergize processing equipment in the protected room or space. Deactivation of processing equipment should not affect the operation of required exhaust ventilation.

Exception 2 states that only the HPM flow must be interrupted in processing equipment operating at temperatures greater than 932°F (500°C).

Exception 3 allows gas cabinet exhaust systems associated with and part of workstations to continue to operate after shutdown.

Exception 4 states that automatic sprinklers are not required where the risk to people or property is lim-

ited, such as when nonmetallic ducts approved for installation without sprinklers are used.

**2703.10.1.2 Combustible tools.** Where the horizontal surface of a combustible tool is obstructed from ceiling sprinkler discharge, automatic sprinkler protection that covers the horizontal surface of the tool shall be provided.

**Exceptions:**

1. An automatic gaseous fire-extinguishing local surface application system shall be allowed as an alternative to sprinklers. Gaseous-extinguishing systems shall be actuated by infrared (IR) or ultraviolet/infrared (UV/IR) optical detectors.
  2. Tools constructed of materials that are listed as Class 1 or Class 2 in accordance with UL 2360 or *approved* for use without internal fire-extinguishing system protection.
- ❖ Automatic sprinkler system discharge from ceiling sprinklers that cannot reach the fire because of obstructions below the sprinkler can allow the fire to grow beyond the capability of the system to extinguish or hold the fire's progress in check until help arrives. Where the surface of a combustible tool being used in an HPM process is thus obstructed, a fire could rapidly spread unimpeded in the workstation and overpower the ceiling sprinkler design capability. This section requires that sprinkler protection be installed to properly cover the entire surface of the tool.

Exception 1 allows surface protection to be by installation of a gaseous fire-extinguishing system, such as a clean agent system, if it is activated by the more sensitive infrared (IR) or ultraviolet/infrared (UV/IR) optical detectors (see also the commentary to the Section 202 definition of "Tool").

Exception 2 allows the use of plastics listed as being compliant with UL 2360 in the construction of combustible semiconductor tools in lieu of providing an automatic fire-extinguishing system. UL 2360 provisions are used to evaluate fire testing plastics utilized in the construction of semiconductor tools to determine their fire propagation and smoke development properties. The fire tests are implemented to evaluate two properties:

- The fire propagation index (FPI), which measures the ease of ignitibility of the plastic and its fire propagation characteristics. It is an index representing the propensity of the material to support fire propagation.
- The smoke-development index (SDI), which is a measurement of the amount of smoke generated. It is an indicator of the extent of smoke contamination of the environment during fire propagation.

In UL 2360, the FPI for a listed Class 1 plastic must not exceed  $6 (m/s^{0.5})/(kW/m)^{2/3}$  for fire propagation beyond the ignition zone. This maximum value is based on a 15-second average value of the fire test

data. The SDI of a listed Class 1 plastic must not exceed  $0.40 (m/s^{0.5})/(kW/m)^{2/3}$  as the criterion for significantly limiting smoke concentration for nonpropagating fires beyond the ignition zone. For a Class 1 plastic to be listed, the material requires an FDI of 6 or less and a SDI of 0.4 or less. Listed Class 1 plastics are considered to be nonpropagating materials in UL 2360.

A listed Class 2 plastic means it has been formulated with a resin that limits the propagation of fire and the development of smoke. Class 2 materials are evaluated using a parallel panel fire test. In this test, an 8-foot-long by 2-foot-wide by  $1/4$ -inch (2438 mm by 610 mm by 6.4 mm) sample of the plastic is placed on a load cell and subjected to a 60 kW exposure fire. For a sample to successfully pass this test and obtain a Class 2 listing, it must not have a visual flame height of 6 feet (1829 mm) or more, a thermal flux less than  $40 kW/m^2$ , a limited heat release rate calculated during the time the sample is tested with the flame source operating and 2 minutes after the flame source is discontinued, a smoke generation rate not to exceed 0.23 grams/second or less, and the total smoke generated is less than 60 grams.

Several polymers inherently resistant to fire that produce very little smoke are classified as Class 1 materials in accordance with Exception 2, including chlorinated polyvinyl chloride (CPVC), ethylene-chlorotrifluoro-ethylene (ECTFE), polyvinylidene fluoride (PVDF) and fire-resistant polypropylene (FRPP). According to Factory Mutual (FM) Global, a major insurer of semiconductor fabrication facilities, 17 manufacturers are producing about 150 different polymers that comply with its *Clean Room Materials Flammability Test Protocol* published as FM 4910, which led to the development of UL 2360.

**2703.10.2 Gas cabinets and exhausted enclosures.** An *approved automatic sprinkler system* shall be provided in gas cabinets and exhausted enclosures containing HPM *compressed gases*.

**Exception:** Gas cabinets located in an HPM room other than those cabinets containing pyrophoric gases.

- ❖ Automatic sprinkler protection is required inside HPM storage cabinets, including workstation cabinets, except those storing gases other than pyrophoric gases (silane and dichlorosilane) located inside HPM rooms.

The exception recognizes the equivalency between automatic sprinkler protection and the fire-resistance-rated separation provided by an HPM room, except in cases of extremely hazardous pyrophoric gases.

**2703.10.3 Pass-throughs in existing exit access corridors.** Pass-throughs in existing *exit access corridors* shall be protected by an *approved automatic sprinkler system*.

- ❖ Exit access corridors in new buildings are not to be used for transporting HPM to the fabrication area. In accordance with IBC Section 415.11.1.7, HPM must be transported by service corridors or piping. This

section addresses HPM facilities that existed before the adoption and enforcement of those requirements. The intent of this section is to allow a pass-through in existing exit access corridor walls for transporting HPM to a fabrication area. A pass-through, such as a storage cabinet, is used to store and receive HPM for the fabrication area. The pass-through must be separated from the exit access corridor by fire-resistance-rated construction, including rated self-closing fire doors, and be protected by internal automatic sprinklers.

**2703.10.4 Exhaust ducts for HPM.** An approved automatic sprinkler system shall be provided in exhaust ducts conveying gases, vapors, fumes, mists or dusts generated from HPM in accordance with this section and the *International Mechanical Code*.

❖ Because of the hazardous nature of the materials exhausted in HPM facilities, exhaust systems must comply with the IMC requirements for hazardous exhaust systems, including automatic sprinklers installed within the ducts. Sections 2703.10.4.1 through 2703.10.4.4.5 contain specific requirements for sprinkler installation in these systems.

**2703.10.4.1 Metallic and noncombustible nonmetallic exhaust ducts.** An approved automatic sprinkler system shall be provided in metallic and noncombustible nonmetallic exhaust ducts where all of the following conditions apply:

1. Where the largest cross-sectional diameter is equal to or greater than 10 inches (254 mm).
2. The ducts are within the building.

3. The ducts are conveying flammable gases, vapors or fumes.

❖ Sprinklers are required in each individual duct where all three of the conditions listed in this section exist.

Commentary Figure 2703.10.4.1 illustrates how to measure the cross-sectional diameter of various duct shapes. This section requires the square and rounded ducts to be protected by automatic sprinklers. The round or elliptical ducts depicted on the right side of the diagram do not require protection.

**2703.10.4.2 Combustible nonmetallic exhaust ducts.** An approved automatic sprinkler system shall be provided in combustible nonmetallic exhaust ducts where the largest cross-sectional diameter of the duct is equal to or greater than 10 inches (254 mm).

**Exceptions:**

1. Ducts listed or approved for applications without automatic sprinkler system protection.
2. Ducts not more than 12 feet (3658 mm) in length installed below ceiling level.

❖ Automatic sprinkler protection is required for all combustible nonmetallic ducts with a cross-sectional diameter equal to or greater than 10 inches (254 mm) because of their ability to add a substantial amount of fuel in case of a fire within the duct system.

Exception 1 states that automatic sprinklers are not required where the risk to people or property is limited, such as when nonmetallic ducts approved for installation without sprinklers are used.

Exception 2 states that when ducts do not exceed 12 feet (3658 mm) in length and are installed exposed below ceiling level, sprinklers may be omitted. A fire within such a system would be readily noticeable and readily accessible for fire attack because of the exposed ductwork.

**2703.10.4.3 Exhaust connections and plenums of combustible workstations.** Automatic fire-extinguishing system protection for exhaust connections and plenums of combustible workstations shall comply with Section 2703.10.1.1.

❖ Refer to Section 2703.10.1.1 for sprinkler protection for combustible workstation exhaust connections and plenums.

**2703.10.4.4 Exhaust duct sprinkler system requirements.** Automatic sprinklers installed in exhaust duct systems shall be hydraulically designed to provide 0.5 gallons per minute (gpm) (1.9 L/min) over an area derived by multiplying the distance between the sprinklers in a horizontal duct by the width of the duct. Minimum discharge shall be 20 gpm (76 L/min) per sprinkler from the five hydraulically most remote sprinklers.

❖ This section, including Sections 2703.10.4.4.1 through 2703.10.4.4.5, addresses the design, installation, maintenance and inspection requirements for sprinklers installed in exhaust duct systems. This section specifies the hydraulic design criteria and minimum flow discharged from sprinklers. Parallel provisions may also be found in Section 21.23.1.3 of NFPA 13.

**2703.10.4.4.1 Sprinkler head locations.** Automatic sprinklers shall be installed at 12-foot (3658 mm) intervals in horizontal ducts and at changes in direction. In vertical runs, automatic sprinklers shall be installed at the top and at alternate floor levels.

❖ This section specifies sprinkler spacing in both horizontal and vertical exhaust ducts. The provisions in Section 21.23.2.3 of NFPA 13 differ from these requirements in that the horizontal spacing is indicated as being 20 feet (6096 mm) and the vertical spacing as 12 feet (3658 mm). In accordance with Section 102.7, the provisions of this section would apply.

**2703.10.4.4.2 Control valve.** A separate indicating control valve shall be provided for sprinklers installed in exhaust ducts.

❖ To isolate the sprinklers installed within the exhaust ducts without depriving the building or other facility components of protection, a separate, approved indicating control valve must be installed to serve the duct system only. This valve should be supervised like any other sprinkler control valve.

**2703.10.4.4.3 Drainage.** Drainage shall be provided to remove sprinkler water discharged in exhaust ducts.

❖ To prevent contamination of process equipment by sprinkler discharge water that might flow back down the duct, this section requires that the ducts have

approved drainage facilities. Prompt drainage of sprinkler discharge water also reduces the likelihood of the duct system collapsing from the weight of retained water. Because the water will likely contain residues of the chemicals being exhausted through the ductwork, it must be disposed of in accordance with applicable environmental laws.

**2703.10.4.4.4 Corrosive atmospheres.** Where corrosive atmospheres exist, exhaust duct sprinklers and pipe fittings shall be manufactured of corrosion-resistant materials or coated with *approved* materials.

❖ Corrosion-resistant sprinklers, piping and fittings must be installed in exhaust ducts conveying corrosive vapors, fumes, mists or dusts to increase the likelihood that the sprinklers will be operable when needed. This is also critical since such sprinklers are concealed and not readily operable by building occupants.

**2703.10.4.4.5 Maintenance and inspection.** Sprinklers in exhaust ducts shall be accessible for periodic inspection and maintenance.

❖ Access panels must be installed in exhaust ducts for inspection and maintenance of sprinklers.

**2703.10.5 Sprinkler alarms and supervision.** *Automatic sprinkler systems* shall be electrically supervised and provided with alarms in accordance with Chapter 9. *Automatic sprinkler system* alarm and supervisory signals shall be transmitted to the *emergency control station*.

❖ Automatic sprinkler systems must be electrically supervised and have alarms installed, in accordance with Section 903.4. The system alarm and supervisory signals should be transmitted to the on-site emergency control station. See Section 202 for the definition of, and Section 2703.1 for the conditions and requirements applicable to, "Emergency control stations."

**2703.11 Manual fire alarm system.** A manual fire alarm system shall be installed throughout buildings containing a Group H-5 occupancy. Activation of the alarm system shall initiate a local alarm and transmit a signal to the *emergency control station*. Manual fire alarm systems shall be designed and installed in accordance with Section 907.

❖ A manual fire alarm system, designed and installed as specified in Section 907.2, must be installed throughout buildings containing a Group H-5 occupancy. System activation is to set off a local alarm, with the alarm signal transmitted to the on-site emergency control station. Note that the local alarm signal is intended only for the area of alarm origin and is not intended to be a general alarm that sounds throughout the building. Refer to the commentary to Chapter 9 for manual fire alarm system requirements. Note that this section correlates with IBC Section 415.11.8.

**2703.12 Emergency alarm system.** Emergency alarm systems shall be provided in accordance with Sections 2703.12.1 through 2703.12.3, Section 5004.9 and Section 5005.4.4. The

*maximum allowable quantity per control area* provisions of Section 5004.1 shall not apply to emergency alarm systems required for HPM.

❖ This section requires an emergency alarm system in all areas where HPM is transported or stored. It also clarifies that the requirement for an emergency alarm system in a Group H-5 facility in the locations identified in Sections 2703.12.1 through 2703.12.1.3 is not dependent on whether the MAQs of Section 5004.1 are exceeded. Emergency alarm systems must comply with Section 908.

**2703.12.1 Where required.** Emergency alarm systems shall be provided in the areas indicated in Sections 2703.12.1.1 through 2703.12.1.3.

❖ This section states that emergency alarm systems must be installed in the locations defined in Sections 2703.12.1.1 through 2703.12.1.3.

**2703.12.1.1 Service corridors.** An *approved* emergency alarm system shall be provided in service corridors, with not less than one alarm device in the service corridor.

❖ An emergency telephone system or manual alarm pull station that is readily accessible to personnel is required in service corridors. These devices must set off an alarm at the emergency control station, as well as activate a local audible signal.

**2703.12.1.2 Corridors and interior exit stairways and ramps.** Emergency alarms for corridors, interior exit stairways and ramps and exit passageways shall comply with Section 5005.4.4.

❖ Because HPM materials would not be in corridors or interior exit stairways, ramps or passageways unless they were being transported to another approved area, the emergency alarm requirements of Section 5005.4.4 for dispensing, use and handling must be complied with.

**2703.12.1.3 Liquid storage rooms, HPM rooms and gas rooms.** Emergency alarms for liquid storage rooms, HPM rooms and gas rooms shall comply with Section 5004.9.

❖ This section mandates compliance with the emergency alarm requirements of Section 5004.9 for hazardous materials in a storage condition. This section addresses storage areas that, by their designation, contain HPM in quantities greater than those listed in Table 5003.1.1(1) or 5003.1.1(2).

**2703.12.2 Alarm-initiating devices.** An *approved* emergency telephone system, local alarm manual pull stations, or other *approved* alarm-initiating devices are allowed to be used as emergency alarm-initiating devices.

❖ This section classifies what constitutes an approved alarm-initiating device, affording maximum design flexibility.

**2703.12.3 Alarm signals.** Activation of the emergency alarm system shall sound a local alarm and transmit a signal to the *emergency control station*.

❖ The alarm signal must be transmitted to the emergency control station to notify trained personnel of an emergency condition. A local alarm is required to alert the occupants of a potential hazardous condition.

**2703.13 Continuous gas detection systems.** A continuous gas detection system shall be provided for HPM gases where the physiological warning threshold level of the gas is at a higher level than the accepted permissible exposure limit (PEL) for the gas and for flammable gases in accordance with Sections 2703.13.1 through 2703.13.2.2.

❖ A gas detection system in the room or area used for the storage or use of HPM gases provides early notification of a leak before the escaping gas reaches hazardous concentration levels.

**2703.13.1 Where required.** A continuous gas detection system shall be provided in the areas identified in Sections 2703.13.1.1 through 2703.13.1.4.

❖ Sections 2703.13.1.1 through 2703.13.1.4 prescribe the locations in a Group H-5 facility where a gas detection system is required.

**2703.13.1.1 Fabrication areas.** A continuous gas detection system shall be provided in *fabrication areas* where gas is used in the fabrication area.

❖ Fabrication areas that use HPM gases must have a gas detection system. It should be noted that gas detection is often installed in workstations as a means of early detection of leaks. Such detection is generally not acceptable as an alternative to gas detection for the fabrication area because a leak may occur at locations that are remote from the workstation.

**2703.13.1.2 HPM rooms.** A continuous gas detection system shall be provided in HPM rooms where gas is used in the room.

❖ HPM rooms where gas is used, which by definition contain more than the MAQs permitted by Tables 5003.1.1(1) and 5003.1.1(2), are required to have a gas detection system.

**2703.13.1.3 Gas cabinets, exhausted enclosures and gas rooms.** A continuous gas detection system shall be provided in gas cabinets and exhausted enclosures. A continuous gas detection system shall be provided in gas rooms where gases are not located in gas cabinets or exhausted enclosures.

❖ In the potential event of a leaking cylinder of a hazardous gas, gas cabinets, exhausted enclosures and gas rooms must have a gas detection system.

**2703.13.1.4 Corridors.** Where gases are transported in piping placed within the space defined by the walls of a *corridor* and the floor or roof above the *corridor*, a continuous gas detection system shall be provided where piping is located and in the *corridor*.

**Exception:** A continuous gas detection system is not required for occasional transverse crossings of the *corridors* by supply piping that is enclosed in a ferrous pipe or tube for the width of the *corridor*.

- ❖ The installation of HPM piping in the space above an exit access corridor, as well as the cavity of the egress corridor wall, presents a potential source of hazard to the building's occupants; therefore, a gas detection system is required for early notification of a potential leak of an HPM gas.

The exception recognizes that when the piping traverses a corridor, the use of an outer-jacket containment pipe around the HPM piping is considered acceptable for the required separation and containment of a potential leak. The assumption is that the open ends of that pipe are in an HPM facility and, therefore, a leak into the outer casing can be monitored. If the adjacent areas that contain the open ends are not in an HPM facility, the "outer-jacket" method cannot be used.

**2703.13.2 Gas detection system operation.** The continuous gas detection system shall be capable of monitoring the room, area or equipment in which the gas is located at or below all the following gas concentrations:

1. Immediately dangerous to life and health (IDLH) values where the monitoring point is within an exhausted enclosure, ventilated enclosure or gas cabinet.
  2. Permissible exposure limit (PEL) levels where the monitoring point is in an area outside an exhausted enclosure, ventilated enclosure or gas cabinet.
  3. For flammable gases, the monitoring detection threshold level shall be vapor concentrations in excess of 25 percent of the lower flammable limit (LFL) where the monitoring is within or outside an exhausted enclosure, ventilated enclosure or gas cabinet.
  4. Except as noted in this section, monitoring for highly toxic and toxic gases shall also comply with Chapter 60.
- ❖ This section harmonizes the code with the widely used clean-room standard NFPA 318 provisions for gas detection, which are much more relevant to the type of monitoring performed in semiconductor manufacturing (inside exhausted enclosures, ventilated enclosures or gas cabinets). Monitoring in the semiconductor industry is designed to detect and alert employees of leaks inside exhausted enclosures, ventilated enclosures and gas cabinets, and is not intended to estimate potential employee breathing zone exposures.

This section requires gas detection based on the potential for health-threatening levels both inside

enclosures and in the employee environment as established by nationally accepted health standards, such as those used by the Occupational Safety and Health Administration (OSHA). The permissible exposure limit (PEL) of a gas is the legal limitation for long-term exposure (8 to 10 hours, normally). The American Conference of Governmental Industrial Hygienists (ACGIH) publishes threshold limit values (TLVs) based on a time-weighted average. State and local laws may also contain limits.

Additionally, flammable gas detection must be installed where dispensing that may result in vapor concentrations in excess of 25 percent of the lower explosive limit (LEL) occurs, as is consistent with IMC Section 510.2 and NFPA 318. LELs can be obtained from suppliers or other printed sources, such as the NFPA *Fire Protection Guide to Hazardous Materials*. Chapter 60 contains additional requirements for monitoring highly toxic and toxic compressed gases.

**2703.13.2.1 Alarms.** The gas detection system shall initiate a local alarm and transmit a signal to the *emergency control station* when a short-term hazard condition is detected. The alarm shall be both visible and audible and shall provide warning both inside and outside the area where the gas is detected. The audible alarm shall be distinct from all other alarms.

- ❖ The required local alarm is intended to alert occupants to a hazardous condition in the vicinity of HPM gas storage or use. The alarm is not intended to be an evacuation alarm; however, it must be monitored to hasten emergency personnel response.

**2703.13.2.2 Shut off of gas supply.** The gas detection system shall automatically close the shutoff valve at the source on gas supply piping and tubing related to the system being monitored for which gas is detected when a short-term hazard condition is detected. Automatic closure of shutoff valves shall comply with the following:

1. Where the gas-detection sampling point initiating the gas detection system alarm is within a gas cabinet or exhausted enclosure, the shutoff valve in the gas cabinet or exhausted enclosure for the specific gas detected shall automatically close.
2. Where the gas-detection sampling point initiating the gas detection system alarm is within a room and *compressed gas* containers are not in gas cabinets or exhausted enclosure, the shutoff valves on all gas lines for the specific gas detected shall automatically close.
3. Where the gas-detection sampling point initiating the gas detection system alarm is within a piping distribution manifold enclosure, the shutoff valve supplying the manifold for the *compressed gas* container of the specific gas detected shall automatically close.

**Exception:** Where the gas-detection sampling point initiating the gas detection system alarm is at the use location or within a gas valve enclosure of a branch line downstream of a piping distribution manifold,

the shutoff valve for the branch line located in the piping distribution manifold enclosure shall automatically close.

- ❖ Where gas detection systems are required, automatic emergency shutoff valves are required to stop the flow of hazardous materials from possibly deteriorating further in an emergency.

There are essentially four different protocols for shutting off valves, depending on the source of the leak. Note that one of these methods is located within the exception. It should be emphasized that the requirements are to shut off the valves only when the type of gas is detected.

**2703.14 Exhaust ventilation systems for HPM.** Exhaust ventilation systems and materials for exhaust ducts utilized for the exhaust of HPM shall comply with Sections 2703.14.1 through 2703.14.3, other applicable provisions of this code, the *International Building Code* and the *International Mechanical Code*.

- ❖ This section is a summary of the ventilation requirements for semiconductor facilities, and references the IBC and IMC for further requirements. Parallel requirements may be found in IMC Section 502.10.

**2703.14.1 Where required.** Exhaust ventilation systems shall be provided in the following locations in accordance with the requirements of this section and the *International Building Code*:

1. *Fabrication areas:* Exhaust ventilation for *fabrication areas* shall comply with the *International Building Code*. The *fire code official* is authorized to require additional manual control switches.
2. *Workstations:* A ventilation system shall be provided to capture and exhaust gases, fumes and vapors at workstations.
3. *Liquid storage rooms:* Exhaust ventilation for liquid storage rooms shall comply with Section 5004.3.1 and the *International Building Code*.
4. *HPM rooms:* Exhaust ventilation for HPM rooms shall comply with Section 5004.3.1 and the *International Building Code*.
5. *Gas cabinets:* Exhaust ventilation for gas cabinets shall comply with Section 5003.8.6.2. The gas cabinet ventilation system is allowed to connect to a workstation ventilation system. Exhaust ventilation for gas cabinets containing highly toxic or toxic gases shall also comply with Chapter 60.
6. *Exhausted enclosures:* Exhaust ventilation for exhausted enclosures shall comply with Section 5003.8.5.2. Exhaust ventilation for exhausted enclosures containing highly toxic or toxic gases shall also comply with Chapter 60.
7. *Gas rooms:* Exhaust ventilation for gas rooms shall comply with Section 5003.8.4.2. Exhaust ventilation

for gas rooms containing highly toxic or toxic gases shall also comply with Chapter 60.

8. *Cabinets containing pyrophoric liquids or Class 3 water-reactive liquids:* Exhaust ventilation for cabinets in *fabrication areas* containing pyrophoric liquids or Class 3 water-reactive liquids shall be as required in Section 2705.2.3.4.

- ❖ Items 1 through 8 list the specific ventilation requirements for semiconductor facilities based on the use of the particular area. Many of these requirements are references to other sections of the code. These are essentially the same requirements found in IMC Section 502.10 (see commentary, Section 2705.2.3.5).

Item 1 requires that fabrication areas must be ventilated as stated in the IBC. This item also gives the fire code official the authority to require additional manual control switches where facility arrangements make the additional switches necessary. Item 2 requires that workstations, typically found in each fabrication area, must have individual exhaust systems to collect any exhaust fumes and vapors. In Item 3, liquid storage rooms in semiconductor facilities are to be treated the same as other liquid storage rooms and ventilated according to the general requirements for hazardous materials found in Section 5004.3.1. Item 4 requires that HPM rooms, which are essentially a Group H-2, H-3 or H-4 occupancy, must be ventilated in the same way as any Group H-2, H-3 or H-4 occupancy would be ventilated, in accordance with Section 5004.3.1. Item 5 states that gas cabinets used in semiconductor facilities are to be treated the same as any other use of gas cabinets with hazardous materials. Gas cabinets can share the exhaust system of an individual workstation. Also, semiconductor facilities tend to make use of both toxic and highly toxic gases; therefore, additional requirements are specifically highlighted for these applications. Items 6 and 7 indicate that exhausted enclosures and gas rooms, respectively, are also regulated just as they are for other applications with hazardous materials. As with gas cabinets, semiconductor facilities tend to make use of both toxic and highly toxic gases; therefore, additional requirements are also specifically highlighted for those applications. Item 8 highlights the increased hazards of pyrophoric liquids and Class 3 water-reactive materials by requiring exhaust ventilation in fabrication area cabinets storing those materials to comply with the special requirements of Section 2705.2.3.4. See the commentary to Section 2705.2.3.4 for further discussion of pyrophoric and water-reactive materials.

**2703.14.2 Penetrations.** Exhaust ducts penetrating *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed

in accordance with Section 711 of the *International Building Code* shall be contained in a shaft of equivalent fire-resistance-rated construction. Exhaust ducts shall not penetrate *fire walls*. Fire dampers shall not be installed in exhaust ducts.

❖ Semiconductor facilities are essentially a combination of many activities involving the storage and use of hazardous materials. These facilities are large and generally complex, and exhaust systems may lead through several areas of a building before the exhaust is processed or released to the atmosphere. This section requires that the protection surrounding an exhaust system is at least equivalent to the fire-resistance rating of the surrounding fire barriers and horizontal assemblies. Ventilation should not be interrupted by a fire damper when a fire or other emergency occurs involving a workstation. This helps reduce the likelihood that hazardous combustion byproducts or hazardous concentrations of HPM will be forced back into the workstation or clean room. Continuous ventilation through a duct enclosed in a fire-resistance-rated shaft is required. Fire walls define separations between buildings. Ducts must never penetrate a barrier common to another building. This reduces the likelihood of tampering with or interrupting the duct integrity.

**2703.14.3 Treatment systems.** Treatment systems for highly toxic and toxic gases shall comply with Chapter 60.

❖ Because of their toxicity hazards, highly toxic and toxic gases should be protected by gas treatment systems. See the commentary to Section 3704 on highly toxic and toxic gases and, in particular, Section 3704.2.2.7 for further discussion of treatment systems.

**2703.15 Emergency power system.** An emergency power system shall be provided in Group H-5 occupancies in accordance with Section 604. The emergency power system shall supply power automatically to the electrical systems specified in Section 2703.15.1 when the normal supply system is interrupted.

❖ A backup emergency power source is considered essential for systems monitoring and protecting hazardous materials in a Group H-5 occupancy. Without an emergency power system, all required electrical controls or equipment monitoring hazardous materials would be rendered inoperative if a power failure or other electrical system failure were to occur. See also the commentary to Section 604.

**2703.15.1 Required electrical systems.** Emergency power shall be provided for electrically operated equipment and connected control circuits for the following systems:

1. HPM exhaust ventilation systems.
2. HPM gas cabinet ventilation systems.
3. HPM exhausted enclosure ventilation systems.
4. HPM gas room ventilation systems.
5. HPM gas detection systems.

6. Emergency alarm systems.
7. Manual fire alarm systems.
8. *Automatic sprinkler system* monitoring and alarm systems.
9. Automatic alarm and detection systems for pyrophoric liquids and Class 3 water-reactive liquids required in Section 2705.2.3.4.
10. Flow alarm switches for pyrophoric liquids and Class 3 water-reactive liquids cabinet exhaust ventilation systems required in Section 2705.2.3.4.
11. Electrically operated systems required elsewhere in this code or in the *International Building Code* applicable to the use, storage or handling of HPM.

❖ This section specifies the types of systems in a Group H-5 occupancy that must be connected to an approved emergency power system. As indicated in Section 604, emergency power systems must be installed, in accordance with the applicable requirements of NFPA 70, NFPA 110 and NFPA 111. Note that the systems included in the list are critical to personnel safety and must remain operable under all conditions of normal power system failure or impairment.

**2703.15.2 Exhaust ventilation systems.** Exhaust ventilation systems are allowed to be designed to operate at not less than one-half the normal fan speed on the emergency power system where it is demonstrated that the level of exhaust will maintain a safe atmosphere.

❖ Emergency power for exhaust ventilation is required to prevent hazardous concentrations of HPM fumes or vapors in areas such as workstations or fabrication areas. Fans for exhaust ventilation draw a considerable amount of current when operating. Running exhaust fans at a reduced speed may be desirable when it will not endanger the operator or result in a hazardous condition. However, exhaust fans must not be run at a speed less than 50 percent of their rating, even if a slower speed will not produce a serious hazard.

**2703.16 Sub-atmospheric pressure gas systems.** Sub-atmospheric pressure gas systems (SAGS) shall be in accordance with NFPA 318.

❖ This section allows the storage and use of HPM gases in subatmospheric pressure gas systems (SAGS) when the systems are installed in accordance with NFPA 318. It is the intent of this section to adopt only the provisions of NFPA 318 relating to SAGS even though the scope of the standard itself covers many more aspects of semiconductor fabrication safety. Those sections in the scope of the reference are Section 3.3.28.5 for the definition, and Section 8.6.2 addressing uses and controls (see the commentary to Section 102.7 regarding the proper application of referenced standards). Semiconductor manufacturing involves the storage, handling and use of a variety of hazardous production materials. Some

of the processes require the use of compressed gases that are classified by the code as being highly toxic, toxic, corrosive, flammable or pyrophoric. It is not uncommon for some of the gases to exhibit multiple hazard classifications. Because of the hazards associated with some of these materials, advancements to improve their safe storage and use have been developed. One improvement is SAGS for certain compressed gases, a primary goal of which is to improve safety by reducing the risk of a gas release. This is accomplished because SAGS only deliver gas when a vacuum is applied to the cylinder connection. In a SAGS, the cylinder valve can be opened, but no gas is released until the pressure downstream of the outlet connection is below atmospheric pressure. This is in contrast to a typical gas cylinder, which releases gas when the cylinder valve is opened. SAGS significantly reduce the risk associated with HPM because they mitigate the likelihood and magnitude of a gas release, and their use is becoming more common. The semiconductor industry has used SAGS successfully for a number of years.

In semiconductor manufacturing, SAGS are commonly used during ion implantation onto a silicon wafer. In ion implanting, charged metal electrons are chemically deposited or embedded onto the wafer to alter the electrical or optical properties of the substance. Known as “dopants,” they are essential in the manufacturing of semiconductors used in integrated circuits and photovoltaics. In optics, dopants are necessary in the production of certain types of lasers. As integrated circuits become more powerful microprocessors, silicon wafers must undergo greater amounts of ion implanting. Some of the common dopant gases packaged and handled using SAGS are presented in Commentary Figure 2703.16.

SAGS are designed so that the gas must be removed from the cylinder using vacuum, which is less than 14.7 pounds per square inch absolute (psia) at normal temperature and pressure (NTP) [e.g., 70°F at 1 atmosphere (21°C at 101 kPa)]. In comparison to conventional compressed gas systems where gas is released because of its stored potential

energy, SAGS either inherently remove this risk or mitigate it by using mechanical controls. In SAGS, the loss of vacuum pressure stops the gas flow.

NFPA 318 classifies SAGS into two categories: Types 1 and 2, based on the type of technology used in the gas storage and transfer system.

A Type 1 SAGS is made up of a gas cylinder filled with an adsorbent matter where the contents are stored at subatmospheric pressure at NTP. A Type 1 SAGS does not meet the code’s definition of “Compressed gas”; it has the characteristics of a low vapor pressure solid. A Type 2 SAGS uses a conventional U.S. Department of Transportation (DOT)-approved compressed gas cylinder, and incorporates an internal pressure regulator or check valve and an excess flow control. These components allow gas to be released only under a vacuum condition. A Type 2 SAGS is designed so that component or process failures, such as the loss of vacuum pressure or the failure of the pressure regulator causes an internal valve to automatically close and prevent the release of the stored gas.

**SECTION 2704  
STORAGE**

**2704.1 General.** Storage of hazardous materials shall comply with Section 2703 and this section and other applicable provisions of this code.

- ❖ This section establishes the proper storage conditions for hazardous materials in fabrication areas, storage areas and storage in equipment and cabinets.

**2704.2 Fabrication areas.** Hazardous materials storage and the maximum quantities of hazardous materials in use and storage allowed in *fabrication areas* shall be in accordance with Sections 2704.2.1 through 2704.2.2.1.

- ❖ This section establishes the applicability of Sections 2704.2.1 through 2704.2.2.1 to the proper storage conditions for hazardous materials in fabrication areas. This includes the location and amount of HPMs in fabrication areas.

Compressed Gas	Formula	IFC Hazard Classification
Arsenic Pentafluoride	AsF <sub>5</sub>	Highly Toxic; Corrosive; Class 1 Water Reactive
Arsine	AsH <sub>3</sub>	Flammable (Liquefied); Highly Toxic
Boron Trifluoride	BF <sub>3</sub>	Toxic; Corrosive; Class 1 Water Reactive
Germanium Tetrafluoride	GeF <sub>4</sub>	Toxic; Corrosive
Hydrogen Selenide	H <sub>2</sub> Se	Flammable (Liquefied); Toxic
Phosphine	PH <sub>3</sub>	Pyrophoric; Highly Toxic
Silicon Tetrafluoride	SiF <sub>4</sub>	Toxic; Corrosive; Class 1 Water Reactive

**Figure 2703.16  
COMMON DOPANT GASES AND THEIR HAZARD CLASSIFICATION**

**2704.2.1 Location of HPM storage in fabrication areas.** Storage of HPM in *fabrication areas* shall be within *approved* or *listed* storage cabinets, gas cabinets, exhausted enclosures or within a workstation as follows:

1. Flammable and *combustible liquid* storage cabinets shall comply with Section 5704.3.2.
  2. Hazardous materials storage cabinets shall comply with Section 5003.8.7.
  3. Gas cabinets shall comply with Section 5003.8.6. Gas cabinets for highly toxic or toxic gases shall also comply with Section 6004.1.2.
  4. Exhausted enclosures shall comply with Section 5003.8.5. Exhausted enclosures for highly toxic or toxic gases shall also comply with Section 6004.1.3.
  5. Workstations shall comply with Section 2705.2.3.
- ❖ Even though the amount of HPM in a fabrication area is controlled, it must be further controlled by storing it in approved cabinets, exhausted enclosures or a workstation. This requirement is intended to limit the exposure to occupants of the fabrication area to only the material in use in that area. Such separation also reduces the size of a possible hazardous material incident.

The larger amounts of HPM typically stored in separate areas present a hazard comparable to other Group H facilities. Therefore, storage rooms must meet similar code requirements. Storage rooms containing HPM in quantities greater than permitted by Tables 5003.1.1(1) and 5003.1.1(2) must comply with the applicable requirements of IBC Section 415.11.5, depending on the state of the material.

**2704.2.2 Maximum aggregate quantities in fabrication areas.** The aggregate quantities of hazardous materials stored or used in a single *fabrication area* shall be limited as specified in this section.

**Exception:** *Fabrication areas* containing quantities of hazardous materials not exceeding the maximum allowable quantities per *control area* established by Sections 5003.1.1, 5704.3.4 and 5704.3.5.

- ❖ This section regulates the total amount of hazardous materials, whether in use or in storage, in a single fabrication area based on the density/quantity of material specified in Table 2704.2.2.1. The exception permits a fabrication area to have a total quantity of HPM of either the quantity specified in Table 2704.2.2.1 or the MAQs specified in Sections 5003.1.1, 5704.3.4 and 5704.3.5, whichever is greater.

**2704.2.2.1 Storage and use in fabrication areas.** The maximum quantities of hazardous materials stored or used in a single *fabrication area* shall not exceed the quantities set forth in Table 2704.2.2.1.

- ❖ See the commentary to Table 2704.2.2.1.

**TABLE 2704.2.2.1.** See page 27-17.

- ❖ The quantity limitations identified in Table 2704.2.2.1 designate the aggregate amounts of hazardous materials allowed to be both stored and used in each fabrication area. The density basis for managing the maximum quantity of specified hazardous materials controls the hazard distribution in the occupancy. Generally, the lower the permitted density, the greater the required separation between containers.

**2704.3 Indoor storage outside of fabrication areas.** The indoor storage of hazardous materials outside of *fabrication areas* shall be in accordance with Sections 2704.3.1 through 2704.3.3.

- ❖ This section introduces the applicability of Sections 2704.3.1 through 2704.3.3 to HPM storage not contained within a fabrication area.

**2704.3.1 HPM storage.** The indoor storage of HPM in quantities greater than those *listed* in Sections 5003.1.1 and 3404.3.4 shall be in a room complying with the requirements of the *International Building Code* and this code for a liquid storage room, HPM room or gas room as appropriate for the materials stored.

- ❖ This section deals with the construction requirements for two types of storage rooms: those classified as HPM rooms or gas rooms, and those used as liquid storage rooms. The size and separation of these rooms are dependent on the type of materials stored.

**2704.3.2 Other hazardous materials storage.** The indoor storage of other hazardous materials shall comply with Sections 5001, 5003 and 5004 and other applicable provisions of this code.

- ❖ This section makes it clear that all hazardous materials, whether they are HPM or not, must comply with the basic applicable requirements of the code.

**2704.3.3 Separation of incompatible hazardous materials.** Incompatible hazardous materials in storage shall be separated from each other in accordance with Section 5003.9.8.

- ❖ This section is intended to prevent potentially incompatible materials from mixing or reacting with each other. In most instances, a noncombustible partition may suffice as the minimum required level of separation. Compliance with Section 5003.9.8 is required.

**TABLE 2704.2.2.1  
QUANTITY LIMITS FOR HAZARDOUS MATERIALS IN A SINGLE FABRICATION AREA IN GROUP H-5<sup>a</sup>**

HAZARD CATEGORY	SOLIDS (pounds/square foot)	LIQUIDS (gallons/square foot)	GAS (cubic feet @ NTP/square foot)

(continued)

**TABLE 2704.2.2.1—continued**  
**QUANTITY LIMITS FOR HAZARDOUS MATERIALS IN A SINGLE FABRICATION AREA IN GROUP H-5**

HAZARD CATEGORY	SOLIDS (pounds/square foot)	LIQUIDS (gallons/square foot)	GAS (cubic feet @ NTP/square foot)
<b>PHYSICAL-HAZARD MATERIALS</b>			
Water reactive			
Class 3	Note b	0.00125	
Class 2	0.25	0.025	Not
Class 1	Not Limited	Not Limited	Applicable
<b>HEALTH-HAZARD MATERIALS</b>			
Corrosives	Not Limited	Not Limited	Not Limited
Highly toxics	Not Limited	Not Limited	Note d
Toxics	Not Limited	Not Limited	Note d

For SI: 1 pound per square foot = 4.882 kg/m<sup>2</sup>, 1 gallon per square foot = 40.7 L/m<sup>2</sup>, 1 cubic foot @ NTP/square foot = 0.305 m<sup>3</sup> @ NTP/m<sup>2</sup>,  
 1 cubic foot = 0.02832 m<sup>3</sup>.

- Hazardous materials within piping shall not be included in the calculated quantities.
- Quantity of hazardous materials in a single fabrication area shall not exceed the maximum allowable quantities per control area in Tables 5003.1.1(1) and 5003.1.1(2).
- Densely packed baled cotton that complies with the packing requirements of ISO 8115 shall not be included in this material class.
- The aggregate quantity of flammable, pyrophoric, toxic and highly toxic gases shall not exceed 9,000 cubic feet at NTP.
- The aggregate quantity of pyrophoric gases in the building shall not exceed the amounts set forth in Table 5003.8.2.

## SECTION 2705 USE AND HANDLING

**2705.1 General.** The use and handling of hazardous materials shall comply with this section, Section 2703 and other applicable provisions of this code.

❖ Section 2705 addresses the use of hazardous materials in fabrication areas, and transportation and handling of hazardous materials in buildings containing fabrication areas. Section 2703, Chapter 50 and the chapters of the code specific to hazardous materials are to be applied to the use and handling of other hazardous materials in the building.

**2705.2 Fabrication areas.** The use of hazardous materials in *fabrication areas* shall be in accordance with Sections 2705.2.1 through 2705.2.3.4.

❖ This section introduces the applicability of Sections 2705.2.1 through 2705.2.3.4 to HPM use in a fabrication area.

**2705.2.1 Location of HPM in use in fabrication areas.** Hazardous production materials in use in *fabrication areas* shall be within *approved* or *listed* gas cabinets, exhausted enclosures or a workstation.

❖ This section addresses four conditions for hazardous materials used in a fabrication area:

- Hazardous materials in use and storage must be in approved or listed gas cabinets, in exhausted enclosures or within a workstation.
- Section 2704 quantity limits for hazardous materials in use and storage apply.
- The amount of HPM per individual workstation is limited.
- Workstation construction, drainage, and containment and clearance requirements apply.

**2705.2.2 Maximum aggregate quantities in fabrication areas.** The aggregate quantities of hazardous materials in a single *fabrication area* shall comply with Section 2704.2.2, and Table 2704.2.2.1. The quantity of HPM in use at a workstation shall not exceed the quantities *listed* in Table 2705.2.2.

❖ This section establishes two quantity limitations for hazardous materials located in a fabrication area:

- Reemphasizes the Section 2704 hazardous materials quantity limitations allowed in each fabrication area by specific reference to Section 2704.2.2 and Table 2704.2.2.1.
- Limits the HPM quantity in use at each workstation. It is important to note that hazardous materials that have a hazard ranking of 1 or 2 (materials that are not HPM) are not subject to the same use limitations as HPM.

**TABLE 2705.2.2.** See page 27-19.

❖ As discussed at the beginning of this chapter, the unique engineering and operational controls inherent in semiconductor fabrication facilities justify what are, in effect, exceptions to an occupancy that would otherwise be classified as Group H-1, H-2, H-3 or H-4. Part of this justification includes limiting the maximum quantities of HPM at an individual workstation, thereby minimizing the hazard potential associated with an accident or equipment failure involving HPM. The table is intended to correlate with the HPM classifications, material conditions and quantity limitations addressed in Table 2704.2.2. It is important to understand that only HPMs are limited to the use quantities addressed in this table.

This table lists the MAQs of several types of hazardous materials that can be maintained at a workstation, either in storage or in use. It also reflects an

increase over the previous edition in the allowable gas quantities, which is intended to reduce the frequency of cylinder change-outs and, thus, the hazards associated with frequent handling of the material. The footnotes acknowledge the added safety of having approved fire-extinguishing and suppression systems in place, as well as the improved conditions with a closed system. See the commentary to Section 2705.2.3.4 for further discussion of pyrophoric and Class 3 water-reactive materials.

**2705.2.3 Workstations.** Workstations in *fabrication areas* shall be in accordance with Sections 2705.2.3.1 through 2705.2.3.4.

❖ This section introduces the applicability of Sections 2705.2.3.1 through 2705.2.3.4 to workstations located in a fabrication area.

**2705.2.3.1 Construction.** Workstations in *fabrication areas* shall be constructed of materials compatible with the materials used and stored at the workstation. The portion of the workstation that serves as a cabinet for HPM gases, Class I flammable liquids or Class II or Class IIIA combustible liquids shall be noncombustible and, if of metal, shall be not less than 0.0478-inch (18 gage) (1.2 mm) steel.

❖ This section addresses specific construction requirements for workstations and, to improve station longevity and avoid an undesirable reaction, requires that the materials of construction be compatible with the HPM used in the workstation. Likewise, HPM gases and flammable liquids must be kept in cabinets that are of substantial construction to prevent damage to HPM containers that could result in an HPM spill.

**2705.2.3.2 Protection of vessels.** Vessels containing hazardous materials located in or connected to a workstation shall be protected as follows:

1. HPM: Vessels containing HPM shall be protected from physical damage and shall not project from the workstation.
2. Hazardous *cryogenic fluids*, gases and liquids: Hazardous cryogenic fluid, gas and liquid vessels located within a workstation shall be protected from seismic forces in an *approved* manner in accordance with the *International Building Code*.
3. *Compressed gases*: Protection for *compressed gas* vessels shall also comply with Section 5303.5.
4. *Cryogenic fluids*: Protection for *cryogenic fluid* vessels shall also comply with Section 5503.5.

❖ HPM vessels located in or connected to a workstation are to be protected from physical damage and seismic forces (see Chapter 53 of the code and IBC Chapter 16). Additionally, Item 1 requires that these vessels be located in and not project from the workstation enclosure. Items 2 through 4 correlate with provisions of the code applicable to the hazards.

**TABLE 2705.2.2  
MAXIMUM QUANTITIES OF HPM AT A WORKSTATION<sup>d</sup>**

HPM CLASSIFICATION	STATE	MAXIMUM QUANTITY
Flammable, highly toxic, pyrophoric and toxic combined	Gas	Combined aggregate volume of all cylinders at a workstation shall not exceed an internal cylinder volume of 39.6 gallons or 5.29 cubic feet
Flammable	Liquid	15 gallons <sup>a, b</sup> 5 pounds <sup>a, b</sup>
	Solid	
Corrosive	Gas	Combined aggregate volume of all cylinders at a workstation shall not exceed an internal cylinder volume of 39.6 gallons or 5.29 cubic feet
	Liquid	
	Solid	
Highly toxic	Liquid	15 gallons <sup>a</sup> 5 pounds <sup>a</sup>
	Solid	
Oxidizer	Gas	Combined aggregate volume of all cylinders at a workstation shall not exceed an internal cylinder volume of 39.6 gallons or 5.29 cubic feet
	Liquid	
	Solid	
Pyrophoric	Liquid	0.5 gallon <sup>c, f</sup> 4.4 pounds <sup>c, f</sup>
	Solid	
Toxic	Liquid	Use-open system: 15 gallons <sup>b</sup> Use-closed system: 60 gallons <sup>b</sup>
	Solid	
Unstable reactive Class 3	Liquid	0.5 gallon <sup>a, b</sup> 5 pounds <sup>a, b</sup>
	Solid	
Water-reactive Class 3	Liquid	0.5 gallon <sup>c, f</sup> See Table 2704.2.2.1
	Solid	

For SI: 1 pound = 0.454 kg, 1 gallon = 3.785 L.

- a. Maximum allowable quantities shall be increased 100 percent for closed system operations. Where Note b also applies, the increase for both notes shall be allowed.
- b. Quantities shall be allowed to be increased 100 percent where workstations are internally protected with an approved automatic fire-extinguishing or suppression system complying with Chapter 9. Where Note b also applies, the increase for both notes shall be allowed. Where Note e also applies, the maximum increase allowed for both Notes b and e shall not exceed 100 percent.
- c. Allowed only in workstations that are internally protected with an approved automatic fire-extinguishing or fire protection system complying with Chapter 9 and compatible with the reactivity of materials in use at the workstation.
- d. The quantity limits apply only to materials classified as HPM.
- e. Quantities shall be allowed to be increased 100 percent for nonflammable, noncombustible corrosive liquids where the materials of construction for workstations are listed or approved for use without internal fire-extinguishing or suppression system protection. Where Note b also applies, the maximum increase allowed for both Notes b and e shall not exceed 100 percent.
- f. A maximum quantity of 5.3 gallons of liquids and 44 pounds of total liquids and solids shall be allowed at a workstation where conditions are in accordance with Section 2705.2.3.5.

**2705.2.3.3 Drainage and containment for HPM liquids.** Each workstation utilizing HPM liquids shall have all of the following:

1. Drainage piping systems connected to a compatible system for disposition of such liquids.
  2. The work surface provided with a slope or other means for directing spilled materials to the containment or drainage system.
  3. An *approved* means of containing or directing spilled or leaked liquids to the drainage system.
- ❖ Federal environmental requirements make it necessary to contain and recover HPM used in the manufacturing process. The design of the workstations must facilitate the recovery of spilled and spent HPM. The drainage system must be designed so that incompatible materials do not mix and the system is compatible with the materials handled.

**2705.2.3.4 Pyrophoric solids, liquids and Class 3 water-reactive liquids.** Pyrophoric liquids and Class 3 water-reactive liquids in containers greater than 0.5-gallon (2 L) but not exceeding 5.3-gallon (20 L) capacity and pyrophoric solids in containers greater than 4.4 pounds (2 kg) but not exceeding 44 pounds (20 kg) shall be allowed at workstations where located inside cabinets and the following conditions are met:

1. Maximum amount per cabinet: The maximum amount per cabinet shall be limited to 5.3 gallons (20 L) of liquids and 44 pounds (20 kg) of total liquids and solids.
2. Cabinet construction: Cabinets shall be constructed in accordance with the following:
  - 2.1. Cabinets shall be constructed of not less than 0.097-inch (2.5 mm) (12 gage) steel.
  - 2.2. Cabinets shall be permitted to have self-closing limited access ports or noncombustible windows that provide access to equipment controls.
  - 2.3. Cabinets shall be provided with self- or manual-closing doors. Manual-closing doors shall be equipped with a door switch that will initiate local audible and visual alarms when the door is in the open position.
3. Cabinet exhaust ventilation system: An exhaust ventilation system shall be provided for cabinets and shall comply with the following:
  - 3.1. The system shall be designed to operate at a negative pressure in relation to the surrounding area.
  - 3.2. The system shall be equipped with monitoring equipment to ensure that required exhaust flow or static pressure is provided.
  - 3.3. Low-flow or static pressure conditions shall send an alarm to the on-site emergency control station. The alarm shall be both visual and audible.
4. Cabinet spill containment: Spill containment shall be provided in each cabinet, with the spill containment

capable of holding the contents of the aggregate amount of liquids in containers in each cabinet.

5. Valves: Valves in supply piping between the product containers in the cabinet and the workstation served by the containers shall fail in the closed position upon power failure, loss of exhaust ventilation and upon actuation of the fire control system.
6. Fire detection system: Each cabinet shall be equipped with an automatic fire detection system complying with the following conditions:
  - 6.1. Automatic detection system: UV/IR, high-sensitivity smoke detection (HSSD) or other *approved* detection systems shall be provided inside each cabinet.
  - 6.2. Automatic shutoff: Activation of the detection system shall automatically close the shutoff valves at the source on the liquid supply.
  - 6.3. Alarms and signals: Activation of the detection system shall initiate a local alarm within the *fabrication area* and transmit a signal to the *emergency control station*. The alarms and signals shall be both visual and audible.

❖ As semiconductor technology progresses to smaller line widths and increased device densities, newer materials are demanded. Conducting and nonconducting structures are fabricated at atomic levels using new metal-bearing agents. A class of materials known as metalorganics is used as precursor for the fabrication of these structures. These materials may possess both pyrophoric and water-reactive properties. Some common metalorganics used are trimethylaluminum (TMA), trimethyl gallium (TMG) and dimethylaluminum hydride (DMAH).

The strict safeguards for the increased workstation quantities allowed by this section should eliminate the need for bulk distribution systems, with larger quantities centralized in a Group H-2 occupancy, that would otherwise have to be installed to meet production requirements. These systems would have to be piped to individual workstations in the fabrication area from the bulk distribution supply location. Extensive runs of piping could result in significant risks, with the potential for leaks from piping or fitting leakage, which can cause accidental damage, installation errors and deinstallation errors. In this application, the piping from the bulk distribution source servicing the workstations becomes a greater risk than the alternative of having a greater quantity localized at the workstation with no exposed piping from a Group H-2 room both to and traversing the fabrication area.

FM has indicated that it has no loss history using these materials at any site, even at the compound semiconductor companies, which use large volumes of these materials. The semiconductor industry reports no loss history with the use of water-reactive or pyrophoric liquids. In addition, semiconductor industry health and safety professionals concur that it

is much safer to reduce the handling frequency of any chemical.

**2705.3 Transportation and handling.** The transportation and handling of hazardous materials shall comply with Sections 2705.3.1 through 2705.3.4.1 and other applicable provisions of this code.

❖ Transportation and handling in this section refers to the movement of hazardous materials through means of egress elements, such as exit access corridors and exit enclosures, and through service corridors.

**2705.3.1 Corridors and enclosures for stairways and ramps.** *Corridors* and enclosures for *exit stairways* and *ramps* in new buildings or serving new fabrication areas shall not contain HPM, except as permitted in corridors by Section 415.11.6.4 of the *International Building Code* and Section 2705.3.2 of this code.

❖ This section is specific to transportation and handling of HPM in both new buildings containing Group H-5 occupancy operations and existing buildings containing new Group H-5 occupancy operations. Transportation or handling of HPM in corridors or stairway and ramp enclosures is not allowed, except for existing buildings containing existing fabrication areas, and as specifically allowed in Section 415.11.6.4 of the IBC, and Section 2705.3.2. In older semiconductor fabrication facilities (a.k.a. “fabs”), hand transportation of HPMs is common practice. However, these older facilities are reaching the end of their service life and are being replaced. In new fabs, liquids and gases are supplied directly to tools via bulk distribution systems because it is safer and less expensive because the liquids and gases are purchased in bulk quantities. As a result, the transportation of HPMs in carts or by hand is fairly infrequent. When delivered by carts or by hand (e.g., exchanging compressed gas cylinders in ion implanters), the amount of HPM is fairly small. Because of the improvements in chemical distribution, very little benefit is gained from providing service corridors in Group H-5 occupancies. Note that this section is specific to HPMs only and neither prohibits nor restricts the transportation or handling of materials having a health-hazard ranking of 1 or 2 in exit access corridors or exit enclosures. The general handling and transportation requirements addressed in Section 5003.10 apply to materials having a health-hazard ranking of 1 or 2 and to conditions not specifically addressed in this section.

**2705.3.2 Transport in corridors and enclosures for stairways and ramps.** Transport in *corridors* and enclosures for *stairways* and *ramps* shall be in accordance with Sections 2705.3.2.1 through 2705.3.3.

❖ This section identifies the requirements for HPM transport in corridors, and stairway and ramp enclosures.

**2705.3.2.1 Fabrication area alterations.** Where existing fabrication areas are altered or modified in existing buildings, HPM is allowed to be transported in existing *corridors* where

such *corridors* comply with Section 5003.10 of this code and Section 415.11.2 of the *International Building Code*.

❖ Corridors must comply with the requirements of Section 1018 and must be separated from fabrication areas in accordance with IBC Section 415.11.2. Additionally, corridors in new buildings are not to be used for transporting HPM to the fabrication area; HPM must be transported in service corridors or piping. This section addresses HPM facilities that existed before the adoption and enforcement of the IBC. It permits the transport of HPM in corridors in existing buildings under the conditions specified in IBC Section 415.11. When alterations are made to a fabrication area, those corridors must be upgraded.

**2705.3.2.2 HPM transport in corridors and enclosures for stairways and ramps.** Nonproduction HPM is allowed to be transported in *corridors* and enclosures for *stairways* and *ramps* where utilized for maintenance, lab work and testing when the transportation is in accordance with Section 5003.10.

❖ This section requires that the transportation of non-production HPMs comply with Section 5003.10, which establishes the design criteria and use parameters for carts and trucks and also includes the following requirements for on-site transportation of hazardous materials:

- Liquids packaged in containers of a volume of 5 gallons (19 L) or greater can only be transported on hand carts or hand trucks.
- Not more than four 55-gallon containers (833 L) can be handled utilizing acceptable drum trucks or on pallets.
- Compressed gas containers and cylinders require transportation using approved hand trucks.
- For HPMs transported by hand, the weight of the packaging is limited based on the contents being a solid, liquid or gas.

**2705.3.3 Service corridors.** Where a new *fabrication area* is constructed, a service corridor shall be provided where it is necessary to transport HPM from a liquid storage room, HPM room, gas room or from the outside of a building to the perimeter wall of a *fabrication area*. Service corridors shall be designed and constructed in accordance with the *International Building Code*.

❖ Under this section, in new buildings, or where a fabrication area is added in an existing building, service passageways are separate spaces dedicated to the transportation of HPM between cutoff rooms, the perimeter walls of fabrication areas and the building's exterior. Service passageways must not be used as elements of a means of egress. Requirements of Section 2705.3.4 must govern the number, capacity and type of HPM containers transported in service passageways.

## SEMICONDUCTOR FABRICATION FACILITIES

**2705.3.4 Carts and trucks.** Carts and trucks used to transport HPM in *corridors* and enclosures for *stairways* and *ramps* shall comply with Section 5003.10.3.

❖ This section identifies the requirements for carts and trucks used to transport HPM in corridors and stairway and ramp enclosures in existing buildings containing existing fabrication areas. Both Section 2705.3.2 and this section are specific to HPM, and specific only to HPM in glass containers, HPM gas cylinders and the carts and trucks allowed for the transport of HPM through corridors and stairway and ramp enclosures. The general handling and transportation requirements addressed in Section 5003.10 apply to materials having a hazard ranking of 1 or 2 and to conditions not specifically addressed in Section 2705.3.2 and this section.

**2705.3.4.1 Identification.** Carts and trucks shall be marked to indicate the contents.

❖ Cart or truck enclosures must bear placards or signs indicating the contents transported. A combination of DOTn and NFPA 704 placards is ideal for this purpose. Materials possibly posing a danger of reaction if mixed should never be transported together.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 28: Lumber Yards and Agro-industrial, Solid Biomass and Woodworking Facilities

## General Comments

Woodworking, agro-industrial, solid biomass feedstock and forest product processing facilities tend to be located close to the source of the raw material, but facilities manufacturing finished products for the building trade industries may be found in or near most urban areas. Any facility using mechanical methods to work wood and solid biomass into a more finished form produces dust or debris. The smaller the fuel package, the more easily ignitable it will be. In fact, extremely fine wood dust or wood flour may even produce deflagrations (explosions) under the right conditions. Explosion prevention practices must be implemented to minimize the potential for such hazards. Accumulations of dust must be prevented, controlled mechanically or removed frequently. Automatic fire suppression systems are required by Section 903.2.4.1. Deflagration venting (see NFPA 69 and NFPA 495) is required where substantial amounts of dust are usually present. Areas where dust suspensions exist are considered Class II hazardous locations by NFPA 70. Manual fire-fighting equipment must be provided in the immediate vicinity of each machine because dust cannot be completely eliminated in any woodworking or wood-processing area.

Methods and procedures used to control hazards associated with wood, agro-industrial, solid biomass feedstock and forest product storage, sale and processing must recognize not only the fuel properties but the need to control and eliminate ignition sources, minimize the effect of fires and explosions, and facilitate fire control efforts by occupants at the incipient phase and fire

fighters at more advanced stages. Adherence to these requirements will help secure these objectives.

## Purpose

Most everyone is familiar with the hazards of wood as a fuel; however, the scale of wood, agro-industrial, solid biomass feedstock and forest product storage, manufacturing and processing operations stretches the limitations of their understanding. Wood has long been used as a reference fuel for understanding fire, but the sheer volume of materials present and the variety of fuel packages represented in these occupancies make this a hazard requiring special attention.

Sawdust, wood chips, shavings, bark mulch, shorts, finished planks, sheets, posts, poles, timber and raw logs represent a broad continuum of fuels. What they all bear in common is the hazard they represent once ignited; what is unique about each of these materials is the ease or difficulty with which any single fuel package may be ignited. The regulations recognize both of these concerns.

Provisions of this chapter are intended to prevent fires and explosions, facilitate fire control and reduce exposures to and from facilities storing, selling or processing wood and forest products.

This chapter requires active and passive fire protection features to reduce on- and off-site exposures, limit fire size and development, and facilitate fire fighting by employees and the fire service. Design and maintenance of these facilities must provide access to equipment and exposures to facilitate fire control.

## SECTION 2801 GENERAL

**2801.1 Scope.** The storage, manufacturing and processing of solid biomass feedstock, timber, lumber, plywood, nonmetallic pallets, veneers and agro-industrial byproducts shall be in accordance with this chapter.

❖ These provisions are intended to prevent fires and explosions in lumber yards, woodworking plants and lumber drying and other similar operations. Further, provisions are intended to facilitate fire-fighting operations in these occupancies in the event of a fire.

**2801.2 Permit.** Permits shall be required as set forth in Section 105.6.

❖ Section 105.6.26 has a permit threshold amount for lumber storage of 100,000 board feet [8,333 cubic feet (236 m<sup>3</sup>)] of lumber. The board foot is a measurement used in the lumber and building trades. One board foot (0.93 m<sup>2</sup>) is the cubic volume of a piece of lumber 1 foot square (0.93 m<sup>2</sup>) and 1 inch (25 mm) thick or approximately 0.083 cubic foot (0.002 m<sup>3</sup>). Then, 100,000 board feet [8,333 cubic feet (236 m<sup>3</sup>)] is a cubic volume of 8,333 cubic feet (236 m<sup>3</sup>) or a

solid pile of lumber approximately 20 feet, 5 inches by 20 feet, 5 inches (6223 mm by 6223 mm) by the maximum allowable height of 20 feet (6096 mm). The permit requirement is intended to facilitate the regulation of hazards presented by quantities of lumber exceeding that amount.

## SECTION 2802 DEFINITIONS

**2802.1 Definitions.** The following terms are defined in Chapter 2:

**AGRO-INDUSTRIAL.**

**BIOMASS.**

**COLD DECK.**

**FINES.**

**HOGGED MATERIALS.**

**PLYWOOD AND VENEER MILLS.**

**RAW PRODUCT.**

**SOLID BIOFUEL.**

**SOLID BIOMASS FEEDSTOCK.**

**STATIC PILES.**

**TIMBER AND LUMBER PRODUCTION FACILITIES.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 2803 GENERAL REQUIREMENTS

**2803.1 Open yards.** Open yards required by the *International Building Code* shall be maintained around structures.

❖ The *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) requires that certain buildings face an open space on at least one side. The open spaces may be a yard required for the purpose of providing light and ventilation (see the commentary to the IBC Section 202 definition of “Yard” and IBC Section 1206) or they may be a public way provided in order to achieve an increase in building area called a “frontage increase” (see the commentary to IBC Section 202 definition of “Public way” and IBC Section 506.3), or to allow a building to be considered an “unlimited area building” (see the commentary to IBC Section 507). Regardless of the purpose of the open space, this section requires that the space be maintained and be free of obstructions associated with the outdoor storage of the materials regulated by Chapter 28, which could interfere with

the function of the open space, especially that of providing fire department access to the building.

**2803.2 Dust control.** Equipment or machinery located inside buildings that generates or emits *combustible dust* shall be provided with an *approved* dust collection and exhaust system installed in accordance with Chapter 22 and the *International Mechanical Code*. Equipment or systems that are used to collect, process or convey *combustible dusts* shall be provided with an *approved* explosion control system.

❖ The basic wood-processing activities related to lumber yards and woodworking facilities generate large volumes of wood particles suspended in the air, creating a potentially explosive form of dust. Where such activities are located inside of buildings, this section requires that combustible dust be controlled by an approved dust-collection and exhaust system designed and installed in accordance with Chapter 22, and Sections 510 and 511 of the *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>). There are two basic designs of dust collection systems. One is a single-stage system that consists of a single dust collector in the form of a cyclone separator or a combination cyclone/baghouse unit. The other is a two-stage system that consists of a cyclone separator followed by a bag-type filter house.

An approved explosion control system is also required for the equipment and systems that collect and convey the combustible dust. Such systems should be installed in accordance with Section 911.

**2803.2.1 Explosion venting.** Where a dust explosion hazard exists in equipment rooms, buildings or other enclosures, such areas shall be provided with explosion (*deflagration*) venting or an *approved* explosion suppression system complying with Section 911.

❖ When wood dust is ignited while suspended in air in concentrations above the minimum combustible concentration (MCC), it burns violently, producing a deflagration. This likelihood depends on the concentration of fuel per unit volume. Most of the time, dust-collection systems remove the larger dust particles, allowing the finer particles to pass through the system and reenter the production area. The finer dust can create an explosion and fire hazard unless an approved suppression system is used.

**2803.3 Waste removal.** Sawmills, planning mills and other woodworking plants shall be equipped with a waste removal system that will collect and remove sawdust and shavings. Such systems shall be installed in accordance with Chapter 22 and the *International Mechanical Code*.

**Exception:** Manual waste removal where *approved*.

❖ Like many other organic materials, sawdust, wood chips and other similar waste materials are susceptible to spontaneous heat. Pileings and debris must be turned over or consumed regularly to minimize the potential for spontaneous combustion. Some waste material is used as fuel and some might go to pulp or particleboard manufacturers. Finer material is

removed by air-moving equipment, cyclones or air bags. Chapter 22 and the IMC give the installation requirements for waste removal systems.

**2803.3.1 Housekeeping.** Provisions shall be made for a systematic and thorough cleaning of the entire plant at sufficient intervals to prevent the accumulations of *combustible dust* and spilled combustible or flammable liquids.

- ❖ Good housekeeping should be maintained at all times, including regular and frequent cleaning of material-handling equipment. Combustible waste materials, such as bark, chips and other debris, should not be allowed to accumulate in amounts that will constitute a fire hazard. Air-moving systems should be designed to remove or dilute transient flammable vapors.

**2803.3.2 Metal scrap.** Provision shall be made for separately collecting and disposing of any metal scrap so that such scrap will not enter the wood handling or processing equipment.

- ❖ Waste material from rough milling is carried by a belt conveyor to the wood hog, which cuts the waste into small pieces. The conveyor should have a magnetic separator to keep metal from causing fires in the hog, pneumatic conveyors and waste-storage silos. Waste material that is swept up and carried to the hog is hazardous because the trash often contains metal objects.

**2803.4 Electrical equipment.** Electrical wiring and equipment shall comply with NFPA 70.

- ❖ Arcs, sparks and loose connections often supply the ignition source that a vapor or combustible material needs for fire. Electrical equipment must be listed for the use it is installed for and comply with the requirements of NFPA 70.

**2803.5 Control of ignition sources.** Protection from ignition sources shall be provided in accordance with Sections 2803.5.1 through 2803.5.3.

- ❖ The two key points that will reduce fire losses in storage areas of forest products are reduction in the sources of ignition and a positive program for detecting incipient fires. The following subsections address sources of ignition. Section 2804 addresses programs and systems for early detection of fires.

**2803.5.1 Cutting and welding.** Cutting and welding shall comply with Chapter 35.

- ❖ No cutting, welding or other use of open flames and spark-producing equipment are allowed in the storage area without a permit.

**2803.5.2 Static electricity.** Static electricity shall be prevented from accumulating on machines and equipment subject to static electricity buildup by permanent grounding and bonding wires or other *approved* means.

- ❖ Static electricity builds up on operating machines because of the movement of product and machine. Proper grounding and bonding of equipment prevents static electricity from producing an ignition source and igniting a fire.

**2803.5.3 Smoking.** Where smoking constitutes a fire hazard, the *fire code official* is authorized to order the *owner* or occupant to post *approved* “No Smoking” signs complying with Section 310. The *fire code official* is authorized to designate specific locations where smoking is allowed.

- ❖ Smoking must not be allowed in a woodworking facility. Considering the abundance of existing fuel, with much of it in an easily ignitable form, smoking controls are an absolute necessity in lumber yards and forest products facilities. Smoking materials being discarded improperly are an ignition threat in woodworking facilities.

**2803.6 Fire apparatus access roads.** Fire apparatus access roads shall be provided for buildings and facilities in accordance with Section 503.

- ❖ Required driveways provide access for fire apparatus and create fire breaks between piles. Access roads must be sized to allow fire emergency equipment to enter and perform emergency operations. Section 503 gives required dimensions for access roads.

**2803.7 Access plan.** Where storage pile configurations could change because of changes in product operations and processing, the access plan shall be submitted for approval when required by the *fire code official*.

- ❖ A site plan showing access to the facilities with consideration given to pile location, access roads, hydrant locations and building locations must be presented to the fire code official for approval prior to construction.

## SECTION 2804 FIRE PROTECTION

**2804.1 General.** Fire protection in timber and lumber production mills, plywood and veneer mills and agro-industrial facilities shall comply with Sections 2804.2 through 2804.4.

- ❖ This section introduces and establishes the applicability of Sections 2804.2 through 2804.4.

**2804.2 Fire alarms.** An *approved* means for transmitting alarms to the fire department shall be provided in timber and lumber production mills and plywood and veneer mills.

- ❖ The fire department must be notified if a fire occurs in the facility. How the fire department is notified must be approved by the local fire code official. This may be by a manual fire alarm system with pull stations, monitored phone lines or another approved system.

**2804.2.1 Manual fire alarms.** A manual fire alarm system complying with Section 907.2 shall be installed in areas of timber and lumber production mills and for plywood and veneer mills that contain product dryers.

**Exception:** Where dryers or other sources of ignition are protected by a supervised *automatic sprinkler system* complying with Section 903.

- ❖ Manual fire alarm systems usually have means for local notification, but according to Section 2804.2,

alarm systems must have the means to transmit the alarm to fire departments.

#### 2804.3 Portable fire extinguishers or standpipes and hose.

Portable fire extinguishers or standpipes and hose supplied from an *approved* water system shall be provided within a 50-foot (15 240 mm) distance of travel from any machine producing shavings or sawdust. Portable fire extinguishers shall be provided in accordance with Section 906 for extra-high hazards.

❖ The degree of protection will vary from facility to facility, but the basic recommendation is for a water system of mains and hydrants capable of supplying at least 1,000 gallons per minute (gpm) (60 L/s). Standpipes will provide a hose within 50 feet (15 240 mm) of shaving and sanding machines. Portable fire extinguishers are good initial fire knockdown equipment. Section 906 gives these requirements.

**2804.4 Automatic sprinkler systems.** *Automatic sprinkler systems* shall be installed in accordance with Section 903.3.1.1.

❖ This section does not require the installation of a sprinkler system. Rather, where a sprinkler system is provided as required by the occupancy group classification, this section mandates it be installed in accordance with Section 903.3.1.1, which references NFPA 13.

### SECTION 2805 PLYWOOD, VENEER AND COMPOSITE BOARD MILLS

**2805.1 General.** Plant operations of plywood, veneer and composite board mills shall comply with Sections 2805.2 and 2805.3.

❖ This section addresses protection of dryers and installation requirements for thermal oil-heating systems.

**2805.2 Dryer protection.** Dryers shall be protected throughout by an *approved*, automatic deluge water-spray suppression system complying with Chapter 9. Deluge heads shall be inspected quarterly for pitch buildup. Deluge heads shall be flushed during regular maintenance for functional operation. Manual activation valves shall be located within 75 feet (22 860 mm) of the drying equipment.

❖ A deluge system is a good protective measure for the interior of dryers. This kind of protection is especially important in veneer mills where the temperature of the dryer may approach 392°F (200°C), which is the nominal ignition temperature of wood. Smoke sensors should activate the deluge system and automatically shut down fans, burners and drive machinery. Manual trips should also be installed at each end of the dryer.

**2805.3 Thermal oil-heating systems.** Facilities that use heat transfer fluids to provide process equipment heat through piped, indirect heating systems shall comply with this code and NFPA 664.

❖ The transfer of heated fluids for process equipment presents a fire hazard. A ruptured pipe line could expose fine particles of wood products to the heated fluid, thus creating the potential for a fire. The code and Chapter 9 of NFPA 664 address the requirements for installation of this equipment.

### SECTION 2806 LOG STORAGE AREAS

**2806.1 General.** Log storage areas shall comply with Sections 2806.2 through 2806.3.

❖ The intent of this section is to provide fire protection advice for minimizing fire hazards in log-yard storage areas that contain saw, plywood or pulpwood logs stored in ranked piles, usually referred to as “cold decks”. Stacked piles of cordwood are not addressed unless they are stored in ranked piles.

**2806.2 Cold decks.** Cold decks shall not exceed 500 feet (152.4 m) in length, 300 feet (91 440 mm) in width and 20 feet (6096 mm) in height. Cold decks shall be separated from adjacent cold decks or other exposures by not less than 100 feet (30 480 mm).

**Exception:** The size of cold decks shall be determined by the *fire code official* where the decks are protected by special fire protection including, but not limited to, additional fire flow, portable turrets and deluge sets, and hydrant hose houses equipped with *approved* fire-fighting equipment capable of reaching the entire storage area in accordance with Chapter 9.

❖ Because of the fire load that they present, cold decks (see commentary to the Section 202 definition of “Cold deck”) must be limited in size and isolated from one another as prescribed in this section. All sides of the cold deck should be accessible to fire apparatus over hard-surface fire apparatus access roads. The suggested width of a cold deck fire apparatus access road is one and one-half times the height of the pile but a minimum of 20 feet (6096 mm) between alternate rows of two pile groups separated by a clear space of 100 feet (30 480 mm). See the commentary to Section 503 for further discussion of fire apparatus access roads.

**2806.3 Pile stability.** Log and pole piles shall be stabilized by *approved* means.

❖ Stabilizing the log and pole piles minimizes hazards in two ways. In a fire, the piles become weak and can fall on the fire fighters, but the stabilizing method will

assist in their protection. The method also minimizes the risk of logs falling on people and causing death or injury when no fire emergency exists.

### SECTION 2807 STORAGE OF WOOD CHIPS AND HOGGED MATERIAL ASSOCIATED WITH TIMBER AND LUMBER PRODUCTION FACILITIES

**2807.1 General.** The storage of wood chips and hogged materials associated with timber and lumber production facilities shall comply with Sections 2807.2 through 2807.5.

❖ This section gives fire protection guidance for minimizing fire hazards in yard storage areas containing wood chips and hogged materials. Each individual facility will have its own special conditions for yard use, handling procedures and topography. Fire safety is also affected by climate conditions, wood species and the age of the piles.

**2807.2 Size of piles.** Piles shall not exceed 60 feet (18 288 mm) in height, 300 feet (91 440 mm) in width and 500 feet (152 m) in length. Piles shall be separated from adjacent piles or other exposures by *approved* fire apparatus access roads.

**Exception:** The *fire code official* is authorized to allow the pile size to be increased where additional fire protection is provided in accordance with Chapter 9. The increase shall be based on the capabilities of the system installed.

❖ Restrictions on pile size are established for practical reasons. When the piles are made low and narrow, fire extinguishment is enhanced. When the piles are extremely high and wide, fire extinguishment is hampered and arrangements must be made for fire-fighting service. Piles should also be constructed with an access roadway to the top of the pile to make all parts of the pile accessible to fire fighters.

**2807.3 Pile fire protection.** Automatic sprinkler protection shall be provided in conveyor tunnels and combustible enclosures that pass under a pile. Combustible or enclosed conveyor systems shall be equipped with an *approved automatic sprinkler system*.

❖ Automatic sprinklers are needed because of the difficulty of manual fire suppression operations in concealed, enclosed and elevated areas.

**2807.4 Material-handling equipment.** *Approved* material-handling equipment shall be readily available for moving wood chips and hogged material.

❖ Bulldozers and power-operated shovel and scoop vehicles are examples of the material-handling equipment needed to move stored material and, thus, make fire fighting easier.

**2807.5 Emergency plan.** The *owner* or operator shall develop a plan for monitoring, controlling and extinguishing

spot fires. The plan shall be submitted to the *fire code official* for review and approval.

❖ As in all potential hazards, an emergency plan should be designed for monitoring and fighting spot fires. The plan must be submitted to the fire code official for review and approval.

### SECTION 2808 STORAGE AND PROCESSING OF WOOD CHIPS, HOGGED MATERIAL, FINES, COMPOST, SOLID BIOMASS FEEDSTOCK AND RAW PRODUCT ASSOCIATED WITH YARD WASTE, AGRO- INDUSTRIAL AND RECYCLING FACILITIES

**2808.1 General.** The storage and processing of wood chips, hogged materials, fines, compost, solid biomass feedstock and raw product produced from yard waste, debris and agro-industrial and recycling facilities shall comply with Sections 2808.2 through 2808.10.

❖ This section contains fire protection guidance for minimizing fire hazards in yard storage areas containing wood chips and hogged materials, fines, compost, raw materials and solid biomass feedstock.

**2808.2 Storage site.** Storage sites shall be level and on solid ground, elevated soil lifts or other all-weather surface. Sites shall be thoroughly cleaned before transferring wood products to the site.

❖ The storage site should be reasonably level, solid ground or paved with blacktop, concrete or other hard surface material. The surface must be thoroughly cleaned of scrap and debris before beginning a new pile.

**2808.3 Size of piles.** Piles shall not exceed 25 feet (7620 mm) in height, 150 feet (45 720 mm) in width and 250 feet (76 200 mm) in length.

**Exception:** The *fire code official* is authorized to allow the pile size to be increased where a fire protection plan is provided for approval that includes, but is not limited to, the following:

1. Storage yard areas and materials-handling equipment selection, design and arrangement shall be based upon sound fire prevention and protection principles.
2. Factors that lead to spontaneous heating shall be identified in the plan, and control of the various factors shall be identified and implemented, including provisions for monitoring the internal condition of the pile.
3. The plan shall include means for early fire detection and reporting to the public fire department; and facilities needed by the fire department for fire extinguishment including a water supply and fire hydrants.

4. Fire apparatus access roads around the piles and access roads to the top of the piles shall be established, identified and maintained.
5. Regular yard inspections by trained personnel shall be included as part of an effective fire prevention maintenance program.

Additional fire protection called for in the plan shall be provided and shall be installed in accordance with this code. The increase of the pile size shall be based upon the capabilities of the installed fire protection systems and features.

- ❖ Restrictions on pile sizes are established for good and practical reasons. When the piles are made low and narrow, fire extinguishment is enhanced. When the piles are extremely high and wide, fire extinguishment is hampered and arrangements must be made for fire-fighting service. This section provides tools and guidance for fire code officials when proposals to increase pile size are submitted. The protection needed for increased pile size includes fire flows through a hydrant system, fire apparatus access roads, means for monitoring pile temperatures, a means of notifying the fire department and a sound fire prevention maintenance program. The exception provides for these features to be addressed in a fire protection plan submittal to the fire code official for approval. The systems installed are covered by various portions of the code, such as fire apparatus access roads covered in Chapter 5. The exception also replaces and codifies criteria that were formerly contained in referenced standards (NFPA 46 and NFPA 230) but have been withdrawn by NFPA.

**2808.4 Pile separation.** Piles shall be separated from adjacent piles by *approved* fire apparatus access roads.

- ❖ In order to slow the spread of fire from pile to pile, as well as to provide the fire department with tactical access to all parts of the pile storage area, piles must be subdivided by fire apparatus access roads at least 20 feet (6096 mm) in clear width at the base of the piles, in accordance with Section 503.2.1 (see also commentary, Section 2809.3).

**2808.5 Combustible waste.** The storage, accumulation and handling of combustible materials and control of vegetation shall comply with Chapter 3.

- ❖ Section 304 addresses vegetation and combustible waste requirements for minimizing hazards.

**2808.6 Static pile protection.** Static piles shall be monitored by an *approved* means to measure temperatures within the static piles. Internal pile temperatures shall be monitored and recorded weekly. Such records shall be maintained. An operational plan indicating procedures and schedules for the inspection, monitoring and restricting of excessive internal temperatures in static piles shall be submitted to the *fire code official* for review and approval.

- ❖ Inherent to long-term bulk storage of chips, fines, compost and hogged materials is internal heating, which can progress to spontaneous combustion

under certain conditions. Unless procedures are established for measuring internal temperatures, fires could burn undetected for long periods before smoke is seen or produced at the surface. These piles must be monitored on a fixed schedule and records kept of the results of these inspections.

**2808.7 Pile fire protection.** Automatic sprinkler protection shall be provided in conveyor tunnels and combustible enclosures that pass under a pile. Combustible conveyor systems and enclosed conveyor systems shall be equipped with an *approved automatic sprinkler system*.

- ❖ Automatic sprinklers are needed because of the difficulty of manual fire suppression operations in concealed, enclosed and elevated areas (see commentary, Section 2807.3).

**2808.8 Fire extinguishers.** Portable fire extinguishers complying with Section 906 and with a minimum rating of 4-A:60-B:C shall be provided on all vehicles and equipment operating on piles and at all processing equipment.

- ❖ Each vehicle operating in the area must be equipped with a portable fire extinguisher that provides the fire extinguishing equivalent of 5 gallons (19 L) of water for use on a substantial Class A fire and is effective for flammable liquids and energized electrical components.

**2808.9 Material-handling equipment.** *Approved* material-handling equipment shall be available for moving wood chips, hogged material, wood fines and raw product during fire-fighting operations.

- ❖ Bulldozers and power-operated shovel and scoop vehicles are examples of the material-handling equipment needed to move stored material and, thus, make fire fighting easier. Pile surfaces can usually be removed with this type of equipment.

**2808.10 Emergency plan.** The *owner* or operator shall develop a plan for monitoring, controlling and extinguishing spot fires and submit the plan to the *fire code official* for review and approval.

- ❖ As in all potential hazards, an emergency plan should be designed for monitoring and fighting spot fires. The plan must be submitted to the fire code official for review and approval.

## SECTION 2809 EXTERIOR STORAGE OF FINISHED LUMBER AND SOLID BIOFUEL PRODUCTS

**2809.1 General.** Exterior storage of finished lumber and solid biofuel products shall comply with Sections 2809.1 through 2809.5.

- ❖ The following sections address the size and height of piles, access roads and fire protection requirements for exterior lumber and solid biofuel storage.

**2809.2 Size of piles.** Exterior storage shall be arranged to form stable piles with a maximum height of 20 feet (6096

mm). Piles shall not exceed 150,000 cubic feet (4248 m<sup>3</sup>) in volume.

❖ Bulk dimension lumber and solid biofuel represent fuel packages of considerable volume in occupancies such as wholesale and retail yards and distribution warehouses. Complicating matters, these facilities are often located in urban areas and close to the consumer. Forest products processing plants and sawmills, on the other hand, are usually closer to the raw material. Though dimension lumber may be harder to ignite than sawdust, scrap or waste, once ignited, it may expose more people and property to danger. To manage this hazard, the code places limitations on pile heights and sizes, requires fire apparatus access roadways (see Section 2809.3) and prescribes fire protection features (see Section 2809.5).

For example, pile limitations provide a means of controlling the size of potential fires and facilitate the fire-fighting process. Lumber in open piles is often stacked on dunnage to prevent damage. Spaces formed by this material create a flue space that may not only contribute to fire spread, but also may result in structural collapse of the pile.

**2809.3 Fire apparatus access roads.** Fire apparatus access roads in accordance with Section 503 shall be located so that a maximum grid system unit of 50 feet by 150 feet (15 240 mm by 45 720 mm) is established.

❖ Fire apparatus access roads must be spaced on a maximum grid system as required by this section to

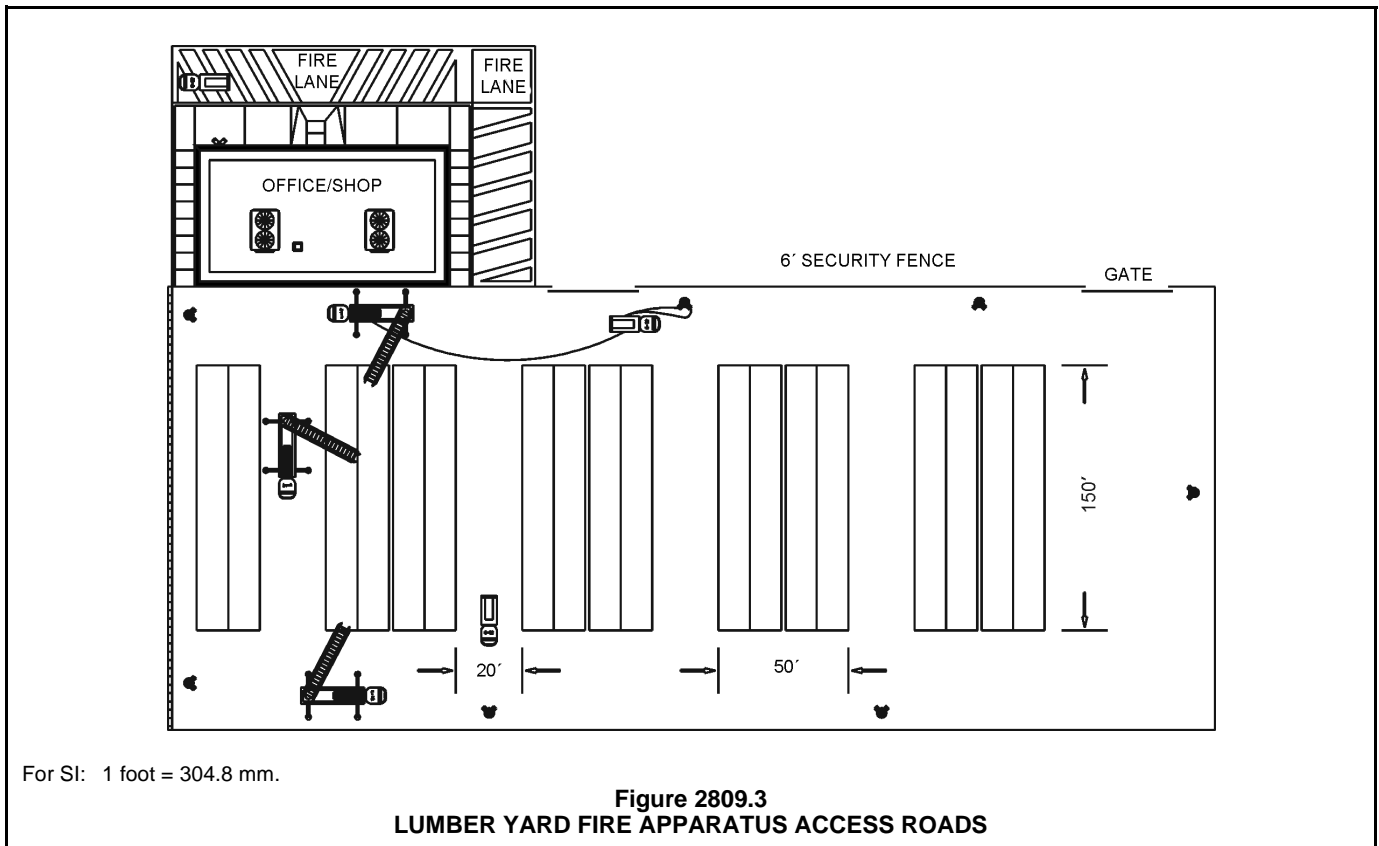

provide not only fire department access to all parts of the pile array, but also fire breaks between piles. This section correlates with Section 2809.2 by effectively limiting lumber piles to 150,000 cubic feet each (150 feet by 50 feet by 20 feet high or 1,800,000 board feet) (4248 m<sup>3</sup>) between fire apparatus access roads. The fire apparatus access roads must be arranged to provide clear, unobstructed access to required yard hydrants (see Section 2809.5), be a minimum of 20 feet (6096 mm) wide in accordance with Section 503.2.1, have an all-weather driving surface in accordance with Section 503.2.3, and provide adequate turning radii in accordance with Section 503.2.4 (see Commentary Figure 2809.3). Where Appendix D is also adopted, approved turnarounds must be provided so that the fire apparatus can maneuver to protect exposures, as well as fire fighters.

**2809.4 Security.** Permanent storage areas shall be surrounded with an *approved* fence. Fences shall be not less than 6 feet (1829 mm) in height.

**Exceptions:**

1. Lumber piles inside of buildings and production mills for lumber, plywood and veneer.
2. Solid biofuel piles inside of buildings and agro-industrial processing facilities for solid biomass feedstock.

❖ Fences for site security must be installed around the perimeter of the storage yard to limit access to stored materials and deter theft, vandalism and arson. This

section assumes that equivalent security is provided where storage is confined to a building. Open structures or weather shelters over stored materials do not qualify for the exception.

*Pumping Apparatus Driver/Operator Handbook*. Stillwater, OK: International Fire service Training Association, 2015.

**2809.5 Fire protection.** An *approved* hydrant and hose system or portable fire-extinguishing equipment suitable for the fire hazard involved shall be provided for open storage yards. Hydrant and hose systems shall be installed in accordance with NFPA 24. Portable fire extinguishers complying with Section 906 shall be located so that the distance of travel from the nearest unit does not exceed 75 feet (22 860 mm).

❖ Open storage yards can involve significant land areas and are often situated a substantial distance from public rights-of-way and public fire mains. Yard hydrant and private fire service main systems facilitate ready access to water for fire fighting by public or private fire-fighting forces. The yard hydrant system must be fed by a water supply of sufficient volume and duration to provide adequate protection where the public water supply provides inadequate volume or pressure to protect the facility. The fire flows required will, of necessity, be substantial because of the large land areas that can be included within the boundaries of a lumber yard. Water may need to be delivered to the scene by fire department tankers in rural areas where there is no public water supply. Further information and guidance on water supplies may be obtained from NFPA 1142 and the International Fire Service Training Association (IFSTA) *Pumping Apparatus Driver/Operator Handbook*. Installation of private fire protection systems must conform to the appropriate NFPA standards, including: yard hydrants and private fire mains (NFPA 24); water tanks for private fire protection (NFPA 22) and stationary fire pumps (NFPA 20).

Portable fire extinguishers must be provided for incipient fire fighting and be protected from freezing. Additionally, approved hose houses, properly equipped as described in NFPA 24, may be connected to the yard hydrant system. Travel distance to an extinguisher is limited to 75 feet (22 860 mm) so that manual efforts can be undertaken while the fire is still small enough to respond to first-aid fire-fighting efforts.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code*. Washington, DC: International Code Council, 2014.

NFPA 1142—*Standard on Water Supplies for Suburban and Rural Fire Fighting 2012 Edition*. Quincy MA: National Fire Protection Association, 2012.

# Chapter 29: Manufacture of Organic Coatings

## General Comments

The term “organic coatings” is used to describe diverse compounds formulated to protect buildings, machines and objects from the effects of weather, corrosion and hostile environmental exposures. Paint for architectural and industrial uses comprises the bulk of organic coating production. Most paints remain solvent-based, though the use of water-based products is becoming more widespread. The most common solvents include: mineral spirits, naphtha (VM&P), xylene, toluene, methyl ethyl ketone (MEK), methyl isobutyl ketone (MIBK), acetone, ethyl acetate, butyl acetate, butanol, isopropanol, ethylene glycol and propylene glycol, most of which are Class I flammable liquids with flash points less than 100°F (38°C). Other coatings are asphaltic and bituminous (for example, roofing tar). Most products in this category are Class II combustible liquids with flash points between 100°F and 140°F (38°C and 60°C).

The manufacture of organic coatings encompasses operations that produce decorative and protective coatings for architectural uses, industrial products and other specialized purposes. Requirements of this chapter address the hazards associated with the manufacture of solvent-based organic coatings. Water-based materials are exempt from these requirements.

In 1990, Harris and Swartz explained that the manufacture of organic coatings consists of the following six steps:

- Pigment dispersion.
- Mixing of raw materials and intermediates.
- Thinning and tinting.
- Quality-control testing and adjustment.
- Filtering.
- Filling into shipping containers.

Of these six steps, those involving mixing, thinning and container filling are of the most concern. Organic solvents are producers of static electricity, especially when agitated. If dissipation of static electricity is not controlled, agitation of these fluids can release enough energy to ignite flammable vapors. Static sparks are the most common source of ignition in organic coating fires.

By far, the most hazardous organic coating to manufacture is nitrocellulose lacquer because of the release of Class I flammable liquid vapors. Nitrocellulose is commonly shipped and stored alcohol-wet. This material becomes increasingly unstable as temperatures increase, thus making it capable of breaking down and burning in the absence of oxygen. Flammable vapors nearly always exist where organic coatings are manu-

factured. Consequently, the risk of ignition is usually present. Special precautions must be used to protect electrical and mechanical ignition sources.

Requirements of this chapter focus on the separation and control of ignition and fuel sources. Housekeeping is also emphasized to limit the quantity of ignitable material. Storage of flammable and combustible liquids must conform to Chapter 57. Application of organic coatings and other flammable finishes must conform to Chapter 24. Aerosol-charging operations and storage should conform to both Chapter 51 and NFPA 30B. Organic peroxide storage must conform to Chapter 62. Cellulose nitrate storage and handling are regulated by Chapter 65.

*Hazards.* In declining order, the most hazardous organic coating processes are nitrocellulose lacquer manufacturing and aerosol-charging operations, followed by those involving Class I flammable liquids, Class II combustible liquids and resin manufacturing. Manufacture of water-based products poses little hazard, although many water-based coatings exhibit a flash point when tested in a closed-cup apparatus. Research conducted by the National Paint and Coatings Association (NPCA) in 1977, however, indicates that these products pose little fire hazard. Ignition of solvent vapors released from products during the manufacturing process and flammable liquid spills are considered the most serious hazards encountered in daily operations. Concern about both of these scenarios is compounded by the fact that the mixing, pumping, agitation and filtering of organic chemicals generate large amounts of static electricity, which is the most common ignition source in paint and coating fires.

*Nitrocellulose.* Hazards associated with nitrocellulose deserve special attention. Nitrocellulose is a generic term used to describe a group of highly flammable organic fibers and other solid materials, usually cotton or wood, in fibrous or finely divided form with nitrogen contents between 10.5 and 12.6 percent. The most dangerous characteristic of these materials is their ability to support combustion in the absence of oxygen. This quality makes fire extinguishment extremely difficult. These materials are usually shipped and stored in 55-gallon (208 L) drums; however, dry product may be found in either fiber or cardboard drums.

Nitrocellulose is usually stored in one of four raw forms: solvent-wet, water-wet, plasticized or dry. Of these four forms, solvent-wet nitrocellulose (with alcohol as the usual solvent) is most common, while dry is most hazardous. Dry nitrocellulose must be avoided in all operations. Solvent-wet nitrocellulose possesses the same relative hazard as the solvent. Though relatively stable at room temperature, alcohol-wet nitrocellulose

decomposes rapidly as temperatures increase; therefore, maintaining room temperature and adequate ventilation is extremely important. Metal drums of the material must be carefully handled to prevent ignition. Drums should never be pushed across the floor or any other surface. Relatively small amounts of frictional heat may ignite the material inside the drum. Burning nitrocellulose produces harmful oxides of nitrogen and carbon monoxide (see commentary, Chapter 65).

*Spills.* Good housekeeping and prompt responses to spills are extremely important fire protection practices. Though not always successful in preventing a disaster, the prompt response of the occupants can often keep the hazard contained and under control until help arrives. Such was the case at a Sherwin-Williams paint warehouse in Dayton, Ohio, in May 1987, where the quick response of employees to a small spill [8 gallons to 10 gallons (30 L to 38 L)] saved a worker whose clothing caught on fire. It is very likely that the employees' training and experience prevented their coworker's death.

After their spill control efforts failed, the employees promptly evacuated the building and activated the fire alarm system, resulting in the notification of other employees working in different areas of the building, as well as the local fire department through the central station. Sherwin-Williams employees at the Dayton facility were well trained and well drilled in spill and emergency response procedures. After the incident, employee interviews conducted by the fire department, National Fire Protection Association (NFPA) and Building Officials and Code Administrators (BOCA) investigators suggested that this program had successfully averted disasters in the past.

*Mechanical Ignition Sources.* During the Sherwin-Williams warehouse incident, a Type E lift truck was operated in an area that should have been restricted to Type EE or EX lift trucks (see NFPA 505). Many fire investigators believe the Type E lift truck was the ignition source; however, other possible causes, including static electricity, could not be eliminated. The estimated total loss in damages resulting from this fire topped \$49 million, thus requiring an extensive environmental cleanup effort.

*Static Electricity.* Arcs and sparks from static discharge are the most common ignition sources in organic coating manufacturing plants. As stated earlier, organic chemicals produce a great deal of static electricity. Special measures are required to successfully dissipate this energy without causing ignition. NFPA 77 describes recommended practices for controlling this ignition source.

*Ignition Source Control.* In this case, fire prevention means preventing ignition. Because the fuel sources (flammable liquids and vapors) usually exist, as do ignition sources (static electricity, electric motors and fix-

tures), keeping the two apart is nearly impossible. Safeguards must, therefore, be placed to minimize the likelihood that a flammable mixture will be ignited. Some of the most fundamental practices for controlling ignition sources are:

- Installing grounds.
- Observing bonding practices.
- Installing and maintaining electrical equipment classified for hazardous locations.
- Using nonsparking tools.

Purging and inerting systems are often employed where static electricity cannot be adequately dissipated (for example, pebble mixers).

*Housekeeping.* Good housekeeping practices, including the cleanup of spills and residues, are imperative. Cleanup programs should follow a regular schedule, and every effort should be made to keep the plant as clean and orderly as possible. Nitrocellulose residues should be swept up using a wet-chamber vacuum only. Loose material and scraps must be stored in metal containers with tight-fitting, self-closing or automatic-closing lids.

Installed fire protection systems must conform to the code and the requirements of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) or another building code in effect at the time of construction, addition or alteration. Automatic sprinklers, foam-water sprinklers or deluge foam-water sprinklers must be installed and maintained, in accordance with the code and the appropriate referenced standard indicated in Chapter 9 of the code where required by the IBC or the code. Process hazards should be protected by special hazard systems designed, installed and maintained in accordance with the code and the appropriate NFPA standard (see Table 901.6.1) where flammable liquids exist. A method must be provided to notify employees and plant fire brigade personnel if a fire occurs. Portable fire extinguishers must be provided in the organic coating area and throughout the facility as provided in Section 2903.5 and Chapter 9.

### Purpose

Chapter 29 regulates materials and processes associated with the manufacture of paints, as well as bituminous, asphaltic and other organic coatings used for protective or decorative purposes. Painting and processes related to the manufacture of nonflammable and noncombustible or water-based products are exempt from the provisions of this chapter. Application of organic coatings is covered by Chapter 24. Elimination of ignition sources, maintenance of fire protection equipment and isolation or segregation of hazardous operations are emphasized.

## SECTION 2901 GENERAL

**2901.1 Scope.** Organic coating manufacturing processes shall comply with this chapter, except that this chapter shall not apply to processes manufacturing nonflammable or water-thinned coatings or to operations applying coating materials.

❖ Manufacture of flammable and combustible paints and other protective or decorative coatings is regulated by this chapter. Materials and processes associated with organic coatings manufacture may present explosion hazards from the ignition of vapors or dusts. Manufacture of nonflammable or water-based products and painting operations are not regulated by this chapter because hazards associated with those operations are insignificant.

**2901.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ Any manufacturing operation producing more than 1 gallon (4 L) of an organic coating per day must obtain approval from the fire code official. The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of activities requiring an operational permit and Section 105.6.35 for discussion of the specific operational permit for organic coating manufacturing operations. The process also notifies the fire department of the need for prefire planning for the hazardous property.

**2901.3 Maintenance.** Structures and their service equipment shall be maintained in accordance with this code and NFPA 35.

❖ NFPA 35 is referenced to cover maintenance requirements not specifically addressed by this chapter. Note that the prescribed extent of the reference to NFPA 35 is to only its maintenance provisions, not the entire standard. See commentary to Section 102.7.

## SECTION 2902 DEFINITION

**2902.1 Definition.** The following term is defined in Chapter 2:

### ORGANIC COATING.

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated term used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 2903 GENERAL PRECAUTIONS

**2903.1 Building features.** Manufacturing of organic coatings shall be done only in buildings that do not have pits or *basements*.

❖ The IBC classifies organic coating processes in Group H-2 or H-3 occupancies, depending on the types and amounts of materials, when the maximum allowable quantity per control area (MAQ) of hazardous materials in Table 307.1(1) of that code is exceeded. Basements, pits or depressed first-floor construction are prohibited because of the tendency for hazardous materials vapors to accumulate in low areas and the difficulty in fighting fires in such areas and occupancies.

**2903.2 Location.** Organic coating manufacturing operations and operations incidental to or connected with organic coating manufacturing shall not be located in buildings having other occupancies.

❖ Incidental occupancies involve operations and activities closely related to the primary occupancy and are necessary for efficient, continuous and safe organic coatings manufacture. Administration, storage, shipping and receiving, as well as other related but not indispensable operations, should be located in separate buildings. Separations must have a fire-resistance rating, separation distance or a combination of the two as required by the IBC.

**2903.3 Fire-fighting access.** Organic coating manufacturing operations shall be accessible from not less than one side for the purpose of fire control. *Approved aisles* shall be maintained for the unobstructed movement of personnel and fire suppression equipment.

❖ Access from at least one side conforming to Sections 503 and 504 is required. Fire department connections, fire protection valves, yard hydrants and related fire-fighting equipment should be sited with respect to the provided access and hazards present (see commentary, Chapter 5). Fire department preincident plans should consider operational alternatives if the access is unusable when only one means of access is provided. Design and layout of equipment and processes must facilitate access for fire control. If provided, standpipes and hose reels should be located at intersections between aisles to facilitate movement of hose lines. Portable fire extinguishers must be located in the path of egress travel.

**2903.4 Fire protection systems.** *Fire protection systems* shall be installed, maintained, periodically inspected and tested in accordance with Chapter 9.

❖ Fire protection must be continuously maintained in order to remain effective. Prior permission of the fire code official is required for temporary outages for maintenance, repair, testing, alterations or additions. The fire code official may require special protection or precautions during any outage period. Every effort

## MANUFACTURE OF ORGANIC COATINGS

must be made to restore service as quickly as possible (see commentary, Chapter 9).

**2903.5 Portable fire extinguishers.** Not less than one portable fire extinguisher complying with Section 906 for extra hazard shall be provided in organic coating areas.

- ❖ At least one fire extinguisher is required, sized and located for the extra hazardous nature of organic coatings operations. The addition of wheeled fire extinguishers could provide more extinguishing agent, longer discharge time and greater stream reach for the higher hazard in large area operations.

**2903.6 Open flames.** Open flames and direct-fired heating devices shall be prohibited in areas where flammable vapor-air mixtures exist.

- ❖ Only indirect heat equipment employing hot water, steam or warm air, or heat equipment approved for use in Class I, Division 2, Group D hazardous locations must be used where flammable vapor-air mixtures exist.

**2903.7 Smoking.** Smoking shall be prohibited in accordance with Section 310.

- ❖ Smoking is prohibited in and around organic coating manufacturing areas, in accordance with Section 310, to control this ignition source. Approved signs must be posted at entrances and throughout the manufacturing area. Locations approved for smoking should be separated from the manufacturing area by fire-resistance-rated construction and provided with separate ventilation.

**2903.8 Power equipment.** Power-operated equipment and industrial trucks shall be of a type *approved* for the location.

- ❖ Section 309 of the code, Section 7-6 of NFPA 35 and NFPA 505 provide guidance on use, classification of hazards and selection of industrial lift trucks.

**2903.9 Tank maintenance.** The cleaning of tanks and vessels that have contained flammable or *combustible liquids* shall be performed under the supervision of persons knowledgeable of the fire and explosion potential.

- ❖ Trained people well versed in the hazards of the tank cleaning process must supervise the cleaning of tanks containing flammable or combustible vapors. NFPA 326 provides useful guidance on tank-cleaning safety practices. Oxygen deficiency and explosion potential hazards are paramount concerns.

**2903.9.1 Repairs.** Where necessary to make repairs involving “hot work,” the work shall be authorized by the responsible individual before the work begins.

- ❖ Extreme caution must be exercised when welding and cutting in or around flammable or combustible liquid tanks. Chapter 35 specifies safety requirements for welding and cutting operations and, in Section 3510, regulates hot work on tanks containing, or having contained, flammable or combustible liquids. Specific reference to NFPA 326 is also included in that section. See the commentary to Section 3510.

**2903.9.2 Empty containers.** Empty flammable or *combustible liquid* containers shall be removed to a detached, outside location and, if not cleaned on the premises, the empty containers shall be removed from the plant as soon as practical.

- ❖ Partially full and empty containers may pose an even greater hazard than full containers. Residual liquid must be completely removed and flammable vapors vented or purged from containers before they can be considered safe. Unused containers must be promptly removed from the premises. A special detached storage facility may be used for containers awaiting cleaning or disposal (see commentary, Section 5003.2.5).

**2903.10 Drainage.** Drainage facilities shall be provided to direct flammable and *combustible liquid* leakage and fire protection water to an *approved* location away from the building, any other structure, storage area or adjoining premises.

- ❖ Site drainage must be arranged to minimize hazards to adjacent properties and constructed to keep spills on site and away from significant buildings, means of egress and access routes. See Chapter 57 for further guidance on above-ground diking and drainage.

**2903.11 Alarm system.** An *approved* fire alarm system shall be provided in accordance with Section 907.

- ❖ A manual fire alarm system is required in areas where organic coatings are manufactured (see commentary, Section 907.2.5).

## SECTION 2904 ELECTRICAL EQUIPMENT AND PROTECTION

**2904.1 Wiring and equipment.** Electrical wiring and equipment shall comply with this chapter and shall be installed in accordance with NFPA 70.

- ❖ NFPA 70 and the requirements of this section apply to electrical wiring and equipment to reduce the fire hazard associated with the presence of such equipment in areas where organic coatings are being manufactured.

**2904.2 Hazardous locations.** Where Class I liquids are exposed to the air, the design of equipment and ventilation of structures shall be such as to limit the Class I, Division 1, locations to the following:

1. Piping trenches.
2. The interior of equipment.
3. The immediate vicinity of pumps or equipment locations, such as dispensing stations, open centrifuges, plate and frame filters, opened vacuum filters, change cans and the surfaces of open equipment. The immediate vicinity shall include a zone extending from the vapor liberation point 5 feet (1524 mm) horizontally in all directions and vertically from the floor to a level 3 feet (914 mm) above the highest point of vapor liberation.

- ❖ Class I, Division 1, hazardous locations are areas where flammable or explosive vapors generally exist

in quantities sufficient to support an ignition (vapor-air concentrations within the flammable range). Piping trenches and other depressed areas will accumulate vapors because these vapors are usually heavier than air. Vapor production generally creates higher concentrations where flammable liquids are dispensed. Other areas must be adequately ventilated to disperse and dilute vapors to prevent flammable or explosive concentrations. The zone description in Item 3 should be used to define the limitations of the "immediate vicinity." Most flammable vapors are susceptible to ignition within relatively narrow concentrations in air so these boundaries provide a relatively good safety margin.

**2904.2.1 Other locations.** Locations within the confines of the manufacturing room where Class I liquids are handled shall be Class I, Division 2, except locations indicated in Section 2904.2.

❖ Class I, Division 2, locations include all areas where flammable vapors may be liberated in sufficient quantities to present a hazard should an accidental release or spill occur. Areas extending beyond the boundaries defined in Section 2904.2, such as processing areas for Class I liquids, should be considered as such locations. NFPA 497 provides useful guidance for determining the extent of electrically classified boundaries. When Class II liquids are handled and the ambient temperature is cooler than the liquid's flash point, ordinary electrical equipment may be used, provided precautions are taken to prevent hot metal or slag from falling into the liquid.

**2904.2.2 Ordinary equipment.** Ordinary electrical equipment, including switchgear, shall be prohibited, except where installed in a room maintained under positive pressure with respect to the hazardous area. The air or other media utilized for pressurization shall be obtained from a source that will not cause any amount or type of flammable vapor to be introduced into the room.

❖ Electrical equipment not classified for use in hazardous locations must be installed in separate rooms and provided with positive-pressure ventilation to prevent infiltration of flammable vapors. Care must be taken to avoid using air for ventilation that is contaminated with flammable vapors. Outside air taken from a source well above the adjacent grade is usually preferred. NFPA 496 provides useful guidance on the design of purged enclosures for electrical equipment.

**2904.3 Bonding.** Equipment including, but not limited to, tanks, machinery and piping shall be bonded and connected to a ground where an ignitable mixture is capable of being present.

❖ Both bonding and grounding prevent the accumulation of static charges and accidental release of electrical energy that could cause an ignition. The bond and ground may be physically applied or be a part of the design of the apparatus (see Commentary Figure 2904.3).

**2904.3.1 Piping.** Electrically isolated sections of metallic piping or equipment shall be grounded or bonded to the other grounded portions of the system.

❖ In order to maintain the continuity of the grounding path for all portions of a tank and piping system that

do not form a continuous conductive path, each electrically isolated section of piping must be independently grounded or, alternatively, be bonded to another properly grounded portion of the system.

**2904.3.2 Vehicles.** Tank vehicles loaded or unloaded through open connections shall be grounded and bonded to the receiving system.

- ❖ The bond between the tank vehicle and the receiving system may be designed into the dispensing equipment or require physical attachment by the operator (a bond wire is often part of the dispensing hose). The system must also be grounded.

**2904.3.3 Containers.** Where a flammable mixture is transferred from one portable container to another, a bond shall be provided between the two containers, and one shall be grounded.

- ❖ Like tank vehicles, the dispensing hose may have the bond designed into the equipment or, if no such bond exists, a separate bond may need to be applied by the operator. A system ground must also be present.

**2904.4 Ground.** Metal framing of buildings shall be grounded with resistance of not more than 5 ohms.

- ❖ In order to reduce the likelihood of static electricity being generated involving any portion of the structure, the metal structural frame of Type II metal buildings or, for that matter, the metal frame of a building of any construction type, must be bonded together and grounded with a maximum resistance of 5 ohms.

## SECTION 2905 PROCESS STRUCTURES

**2905.1 Design.** Process structures shall be designed and constructed in accordance with the *International Building Code*.

- ❖ The IBC classifies organic coating processes in occupancy Group H-2 or H-3, depending on the type and amounts of materials, when the MAQ of hazardous materials in Table 307.1(1) of that code is exceeded. IBC Section 418 further regulates these structures as to their physical configuration, location and finished product storage. See the commentary to IBC Sections 418.1 through 418.6 for further information.

**2905.2 Fire apparatus access.** Fire apparatus access complying with Section 503 shall be provided for the purpose of fire control to not less than one side of organic coating manufacturing operations.

- ❖ Access from at least one side that conforms to Section 503 is required. Fire department connections, fire protection valves, yard hydrants and related fire-fighting equipment should be located for ready access to hazards. Fire department preincident plans should consider operational alternatives if the access is unusable when only one means of access is provided.

**2905.3 Drainage.** Drainage facilities shall be provided in accordance with Section 2903.10 where topographical conditions are such that flammable and *combustible liquids* are capable of flowing from the organic coating manufacturing operation so as to constitute a fire hazard to other premises.

- ❖ Facility design should consider both spill containment and control provisions. Drains must discharge to approved containment basins. The location of containment facilities must not endanger adjacent facilities (see Sections 2903.10 and 5004.2).

**2905.4 Explosion control.** Explosion control shall be provided in areas subject to potential *deflagration* hazards as indicated in NFPA 35. Explosion control shall be provided in accordance with Section 911.

- ❖ Explosion control is required where Class I liquids or flammable dusts create a potential deflagration hazard; as defined by NFPA 35. Section 911 and IBC Section 414.5.1 prescribe requirements for explosion control. NFPA 68 also provides guidance on this subject.

**2905.5 Ventilation.** Enclosed structures in which Class I liquids are processed or handled shall be ventilated at a rate of not less than 1 cubic foot per minute per square foot [ $0.00508 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of solid floor area. Ventilation shall be accomplished by exhaust fans that take suction at floor levels and discharge to a safe location outside the structure. Noncontaminated intake air shall be introduced in such a manner that all portions of solid floor areas are provided with continuous uniformly distributed air movement.

- ❖ Ventilation systems must be designed to prevent the accumulation of vapors in the building where Class I flammable liquids are processed. Uncontaminated air, preferably from a source outside the building, should be distributed to dilute and disperse vapors over the entire solid floor area and then discharge them to a safe location outside the building. A ventilation rate of 1 cubic foot per minute per square foot ( $0.00508 \text{ m}^3/\text{s} \cdot \text{m}^2$ ) is required.

**2905.6 Heating.** Heating provided in hazardous areas shall be by indirect means. Ignition sources such as open flames or electrical heating elements, except as provided for in Section 2904, shall not be permitted within the structure.

- ❖ Only indirect-heat appliances are permitted in hazardous areas. Steam or hot-water radiators and forced warm air may be used, provided the fans and heat sources are located outside the hazardous area. Appliances and devices using or producing open flames, electrical elements or electric arcs are prohibited.

## SECTION 2906 PROCESS MILLS AND KETTLES

**2906.1 Mills.** Mills, operating with close clearances, which process flammable and heat-sensitive materials, such as nitro-

cellulose, shall be located in a detached building or in a non-combustible structure without other occupancies. The amount of nitrocellulose or other flammable material brought into the area shall not be more than the amount required for a batch.

❖ Milling of heat-sensitive materials, such as nitrocellulose, is an extraordinary hazard that must be located in single-purpose buildings, away from other uses and high-hazard operations. Pebble mills pose a special vapor ignition hazard caused by static electricity. Both the grinding material and inner lining of these mills are made of materials with good insulating characteristics. Because static electricity is produced during milling, it has nowhere to go. Generally, the atmosphere inside of this type of mill is made either partially or totally inert using nitrogen or carbon dioxide gas to prevent ignition.

**2906.2 Mixers.** Mixers shall be of the enclosed type or, where of the open type, shall be provided with properly fitted covers. Where flow is by gravity, a shutoff valve shall be installed as close as practical to the mixer, and a control valve shall be provided near the end of the fill pipe.

❖ Like any other part of the manufacturing process, mixing organic chemicals produces large quantities of static electricity. These requirements provide for controlling fires by smothering (closing the cover or lid) and interrupting fuel flow (closing the product valves).

**2906.3 Open kettles.** Open kettles shall be located in an outside area provided with a protective roof; in a separate structure of noncombustible construction; or separated from other areas by a noncombustible wall having a fire-resistance rating of not less than 2 hours.

❖ Kettles and reactors are large warming vessels used to cook various solid, liquid and gaseous materials, including monomers, which are usually solids or liquids, to initiate a controlled chemical reaction to produce resins. Most operations are exothermic and involve controlled polymerization. Finished resins are mixed with solvents, pigments and additives (for example, quality-control agents, texture materials, glass beads, etc.) to form the finished product in organic coating manufacturing. Principal dangers associated with open-fire kettles or reactors include the ignition of flammable vapors and uncontrolled polymerization. Vapors are released to the surrounding atmosphere, and uncontrolled reactions can lead to spills or discharges from the reactor vessel in open kettles. These operations must be conducted in an outside area under protective cover, if possible. Otherwise, open-fire kettles must be operated only in a separate building of noncombustible construction. An area separated from the main facility by a 2-hour fire wall or fire barrier would comply with this requirement. The area must be positively ventilated, with vapors discharged to a safe location away from the combustion air intake.

**2906.4 Closed kettles.** Contact-heated kettles containing solvents shall be equipped with safety devices that, in case of a

fire, will turn off the process heat, turn on the cooling medium and inject inert gas into the kettle.

❖ Closed reactors confine reaction byproducts within the vessel in a closed loop system. Closed kettles or reactors may be either continuous or batch reactors. In the former, reactants are continuously fed into the system as reactant mass and byproducts are removed. Generally, continuous reactors are safer from a fire protection standpoint.

By comparison, reactants are fed into the batch reactor vessel, which is then sealed before the reaction is initiated by the application of heat. Reaction mass and byproducts are removed upon completion of the reaction and a new batch is processed with new raw materials. To interrupt the chemical process once the reaction begins, heat must be removed and the reaction mass cooled. This often requires the simultaneous venting of gaseous byproducts. Normal and emergency pressure relief vents must be arranged to discharge flammable vapors to a safe location when necessary. Automatic inerting of the atmosphere further disrupts the reaction process by displacing oxygen and oxidation byproducts. For further information, see NFPA 35.

**2906.4.1 Vaporizer location.** The vaporizer section of heat-transfer systems that heat closed kettles containing solvents shall be remotely located.

❖ The vaporizer must be located remotely from the process area.

**2906.5 Kettle controls.** The kettle and thin-down tank shall be instrumented, controlled and interlocked so that any failure of the controls will result in a safe condition. The kettle shall be provided with a pressure-rupture disc in addition to the primary vent. The vent piping from the rupture disc shall be of minimum length and shall discharge to an *approved* location. The thin-down tank shall be adequately vented. Thinning operations shall be provided with an adequate vapor removal system.

❖ Reactors must be provided with automatic high-temperature limit switches or other approved automatic temperature control methods. Manual and automatic methods must be provided to interrupt the flow of fuel if a flameout or other emergency occurs. The rupture disc is intended to vent excess pressure if the normal vent fails. Ventilation must be by a condenser of adequate size to prevent the accumulation of a vapor fog in the reactor area.

## SECTION 2907 PROCESS PIPING

**2907.1 Design.** Piping, valves and fittings shall be designed for the working pressures and structural stresses to which the piping, valves and fittings will be subjected, and shall be of steel or other material *approved* for the service intended.

❖ Suitability of piping for the intended purpose is largely determined by compatibility with the material that it

will contain, adequate strength under normal working pressures and durability throughout the intended life of the system. Materials are permitted provided they are approved for the intended service. Piping systems for flammable and combustible liquids must comply with Section 5703.6. Good engineering judgment is needed in the design of these systems.

**2907.2 Valves.** Valves shall be of an indicating type. Terminal valves on remote pumping systems shall be of the dead-man type, shutting off both the pump and the flow of solvent.

- ❖ Indicating valves permit the system operator to determine the position of critical valves at a glance. This aids in prompt control of the product flow if a piping or process failure occurs. Dead-man valves interlocked with product supply pumps cause the interruption of product flow if there is an operator error.

**2907.3 Support.** Piping systems shall be supported adequately and protected against physical damage. Piping shall be pitched to avoid unintentional trapping of liquids, or *approved* drains shall be provided.

- ❖ Ideally, product lines should be designed without trapped sections. Cleaning and purging of the system is made easier without releasing vapors when drains are opened and ignition sources are adequately controlled. Sufficient support and protection of piping prevent product releases if accidents occur in the processing area.

**2907.4 Connectors.** *Approved* flexible connectors shall be installed where vibration exists or frequent movement is necessary. Hose at dispensing stations shall be of an *approved* type.

- ❖ Rigid connectors either loosen from repeated vibration or fail from stresses created. Hose should be reinforced and designed with an integral ground wire to permit container bonding.

**2907.5 Tests.** Before being placed in service, all piping shall be free of leaks when tested for not less than 30 minutes at not less than 1.5 times the working pressure or a minimum of 5 pounds per square inch gauge (psig) (35 kPa) at the highest point in the system.

- ❖ Tests are intended to demonstrate system integrity under both normal and abnormal conditions. The 50-percent margin represents a reasonable safety range if a malfunction occurs. No test provides absolute certainty that a failure will not occur.

## SECTION 2908 RAW MATERIALS IN PROCESS AREAS

**2908.1 Nitrocellulose quantity.** The amount of nitrocellulose brought into the operating area shall not exceed the amount required for a work shift. Nitrocellulose spillage shall be promptly swept up and disposed of properly.

- ❖ Nitrocellulose lacquer production is among the most hazardous organic coatings manufacturing processes. Nitrocellulose can support combustion in the absence of oxygen and is, therefore, considered very

dangerous. As the temperature of alcohol-wet nitrocellulose increases, it becomes unstable. Relatively small amounts of energy are required to initiate combustion. Small amounts of finely divided nitrocellulose fiber should be cleaned up only with a wet-vacuum apparatus. Loose nitrocellulose material, scraps and waste should be stored underwater in a metal container with a tight-fitting, self-closing or automatic-closing lid. The waste container should be removed from the building daily and its contents burned at an approved site. See Chapter 65 for further regulation of pyroxilin plastics.

**2908.2 Organic peroxides quantity.** Organic peroxides brought into the operating area shall be in the original shipping container. When in the operating area, the organic peroxide shall not be placed in locations exposed to ignition sources, heat or mechanical shocks.

- ❖ Organic peroxides are both flammable materials and strong oxidizers. Many organic peroxides are principal components in more dangerous compounds such as blasting agents. Contamination may sensitize organic peroxides, making them especially sensitive to heat and shock. Organic peroxides should be kept in their original shipping containers to permit easy identification and prevent accidents while transferring contents to other containers.

## SECTION 2909 RAW MATERIALS AND FINISHED PRODUCTS

**2909.1 General.** The storage, handling and use of flammable and *combustible liquids* in process areas shall be in accordance with Chapter 57.

- ❖ Chapter 57 details requirements for the storage and handling of flammable liquids. Moreover, it prescribes limitations on the size and location of containers, tanks and piles of flammable liquids in storage. The protection of flammable liquids in bulk storage has been the topic of considerable debate in the aftermath of the 1987 Sherwin-Williams warehouse fire. Fire code officials should carefully consider protection requirements. Annexes D and E of NFPA 30 contain extensive discussions of recommended protection for bulk flammable liquid storage. Also, investigations have been completed of flammable liquid storage in plastic containers. Reports from these tests conducted by the National Fire Protection Research Foundation (NFPRF) are available from NFPA.

**2909.2 Tank storage.** Tank storage for flammable and *combustible liquids* located inside of structures shall be limited to storage areas at or above grade which are separated from the processing area in accordance with the *International Building Code*. Processing equipment containing flammable and *combustible liquids* and storage in quantities essential to the continuity of the operations shall not be prohibited in the processing area.

- ❖ Tank storage located below grade is prohibited. Basements located under grade-level storage areas

should be discouraged. Below-grade flammable liquid fires are extremely difficult to fight. Similarly, above-grade spills will flow to lower floors, possibly resulting in spill fires on more than one building level. Tank storage of raw materials must be confined to locations at or above grade level. Tank storage must be separated from the processing area, in accordance with the IBC. If possible, these rooms should be accessible on at least one exterior side of the facility. IBC Section 418.4 contains requirements for the separation of these areas.

**2909.3 Tank vehicle.** Tank car and tank vehicle loading and unloading stations for Class I liquids shall be separated from the processing area, other plant structures, nearest lot line of property that can be built upon or public thoroughfare by a minimum clear distance of 25 feet (7620 mm).

- ❖ Like other separation requirements, the 25-foot (7620 mm) clearance is intended to limit accidental fire exposure to process, storage and adjacent buildings, as well as other areas. Additionally, clearance provides the same protection to the tanker or tank car if an incident involving an adjacent facility occurs. Finally, clearance provides access for establishing fire-fighting operations if an incident occurs.

**2909.3.1 Loading.** Loading and unloading structures and platforms for flammable and *combustible liquids* shall be designed and installed in accordance with Chapter 57.

- ❖ Chapter 57 specifies requirements for flammable liquid loading and unloading. Section 5706.5 and Chapter 28 of NFPA 30 specify requirements for tank vehicle and tank car loading and unloading operations, including separate piping and valves for Class I flammable liquids, and Class II and III combustible liquids; leak detection on the discharge side of dispensing pumps; provisions for bonding dispensing equipment to the tank vehicle; and flow control interlocks.

**2909.3.2 Safety.** Tank cars for flammable liquids shall be unloaded such that the safety to persons and property is ensured. Tank vehicles for flammable and *combustible liquids* shall be loaded and unloaded in accordance with Chapter 57.

- ❖ Section 5706.6 emphasizes the tank vehicle operator's responsibilities. Essentially, the operator must verify that all safety features are properly used and maintained. Before loading or unloading the product, the operator must verify that required bonding is in place, a liquid- and vapor-tight connection has been made and fill or discharge lines are protected from physical damage. The operator must remain with the vehicle during the loading or unloading operation, but not in the cab.

**2909.4 Nitrocellulose storage.** Nitrocellulose storage shall be located on a detached pad or in a separate structure or a room enclosed in accordance with the *International Building Code*. The nitrocellulose storage area shall not be utilized for any other purpose. Electrical wiring and equipment installed

in storage areas adjacent to process areas shall comply with Section 2904.2.

- ❖ Solvent-wet nitrocellulose is the most common type associated with lacquer production. In this case, the solvent is usually an alcohol, which is a Class I flammable liquid. Solvent-wet nitrocellulose possesses the same fire-hazard characteristics as the solvent in which it is stored, with important differences noted. Solvent-wet nitrocellulose becomes increasingly unstable as the temperature rises. Once ignited, nitrocellulose will continue to burn even in the absence of oxygen. Therefore, extra diligence must be used to prevent ignition and fire spread. IBC Section 418.5 contains requirements for the separation of these areas.

**2909.4.1 Containers.** Nitrocellulose shall be stored in closed containers. Barrels shall be stored on end and not more than two tiers high. Barrels or other containers of nitrocellulose shall not be opened in the main storage structure but at the point of use or other location intended for that purpose.

- ❖ Like other materials possessing unusual fire-hazard characteristics that may be susceptible to ignition if improperly handled, nitrocellulose must be kept in its Department of Transportation (DOTn) shipping container until used. This reduces the likelihood of accidents associated with unnecessary transfer operations and allows the material to be readily identified by its shipping and DOTn hazard labels. In order to avoid solvent leakage, containers must not be stored on their sides because nitrocellulose is commonly shipped in a wet solvent. One-drum-high storage is preferred, but two-drum-high storage is allowed. Stacking containers poses the risk of toppling or other physical damage to the container with the potential for spillage or ignition.

**2909.4.2 Spills.** Spilled nitrocellulose shall be promptly wetted with water and disposed of by use or burning in the open at an *approved* detached location.

- ❖ Wetting spills with water will help prevent ignition by diluting the flammable solvent, especially in the case of alcohol-wet nitrocellulose. The spilled material must be swept up immediately and placed in a tightly closed metal container and covered with water. Waste must be disposed of in accordance with applicable federal, state and local environmental regulations, or denitrated.

**2909.5 Organic peroxide storage.** The storage of organic peroxides shall be in accordance with Chapter 62.

- ❖ Organic peroxides pose a dual hazard of being both flammable and oxidizing materials (see Section 5001.1). Additionally, these compounds are sensitive to friction, heat and shock. Detached storage buildings are required when storage exceeds the amounts indicated in Table 5003.8.2 to prevent reactions with other materials. These buildings must be constructed in accordance with requirements of the IBC for Group H occupancies, depending on the classification of the organic peroxide involved. Separation distances

specified in Table 6204.1.2 are intended to reduce the likelihood of an incident causing injury or property damage arising from materials stored adjacent to hazardous operations that may cause personal injury or property damage. Adequate access must be provided to facilitate defensive fire-fighting operations and support the installed protection. If possible, the fire department connection or connections should be of the free-standing type located far away from the building along the fire service access route. An organic peroxide may be stored inside a building of another occupancy group in control areas in accordance with Sections 5003.1.1 and 6203.1.1.

Signs are to be posted at the entrance and in all storage areas. NFPA 704 hazard warning signs and signs indicating: "ORGANIC PEROXIDE STORAGE—NO OPEN FLAMES" are recommended for this purpose.

Organic peroxides must be stored in original shipping containers. This practice serves the following three important purposes: reduces the likelihood of accidents caused by unnecessary handling; keeps the material in labeled containers that clearly identify the contents and the hazard; and reduces the likelihood of contamination, which may sensitize the material or cause it to decay.

**2909.5.1 Size.** The size of the package containing organic peroxide shall be selected so that, as nearly as practical, full packages are utilized at one time. Spilled peroxide shall be promptly cleaned up and disposed of as specified by the supplier.

❖ Any leftover organic peroxide poses a storage and handling problem. Most organic peroxides become increasingly unstable if contaminated with foreign materials. Organic peroxides may spontaneously ignite if exposed to sufficient heat or shock because they are both flammables and oxidizers. Extreme care must be taken when cleaning up organic peroxide spills. Hydrocarbons and other volatile organic chemicals may sensitize an organic peroxide. Excessive heat or friction during cleanup operations could result in a deflagration or explosion if the material is contaminated.

**2909.6 Finished products.** Finished products that are flammable or *combustible liquids* shall be stored outside of structures, in a separate structure, or in a room separated from the processing area in accordance with the *International Building Code*. The storage of finished products shall be in tanks or closed containers in accordance with Chapter 57.

❖ Flammable liquid warehouses must comply with both the IBC and Chapter 57 requirements. Though flammable liquid warehouses are exempt from storage quantity limitations, pile size and height restrictions still apply. Separation requirements are contained in IBC Section 418.6.

## Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

Bradford, W.J. "Chemical Processes." *Industrial Fire Hazards Handbook*, 3rd ed. Quincy, MA: National Fire Protection Association, 1990.

Harris, M.V. and A.B. Swartz. "Chapter 10: Paints and Coatings Manufacture." *Industrial Fire Hazards Handbook*, 3rd ed. Quincy, MA: National Fire Protection Association, 1990.

# Chapter 30: Industrial Ovens

## General Comments

The basic cause of industrial oven and furnace explosions is the ignition of an accumulated combustible mixture within the confined space of the furnace. A dangerous combustible mixture within a furnace consists of an excessive quantity of fuel mixed with air in proportions that will result in rapid or uncontrolled combustion when an ignition source is supplied. The magnitude and intensity of the explosion will depend on the relative quantity of the fuel that has accumulated, and the fuel-air ratio at the moment of ignition. Explosions, including “puffs,” are often the result of improper design of the equipment or control systems, or a malfunction of one or the other.

The most common causes of oven fires and explosions are:

1. An interruption of the fuel supply, air supply or ignition source to the burners that results in a momentary loss of flame, which is subsequently followed by reignition of accumulated fuel-air mixtures.

2. Fuel leakage into an idle furnace resulting in a flammable fuel-air mixture, which causes an explosion upon start-up.
3. Repeated unsuccessful attempts to light the furnace without adequate purging of flammable fuel-air mixtures followed by ignition of the fuel-air mixture.
4. Ignition of flammable vapors emanating from a product or workpiece being dried where the volatiles enter the flammable range due to the materials being heated

This chapter addresses the fuel supply, ventilation, emergency shutdown equipment, fire protection, and the operation and maintenance of industrial ovens.

## Purpose

Compliance with this chapter is intended to reduce the likelihood of fires involving industrial ovens or to manage the impact if a fire should occur. Industrial ovens are sometimes referred to as industrial heat enclosures or industrial furnaces. Heat may be furnished by gas burners, oil burners, electric heaters, infrared lamps, induction heaters or steam radiation systems.

---

## SECTION 3001 GENERAL

**3001.1 Scope.** This chapter shall apply to the installation and operation of industrial ovens and furnaces. Industrial ovens and furnaces shall comply with the applicable provisions of NFPA 86, the *International Fuel Gas Code*, *International Mechanical Code* and this chapter. The terms “ovens” and “furnaces” are used interchangeably in this chapter.

❖ This chapter contains provisions for the installation and operation of industrial ovens and furnaces. If a certain provision is not found in this chapter, applicable provisions of NFPA 86, the *International Mechanical Code*® (IMC®) and the *International Fuel Gas Code*® (IFGC®) must be used.

**3001.2 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is

issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit. Because of the flammable nature of the contents and the operation of industrial ovens, an operational permit is required by Section 105.6.25. The process also notifies the fire department of the need for prefire planning for the hazardous property.

## SECTION 3002 DEFINITIONS

**3002.1 Definitions.** The following terms are defined in Chapter 2:

**FURNACE CLASS A.**

**FURNACE CLASS B.**

**FURNACE CLASS C.**

**FURNACE CLASS D.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper

## INDUSTRIAL OVENS

application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 3003 LOCATION

**3003.1 Ventilation.** Enclosed rooms or *basements* containing industrial ovens or furnaces shall be provided with combustion air in accordance with the *International Mechanical Code* and the *International Fuel Gas Code*, and with ventilation air in accordance with the *International Mechanical Code*.

❖ Placing an oven or furnace below grade presents difficulty in ventilation and offers severe obstacles to proper explosion release. When gas or oil is used, the furnace or oven should be vented separately unless the products of discharge deposit directly into the oven.

**3003.2 Exposure.** When locating ovens, oven heaters and related equipment, the possibility of fire resulting from overheating or from the escape of fuel gas or fuel oil and the possibility of damage to the building and injury to persons resulting from explosion shall be considered.

❖ Ovens and furnaces should be located where they will present the least possible hazard to property and life. To present the least possible hazard, walls or partitions may be needed around the furnaces or ovens.

**3003.3 Ignition source.** Industrial ovens and furnaces shall be located so as not to pose an ignition hazard to flammable vapors or mists or *combustible dusts*.

❖ Industrial ovens should be considered an ignition source and should be separated from any materials that may be easily ignited.

**3003.4 Temperatures.** Roofs and floors of ovens shall be insulated and ventilated to prevent temperatures at combustible ceilings and floors from exceeding 160°F (71°C).

❖ Furnaces and ovens should be designed to minimize their fire hazard when operating at elevated temperatures. Insulation and ventilation are important in preventing heat transfer from the oven to surrounding combustible products.

### SECTION 3004 FUEL PIPING

**3004.1 Fuel-gas piping.** Fuel-gas piping serving industrial ovens shall comply with the *International Fuel Gas Code*. Piping for other fuel sources shall comply with this section.

❖ Electrically wired, oil-fired and special-atmosphere furnaces are covered in this section. Fuel-gas piping is covered in the IFGC.

**3004.2 Shutoff valves.** Each industrial oven or furnace shall be provided with an *approved* manual fuel shutoff valve in accordance with the *International Mechanical Code* or the *International Fuel Gas Code*.

❖ Individual manual shutoff valves are used for equipment isolation. Requirements are found in either the IMC or IFGC.

**3004.2.1 Fuel supply lines.** Valves for fuel supply lines shall be located within 6 feet (1829 mm) of the appliance served.

**Exception:** When *approved* and the valve is located in the same general area as the appliance served.

❖ A fuel supply shutoff valve must be installed in the fuel supply line within 6 feet (1829 mm) of the appliance for easy shutoff of fuel in case of an emergency.

**3004.3 Valve position.** The design of manual fuel shutoff valves shall incorporate a permanent feature which visually indicates the open or closed position of the valve. Manual fuel shutoff valves shall not be equipped with removable handles or wrenches unless the handle or wrench can only be installed parallel with the fuel line when the valve is in the open position.

❖ Manual shutoff valves should have a permanently affixed visual indicator that is easily recognizable, and it should be in the open position. The removable handle requirement prevents fuel supply shutoff for any reason. Accidental shutoff could endanger property and people.

### SECTION 3005 INTERLOCKS

**3005.1 Shut down.** Interlocks shall be provided for Class A ovens so that conveyors or sources of flammable or combustible materials shall shut down if either the exhaust or recirculation air supply fails.

❖ If ventilation or airflow were lost, a safety control circuit would immediately shut down the heating system of the effected section. When necessary, loss of ventilation must shut down the entire system, as well as the conveyor.

### SECTION 3006 FIRE PROTECTION

**3006.1 Required protection.** Class A and B ovens that contain, or are utilized for the processing of, combustible materials shall be protected by an *approved* automatic fire-extinguishing system complying with Chapter 9.

❖ While this section requires that a fire protection system be installed in Class A and B ovens, it does not specify the type of fire-extinguishing system required—although automatic sprinklers would typically be considered the system of choice. As such, as an alternative to sprinklers, protection could be in the form of a water spray or mist system designed and installed in accordance with NFPA 13 or NFPA 750, respectively; or a dry chemical, carbon dioxide (CO<sub>2</sub>),

inert gas or foam system designed and installed in accordance with the applicable standard indicated in Section 904. This type of system must be compatible with the design of the oven and the materials being processed. The extent of the required fire protection system is dictated by the design standard and depends on the construction and arrangement of the oven, as well as the materials handled, and should include oven exhaust ducts.

**3006.2 Fixed fire-extinguishing systems.** Fixed fire-extinguishing systems shall be provided for Class C or D ovens to protect against such hazards as overheating, spillage of molten salts or metals, quench tanks, ignition of hydraulic oil and escape of fuel. It shall be the user's responsibility to consult with the *fire code official* concerning the necessary requirements for such protection.

❖ Class C and D ovens can operate with special processing atmospheres at very high temperatures and can present fire hazards to the areas around them. While this section requires that a fire protection system be installed in Class C and D ovens, it does not specify the type of fire-extinguishing system required, although automatic sprinklers would typically be considered the system of choice. As such, as an alternative to sprinklers, protection could be in the form of a water mist, dry chemical, CO<sub>2</sub> or foam system. The extent of the required fire protection system depends on the construction and arrangement of the oven, as well as the materials handled, and should extend into oven exhaust ducts. Decisions regarding the fire protection system type and design must be made by the owner with the consultation and approval of the fire code official.

**3006.3 Fire extinguishers.** Portable fire extinguishers complying with Section 906 shall be provided not closer than 15 feet (4572 mm) or not more than 50 feet (15 240 mm) or in accordance with NFPA 10. This shall apply to the oven and related equipment.

❖ Portable fire extinguishers of the proper size and type and using an appropriate extinguishing agent must be installed near the oven and related equipment. The distances mentioned in this section should be used unless requirements in NFPA 10 are more stringent. See the commentary to Section 906 for additional discussion of portable fire extinguishers.

## SECTION 3007 OPERATION AND MAINTENANCE

**3007.1 Furnace system information.** An *approved*, clearly worded, and prominently displayed safety design data form or manufacturer's nameplate shall be provided stating the safe operating condition for which the furnace system was designed, built, altered or extended.

❖ The equipment manufacturer establishes the need for adequate operational checks and maintenance.

Specifications, data sheets and procedures provide clear and complete inspection, testing and maintenance instructions.

**3007.2 Oven nameplate.** Safety data for Class A solvent atmosphere ovens shall be furnished on the manufacturer's nameplate. The nameplate shall provide the following design data:

1. The solvent used.
2. The number of gallons (L) used per batch or per hour of solvent entering the oven.
3. The required purge time.
4. The oven operating temperature.
5. The exhaust blower rating for the number of gallons (L) of solvent per hour or batch at the maximum operating temperature.

**Exception:** For low-oxygen ovens, the maximum allowable oxygen concentration shall be included in place of the exhaust blower ratings.

❖ Safety data must be included on the manufacturer's nameplate for Class A solvent atmosphere ovens to ensure that safety personnel, operators and maintenance technicians have the information at hand. This same information should also be included in installation, operation and maintenance procedures. The exception in this case is actually an additional nameplate requirement for low-oxygen ovens.

**3007.3 Training.** Operating, maintenance and supervisory personnel shall be thoroughly instructed and trained in the operation of ovens or furnaces.

❖ Alert and competent operators are essential to safe operations. New operators should be thoroughly trained and tested in the use of the equipment. Regular operators should be reevaluated at regular intervals to make certain their skills and knowledge are current.

**3007.4 Equipment maintenance.** Equipment shall be maintained in accordance with the manufacturer's instructions.

❖ There should be a program for inspecting and maintaining oven safety controls. The operating and supervisory control equipment should be checked and tested regularly.

## Bibliography

The following resource was used in the preparation of the commentary for this chapter of the code.

FM Global Property Loss Prevention Data Sheet 6-9, *Industrial Ovens and Dryers*. Johnson, RI: Factory Mutual Global Research, 2009.

# Chapter 31: Tents and Other Membrane Structures

## General Comments

Though they do not happen often, fires occurring in tents and other membrane structures have historically caused significant loss of life. Perhaps the most notable of these tragedies occurred on July 6, 1944, in Hartford, Connecticut, where a Ringling Bros. and Barnum & Bailey Circus tent caught fire during a matinee performance, killing 167 people and injuring 487. Since then, protection of tents and other membrane structures has focused on construction methods and materials, as well as limiting use and occupancy.

## Construction Methods and Materials

Tents and other membrane structures are constructed of diverse materials, usually fabrics, textiles and films. Section 3102 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) requires these membrane materials to be noncombustible as described in IBC Section 703.5 or meet the fire propagation criteria of NFPA 701. The use of lightweight high-tensile-strength membrane coverings is perhaps the most significant similarity between tents and air-supported structures. Beyond this similarity, an increasingly wide variety of structural configurations is becoming common. Tents include all structures using rigid structural frames or supports for lateral and compressive stability. In the case of air-supported structures, a positive pressure differential between the inside and the outside of the structure, coupled with the favorable tensile properties of the membrane, yields these structural properties.

In every case, anchors and cables are used for either additional structural stability or to act as fail-safe devices against extreme wind, rain or snow loading. The more commonplace membrane coverings include cotton and plastic-canvas fabrics. Exotic new materials, such as high-tensile-strength plastic films, have spawned a new generation of air-supported structures, including the spectacularly covered and domed stadi-

ums built in recent years in many large metropolitan areas. Protecting the structure from collapse and fire remains the most significant fire and life safety concern.

## Occupancy

Fire poses a dual threat to a tent or other membrane structures. First, the fire presents a danger to the occupants by exposing them to heat, smoke and toxic combustion products. Just as important, the fire represents an imminent threat to the structure. Even the best flame-resistant fabrics may ignite or fail under extreme conditions posed by a fire, and the fire's demand for air may compromise the structural support of the air inside of, if not the integrity of the membrane itself, an air-supported structure. Full or partial collapse of the membrane covering of a tent or air-supported structure may occur earlier and with less warning than in any other structural type.

Egress may become difficult, if not nearly impossible, if a collapse occurs; therefore, this chapter limits the storage or handling of combustible materials inside tents and other membrane structures because of their contribution to fuel loading. Similarly, heat energy sources that may ignite the membrane fabric or other combustibles are prohibited or restricted. Even spot lighting must be used with caution to prevent heat energy from igniting the covering. Portable fire extinguishers must be readily available for incipient fire fighting as an additional safeguard against fire.

## Purpose

The requirements in this chapter are intended to protect tents and other membrane structures from fire by requiring regular inspections and continued compliance with fire safety regulations, as well as the applicable requirements of Chapter 31 of the IBC, regulating their use and occupancy.

---

## SECTION 3101 GENERAL

**3101.1 Scope.** Tents, temporary stage canopies and membrane structures shall comply with this chapter. The provisions of Section 3103 are applicable only to temporary tents and membrane structures. The provisions of Section 3104 are applicable to temporary and permanent tents and membrane

structures. Other temporary structures shall comply with the *International Building Code*.

❖ This section defines the kinds of structures covered by this chapter and designates which sections apply to temporary structures and which apply to permanent structures. Structures can range from 10-foot by 10-foot (3048 mm by 3048 mm) canvas shelters to

major indoor sports arenas. The common feature of all types of membrane structures, whether they are air-supported, air-inflated or tensioned membrane structures, is the nature of the structural skin. In all cases, a pliable material is used to create an indoor or protected space by separating the area under the covering from wind, precipitation and temperature extremes. Although most membrane structures are intended for temporary or seasonal use, elegant all-weather permanent membrane structures are becoming increasingly common.

There has been past confusion over the proper application of the requirements of Chapter 31 to temporary structures. Typically this occurs because the fire code official is already involved with the temporary event regarding other operational permits required by the code. For example, a weekend concert is planned at the fair. The fire code official is already involved with various IFC operational permits for Place of Assembly, Carnival/Fair, and Temporary Membrane Structures and Tents. However, when a stage, platform or other temporary structure is erected, the IBC regulates the construction.

This section now sends the code user to the IBC for temporary structures other than tents and membrane structures. IBC Sections 108.2 and 3103 clearly address the design requirements for such temporary structures. IBC Section 3103.1 similarly sends the IBC code user to the IFC for temporary membrane structures and temporary tents. Clearly, the IFC is designed to address “temporary tents” and “temporary membrane structures,” while IBC Section 3103 is intended to address other “temporary structures.”

## SECTION 3102 DEFINITIONS

**3102.1 Definitions.** The following terms are defined in Chapter 2:

**AIR-INFLATED STRUCTURE.**

**AIR-SUPPORTED STRUCTURE.**

**MEMBRANE STRUCTURE.**

**TEMPORARY STAGE CANOPY.**

**TENT.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4 and to the definitions in Section 202).

## SECTION 3103 TEMPORARY TENTS AND MEMBRANE STRUCTURES

**3103.1 General.** Tents and membrane structures used for temporary periods shall comply with this section. Other temporary structures erected for a period of 180 days or less shall comply with the *International Building Code*.

❖ This section addresses tents and membrane structures that are considered temporary in terms of the duration of their erection and use (see Section 3103.5 for the definition of “Temporary” as it applies to membrane structures). This section is intended to ensure that if a membrane structure is used, it will be soundly designed so as not to present a hazard to its users, emergency responders or the public during the time it is in place. See also the commentary to Section 3101.1.

**3103.2 Approval required.** Tents and membrane structures having an area in excess of 400 square feet (37 m<sup>2</sup>) shall not be erected, operated or maintained for any purpose without first obtaining a permit and approval from the *fire code official*.

### Exceptions:

1. Tents used exclusively for recreational camping purposes.
2. Tents open on all sides that comply with all of the following:
  - 2.1. Individual tents having a maximum size of 700 square feet (65 m<sup>2</sup>).
  - 2.2. The aggregate area of multiple tents placed side by side without a fire break clearance of 12 feet (3658 mm), not exceeding 700 square feet (65 m<sup>2</sup>) total.
  - 2.3. A minimum clearance of 12 feet (3658 mm) to all structures and other tents.

❖ Use of membrane structures results in great flexibility and a large volume of weather-protected space; however, these benefits are balanced by the sensitivity of these structures to strict maintenance requirements. The approval process allows the fire code official to exercise strict control to achieve compliance with the requirements of this chapter.

This section sets the minimum size structure that requires approval. Exception 1 exempts from permit requirements tents that are normally used by families or very small groups for short periods under widely varying conditions that would be difficult or impossible for a fire code official to police. Exception 2 exempts from permit requirements, for example, a single tent approximately 25.5 square feet (2.4 m<sup>2</sup>) without sides or multiple tents without sides aggregating an area of not more than 700 square feet (65 m<sup>2</sup>) due to their limited size, limited fire load and limited

occupant load. The fact that these tents have no sides and are separated by a 12-foot (3658 mm) fire break also improves the occupants' situational awareness and provides the potential for occupant escape routes and fire department access all around the perimeter.

**3103.3 Place of assembly.** For the purposes of this chapter, a place of assembly shall include a circus, carnival, tent show, theater, skating rink, dance hall or other place of assembly in or under which persons gather for any purpose.

❖ This section gives examples of common types of assembly use for membrane structures, but leaves the issue open so that the fire code official has the discretion to determine whether some other intended use should be considered a place of assembly that would require permits and approvals.

**3103.4 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations or special structures. Permit applicants should be required to demonstrate that their operation or construction complies with the intent of the code before the permit is issued. See the commentary to Section 105.7 for a general discussion of operations requiring a construction permit. The process also notifies the fire department of the need for prefire planning for the hazardous property.

**3103.5 Use period.** Temporary tents, air-supported, air-inflated or tensioned membrane structures shall not be erected for a period of more than 180 days within a 12-month period on a single premises.

❖ This section gives the fire code official control over the erection, maintenance and use of membrane structures by defining the term "Temporary" for the purpose of applying this chapter. Any membrane structure erected for more than 180 days in any 12-month period at a single location must be considered permanent and would be subject to all requirements for permanent structures as set forth in Section 3104 and the IBC. Note that the limiting factor is how long the structure is erected, not how many days it is in use, as was the case in older editions of the code. Without this level of specificity, a tent or membrane structure could literally remain erected indefinitely as long as it was not used for more than 180 days within any 12-month period, thus retaining its classification as a temporary structure while being, in effect, a permanent one.

**3103.6 Construction documents.** A detailed site and floor plan for tents or membrane structures with an *occupant load* of 50 or more shall be provided with each application for approval. The tent or membrane structure floor plan shall indicate details of the *means of egress* facilities, seating

capacity, arrangement of the seating and location and type of heating and electrical equipment.

❖ The requirement for a floor plan showing means of egress facilities and seating locations eliminates possible conflicts at the time of field inspection. Evaluating means of egress for hastily arranged or movable seating is a challenge to the inspector. The detailed means-of-egress plan allows the inspector to verify that the actual configuration matches the approved plan. The applicant and designer also benefit by having the plans reviewed in detail before construction begins.

**3103.7 Inspections.** The entire tent, air-supported, air-inflated or tensioned membrane structure system shall be inspected at regular intervals, but not less than two times per permit use period, by the permittee, *owner* or agent to determine that the installation is maintained in accordance with this chapter.

**Exception:** Permit use periods of less than 30 days.

❖ The periodic inspections required here are conducted by the permit holder, the owner or his or her agent to make certain the structure continues to meet code requirements and is being properly maintained.

The exception states that structures used for less than 30 days do not need to be reinspected.

**3103.7.1 Inspection report.** Where required by the *fire code official*, an inspection report shall be provided and shall consist of maintenance, anchors and fabric inspections.

❖ This section allows the fire code official to require submittal of a complete inspection report, including completed maintenance work, for each finished inspection by the permit holder, owner or agent.

**3103.8 Access, location and parking.** Access, location and parking for temporary tents and membrane structures shall be in accordance with this section.

❖ This section addresses the issues of fire apparatus access, separation from vehicles and other structures and the need for fire breaks for tents and other membrane structures that are considered temporary in terms of the duration of their erection and use.

**3103.8.1 Access.** Fire apparatus access roads shall be provided in accordance with Section 503.

❖ The same access rules apply to membrane structures and structures erected using conventional construction materials. Because membrane structures can become serious fire hazards, depending on membrane material and structure contents, maintaining code-required fire access roads and lanes is especially important.

**3103.8.2 Location.** Tents or membrane structures shall not be located within 20 feet (6096 mm) of *lot lines*, buildings, other tents or membrane structures, parked vehicles or internal

combustion engines. For the purpose of determining required distances, support ropes and guy wires shall be considered as part of the temporary membrane structure or tent.

**Exceptions:**

1. Separation distance between membrane structures and tents not used for cooking is not required where the aggregate floor area does not exceed 15,000 square feet (1394 m<sup>2</sup>).
  2. Membrane structures or tents need not be separated from buildings when all of the following conditions are met:
    - 2.1. The aggregate floor area of the membrane structure or tent shall not exceed 10,000 square feet (929 m<sup>2</sup>).
    - 2.2. The aggregate floor area of the building and membrane structure or tent shall not exceed the allowable floor area including increases as indicated in the *International Building Code*.
    - 2.3. Required *means of egress* are provided for both the building and the membrane structure or tent including travel distances.
    - 2.4. Fire apparatus access roads are provided in accordance with Section 503.
- ❖ The 20-foot (6096 mm) separation distance is consistent with requirements for conventional structures, especially those that could represent an above-average fire hazard. A fire of any size within a membrane structure would almost certainly involve the membrane itself. Because the support ropes and guy wires are under tension, particularly with large membrane structures, a membrane weakened by fire would fail, causing the ropes or wires to recoil and possibly pull portions of the burning membrane well clear of its original position. Requiring 20 feet (6096 mm) of clear ground around the structure helps reduce the likelihood that burning membrane sections and flying embers would endanger other structures or public trafficways.
- Exception 1 acknowledges the reduced hazard of small membrane structures that do not house cooking appliances.
- Exception 2 lists four criteria for determining whether a membrane structure must conform to the separation criteria of this section. To be exempt, the structure would have to meet all four criteria.
- 3103.8.3 Location of structures in excess of 15,000 square feet in area.** Membrane structures having an area of 15,000 square feet (1394 m<sup>2</sup>) or more shall be located not less than 50 feet (15 240 mm) from any other tent or structure as measured from the sidewall of the tent or membrane structure unless joined together by a corridor.
- ❖ The larger separation distance required by this section is consistent with the hazards presented by the larger structures. The exception for structures connected by corridors considers the smaller hazard

posed by the covering of the corridor. Corridors are not likely to contain significant amounts of combustible materials other than the membrane itself.

**3103.8.4 Membrane structures on buildings.** Membrane structures that are erected on buildings, balconies, decks or other structures shall be regulated as permanent membrane structures in accordance with Section 3102 of the *International Building Code*.

❖ Temporary membrane structures that are placed in a field or parking lot are afforded several safety features, including fire separation distance from other hazards (buildings, vehicles) and separation from other tents, and provide an unobstructed means-of-egress path for the uniformly located exits. When a membrane structure is placed on a building or deck, Section 3103 does not regulate exiting from the temporary membrane structure to a set of stairs or door, nor does it regulate the hazards that could be below the temporary membrane structure. Section 3103 also does not contain requirements regulating the structural loads that the membrane structure would impose on the structure below. For these reasons, what would otherwise be considered as temporary membrane structures are regulated as permanent membrane structures and subject to the provisions of IBC Section 3102.

**3103.8.5 Connecting corridors.** Tents or membrane structures are allowed to be joined together by means of corridors. *Exit* doors shall be provided at each end of such corridor. On each side of such corridor and approximately opposite each other, there shall be provided openings not less than 12 feet (3658 mm) wide.

❖ Corridors connecting membrane structures to each other or to permanent structures must have openings in their side walls for convenient egress in case of an emergency. These openings could also be entry points for emergency response personnel.

**3103.8.6 Fire break.** An unobstructed fire break passageway or fire road not less than 12 feet (3658 mm) wide and free from guy ropes or other obstructions shall be maintained on all sides of all tents and membrane structures unless otherwise *approved by the fire code official*.

❖ This requirement for a clear path makes the membrane structures more accessible to emergency response personnel. It also results in an open space into which flaming embers or other debris can fall without endangering other structures or public trafficways. Measurement of the required width must be consistent with the provisions of Section 3103.8.2.

**3103.9 Anchorage required.** Tents or membrane structures and their appurtenances shall be adequately roped, braced and anchored to withstand the elements of weather and prevent against collapsing. Documentation of structural stability shall be furnished to the *fire code official* on request.

❖ Having secure anchorage to prevent damage or loss caused by wind or precipitation makes good economic sense. This section also gives the fire code

official the authority to review and approve both plans and actual installations to ensure that the structures have been designed and erected using good engineering practices.

**3103.9.1 Tents and membrane structures exceeding one story.** Tents and membrane structures exceeding one story shall be designed and constructed to comply with Chapter 16 of the *International Building Code*.

❖ In recent times, there has been an increasing number of multiple-story tents and membrane structures showing up in jurisdictions across the country. These structures can be seen at concerts, outdoor functions, fairs, etc. Many of these temporary tents and temporary membrane structures have multiple floors and are over 30 feet in height. As the height increases, the potential for collapse increases. Even though the provision of “temporary” limits the usability of these multistory structures to less than 180 days, improper structural design can pose a significant safety hazard to event patrons, performers and first responders.

Section 3103.9 requires that documentation of structural stability be furnished to the fire code official on request but provides no guidance on what an acceptable level of structural integrity is. Since these structures are temporary, they often do not go through a full building code structural analysis and review. This section closes that loophole by requiring that multistory tents and membrane structures be designed and constructed in accordance with IBC Chapter 16. This provides the fire code official with a

solid tool to use to verify proper structural design. Most fire code officials, however, do not routinely review structural integrity. This is most commonly performed by the building code official. But the requirement for a construction permit is in Section 105.7.18 since this is a temporary structure. As such, enforcement of this requirement may take some coordination with the building official prior to the issuance of the IFC construction permit. Commentary Figures 3103.9.1(1) and 3103.9.1(2) illustrate a multistory membrane structure.

**3103.10 Temporary air-supported and air-inflated membrane structures.** Temporary air-supported and air-inflated membrane structures shall be in accordance with Sections 3103.10.1 through 3103.10.4.

❖ This section addresses air-supported and air-inflated membrane structures that are considered temporary in terms of the duration of their erection and use (see Section 3103.5 for the definition of “Temporary” as it applies to these structures). The intent of this section is that if air-supported or air-inflated membrane structures are used, they should be soundly designed so as not to present a hazard to their users, emergency responders or the public during the time they are in place.

**3103.10.1 Door operation.** During high winds exceeding 50 miles per hour (22 m/s) or in snow conditions, the use of doors in air-supported structures shall be controlled to avoid excessive air loss. Doors shall not be left open.

❖ Because the design pressure is critical in maintaining the structural integrity of an air-supported structure,

**Figure 3103.9.1(1)**  
**TWO-STORY MEMBRANE STRUCTURE AT THE AMERICA'S CUP RACE**  
(Photo courtesy of HTS-USA)

doors must not be kept open for extended periods. Controls on door usage help prevent excessive losses of internal pressure. When large openings are necessary, such as for vehicular traffic, vestibules help avoid excessive pressure loss.

**3103.10.2 Fabric envelope design and construction.** Air-supported and air-inflated structures shall have the design and construction of the fabric envelope and the method of anchoring in accordance with Architectural Fabric Structures Institute ASI 77.

❖ The referenced document is both a design manual that contains the engineering formulas needed to calculate stresses and other parameters associated with structural stability and a design standard for air-supported structures.

**3103.10.3 Blowers.** An air-supported structure used as a place of assembly shall be furnished with not less than two blowers, each of which has adequate capacity to maintain full inflation pressure with normal leakage. The design of the blower shall be so as to provide integral limiting pressure at the design pressure specified by the manufacturer.

❖ Requiring two blowers that have the capacity to keep the structure fully inflated builds redundancy into the system. Should one blower fail, the other would be capable of maintaining full inflation while the failed unit was repaired or replaced. The pressure-limiting device is required to prevent overpressurizing the structure and thus causing failure.

**3103.10.4 Auxiliary inflation systems.** Places of public assembly for more than 200 persons shall be furnished with an auxiliary inflation system capable of powering a blower

with the capacity to maintain full inflation pressure with normal leakage in accordance with Section 3103.10.3 for a minimum duration of 4 hours. The auxiliary inflation system shall be either a fully automatic auxiliary engine-generator set or a supplementary blower powered by an internal combustion engine that shall be automatic in operation. The system shall be capable of automatically operating the required blowers at full power within 60 seconds of a commercial power failure.

❖ Because an air-supported structure must be maintained at full design pressure, a power failure that would disable all of the blowers used to maintain that pressure would result in a gradual collapse of the structure as pressure drops as a result of normal leakage. Having an auxiliary power source on site is intended to prevent this situation. This section allows either an auxiliary generator that will supply power to the blowers or a self-contained supplementary blower unit that has an internal combustion engine to drive it.

**3103.11 Seating arrangements.** Seating in tents or membrane structures shall be in accordance with Chapter 10.

❖ See the commentary to Section 3104.14.

**3103.12 Means of egress.** *Means of egress* for temporary tents and membrane structures shall be in accordance with Sections 3103.12.1 through 3103.12.8.

❖ Because of the unique nature of the structures regulated by this chapter, it is vital that their means of egress systems be carefully designed and constructed. This section regulates the access to, number, location, marking and illumination of the means of egress for temporary membrane structures.

Figure 3103.9.1(2)  
 INTERIOR OF TWO-STORY MEMBRANE STRUCTURE  
 (Photo courtesy of Losberger-USA)

**3103.12.1 Distribution.** *Exits* shall be spaced at approximately equal intervals around the perimeter of the tent or membrane structure, and shall be located such that all points are 100 feet (30 480 mm) or less from an *exit*.

❖ The requirement for exits to be equally spaced around the perimeter of the membrane structure considers the probability that any one structure could be used for several different purposes over its life and that each use could represent a different seating arrangement. Because travel distances to an exit must not exceed 100 feet (30 480 mm), exits must be located to minimize travel distances no matter how the seating is arranged.

**3103.12.2 Number.** Tents, or membrane structures or a usable portion thereof shall have not less than one *exit* and not less than the number of *exits* required by Table 3103.12.2. The total width of *means of egress* in inches (mm) shall be not less than the total *occupant load* served by a *means of egress* multiplied by 0.2 inches (5 mm) per person.

❖ This section specifies the use of the exit requirements contained in Table 3103.12.2 to determine the number and size of exits for all membrane structures. The formula given in the last sentence of the section allows for the calculation of total exit requirements for any given number of occupants.

**TABLE 3103.12.2.** See below.

❖ The minimum means of egress widths shown in this table were established on two very different bases. For tents, the widths are possibly conservative because so many in the fire service remember the Ringling Bros. and Barnum & Bailey Circus tent fire that happened in Hartford, Connecticut, in July 1944. In that fire, 167 people died and 487 were injured because they were unable to escape from the burning tent. Also, because the side panels of a tent can be constructed to varying widths without too much difficulty, the wider openings are practical.

On the other hand, means-of-egress widths required for air-supported structures seem to be much more optimistic. The narrower means-of-egress widths are necessary to prevent excess loss of inter-

nal air pressure in the air-supported structure and can be linked to the exit requirements in ASI 77. Excessive inflation pressure losses could lead to the collapse of the structure onto the very occupants the exits are serving.

**3103.12.3 Exit openings from tents.** *Exit* openings from tents shall remain open unless covered by a flame-resistant curtain. The curtain shall comply with the following requirements:

1. Curtains shall be free sliding on a metal support. The support shall be not less than 80 inches (2032 mm) above the floor level at the *exit*. The curtains shall be so arranged that, when open, no part of the curtain obstructs the *exit*.
2. Curtains shall be of a color, or colors, that contrasts with the color of the tent.

❖ The requirement for exit openings to remain free and clear is meant to ensure that the exit is not blocked or hidden from the view of the occupants attempting to exit. Allowing the opening to be covered by an easily moveable curtain is meant to add to the comfort of occupants by protecting them from wind, precipitation and temperature extremes. The requirement for the curtains to be of a contrasting color makes the exits readily identifiable even at a distance.

**3103.12.4 Doors.** *Exit* doors shall swing in the direction of *exit* travel. To avoid hazardous air and pressure loss in air-supported membrane structures, such doors shall be automatic closing against operating pressures. Opening force at the door edge shall not exceed 15 pounds (66 N).

❖ Pressure loss in an air-supported structure is always a concern. The requirement that the door be capable of closing automatically against the internal pressure supporting the membrane structure is intended to protect against this kind of loss. The 15-pound (66 N) force required for opening acknowledges that the door must be held closed against the interior air pressure. This level of opening force is, however, consistent with the requirements of the IBC for exterior doors in conventional buildings.

**TABLE 3103.12.2  
MINIMUM NUMBER OF MEANS OF EGRESS AND MEANS OF  
EGRESS WIDTHS FROM TEMPORARY MEMBRANE STRUCTURES AND TENTS**

OCCUPANT LOAD	MINIMUM NUMBER OF MEANS OF EGRESS	MINIMUM WIDTH OF EACH MEANS OF EGRESS (inches)	
		Tent	Membrane Structure
10 to 199	2	72	36
200 to 499	3	72	72
500 to 999	4	96	72
1,000 to 1,999	5	120	96
2,000 to 2,999	6	120	96
Over 3,000 <sup>a</sup>	7	120	96

For SI: 1 inch = 25.4 mm.

a. When the occupant load exceeds 3,000, the total width of means of egress (in inches) shall be not less than the total occupant load multiplied by 0.2 inches per person.

**3103.12.5 Aisle.** The width of *aisles* without fixed seating shall be in accordance with the following:

1. In areas serving employees only, the minimum *aisle* width shall be 24 inches (610 mm) but not less than the width required by the number of employees served.
  2. In public areas, smooth-surfaced, unobstructed *aisles* having a minimum width of not less than 44 inches (1118 mm) shall be provided from seating areas, and *aisles* shall be progressively increased in width to provide, at all points, not less than 1 foot (305 mm) of *aisle* width for each 50 persons served by such *aisle* at that point.
- ❖ The first requirement for areas serving only employees is indefinite because the configuration of the area could vary widely from one use to another. Required width beyond 24 inches (610 mm) would have to be determined based on seating arrangements, if any, and traffic patterns in the affected area. Guidance for assembly areas of fixed conventional structures is given in Chapter 10 of the code as well as in Chapter 10 of the IBC. The judgment of the fire code official would also have to be considered in the final decision.

The second requirement is quite specific for public-use areas. The wide aisles are intended to make egress quicker and easier because a fire in an air-supported structure could easily burn through the membrane covering and cause the structure to collapse on the occupants.

**3103.12.5.1 Arrangement and maintenance.** The arrangement of *aisles* shall be subject to approval by the *fire code official* and shall be maintained clear at all times during occupancy.

- ❖ This section gives the fire code official the authority to approve seating arrangements in air-supported structures and to inspect those arrangements periodically to verify that they have not been changed to an unacceptable configuration or that they have become obstructed or their use otherwise compromised. This is consistent with Section 1030.2.

**3103.12.6 Exit signs.** *Exits* shall be clearly marked. *Exit* signs shall be installed at required *exit* doorways and where otherwise necessary to indicate clearly the direction of egress where the *exit* serves an *occupant load* of 50 or more.

- ❖ This charging statement establishes the requirement for exit signs. See the commentary to Section 1011.2 for further discussion of exit sign requirements.

**3103.12.6.1 Exit sign illumination.** *Exit* signs shall be either *listed* and *labeled* in accordance with UL 924 as the internally illuminated type and used in accordance with the listing or shall be externally illuminated by luminaires supplied in either of the following manners:

1. Two separate circuits, one of which shall be separate from all other circuits, for *occupant loads* of 300 or less.
2. Two separate sources of power, one of which shall be an *approved* emergency system, shall be provided

where the *occupant load* exceeds 300. Emergency systems shall be supplied from storage batteries or from the on-site generator set, and the system shall be installed in accordance with NFPA 70. The emergency system provided shall have a minimum duration of 90 minutes when operated at full design demand.

- ❖ Because there is always the possibility of power failure in a fire or other emergency, exit signs must have a power source—batteries, backup power or auxiliary power—that will keep them illuminated if the primary power source to the structure's lighting system fails. The requirement for this power source is established in Section 604.2.3 and is further defined in Section 1011.6.3. This section also provides correlation with Section 1011.4 since internally illuminated exit signs listed in accordance with UL 924, including electrically powered, self-luminous and photoluminescent types, all provide for a minimum of 90 minutes of luminosity upon loss of normal power.

**3103.12.7 Means of egress illumination.** *Means of egress* shall be illuminated with light having an intensity of not less than 1 footcandle (11 lux) at floor level while the structure is occupied. Fixtures required for *means of egress* illumination shall be supplied from a separate circuit or source of power.

- ❖ All means of egress must be continuously illuminated by artificial lighting during the entire time the air-supported structure is occupied so that the paths of exit travel are always visible and available for evacuation of the occupants during emergencies. The code makes a special point of noting that the exit discharge must also be provided with adequate illumination so that occupants can safely find the public way should the emergency occur at night.

The intensity of floor lighting illuminating the entire means of egress, including open-plan spaces, aisles, corridors, exit access passageways and exit doors, must not be less than 1 foot candle (11 lux). It has been found that this low level of lighting renders enough visibility for the occupants to evacuate the building safely. This lighting level is measured at the floor to make the floor surface visible. Levels of illumination above the floor may be higher or lower.

The means of egress must be illuminated, especially in times of emergency when the occupants must have a lighted path of exit travel to evacuate the building safely.

So that there will be a continuing source of electrical energy for lighting the means of egress when the main power supply is lost, the means-of-egress lighting system must be connected to an emergency electrical system that consists of storage batteries, unit equipment or an on-site generator. This emergency power-generating facility must be capable of supplying electricity for at least 90 minutes, thereby giving the occupants sufficient time to leave the premises. In most cases, where the loss of the main electrical supply is attributed to a malfunction in the distribution system of the electric power company, experience

has shown that such power outages do not usually last as long as 90 minutes.

**3103.12.8 Maintenance of means of egress.** The required width of *exits*, *aisles* and passageways shall be maintained at all times to a *public way*. Guy wires, guy ropes and other support members shall not cross a *means of egress* at a height of less than 8 feet (2438 mm). The surface of *means of egress* shall be maintained in an *approved* manner.

❖ It is important for occupant safety that the pathway from any point in the building to the exit discharge be kept clear so that occupants can exit the structure at any time without obstructions in the egress path. This requirement applies to all structures, but it is especially important for membrane structures and tents because of the added hazards that they present. The structural stability of tents relies on ropes or cables and stakes which, if not carefully arranged, can become an impediment to occupant egress flow. A clearly defined and well-lighted egress path without any rope or guy wire vertical or horizontal impingement is essential for these types of structures.

As the pace of exit travel becomes hurried during emergency situations, the probability of slipping on smooth or slick surfaces increases. To minimize the hazard in buildings, floor surfaces in the means of egress are required to be slip resistant by Section 1003.4. However, in tents and membrane structures, the structure “floor” may very well be dirt, gravel, grass or other nontraditional surfaces that defy traditional regulation. The fire code official must apply common sense in reviewing egress path surfaces, applying safety criteria for them and then requiring that the required conditions be maintained throughout the occupancy of the structure.

## SECTION 3104 TEMPORARY AND PERMANENT TENTS AND MEMBRANE STRUCTURES

**3104.1 General.** Tents and membrane structures, both temporary and permanent, shall be in accordance with this section. Permanent tents and membrane structures shall also comply with the *International Building Code*.

❖ This section addresses tents and membrane structures that are considered either temporary or permanent in terms of the duration of their erection and use (see Section 3103.5 for the definition of “Temporary” and, by default, “Permanent” as they apply to membrane structures). This section is intended to ensure that if a tent or other membrane structure is used, it will be soundly designed so as not to present a hazard to its users, emergency personnel or the public during the time it is in place, whether that is more or less than 180 days per calendar year.

**3104.2 Flame propagation performance treatment.** Before a permit is granted, the *owner* or agent shall file with the *fire code official* a certificate executed by an *approved* testing laboratory certifying that the tents and membrane structures and their appurtenances; sidewalls, drops and tarpaulins;

floor coverings, bunting and combustible decorative materials and effects, including sawdust where used on floors or passageways, are composed of material meeting the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701 or shall be treated with a flame retardant in an *approved* manner and meet the flame propagation performance criteria of Test Method 1 or Test Method 2, as appropriate, of NFPA 701, and that such flame propagation performance criteria are effective for the period specified by the permit.

❖ The reference to NFPA 701 in this section is consistent with the requirements of IBC Section 3102 for structural materials, IBC Sections 802 and 806 and Section 807 of the code for decorative materials. Making certain the structure and as much of its contents as possible are either noncombustible or are treated to make them less prone to flame propagation is an important first step in fire safety. This section also gives the fire code official the authority to inspect the facility, its contents and documentation of applied flame-retardant treatment to ensure permit requirements have been met.

**3104.3 Label.** Membrane structures or tents shall have a permanently affixed label bearing the identification of size and fabric or material type.

❖ This required label gives the fire code official important information about the membrane and the designed size of the structure. This information will help him or her determine whether the structure and its covering meet code requirements.

**3104.4 Certification.** An affidavit or affirmation shall be submitted to the *fire code official* and a copy retained on the premises on which the tent or air-supported structure is located. The affidavit shall attest to all of the following information relative to the flame propagation performance criteria of the fabric:

1. Names and address of the *owners* of the tent or air-supported structure.
2. Date the fabric was last treated with flame-retardant solution.
3. Trade name or kind of chemical used in treatment.
4. Name of person or firm treating the material.
5. Name of testing agency and test standard by which the fabric was tested.

❖ The certificate is another piece of information the fire code official must have to make a decision on code compliance. The certificate will indicate whether the membrane fabric needs retreatment and at what frequency to maintain its low flame propagation properties.

**3104.5 Combustible materials.** Hay, straw, shavings or similar combustible materials shall not be located within any tent or membrane structure containing an assembly occupancy, except the materials necessary for the daily feeding and care of animals. Sawdust and shavings utilized for a public performance or exhibit shall not be prohibited provided the sawdust

and shavings are kept damp. Combustible materials shall not be permitted under stands or seats at any time.

❖ This section contains a “laundry list” of unacceptable practices. Hay, straw, shavings and sawdust are all readily ignitable materials. Minimizing their use is important to fire safety. A carelessly discarded match or other smoking material could easily cause any of these materials to catch fire.

Requiring finely divided combustible materials, such as sawdust and shavings, to be maintained damp significantly reduces their ignition potential.

Keeping areas under seating areas free of readily ignitable combustible materials removes a significant fire hazard from these areas of high-occupant density.

**3104.6 Smoking.** Smoking shall not be permitted in tents or membrane structures. *Approved* “No Smoking” signs shall be conspicuously posted in accordance with Section 310.

❖ Because smoking is prohibited in membrane structures, the requirement for posting signage is obvious. Because no specification exists for standard signs, each jurisdiction having authority is responsible for establishing its own criteria. To be approved, signs must be large enough to be read from a distance and be worded simply and clearly.

**3104.7 Open or exposed flame.** Open flame or other devices emitting flame, fire or heat or any flammable or *combustible liquids*, gas, charcoal or other cooking device or any other unapproved devices shall not be permitted inside or located within 20 feet (6096 mm) of the tent or membrane structures while open to the public unless *approved* by the *fire code official*.

❖ This section gives the fire code official the authority to approve an open-flame or exposed-flame appliance if it is determined that it poses a minimal fire hazard when properly used. These might include catalytic heaters that are located well away from the membrane walls, and any combustible materials or limited cooking facilities using charcoal or liquefied petroleum gas (LP gas) for fuel and located under a tent or membrane structure. Such approvals, however, would be subject to the provisions of Section 308.

**3104.8 Fireworks.** Fireworks shall not be used within 100 feet (30 480 mm) of tents or membrane structures.

❖ Fireworks, whether designed to explode at ground level or as aerial displays, result in hot embers that could become a source of ignition if they contact the membrane of the structure. Establishing a 100-foot (30 480 mm) clear zone not only reduces the likelihood of hot embers contacting the membrane but also gives air-borne embers time to cool before they can reach membrane level.

**3104.9 Spot lighting.** Spot or effect lighting shall only be by electricity, and all combustible construction located within 6 feet (1829 mm) of such equipment shall be protected with

*approved* noncombustible insulation not less than 9<sup>1</sup>/<sub>4</sub> inches (235 mm) thick.

❖ Spotlights can generate considerable heat. The metal housings of these lights generally become too hot to touch if they are on for more than a minute or two. Requiring that they be positioned well away from combustible materials and that the nearby combustibles be insulated helps ensure that the heat from the lights does not become an ignition source for either the membrane structure or combustibles inside the structure. Noncombustible insulation must conform to the requirements of IBC Section 720.

**3104.10 Safety film.** Motion pictures shall not be displayed in tents or membrane structures unless the motion picture film is safety film.

❖ The display of motion pictures on cellulose nitrate film is prohibited because of the extreme hazards associated with this type of material; however, such motion pictures are extremely rare because production of the raw film was suspended in 1951. Most known motion pictures printed on cellulose nitrate film are in the possession of special film repositories, such as the National Archives and the Smithsonian Institution, or are being restored by conservators.

**3104.11 Clearance.** There shall be a minimum clearance of at least 3 feet (914 mm) between the fabric envelope and all contents located inside membrane structures.

❖ The 3-foot (914 mm) clearance is intended not only to give fire fighters all-sides hose stream and overhaul access to burning materials, but also to reduce exposure of the membrane envelope if stored material becomes involved in a fire.

**3104.12 Portable fire extinguishers.** Portable fire extinguishers shall be provided as required by Section 906.

❖ Section 906 states that portable extinguishers are required in Group A occupancies and in special-hazards areas as designated by the fire code official. This section also refers to NFPA 10 for guidance on selection and placement of the extinguishers. Employees and staff who will be manning the membrane structure must be trained to use the extinguishers because they are likely to become the first line of emergency response in case of a fire.

**3104.13 Fire protection equipment.** Fire hose lines, water supplies and other auxiliary fire equipment shall be maintained at the site in such numbers and sizes as required by the *fire code official*.

❖ This section gives the fire code official the authority to establish reasonable equipment requirements for membrane structures. Because the size, construction and intended use of membrane structures vary so widely, each installation must be evaluated individually.

**3104.14 Occupant load factors.** The *occupant load* allowed in an assembly structure, or portion thereof, shall be determined in accordance with Chapter 10.

❖ This reference to Chapter 10 tells us that a membrane structure used as a place of assembly is treated in the same way that a permanent structure would be. The same means-of-egress requirements apply whether the structure is conventional construction or a membrane structure.

**3104.15 Heating and cooking equipment.** Heating and cooking equipment shall be in accordance with Sections 3104.15.1 through 3104.15.7.

❖ Because of the unique nature of the structures regulated by this chapter, it is vital that ignition sources be carefully regulated. This section regulates the dual hazards of heat-producing appliances and cooking equipment in membrane structures.

**3104.15.1 Installation.** Heating or cooking equipment, tanks, piping, hoses, fittings, valves, tubing and other related components shall be installed as specified in the *International Mechanical Code* and the *International Fuel Gas Code*, and shall be approved by the fire code official.

❖ This section refers to the cooking equipment installation requirements contained in the *International Fuel Gas Code*® (IFGC®) and *International Mechanical Code*® (IMC®), and gives the fire code official the authority to inspect and approve completed installations. Because of the special hazards that exist in membrane structures of all kinds, the importance of proper installation cannot be stressed enough.

Another issue with respect to this section is the question of whether cooking that produces grease-laden vapors is allowed inside of a tent or membrane structure without requiring the ventilation and fire suppression systems normally required for commercial cooking operations by Sections 609 and 904.2.1 and the referenced standards. Literally speaking, there is nothing in Chapter 31 that would specifically exempt cooking operations in any tent or membrane structure (whether or not it is open to the public) from the ventilation or fire suppression system requirements of the code or IMC for commercial cooking appliances that produce grease or smoke. The provisions of Section 3104.15 are equally applicable to all tents, canopies or membrane structures in which cooking is conducted.

It should be noted, however, that a key element in the use of a tent or membrane structure for commercial cooking and the application of ventilation and cooking fire suppression requirements is the evaluation and approval of the fire code official. Temporary facilities such as tents or membrane structures present a unique circumstance in which the strict application of code requirements to what is, in all likelihood, a temporary operation may not be practical or desirable. When applying the provisions of Section 104.8,

the judicious review and application of the code to these circumstances should focus on the scope, nature and duration of the hazards created by the cooking operation and how best to mitigate them in a manner acceptable to all parties concerned while maintaining public safety. Consistent with Section 3104.7, in conducting such an evaluation, special attention should be paid to cooking operations using charcoal or other solid fuels due to the potential for sparks or flying embers coming into contact with membrane materials.

**3104.15.2 Venting.** Gas, liquid and solid fuel-burning equipment designed to be vented shall be vented to the outside air as specified in the *International Fuel Gas Code* and the *International Mechanical Code*. Such vents shall be equipped with approved spark arresters where required. Where vents or flues are used, all portions of the tent or membrane structure shall be not less than 12 inches (305 mm) from the flue or vent.

❖ As with the installation requirements in Section 3104.15.1, venting must comply with the applicable provisions of the IFGC and IMC, and be approved by the fire code official. The 12-inch (305 mm) separation between the vent or flue stack and the membrane fabric and support structures is intended to prevent heating of those elements to possible points of ignition.

**3104.15.3 Location.** Cooking and heating equipment shall not be located within 10 feet (3048 mm) of *exits* or combustible materials.

❖ This location requirement is intended to help make certain that equipment items would not be likely to block a means of egress during a fire or other emergency. Equipment locations would be subject to the approval of the fire code official in all cases.

**3104.15.4 Operations.** Operations such as warming of foods, cooking demonstrations and similar operations that use solid flammables, butane or other similar devices that do not pose an ignition hazard, shall be approved.

❖ This section authorizes the listed operations, but at the same time authorizes the fire code official to make certain the operations meet the requirements of the other subsections within this section.

**3104.15.5 Cooking tents.** Tents with sidewalls or drops where cooking is performed shall be separated from other tents or membrane structures by not less than 20 feet (6096 mm).

❖ This separation requirement is consistent with the overall requirement covering open or exposed flames that is contained in Section 3104.7. The 20-foot (6096 mm) separation provides protection from hot embers from a fire reaching the main membrane structure. The requirements for keeping the open area free of combustible materials or debris that could limit access to emergency response personnel also apply.

**3104.15.6 Outdoor cooking.** Outdoor cooking that produces sparks or grease-laden vapors shall not be performed within 20 feet (6096 mm) of a tent or membrane structure.

- ❖ As with cooking in tents, the 20-foot (6096 mm) separation is intended to separate this potential source of ignition from the membrane structure. Requirements for keeping the open area free of combustible materials or other debris that could hinder emergency response efforts also apply.

**3104.15.7 Electrical heating and cooking equipment.** Electrical cooking and heating equipment shall comply with NFPA 70.

- ❖ This reference to NFPA 70 establishes the requirements for the equipment and its installation.

**3104.16 LP-gas.** The storage, handling and use of LP-gas and LP-gas equipment shall be in accordance with Sections 3104.16.1 through 3104.16.3.

- ❖ Because of the unique nature of the structures regulated by this chapter, it is vital that the storage, handling and use of hazardous materials in or around such structures be carefully regulated. In general, Chapter 61 regulates LP-gas. This section specifically regulates its storage, handling and use in connection with membrane structures.

**3104.16.1 General.** LP-gas equipment such as tanks, piping, hoses, fittings, valves, tubing and other related components shall be *approved* and in accordance with Chapter 61 and with the *International Fuel Gas Code*.

- ❖ The requirements stated in this section mean that LP-gas containers and all associated equipment used in or around membrane structures of any kind will be inspected and must meet basically the same requirements as similar installations and equipment in conventional structures.

**3104.16.2 Location of containers.** LP-gas containers shall be located outside. Safety release valves shall be pointed away from the tent or membrane structure.

- ❖ Containers must be located outdoors to prevent vapors from safety-release valves, inadvertent spills during filling or from any other source from accumulating inside the membrane structure to flammable levels. Requiring the safety-release valves to be pointed away from the structure also helps to ensure that vapors do not infiltrate the structure.

**3104.16.2.1 Containers 500 gallons or less.** Portable LP-gas containers with a capacity of 500 gallons (1893 L) or less shall have a minimum separation between the container and structure not less than 10 feet (3048 mm).

- ❖ The 10-foot (3048 mm) separation distance is consistent with the requirements of Table 6104.3. See the commentary to Section 6104.3 and Table 6104.3 for further discussion.

**3104.16.2.2 Containers more than 500 gallons.** Portable LP-gas containers with a capacity of more than 500 gallons

(1893 L) shall have a minimum separation between the container and structures not less than 25 feet (7620 mm).

- ❖ The 25-foot (7620 mm) separation distance is consistent with the requirements of Table 6104.3. See the commentary to Section 6104.3 and Table 6104.3 for further discussion.

**3104.16.3 Protection and security.** Portable LP-gas containers, piping, valves and fittings that are located outside and are being used to fuel equipment inside a tent or membrane structure shall be adequately protected to prevent tampering, damage by vehicles or other hazards and shall be located in an *approved* location. Portable LP-gas containers shall be securely fastened in place to prevent unauthorized movement.

- ❖ LP-gas containers and associated equipment must be protected from impact by vehicles or other objects that could cause damage and leakage. They must also be protected from tampering, vandalism and theft. See Sections 312 and 6107 for additional guidance on protection and security.

**3104.17 Flammable and combustible liquids.** The storage of flammable and *combustible liquids* and the use of flammable-liquid-fueled equipment shall be in accordance with Sections 3104.17.1 through 3104.17.3.

- ❖ Because of the unique nature of the structures regulated by this chapter, it is vital that the storage, handling and use of hazardous materials in or around such structures be carefully regulated. In general, Chapter 57 regulates flammable and combustible liquids. This section specifically regulates their storage, handling and use in connection with membrane structures.

**3104.17.1 Use.** Flammable-liquid-fueled equipment shall not be used in tents or membrane structures.

- ❖ Equipment of any kind that uses a flammable liquid for fuel must not be used inside a membrane structure because of the possibility of fuel leakage as well as the risk of accumulation of noxious exhaust fumes. Fluid leaks could vaporize and reach a flammable concentration. Exhaust fumes normally contain carbon monoxide and other gases that are harmful to occupants. Membrane structures, particularly air-supported and air-inflated structures, are not ventilated to the same extent that conventional structures are. Harmful vapors and fumes, therefore, are not diluted or dispersed as quickly or as efficiently as they are in those structures.

**3104.17.2 Flammable and combustible liquid storage.** Flammable and *combustible liquids* shall be stored outside in an *approved* manner not less than 50 feet (15 240 mm) from tents or membrane structures. Storage shall be in accordance with Chapter 57.

- ❖ This section provides a general separation requirement for containers used to store flammable or combustible liquids. The more detailed requirements are contained in Chapter 57 and depend, for the most

part, on whether the liquid is Class I, II or III and the quantity of the liquid being stored. Storage arrangements must comply with Chapter 57 requirements. They should, however, be discussed in advance with the fire code official to make certain all affected parties are in agreement.

**3104.17.3 Refueling.** Refueling shall be performed in an *approved* location not less than 20 feet (6096 mm) from tents or membrane structures.

- ❖ This section gives only a general guideline for location of a refueling station and gives the fire code official the authority to approve the selected location. When planning a station of this kind, the requirements of Chapter 57 must be considered. Some of the requirements of Sections 2304, 2305 and 2306 might also apply if vehicles are being refueled.

**3104.18 Display of motor vehicles.** Liquid- and gas-fueled vehicles and equipment used for display within tents or membrane structures shall be in accordance with Sections 3104.18.1 through 3104.18.5.3.

- ❖ This statement is an introduction to the subsections that follow. It contains only the kinds of structures, vehicles and equipment covered by the overall section. The provisions of these sections are similar to Section 314 on indoor displays.

**3104.18.1 Batteries.** Batteries shall be disconnected in an appropriate manner.

- ❖ Requiring that batteries be disconnected serves two purposes. First, it prevents unauthorized persons from starting and running engines that exhaust noxious fumes. Second, it removes a potential ignition source from the site by opening the battery-powered electrical circuit, thereby removing the possibility that the circuit could give off a stray spark. Equipment/vehicle manufacturers will, in all likelihood, have a recommended procedure in their owner's manuals for disconnecting batteries safely. The fire code official would also want to make sure the procedures used present no hazards.

**3104.18.2 Fuel.** Vehicles or equipment shall not be fueled or defueled within the tent or membrane structure.

- ❖ This section requires that all equipment and vehicle fueling must be conducted outdoors to avoid the accumulation of ignitable vapors within the membrane structure.

**3104.18.2.1 Quantity limit.** Fuel in the fuel tank shall not exceed one-quarter of the tank capacity or 5 gallons (19 L), whichever is less.

- ❖ Vehicles and equipment on display are allowed only a limited quantity of fuel in their tanks. Full fuel tanks could leak if temperatures reach a level that would cause the contained fuel to expand beyond the capacity of the tank. This kind of liquid spill would evaporate with the potential for enough flammable vapor to accumulate to reach a flammable level. Full tanks also leave very little room for vapors given off by the contained fuel. Practically all fuel tanks have

some kind of pressure-release valve built in to prevent overpressurization of the tank. Leaving three quarters of the tank empty allows space for moderate quantities of vapor to accumulate without being released to the building atmosphere.

**3104.18.2.2 Inspection.** Fuel systems shall be inspected for leaks.

- ❖ This statement places an inspection requirement on the party displaying the vehicles or equipment. The requirement should be looked at as being a routine housekeeping chore. The statement also gives the fire code official the authority to inspect the facility to achieve compliance with code requirements.

**3104.18.2.3 Closure.** Fuel tank openings shall be locked and sealed to prevent the escape of vapors.

- ❖ Locking and sealing fuel tank openings not only prevents vapors from escaping from the tanks, but will also deter malicious mischief that could result in a fire by denying access to a fuel source. Locking and sealing the fill pipe also deters vandalism to the vehicle that could occur by placing foreign objects or substances into the fuel tank.

**3104.18.3 Location.** The location of vehicles or equipment shall not obstruct *means of egress*.

- ❖ If the structure is occupied, blocking a means of egress would interfere with orderly evacuation of the space. Whether the structure is occupied or not, blocking a means of egress could interfere with access for emergency response personnel.

**3104.18.4 Places of assembly.** When a compressed natural gas (CNG) or liquefied petroleum gas (LP-gas) powered vehicle is parked inside a place of assembly, all the following conditions shall be met:

1. The quarter-turn shutoff valve or other shutoff valve on the outlet of the CNG or LP-gas container shall be closed and the engine shall be operated until it stops. Valves shall remain closed while the vehicle is indoors.
2. The hot lead of the battery shall be disconnected.
3. Dual-fuel vehicles equipped to operate on gasoline and CNG or LP-gas shall comply with this section and Sections 3104.18.1 through 3104.18.5.3 for gasoline-powered vehicles.

- ❖ The three requirements given in this section are applicable to vehicles powered by compressed natural gas (CNG) or LP-gas, but they are consistent with the requirements for gasoline-fueled vehicles given elsewhere in the code.

The first requirement is intended to prevent vapor buildup in confined spaces, such as inside an engine compartment. Fuel left standing in a warm engine will "cook off" (vaporize) after the engine is turned off. Requiring the engine to be left running after the supply valve is closed means that all fuel left in the engine will be burned off through internal combustion, leaving the engine relatively free of fuel that could vaporize.

The second requirement is a restatement of Section 3104.18.1 (see the commentary to that section).

The third requirement states that specialty vehicles designed to run on either gasoline or CNG/LP-gas must comply with the same requirements as vehicles designed to run on gasoline alone.

**3104.18.5 Competitions and demonstrations.** Liquid and gas-fueled vehicles and equipment used for competition or demonstration within a tent or membrane structure shall comply with Sections 3104.18.5.1 through 3104.18.5.3.

❖ The provisions of this section introduce Sections 3104.18.5.1 through 3104.18.5.3, which contain requirements for controlling the hazards associated with the use of liquid-fueled vehicles, or the equipment inside of tents or other membrane structures.

**3104.18.5.1 Fuel storage.** Fuel for vehicles or equipment shall be stored in *approved* containers in an *approved* location outside of the structure in accordance with Section 3104.17.2.

❖ This section gives the fire code official the authority to approve both the storage containers used and the location of those containers. The site designer, competition manager or other responsible party must have the fire code official's approval before the storage scheme is put into use. See also Section 6104 for further discussion of LP-gas storage, and Sections 2303 and 2306 for additional information on the storage of CNG.

**3104.18.5.2 Fueling.** Refueling shall be performed outside of the structure in accordance with Section 3104.17.3.

❖ This section refers back to Section 3104.17.3, which states a requirement for a 20-foot (6096 mm) separation between the fueling station and the membrane structure. Further information on fueling with LP gas is contained in Section 6106. Similar information covering CNG is contained in Sections 2304, 2307 and 2308.

**3104.18.5.3 Spills.** Fuel spills shall be cleaned up immediately.

❖ Controlling spills is important to fire safety. Section 2305.3 gives requirements for spill containment. The requirements for immediate cleanup are intended to prevent the buildup of flammable vapors to hazardous levels. Provisions for fuel spill containment and cleanup would require approval from the fire code official.

**3104.19 Separation of generators.** Generators and other internal combustion power sources shall be separated from tents or membrane structures by not less than 20 feet (6096 mm) and shall be isolated from contact with the public by fencing, enclosure or other *approved* means.

❖ This section states two requirements. First, consistent with other separation requirements, generators and other equipment driven by internal combustion engines must be kept separated from the membrane structure to minimize fire hazards if the generator or other equipment should fail and catch on fire. Sec-

ond, the isolation requirement is intended to both keep the public from coming into contact with hazardous equipment and protect the equipment from vandalism or accidental damage by the public.

**3104.20 Standby personnel.** Where, in the opinion of the *fire code official*, it is essential for public safety in a tent or membrane structure used as a place of assembly or any other use where people congregate, because of the number of persons, or the nature of the performance, exhibition, display, contest or activity, the *owner*, agent or lessee shall employ one or more qualified persons, as required and *approved*, to remain on duty during the times such places are open to the public, or when such activity is being conducted.

❖ This section authorizes the fire code official, at his or her discretion, to require the owner of a tent or membrane structure-based venue used for public assembly purposes to provide qualified supervisory personnel to enhance the safety profile of the event during its duration.

**3104.20.1 Duties.** Before each performance or the start of such activity, standby personnel shall keep diligent watch for fires during the time such place is open to the public or such activity is being conducted and take prompt measures for extinguishment of fires that occur and assist in the evacuation of the public from the structure.

❖ This section enumerates the duties and responsibilities of the individuals employed as standby personnel. These duties are that they: maintain a careful fire watch during whatever event is occurring, respond immediately to control fires and assist patrons in safely exiting the structure. They also could serve as ushers, tour guides or service supervisors for table seating; or in some other capacity related to making sure occupants are moved to or from assigned places in an orderly manner.

**3104.20.2 Crowd managers.** There shall be trained crowd managers or crowd manager/supervisors at a ratio of one crowd manager/supervisor for every 250 occupants, as *approved*.

❖ The key to this section is that the crowd managers must be trained in crowd management procedures appropriate to the activity being carried on in the membrane structure and they must be present in the required numbers. Training of personnel and the duties assigned to them would have to be approved by the fire code official. See also the commentary to Section 403.3 for further information on crowd managers.

**3104.21 Combustible vegetation.** Combustible vegetation that could create a fire hazard shall be removed from the area occupied by a tent or membrane structure, and from areas within 30 feet (9144 mm) of such structures.

❖ Because dry grass and weeds both within and outside of a membrane structure represent a significant fuel accumulation and fire hazard, this section requires that all combustible vegetation be removed from within the membrane structure and from the

area outside of and within a 30-foot (9144 mm) perimeter of the structure. Where the membrane structure is a tent that relies on ropes and stakes for its structural stability, the 30-foot (9144 mm) perimeter is to be measured outward from the furthest reach of the stake line, which is consistent with Section 3103.8.2. This will reduce the chances that a grass or brush fire originating outside the tent will damage the structural support system, which could lead to failure and collapse of the tent with potential injury to occupants. See the commentary to Section 304.1.2 for further information on combustible vegetation.

**3104.22 Combustible waste material.** The floor surface inside tents or membrane structures and the grounds outside and within a 30-foot (9144 mm) perimeter shall be kept free of combustible waste and other combustible materials that could create a fire hazard. Such waste shall be stored in *approved* containers and removed from the premises not less than once a day during the period the structure is occupied by the public.

❖ Accumulated waste, trash or debris and the fire load they represent can become a serious fire hazard if allowed to remain within a membrane structure or in close proximity outside of the structure. Accordingly, this section requires frequent collection and removal of trash and other combustibles from the area inside the structure and within a 30-foot (9144 mm) perimeter of the structure. Consistent with Section 3103.8.2, where the membrane structure is a tent that relies on ropes and stakes for its structural stability, the 30-foot (9144 mm) perimeter should be measured outward from the furthest reach of the stake line to reduce the chances that a trash fire originating outside the tent will damage the structural support system, which could lead to failure and collapse of the tent. Once collected and moved outside the structure, the trash and other combustible waste materials must be kept in an approved container, which should also be located outside of the 30-foot (9144 mm) perimeter. See Section 304.3 for requirements for approved trash containers. See also the commentary to Sections 304.1 and 304.1.1 for further information on waste accumulation.

## SECTION 3105 TEMPORARY STAGE CANOPIES

**3105.1 General.** Temporary stage canopies shall comply with Section 3104, Sections 3105.2 through 3105.8 and ANSI E1.21.

❖ Temporary stage canopies are by their nature very specialized and complex structures. The nature of the structures must accommodate a wide variety of changing components such as audio equipment, video walls and scenery. The entertainment industry is continually evolving with new ways to improve shows creating larger and more complex spectacles.

There were four high-profile temporary stage canopy collapses during the 2011 summer concert sea-

son: August 7 at Brady District Block Party, Tulsa, Oklahoma; July 17 at the Cisco Ottawa Blues Festival in Ottawa, Canada; August 13 at the Indiana State Fairgrounds, which resulted in seven people killed and 50 injured; and August 18 at the Pukkelpop Festival in Kiewit, Belgium. In the summer of 2012, another life was lost at a Radiohead concert in Toronto, Canada. All resulted in tremendous property damage and two in multiple fatalities. The obvious concern is for the safety of the performers, audiences, stagehands, lighting technicians, security personnel and every other profession or individual in close proximity to a temporary stage.

Due to the unique design of temporary stage canopies, it is difficult for most fire inspectors to find adequate guidance in current code language to satisfactorily regulate these specialized structures. This section introduces new regulations for these unique structures that will improve the safety profile of their construction and use, and provides an appropriate referenced standard to guide the fire code official in enforcing the new section. ANSI E1.21 was produced by the Entertainment Services and Technology Association (ESTA). ESTA recently merged with an international organization, Professional Lighting and Sound Association (PLASA). Fire code officials may download the standard at no charge, provided they register at [www.plasa.org](http://www.plasa.org). ANSI E1.21 includes requirements that the temporary stage canopy be designed not only to support the weight of the equipment, but also to withstand seismic loads, wind loads, rain and snow loading, and uplift. There is a necessity for a design professional to fully analyze and design the structure to comply with the structural loads. Section 3.4 of ANSI E1.21 requires: engineering drawings and calculations for the design; allowable payload; and maximum wind speed during the erection process and use of the structure. Commentary Figures 3105.1(1) and 3105.1(2) illustrate temporary stage structures.

**3105.2 Approval.** Temporary stage canopies in excess of 400 square feet (37 m<sup>2</sup>) shall not be erected, operated or maintained for any purpose without first obtaining approval and a permit from the *fire code official* and the building official.

❖ This section requires that both the fire code official and the building official issue a permit to construct a temporary stage canopy where the structure exceeds 400 square feet in area. This provides coordination of the respective expertise of the fire code official and the building official. The size is consistent with the threshold provided in Section 3103.2.

**3105.3 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a

general discussion of operations requiring an operational permit. Because of the hazards inherent in the construction and the operation of temporary stage canopies, an operational permit is required by Section 105.6.45 and a construction permit is required by Section 105.7.18. The process also notifies the fire department of the need for prefire planning for the operation.

**Figure 3105.1(1)  
TEMPORARY STAGE CANOPY  
IN AN OUTDOOR SETTING**

**3105.4 Use period.** Temporary stage canopies shall not be erected for a period of more than 45 days.

❖ Temporary stage canopies are very complex and specialized for each individual event. The nature of these structures must accommodate a wide variety of changing components, such as audio and lighting equipment, video walls and scenery. As such, one difference when compared to other temporary structures regulated in Chapter 31 of the code is that the time period considered as “temporary” for temporary stage canopies in this section is a maximum of 45

days. For structures to be used longer than that period, they would be treated as permanent structures and be regulated by the IBC. This use period is based on the provisions of the referenced standard ANSI E1.21, which defines “temporary” as “A period of time that is less than 6 weeks in duration.”

**3105.5 Required documents.** The following documents shall be submitted to the *fire code official* and the building official for review before a permit is approved:

1. Construction documents: *Construction documents* shall be prepared in accordance with the *International Building Code* by a registered design professional. *Construction documents* shall include:
  - 1.1. A summary sheet showing the building code used, design criteria, loads and support reactions.
  - 1.2. Detailed construction and installation drawings.
  - 1.3. Design calculations.
  - 1.4. Operating limits of the structure explicitly outlined by the registered design professional including environmental conditions and physical forces.
  - 1.5. Effects of additive elements such as video walls, supported scenery, audio equipment, vertical and horizontal coverings.
  - 1.6. Means for adequate stability including specific requirements for guying and cross-bracing, ground anchors or ballast for different ground conditions.
2. Designation of responsible party: The *owner* of the temporary stage canopy shall designate in writing a person to have responsibility for the temporary stage canopy on the site. The designated person shall have sufficient knowledge of the construction documents, manufacturer’s recommendations and operations plan to make judgments regarding the structure’s safety and to coordinate with the *fire code official*.
3. Operations plan: The operations plan shall reflect manufacturer’s operational guidelines, procedures for environmental monitoring and actions to be taken under specified conditions consistent with the *construction documents*.

❖ This section is a summary of the relevant requirements of ANSI E1.21 necessary to provide guidance to the fire code official. Stage canopies are subject to more diverse loads than most permanent structures. Because of varying equipment weight, changing weather conditions and the need to raise and lower the roof to install equipment, a design professional must fully analyze the structure and a responsible person who understands this complexity of considerations must be on site. The operations plan must identify the responsible person, designate safe evacuation routes and locations, and evaluate the potential for canceling the show when the weather creates an unsafe condition.

**3105.6 Inspections.** Inspections shall comply with Section 106 and Sections 3105.6.1 and 3105.6.2.

❖ This section simply introduces the inspection requirements that follow.

**3105.6.1 Independent inspector.** The *owner* of a temporary stage canopy shall employ a qualified, independent approved agency or individual to inspect the installation of a temporary stage canopy.

❖ It is unlikely many fire inspectors will be familiar with the specialized nature of these structures. Accordingly, this section requires a qualified specialized inspector to be employed by the owner to inspect and report to the authority having jurisdiction and the designated responsible person. An Entertainment Technician Certification Program (ETCP) certification exists that would demonstrate competence to inspect the majority of temporary stage canopies. For large, unusually complex canopies there is latitude for the fire code official to require inspection by a structural engineer familiar with these types of temporary structures. Although it is not specified in the code, IBC Chapter 17, *Special Inspections and Tests*, could be used as a guide for this particular inspection requirement. The use of a special inspector could be a condition of approval from the building and fire code official.

**3105.6.2 Inspection report.** The inspecting agency or individual shall furnish an inspection report to the *fire code official*. The inspection report shall indicate that the temporary stage canopy was inspected and was or was not installed in accordance with the approved *construction documents*. Discrepancies shall be brought to the immediate attention of the installer for correction. Where any discrepancy is not corrected, it shall be brought to the attention of the *fire code official* and the designated responsible party.

❖ The specialized inspector must perform a construction inspection and issue a report, the primary objective of which is to verify that the temporary stage canopy was constructed in accordance with the approved construction documents and the conditions of the construction permit. Discrepancies must be identified and corrected before the structure can be utilized/occupied. Failure to correct any discrepancy must be reported to the fire code official and the responsible party that was designated in accordance with Section 3105.5(2).

**3105.7 Means of egress.** The *means of egress* for temporary stage canopies shall comply with Chapter 10.

❖ This section simply directs the code user to Chapter 10 for means of egress requirements.

Figure 3105.1(2)  
TEMPORARY STAGE CANOPY AFTER STRUCTURAL COLLAPSE AT THE INDIANA STATE FAIR—AUGUST 13, 2011  
(Photo courtesy of Anne vonWeller)

**3105.8 Location.** Temporary stage canopies shall be located a distance from property lines and buildings to accommodate distances indicated in the construction drawings for guy wires, cross-bracing, ground anchors or ballast. Location shall not interfere with egress from a building or encroach on fire apparatus access roads.

❖ Separation distance requirements of this section are consistent with requirements for conventional structures, especially those that could represent an above-average fire hazard. A fire of any size within a temporary stage structure would almost certainly involve any membrane coverings and structural support elements. Because the support ropes and ground anchors are under tension, particularly with large structures, a structure weakened by fire would likely fail, causing the ropes or wires to recoil and possibly pull portions of the burning temporary stage structure out of its original position. Requiring clear space around the structure helps reduce the likelihood that burning membrane sections and flying embers would endanger other structures or interfere with the functions of the open space, which include providing a clear egress path from the stage canopy or any structure adjacent to it and fire department access to the structure. Note that Section 3103.8.2 considers guy wires to be part of the structure when measuring open spaces around structures and it would seem prudent to apply that principle to this section as well.

# Chapter 32: High-Piled Combustible Storage

## General Comments

High-piled combustible storage facilities present great challenges in fire incident management. The sheer mass of commodities in concentrated form, along with a different configuration for access to those commodities, has led to the development of some unique fire protection and life safety measures. Experience with automatic sprinkler protection has demonstrated over the years that such systems are reliable and effective in suppressing fires and in supplementing manual fire suppression and extinguishing operations. However, the design and maintenance of any system or measure is essential to ensuring that, when needed, it will serve its function until such time as the fire service arrives to take command of the incident.

Chapter 32 presents fundamental concepts of fire and life safety protection within high-piled combustible storage areas and buildings. Fire tests and past fire experience have shown that the class and quantity of commodities, their relationship to one another and the maintenance and inspection of the systems and building are essential in preventing fires or limiting the spread of fire. This chapter has provisions aimed at verifying the proper design and installation of given fire and life safety protection systems. In some cases, the referenced standards will contain more specific design and installation criteria than are found in this chapter.

Other chapters of the code that contain provisions related to Chapter 32 are Chapters 3, 4, 5, 7, 9 and 10. The *International Building Code*® (IBC®) is mentioned within this chapter, which addresses construction classification, occupancy, fire protection features, means of egress and structural requirements.

This chapter does not specifically cover miscellaneous combustible materials storage (see Section 315)

or storage facilities of unusual design. Under those circumstances, the provisions of Chapter 1, specifically Section 102.7, would apply. Unusual storage facilities may include, but are not limited to, storage warehouses located on piers, storage of vehicles, refrigerated storage, underground storage facilities and air-supported storage structures. Each type of specialty storage offers a challenge to the fire department that will require unconventional fire incident management planning and unusual fire-fighting techniques. Access by fire-fighting vehicles and personnel is the greatest of those challenges. As a result, preplanning of the design of the storage facility may require coordination with the fire code official and fire service to determine the means and methods of the fire service to handle an approach by water, addressing floating burning debris from a fire, hazards of other neighboring piers and vessels, etc.

## Purpose

Chapter 32 provides guidance for reasonable protection of life from hazards associated with high-piled combustible storage. It contains requirements for identifying various classes of commodities; general fire and life protection safety features; and housekeeping and maintenance requirements. This chapter attempts to define potential fire severity and determine fire and life safety protection measures needed to control or suppress a potential fire. Design considerations for the construction, occupancy and fire protection features of the building or structure accommodating the high-piled combustible storage is the responsibility of the design professional and the building owner. Housekeeping, building maintenance and development and upkeep of an evacuation plan are the responsibility of the building owner, tenant or lessee.

---

## SECTION 3201 GENERAL

**3201.1 Scope.** *High-piled combustible storage* shall be in accordance with this chapter. In addition to the requirements of this chapter, the following material-specific requirements shall apply:

1. Aerosols shall be in accordance with Chapter 51.
2. Flammable and *combustible liquids* shall be in accordance with Chapter 57.
3. Hazardous materials shall be in accordance with Chapter 50.

4. Storage of combustible paper records shall be in accordance with NFPA 13.
5. Storage of *combustible fibers* shall be in accordance with Chapter 37.
6. General storage of combustible material shall be in accordance with Chapter 3.

❖ This section is intended as an introduction and references those other chapters within the code that are to be used in conjunction with Chapter 32, when applicable. In many cases, the referenced chapter contains more stringent provisions regarding fire

protection and life safety measures, and may also cite other referenced standards. For example, Chapter 28 references NFPA 30B, Chapter 57 references NFPA 30 and Chapter 50 references NFPA 704.

**3201.2 Permits.** A permit shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit. The permit process also notifies the fire department of the need for prefire planning for the hazardous property.

**3201.3 Construction documents.** At the time of building permit application for new structures designed to accommodate high-piled storage or for requesting a change of occupancy/use, and at the time of application for a storage permit, plans and specifications shall be submitted for review and approval. In addition to the information required by the *International Building Code*, the storage permit submittal shall include the information specified in this section. Following approval of the plans, a copy of the *approved* plans shall be maintained on the premises in an *approved* location. The plans shall include all of the following:

1. Floor plan of the building showing locations and dimensions of *high-piled storage areas*.
2. Usable storage height for each storage area.
3. Number of tiers within each rack, if applicable.
4. Commodity clearance between top of storage and the sprinkler deflector for each storage arrangement.
5. Aisle dimensions between each storage array.
6. Maximum pile volume for each storage array.
7. Location and classification of commodities in accordance with Section 3203.
8. Location of commodities that are banded or encapsulated.
9. Location of required fire department access doors.
10. Type of fire suppression and fire detection systems.
11. Location of valves controlling the water supply of ceiling and in-rack sprinklers.
12. Type, location and specifications of smoke removal and curtain board systems.
13. Dimension and location of transverse and longitudinal flue spaces.
14. Additional information regarding required design features, commodities, storage arrangement and fire protection features within the high-piled storage area shall be provided at the time of permit, when required by the *fire code official*.

❖ Section 3201.3 contains provisions that are unique to the needs of the fire department. These construction

document requirements are in addition to those encountered in the IBC and specifically require detailed information that is essential for the permit review process and for future use when conducting fire inspections, in the development of the fire department's prefire emergency plans and when conducting fire incident management during an emergency. Items 1, 2, 3 and 5 are general requirements that address the general description of work for which the application must be submitted. Item 4 is significant because the height of any storage in relation to the sprinkler heads will determine sprinkler effectiveness. Sprinklers should be designed for the maximum allowable heights of the stored commodities and the minimum amount of unobstructed space below the sprinkler heads. Items 6, 7 and 8 recognize that a storage building can contain multiple classes and groups of commodities. As a result, this section requires that the construction documents illustrate the location, size and classification of the various types of commodities. Items 9, 10, 11 and 12 are important for the development of a prefire emergency plan. Such a plan can be established by the building owner or the tenant in cooperation with the local fire department that will be called to the building during an emergency. Developing and maintaining a prefire emergency plan can help during the incipient stages of a fire by reducing the amount of damage from the fire and containing the fire within a short time. Item 13 requires a detailed description of the locations of transverse and longitudinal flue spaces. The provisions for minimum flue space dimensions are contained in Section 3208.3. Item 14 allows the fire code official to use the enforcement powers of that office to collect more detailed information to make a more educated decision. These provisions recognize that technology is evolving. As a result, the situation presented to the fire code official can require that additional fire protection and life safety measures be applied to address those new designs for storage or new class of commodity.

**3201.4 Evacuation plan.** Where required by the *fire code official*, an evacuation plan for public accessible areas and a separate set of plans indicating location and width of *aisles*, location of *exits*, *exit access* doors, *exit* signs, height of storage, and locations of hazardous materials shall be submitted at the time of permit application for review and approval. Following approval of the plans, a copy of the *approved* plans shall be maintained on the premises in an *approved* location.

❖ Section 3201.4 contains provisions that are designed to compel additional information about the facility in terms of the layout of the egress system. This feature serves both the occupants of the building or structure and the fire department by addressing unique conditions. The plans are to be accessible at the site and are for use by the fire code official or fire department during inspections of the building or structure. Maintenance of the plans is the responsibility of the building owner, tenant or lessee.

Note that Chapter 4 addresses fire safety and

evacuation plans for various occupancies. High-piled storage is not addressed directly, but larger Group M and F occupancies are required to provide these plans. Such occupancies have the possibility of containing high-piled storage.

### SECTION 3202 DEFINITIONS

**3202.1 Definitions.** The following terms are defined in Chapter 2:

**ARRAY.**

**ARRAY, CLOSED.**

**AUTOMATED RACK STORAGE.**

**BIN BOX.**

**COMMODITY.**

**EARLY SUPPRESSION FAST-RESPONSE (ESFR) SPRINKLER.**

**EXPANDED PLASTIC.**

**EXTRA-HIGH-RACK COMBUSTIBLE STORAGE.**

**HIGH-PILED COMBUSTIBLE STORAGE.**

**HIGH-PILED STORAGE AREA.**

**LONGITUDINAL FLUE SPACE.**

**MANUAL STOCKING METHODS.**

**MECHANICAL STOCKING METHODS.**

**SHELF STORAGE.**

**SOLID SHELVING.**

**TRANSVERSE FLUE SPACE.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

### SECTION 3203 COMMODITY CLASSIFICATION

**3203.1 Classification of commodities.** Commodities shall be classified as Class I, II, III, IV or high hazard in accordance with this section. Materials listed within each commodity classification are assumed to be unmodified for improved combustibility characteristics. Use of flame-retarding modifiers or the physical form of the material could change the classification. See Section 3203.7 for classification of Group A, B and C plastics.

❖ The classification of commodities contains information addressing the materials that make up the commodity and its packaging (see Commentary Figure 3203.1). As an example, lubricating fluid in metal

cans is designated as Class III, whereas lubricating fluid in plastic containers is designated as Class IV. Although this section addresses only the classification, such factors as the location of the commodity, location relative to other commodities of differing classes, flue spaces, fire protection, ventilation, access and egress will affect the storage layout. Among the most important considerations are the packaging of the commodity and the type of support the commodity is resting on (e.g., pallets). For rack storage, the distinction between the classes is made with respect to the arrangement of the products; for example, products encapsulated with plastic wrap and those products not encapsulated. The plastic wrap acts effectively as a container for the entire arrangement of products, and because it encapsulates five of the six sides of the arrangement, it can prevent sprinklers from having an effect on the products if they do ignite and makes it difficult for prewetting of the surrounding commodities. The encapsulated category can be considered nonencapsulated by removing, at a minimum, the plastic wrap from the top of the arranged products, thus allowing some penetration for the sprinklers.

Low Fire Hazard	
Class I	Essentially noncombustible products on noncombustible pallets
High Fire Hazard	
Class II	Essentially Class I products on wood pallets or crates
Class III	Essentially wood, paper and fiber products and Group C plastics (limited Class A and B plastics)
Class IV	Essentially Class I, II or III containing significant Group A plastics (unlimited Class B plastics and free-flowing Group A plastics)
High Hazard	
—	Essentially present fire hazard beyond Class I, II, III or IV

**Figure 3203.1  
CLASSIFICATION LEVELS**

**3203.2 Class I commodities.** Class I commodities are essentially noncombustible products on wooden pallets, in ordinary corrugated cartons with or without single-thickness dividers, or in ordinary paper wrappings with or without pallets. Class I commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 3203.7.4. Examples of Class I commodities include, but are not limited to, the following:

- Alcoholic beverages not exceeding 20-percent alcohol
- Appliances noncombustible, electrical
- Cement in bags
- Ceramics
- Dairy products in nonwax-coated containers (excluding bottles)

## HIGH-PILED COMBUSTIBLE STORAGE

Dry insecticides  
Foods in noncombustible containers  
Fresh fruits and vegetables in nonplastic trays or containers  
Frozen foods  
Glass  
Glycol in metal cans  
Gypsum board  
Inert materials, bagged  
Insulation, noncombustible  
Noncombustible liquids in plastic containers having less than a 5-gallon (19 L) capacity  
Noncombustible metal products

❖ Class I commodities are basically noncombustible products packaged in corrugated cardboard cartons. The products may be arranged on combustible pallets. Examples of products that create this hazard are listed in this section.

**3203.3 Class II commodities.** Class II commodities are Class I products in slatted wooden crates, solid wooden boxes, multiple-thickness paperboard cartons or equivalent combustible packaging material with or without pallets. Class II commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 3203.7.4. Examples of Class II commodities include, but are not limited to, the following:

Alcoholic beverages not exceeding 20-percent alcohol, in combustible containers  
Foods in combustible containers  
Incandescent or fluorescent light bulbs in cartons  
Thinly coated fine wire on reels or in cartons

❖ Class II commodities consist of noncombustible products packaged in slatted wooden crates, solid wooden boxes, multiple-thickness paperboard cartons or equivalent combustible packaging materials that may or may not be arranged on pallets. If the commodity is stored on a rack storage system, it will generally be placed on wooden pallets. Examples of products that create this hazard are listed in this section.

**3203.4 Class III commodities.** Class III commodities are commodities of wood, paper, natural fiber cloth, or Group C plastics or products thereof, with or without pallets. Products are allowed to contain limited amounts of Group A or B plastics, such as metal bicycles with plastic handles, pedals, seats and tires. Group A plastics shall be limited in accordance with Section 3203.7.4. Examples of Class III commodities include, but are not limited to, the following:

Aerosol, Level 1 (see Chapter 51)  
Biomass briquettes, bagged, and static piles  
Biomass pellets, bagged, and static piles  
Charcoal  
Combustible fiberboard  
Cork, baled  
Corn cobs, static piles  
Corn stover, baled and chopped  
Feed, bagged  
Fertilizers, bagged

Firewood  
Food in plastic containers  
Forest residue, round wood or chipped (branches, bark, cross-cut ends, edgings and treetops)  
Furniture: wood, natural fiber, upholstered, nonplastic, wood or metal with plastic-padded and covered armrests  
Glycol in combustible containers not exceeding 25 percent  
Lubricating or hydraulic fluid in metal cans  
Lumber  
Mattresses, excluding foam rubber and foam plastics  
Noncombustible liquids in plastic containers having a capacity of more than 5 gallons (19 L)  
Paints, oil base, in metal cans  
Paper, waste, baled  
Paper and pulp, horizontal storage, or vertical storage that is banded or protected with approved wrap  
Paper in cardboard boxes  
Peanut hulls, bagged, and static piles  
Pillows, excluding foam rubber and foam plastics  
Plastic-coated paper food containers  
Plywood  
Rags, baled  
Recovered construction wood  
Rice hulls, bagged, and static piles  
Rugs, without foam backing  
Seasonal grasses, baled and chopped  
Straw, baled  
Sugar, bagged  
Wood, baled  
Wood chips, bagged, and static piles  
Woody biomass, round wood or chipped (vase-shaped stubby bushes, bamboo, willows; branches, bark and stem wood)  
Wood doors, frames and cabinets  
Wood pellets, bagged, and static piles  
Yarns of natural fiber and viscose

❖ Class III commodities are products of wood, paper, natural fiber or Group C plastics that may be arranged with or without pallets. The limitations concerning Group A are determined by Section 3203.7.4 and Figure 3203.7.4. Limited Group B plastics are allowed. Examples of products that create this hazard are listed in this section.

**3203.5 Class IV commodities.** Class IV commodities are Class I, II or III products containing Group A plastics in ordinary corrugated cartons and Class I, II and III products with Group A plastic packaging, with or without pallets. Group B plastics and free-flowing Group A plastics are also included in this class. The total amount of nonfree-flowing Group A plastics shall be in accordance with Section 3203.7.4. Examples of Class IV commodities include, but are not limited to, the following:

Aerosol, Level 2 (see Chapter 51)  
Alcoholic beverages, exceeding 20-percent but less than 80-percent alcohol, in cans or bottles in cartons  
Clothing, synthetic or nonviscose  
Combustible metal products (solid)  
Furniture, plastic upholstered

Furniture, wood or metal with plastic covering and padding  
Glycol in combustible containers (greater than 25 percent and less than 50 percent)

Linoleum products

Paints, oil base in combustible containers

Pharmaceutical, alcoholic elixirs, tonics, etc.

Rugs, foam back

Shingles, asphalt

Thread or yarn, synthetic or nonviscose

- ❖ Class IV commodities represent Class I, II or III products containing an appreciable amount of Group A plastics. These plastics can be a part of the actual product or may be part of the packaging. Packing is in ordinary corrugated cardboard cartons, and arrangement may or may not be on pallets. This class also allows unlimited Group B plastics and free-flowing Group A plastics. Examples of products that create this hazard are listed in this section.

**3203.6 High-hazard commodities.** High-hazard commodities are high-hazard products presenting special fire hazards beyond those of Class I, II, III or IV. Group A plastics not otherwise classified are included in this class. Examples of high-hazard commodities include, but are not limited to, the following:

Aerosol, Level 3 (see Chapter 51)

Alcoholic beverages, exceeding 80-percent alcohol, in bottles or cartons

Commodities of any class in plastic containers in carousel storage

Flammable solids (except solid combustible metals)

Glycol in combustible containers (50 percent or greater)

Lacquers that dry by solvent evaporation, in metal cans or cartons

Lubricating or hydraulic fluid in plastic containers

Mattresses, foam rubber or foam plastics

Pallets and flats that are idle combustible

Paper and pulp, rolled, in vertical storage that is unbanded or not protected with an *approved* wrap

Paper, asphalt, rolled, horizontal storage

Paper, asphalt, rolled, vertical storage

Pillows, foam rubber and foam plastics

Pyroxylin

Rubber tires

Vegetable oil and butter in plastic containers

- ❖ High-hazard commodities present a hazard inasmuch as they contain materials that readily support combustion or materials that can support a physical or health hazard. Those products that represent a physical hazard are those presenting a detonation hazard, deflagration hazard or that readily support combustion. The products representing a health hazard are those that present a risk to people from handling or exposure to the product. Examples of products that create this kind of hazard are listed in this section.

High-hazard commodities are not to be confused with high-hazard occupancy Group H. The term "high-hazard," in the context of this chapter, describes storage commodities that can present high-challenge fires. While some of the commodities listed

may result in a Group H occupancy classification, others will not.

**3203.7 Classification of plastics.** Plastics shall be designated as Group A, B or C in accordance with Sections 3203.7.1 through 3203.7.4.

- ❖ The classification of plastics is contained in Sections 3203.7.1 through 3203.7.4. This section recognizes that plastics tend to have high heat content and burning rates (heat release rates). For example, a Class IV commodity could be evaluated as a high-hazard commodity because of the quantity of Group A plastic cushioning within the container used to sustain or hold the product.

**3203.7.1 Group A plastics.** Group A plastics are plastic materials having a heat of combustion that is much higher than that of ordinary combustibles, and a burning rate higher than that of Group B plastics. Examples of Group A plastics include, but are not limited to, the following:

ABS (acrylonitrile-butadiene-styrene copolymer)

Acetal (polyformaldehyde)

Acrylic (polymethyl methacrylate)

Butyl rubber

EPDM (ethylene propylene rubber)

FRP (fiberglass-reinforced polyester)

Natural rubber (expanded)

Nitrile rubber (acrylonitrile butadiene rubber)

PET or PETE (polyethylene terephthalate)

Polybutadiene

Polycarbonate

Polyester elastomer

Polyethylene

Polypropylene

Polystyrene (expanded and unexpanded)

Polyurethane (expanded and unexpanded)

PVC (polyvinyl chloride greater than 15-percent plasticized, e.g., coated fabric unsupported film)

SAN (styrene acrylonitrile)

SBR (styrene butadiene rubber)

- ❖ Group A plastics are generally considered a high-hazard commodity because they have the highest burning rate (heat release rates) of the materials in the classes and groups. Examples of products that create this hazard include:

- Polyurethane foams used in sofas and beds.
- Polypropylene plastic toys.
- Majority of stuffed animals and toys.
- Rubber tires.

**3203.7.2 Group B plastics.** Group B plastics are plastic materials having a heat of combustion and a burning rate higher than that of ordinary combustibles, but not as high as those of Group A plastics. Examples of Group B plastics include, but are not limited to, the following:

Cellulosics (cellulose acetate, cellulose acetate butyrate, ethyl cellulose)

Chloroprene rubber

Fluoroplastics (ECTFE, ethylene-chlorotrifluoroethylene copolymer; ETFE, ethylene-tetrafluoroethylene

copolymer; FEP, fluorinated ethylene-propylene copolymer)

Natural rubber (nonexpanded)

Nylon (Nylon 6, Nylon 6/6)

PVC (polyvinyl chloride greater than 5-percent, but not exceeding 15-percent plasticized)

Silicone rubber

- ❖ Group B plastics represent the next level of plastics that have a heat of combustion and burning rate higher than that of ordinary combustibles, but less than Group A plastics. Examples of products that create this hazard include nylon rugs and nylon ropes.

**3203.7.3 Group C plastics.** Group C plastics are plastic materials having a heat of combustion and a burning rate similar to those of ordinary combustibles. Examples of Group C plastics include, but are not limited to, the following:

Fluoroplastics (PCTFE, polychlorotrifluoroethylene;

PTFE, polytetrafluoroethylene)

Melamine (melamine formaldehyde)

Phenol

PVC (polyvinyl chloride, rigid or plasticized less than 5 percent, e.g., pipe, pipe fittings)

PVDC (polyvinylidene chloride)

PVDF (polyvinylidene fluoride)

PVF (polyvinyl fluoride)

Urea (urea formaldehyde)

- ❖ Group C plastics are those products that can be similar to ordinary combustibles because of their heat of combustion and burning rates, which will be less than Group A and B plastics. Examples of products that create this hazard include hard, polyvinyl chloride (PVC) piping used in many swimming pools and irrigation products, and melamine dishware.

**3203.7.4 Limited quantities of Group A plastics in mixed commodities.** Figure 3203.7.4 shall be used to determine the quantity of Group A plastics allowed to be stored in a package or carton or on a pallet without increasing the commodity classification.

- ❖ Limited quantities of Group A plastics can be allowed within other classes of commodities. Figure 3203.7.4 shows the pertinent requirements, or limits, for determining to which class the limited amount of Group A plastic is assigned.

**FIGURE 3203.7.4.** See page 32-7.

- ❖ The figure represents an empirical judgment (as a result of fire testing experience) of the risks associated with assigning a limited amount of Group A plastics to another commodity class. The figure is intended to help determine the commodity classification of a mixed commodity in a package or carton or on a pallet when plastics are involved. Plastics can be involved (mixed) with products through the use of packaging or can be contained in or integrated into the actual product.

## SECTION 3204

### DESIGNATION OF HIGH-PILED STORAGE AREAS

**3204.1 General.** *High-piled storage areas*, and portions of *high-piled storage areas* intended for storage of a different commodity class than adjacent areas, shall be designed and specifically designated to contain Class I, Class II, Class III, Class IV or high-hazard commodities. The designation of a *high-piled combustible storage area*, or portion thereof intended for storage of a different commodity class, shall be based on the highest hazard commodity class stored except as provided in Section 3204.2.

- ❖ This section establishes designation requirements for different commodity classes, and designates areas within buildings for use in determining general fire protection and life safety features.

The highest hazard commodity will drive the classification of the storage area. Section 3204.2 offers an exception to this by taking advantage of the hydraulic design of sprinkler systems. Additionally, lower-hazard commodities can be separated from higher-hazard commodities in accordance with Sections 3206.3.2.1 and 3206.3.2.2.

**3204.2 Designation based on engineering analysis.** The designation of a *high-piled combustible storage area*, or portion thereof, is allowed to be based on a lower hazard class than that of the highest class of commodity stored when a limited quantity of the higher hazard commodity has been demonstrated by engineering analysis to be adequately protected by the *automatic sprinkler system* provided. The engineering analysis shall consider the ability of the sprinkler system to deliver the higher density required by the higher hazard commodity. The higher density shall be based on the actual storage height of the pile or rack and the minimum allowable design area for sprinkler operation as set forth in the density/area figures provided in NFPA 13. The contiguous area occupied by the higher hazard commodity shall not exceed 120 square feet (11 m<sup>2</sup>) and additional areas of higher hazard commodity shall be separated from other such areas by 25 feet (7620 mm) or more. The sprinkler system shall be capable of delivering the higher density over a minimum area of 900 square feet (84 m<sup>2</sup>) for wet pipe systems and 1,200 square feet (111 m<sup>2</sup>) for dry pipe systems. The shape of the design area shall be in accordance with Section 903.

- ❖ This section allows the designer to make use of the benefits of hydraulic design. In other words, in an area rated for a low-hazard commodity it is likely that in some portions of that space the available water and pressure will be sufficient for a higher-hazard commodity. This is true since sprinklers are designed for the most hydraulically remote areas; therefore, areas closer to the riser will receive more water and higher pressure. There are certain criteria accompanying this allowance that limit the size of the higher-hazard storage areas to 120 square feet (11 m<sup>2</sup>) each and require that they be separated from other similar

areas by 25 feet (7620 mm) (see Commentary Figure 3204.2). It also provides minimum areas in which this increased water supply needs to be available. It should be noted that there are some potential maintenance limitations. It may be difficult to keep track of these particular designated areas and the separation between the areas; therefore, it is suggested that the areas be delineated on the floor using durable traffic-type paint or tape. Recording the areas on a scaled floor plan available to inspectors could also be useful.

NFPA 13 also offers another alternative that allows higher-hazard commodities to be dispersed throughout a lower-hazard commodity storage area. There are limitations on how many commodities can be in

each mixed commodity area. The commodities must be randomly dispersed (see NFPA 13).

**SECTION 3205  
HOUSEKEEPING AND MAINTENANCE**

**3205.1 Rack structures.** The structural integrity of racks shall be maintained.

❖ This section’s emphasis on “structural integrity” has its roots in the IBC, specifically Chapters 16 and 22, which govern the structural design of rack storage installations. The integrity of rack storage includes such items as the primary structural components, the connections, bracing members and relationship with

**FIGURE 3203.7.4  
MIXED COMMODITIES<sup>a, b</sup>**

- a. This figure is intended to determine the commodity classification of a mixed commodity in a package, carton or on a pallet where plastics are involved.
- b. The following is an example of how to apply the figure: A package containing a Class III commodity has 12-percent Group A expanded plastic by volume. The weight of the unexpanded Group A plastic is 10 percent. This commodity is classified as a Class IV commodity. If the weight of the unexpanded plastic is increased to 14 percent, the classification changes to a high-hazard commodity.

c. Percent by volume =  $\frac{\text{Volume of plastic in pallet load}}{\text{Total volume of pallet load, including pallet}}$

d. Percent by weight =  $\frac{\text{Weight of plastic in pallet load}}{\text{Total weight of pallet load, including pallet}}$

## HIGH-PILED COMBUSTIBLE STORAGE

the superstructure of the building. Racks can be a very significant part of the structure and pose structural failure concerns, especially for the fire suppression forces that may be operating in close proximity to the racks.

**3205.2 Ignition sources.** Clearance from ignition sources shall be provided in accordance with Section 305.

❖ Section 3205.2 directs the reader to Section 305, which addresses housekeeping provisions for such things as open flames, heaters, flame-producing devices, light fixtures and materials subject to spontaneous combustion. The responsibility for the care and maintenance of the building rests with the building owner or the tenant.

**3205.3 Smoking.** Smoking shall be prohibited. *Approved* “No Smoking” signs shall be conspicuously posted in accordance with Section 310.

❖ This section prohibits smoking within combustible storage areas to limit the chance for a fire to ignite. Section 310 is referenced for signage requirements.

**3205.4 Aisle maintenance.** When restocking is not being conducted, aisles shall be kept clear of storage, waste material and debris. Fire department access doors, aisles and *exit* doors shall not be obstructed. During restocking operations using manual stocking methods, a minimum unobstructed aisle width of 24 inches (610 mm) shall be maintained in 48-

inch (1219 mm) or smaller aisles, and a minimum unobstructed aisle width of one-half of the required aisle width shall be maintained in aisles greater than 48 inches (1219 mm). During mechanical stocking operations, a minimum unobstructed aisle width of 44 inches (1118 mm) shall be maintained in accordance with Section 3206.9.

❖ This section emphasizes the importance of keeping aisles and access corridors open at all times for both occupant egress and fire-fighter access. Such aisles also serve as fire breaks. Miscellaneous storage, waste and other objects in the aisles negate or reduce these functions; therefore, the owner or tenant needs to have a rigorous maintenance program in place. This section is applicable to buildings that are accessible by the public, as well as those that are not. Restocking operations have the potential for being another impediment. Establishing minimum aisle widths coupled with strict enforcement increases the likelihood that clear aisle space will be available.

**3205.5 Pile dimension and height limitations.** Pile dimensions and height limitations shall comply with Section 3207.3.

❖ Pile dimensions and height limitations are directly regulated by the commodity class and the size of the storage area in accordance with Section 3207.3 and Table 3206.2. Section 3207.3 simply references

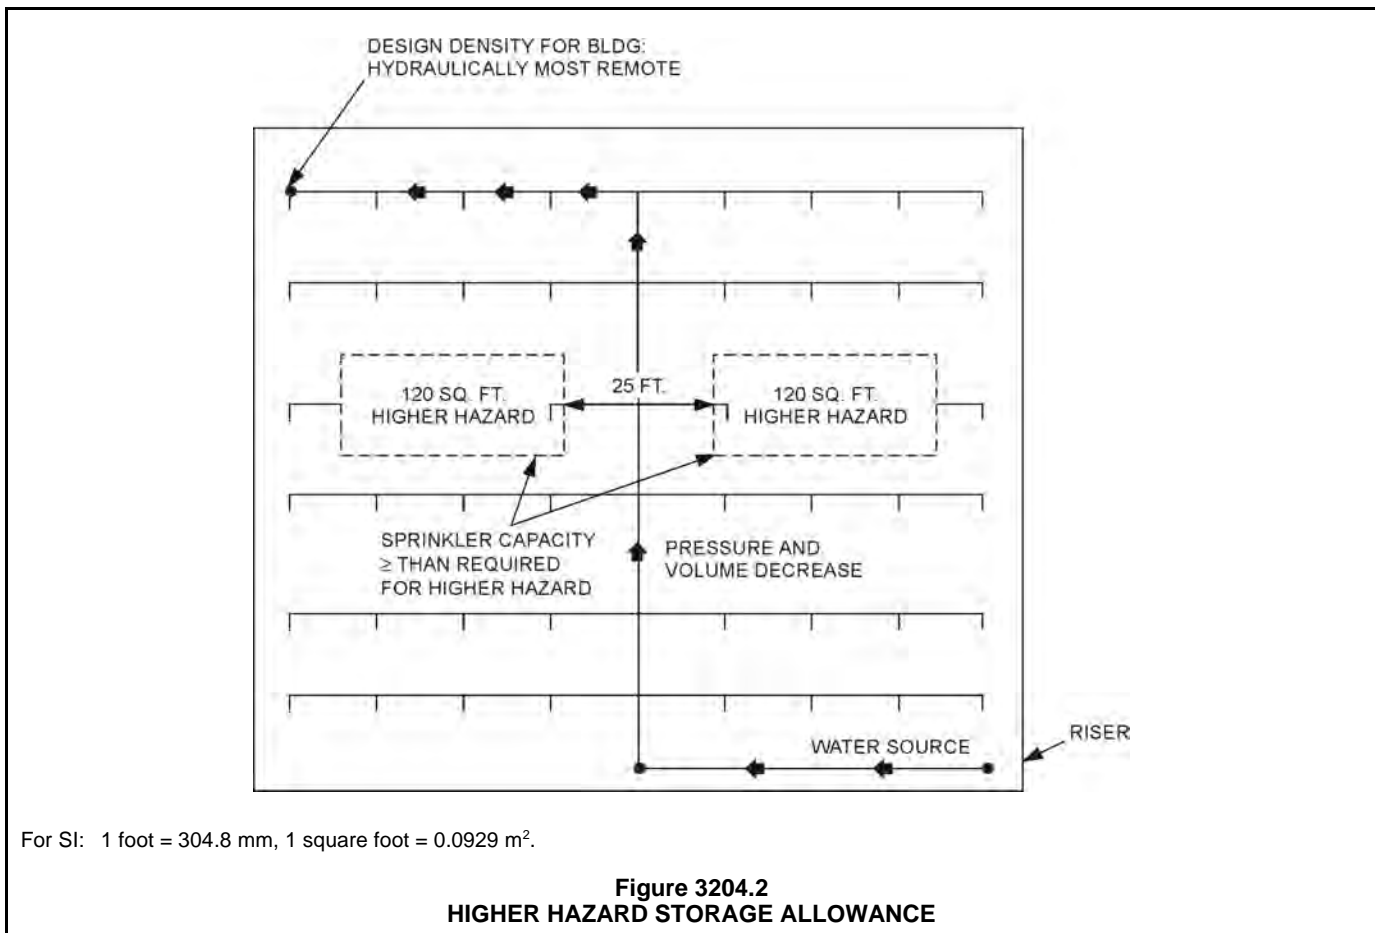

Table 3206.2, which provides these limitations. The only real variation in pile sizes is when a designer chooses Option 2 in the table, which omits the use of sprinklers. Therefore, control of combustibles is more critical and the code has more restrictive height limitations.

**3205.6 Designation of storage heights.** Where required by the *fire code official*, a visual method of indicating the maximum allowable storage height shall be provided.

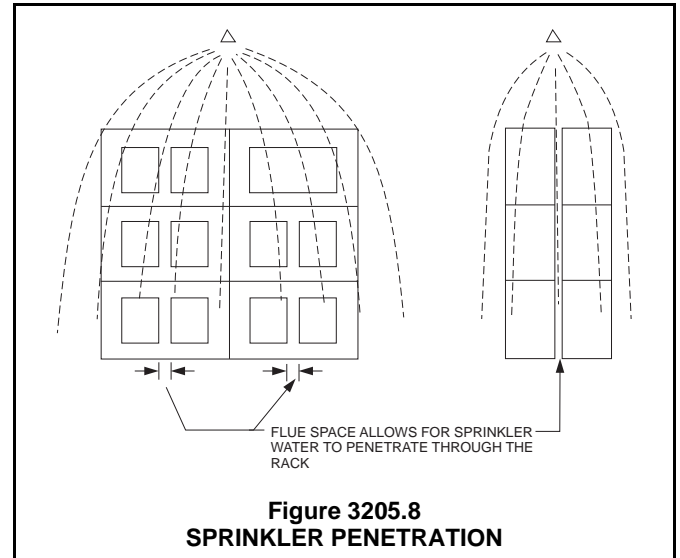

- ❖ The storage height of commodities is one of the most important variables when determining the adequacy of an automatic sprinkler system. A small increase in the height of storage can have major implications as to the minimum volume of water required to either control or suppress a fire involving high-piled combustible storage. This section was developed to provide code officials with a means of visually identifying the maximum allowable storage height in occupancies housing high-piled combustible storage. The requirement is not mandatory for all high-piled combustible storage, it is only required when specified by the fire code official. When applied, the requirement provides building owners and employees with a visual means of increasing the likelihood that the maximum allowable storage height will not be exceeded. This section does not specify the method required to satisfy its requirements. Compliance approaches could include the installation of barriers in rack sections; painting a line indicating the maximum storage height on the interior wall of the storage area or on the rack; posting signs; displaying a floor plan with storage heights indicated; or suspending objects from the roof structure. If the suspended objects method is selected, fire code officials should confirm that the design of the device does not create obstructions to the sprinkler discharge. A list of all possible methods to indicate maximum storage heights is not included in this section in order to avoid a “laundry list approach” that may limit creativity for a particular storage area.

**3205.7 Arrays.** Arrays shall comply with Section 3207.4.

- ❖ This section directs the reader to Section 3207.4, which in turn is governed by referenced standard NFPA 13. More specifically, it requires that any necessary spacings in accordance with the design be provided from the array to the ceiling to ensure sprinkler effectiveness.

**3205.8 Flue spaces.** Flue spaces shall comply with Section 3208.3.

- ❖ This section directs the reader to Section 3208.3, which in turn is governed by Table 3208.3 and provides criteria for flue spaces. Flue spaces are critical to sprinkler system effectiveness. See the definitions in Section 202 for “Flue spaces,” “Longitudinal” and “Transverse” (see Commentary Figure 3205.8).

**Figure 3205.8  
SPRINKLER PENETRATION**

## SECTION 3206 GENERAL FIRE PROTECTION AND LIFE SAFETY FEATURES

**3206.1 General.** Fire protection and life safety features for *high-piled storage areas* shall be in accordance with Sections 3206.2 through 3206.10.

- ❖ This section establishes the minimum requirements for fire protection and life safety features. These provisions include separation requirements; automatic sprinklers; fire detection; access and egress; smoke and heat removal; hose connections; minimum dimensions for aisles; clear heights; dead ends; and fire extinguishers. In addition to the fire protection and life safety requirements, Table 3206.2 contains provisions concerning commodity class and size of storage area requirements that define which fire protection and life safety requirements are to be used in the building design. Although this section addresses minimum fire protection and life safety features, the provisions that require proper maintenance of those features are included in Section 3205 and Chapter 3.

The responsibility for the care and maintenance of the fire protection and life safety features rests with the building owner, tenant or lessee. The responsibility for notifying the fire service (local fire department) when fire protection systems are inoperable also rests with the building owner, tenant or lessee. This notification is necessary so that another means of protection is provided and that the fire department response and fireground management operations are based on system condition (see commentary, Section 901.7).

**3206.2 Extent and type of protection.** Where required by Table 3206.2, fire detection systems, smoke and heat removal and automatic sprinkler design densities shall extend the lesser of 15 feet (4572 mm) beyond the *high-piled storage area* or to a permanent partition. Where portions of *high-*

## HIGH-PILED COMBUSTIBLE STORAGE

*piled storage areas* have different fire protection requirements because of commodity, method of storage or storage height, the fire protection features required by Table 3206.2 within this area shall be based on the most restrictive design requirements.

❖ The fire protection features noted in this section include a requirement for the extension of those features 15 feet (4572 mm) beyond the storage area if no partitions are present [see Commentary Figure 3206.2(1)]. For the fire protection systems to be effective, they must be designed with the knowledge that a fire within a storage area (high piled or rack) has the potential of jumping the aisle into another area of the same building. Note also that where mixed classes are stored in an area, the fire detection and protection system must be designed for the most hazardous commodity, except as allowed in Section 3204.2. The size of the high-piled storage area should include the aisles as required by NFPA 13 (only for rack storage). See the discussion in Section 3206.9 and the definition of “High-piled storage area.” The 15-foot (4572 mm) extension of protection should include the aisle width when determining how far to extend the protection [see Commentary Figure 3206.2(2)].

**TABLE 3206.2.** See page 32-11.

❖ In addition to the provisions of Sections 3206 through 3210, this table defines, through a prescriptive approach, the fire protection requirements for high-piled storage. The table bases the requirements on the commodity class and size of the high-piled storage area to indicate the necessary automatic fire-extinguishing system, fire detection, building access, smoke and heat removal, and curtain boards. In addition, the type of commodity and size of the high-piled storage area govern the limitations for the size, height and volume of solid-piled storage, shelf storage and palletized storage. The table presents the requirements in two commodity groupings. These groupings are Class I through IV commodities and high-hazard commodities. Essentially, all the same requirements apply, but at lower thresholds for high-hazard commodities.

Some of the key footnotes to the table are as follows:

- Note a reminds the reader that sprinkler systems must comply with the high-piled storage protection strategies found in NFPA 13 to be considered protected in accordance with the table.

- Note g requires special fire protection features, such as fire protection of exposed steel in very large high-piled storage areas. This is likely due to the potential size of a fire event with such a large amount of storage.
- Note h limits high-hazard storage areas to 500,000 square feet (46 450 m<sup>2</sup>). Each 500,000-square-foot (46 450 m<sup>2</sup>) area would be required to be separated with a 2-hour fire wall (separate buildings).
- Note i indicates that a fire detection system is not required by the table if the high-piled storage area is sprinklered. Without this footnote it would be unclear whether smoke detection would be required where sprinklers are voluntarily provided.
- Note j makes an exception to the smoke and heat removal requirements where early suppression fast response (ESFR) sprinklers or control mode special application sprinklers with a response time index of 50 or less listed to control a fire with 12 or fewer sprinklers are used. Similar exceptions are found in Section 910.1.

**Example:** A storage area contains 200,000 square feet (18 580 m<sup>2</sup>) of high-piled storage classified as commodity Class I. It is a single-story building with floor space only, no rack storage and is protected by standard automatic sprinklers. The subject building would be required to comply with the following:

- Automatic fire-extinguishing system throughout (see Section 3206.4).
- Building access (see Section 3206.6).
- Smoke and heat removal (see Section 3206.7).
- Maximum pile dimension of 100 feet (30 480 mm) (see Section 3206.9).
- Maximum permissible storage height of 40 feet (12 192 mm).
- Maximum pile volume of (100 feet by 100 feet by 40 feet tall) 400,000 cubic feet (11 328 m<sup>3</sup>).

**3206.3 Separation of high-piled storage areas.** *High-piled storage areas* shall be separated from other portions of the building where required by Sections 3206.3.1 through 3206.3.2.2.

❖ This section sets forth the requirements for separating the storage area from other uses within the same building and for multiple classifications and heights of storage.

**TABLE 3206.2  
GENERAL FIRE PROTECTION AND LIFE SAFETY REQUIREMENTS**

COMMODITY CLASS	SIZE OF HIGH-PILED STORAGE AREA <sup>a</sup> (square feet) (see Sections 3206.2 and 3206.4)	ALL STORAGE AREAS (See Sections 3206, 3207 and 3208) <sup>b</sup>				SOLID-PILED STORAGE, SHELF STORAGE AND PALLETIZED STORAGE (see Section 3207.3)		
		Automatic fire-extinguishing system (see Section 3206.4)	Fire detection system (see Section 3206.5)	Building access (see Section 3206.6)	Smoke and heat removal (see Section 3206.7)	Maximum pile dimension <sup>c</sup> (feet)	Maximum permissible storage height <sup>d</sup> (feet)	Maximum pile volume (cubic feet)
I-IV	0-500	Not Required <sup>a</sup>	Not Required	Not Required <sup>e</sup>	Not Required	Not Required	Not Required	Not Required
	501-2,500	Not Required <sup>a</sup>	Yes <sup>i</sup>	Not Required <sup>e</sup>	Not Required	100	40	100,000
	2,501-12,000 Public accessible	Yes	Not Required	Not Required <sup>e</sup>	Not Required	100	40	400,000
	2,501-12,000 Nonpublic accessible (Option 1)	Yes	Not Required	Not Required <sup>e</sup>	Not Required	100	40	400,000
	2,501-12,000 Nonpublic accessible (Option 2)	Not Required <sup>a</sup>	Yes	Yes	Yes <sup>j</sup>	100	30 <sup>f</sup>	200,000
	12,001-20,000	Yes	Not Required	Yes	Yes <sup>j</sup>	100	40	400,000
	20,001-500,000	Yes	Not Required	Yes	Yes <sup>j</sup>	100	40	400,000
	Greater than 500,000 <sup>g</sup>	Yes	Not Required	Yes	Yes <sup>j</sup>	100	40	400,000
High hazard	0-500	Not Required <sup>a</sup>	Not Required	Not Required <sup>e</sup>	Not Required	50	Not Required	Not Required
	501-2,500 Public accessible	Yes	Not Required	Not Required <sup>e</sup>	Not Required	50	30	75,000
	501-2,500 Nonpublic accessible (Option 1)	Yes	Not Required	Not Required <sup>e</sup>	Not Required	50	30	75,000
	501-2,500 Nonpublic accessible (Option 2)	Not Required <sup>a</sup>	Yes	Yes	Yes <sup>j</sup>	50	20	50,000
	2,501-300,000	Yes	Not Required	Yes	Yes <sup>j</sup>	50	30	75,000
	300,001-500,000 <sup>g,h</sup>	Yes	Not Required	Yes	Yes <sup>j</sup>	50	30	75,000

For SI: 1 foot = 304.8 mm, 1 cubic foot = 0.02832 m<sup>3</sup>, 1 square foot = 0.0929 m<sup>2</sup>.

- Where automatic sprinklers are required for reasons other than those in Chapter 32, the portion of the sprinkler system protecting the high-piled storage area shall be designed and installed in accordance with Sections 3207 and 3208.
- For aisles, see Section 3206.9.
- Piles shall be separated by aisles complying with Section 3206.9.
- For storage in excess of the height indicated, special fire protection shall be provided in accordance with Note g where required by the fire code official. See Chapters 51 and 57 for special limitations for aerosols and flammable and combustible liquids, respectively.
- Section 503 shall apply for fire apparatus access.
- For storage exceeding 30 feet in height, Option 1 shall be used.
- Special fire protection provisions including, but not limited to, fire protection of exposed steel columns; increased sprinkler density; additional in-rack sprinklers, without associated reductions in ceiling sprinkler density; or additional fire department hose connections shall be provided required by the fire code official.
- High-piled storage areas shall not exceed 500,000 square feet. A 2-hour fire wall constructed in accordance with Section 706 the *International Building Code* shall be used to divide high-piled storage exceeding 500,000 square feet in area.
- Not required where an automatic fire-extinguishing system is designed and installed to protect the high-piled storage area in accordance with Sections 3207 and 3208.
- Not required where storage areas are protected by either early suppression fast response (ESFR) sprinkler systems or control mode special application sprinklers with a response time index of 50 (m • s)<sup>1/2</sup> or less that are listed to control a fire in the stored commodities with 12 or fewer sprinklers, installed in accordance with NFPA 13.

# HIGH-PILED COMBUSTIBLE STORAGE

**3206.3.1 Separation from other uses.** Mixed occupancies shall be separated in accordance with the *International Building Code*.

❖ IBC Section 508 describes the provisions governing the condition when a building contains more than one of the occupancy groups identified in IBC Sections 303 through 312 (see also the occupancy classification definitions in Section 202 of the code). Buildings very often will contain more than one occupancy group classification; for example, an office (Group B, business) connected to a storage area (Group S-1, moderate-hazard storage). Once a building is determined to house more than one occupancy group, the codes require that a combination of potential fire and life safety hazards be addressed. IBC Section 508.3 provides for several conditions under which certain dissimilar occupancies are treated: accessory occupancies, nonseparated occupancies and separated occupancies. It should be noted that when the mixed occupancy building is separated by a fire wall it technically becomes two buildings (see the definition of “Building area” in Section 202). As a result, the provisions of IBC Sections 503 through 507 will need to be reviewed for applicability and the evaluation and design adjusted for that difference.

**3206.3.2 Multiple high-piled storage areas.** Multiple *high-piled storage areas* shall be in accordance with Section 3206.3.2.1 or 3206.3.2.2.

❖ This section delineates how to determine fire and life safety requirements for a single building or area containing multiple classes of commodities.

**3206.3.2.1 Aggregate area.** The aggregate of all *high-piled storage areas* within a building shall be used for the application of Table 3206.2 unless such areas are separated from each other by 1-hour *fire barriers* constructed in accordance with Section 707 the *International Building Code*. Openings in such *fire barriers* shall be protected by opening protectives having a 1-hour *fire protection rating*.

❖ This section is intended to recognize that, in actual storage circumstances, storage arrays do not always correspond to any one commodity classification. It is not unusual for arrays to consist of thousands of products. As a result, this section recognizes that, in storage areas, multiple commodity classifications may be contained in one area and must be treated as an aggregate when applying Table 3206.2. As an alternative, this provision allows for each class of commodity to be separated within the same building by 1-hour fire barriers constructed in accordance with IBC Section 707, which applies to fire barriers used for separating fire areas. To maintain integrity of the separation of fire areas, fire barriers must be continuous from the top of the floor below to the underside of the roof slab or deck above and be securely attached thereto. As with any fire-resistance-rated assembly, consideration must be given to openings and penetrations. The number and size of openings in the fire barrier must comply with the provisions of IBC Sec-

tion 707, and the opening protectives must have a minimum fire protection rating of 1 hour. Note that IBC Section 716.5 allows an opening protective fire protection rating of  $\frac{3}{4}$  hour for nonexit-enclosure fire barriers; however, this section, with its specific requirement of a 1-hour opening protective assembly rating, would supersede that requirement. Penetrations of fire barriers must comply with IBC Section 714. Maintenance of the fire-resistance-rated construction rests with the building owner or the tenant as described in Section 703. The main purpose for this section is to determine what area is required to be used when addressing Table 3206.2. Section 3206.3.2.2 is focused on the need to separate different hazard levels of storage in order to increase or reduce the fire protection requirements (see also commentary, Section 3206.3.2.2).

**3206.3.2.2 Multiclass high-piled storage areas.** *High-piled storage areas* classified as Class I through IV not separated from *high-piled storage areas* classified as high hazard shall utilize the aggregate of all *high-piled storage areas* as high hazard for the purposes of the application of Table 3206.2. To be considered as separated, 1-hour *fire barriers* shall be constructed in accordance with Section 707 of the *International Building Code*. Openings in such *fire barriers* shall be protected by opening protectives having a 1-hour *fire protection rating*.

**Exception:** As provided for in Section 3204.2.

❖ This section is intended to recognize that, in actual circumstances, storage arrays may contain a combination of Class I through IV commodities alongside high-hazard commodities. It is not unusual for arrays to consist of thousands of products. As in Section 3206.3.2.1, this section recognizes that in storage areas multiples of commodity classifications may be contained in one area and must be treated as an aggregate under the highest hazard commodity class category found in that area when applying Table 3206.2. As with Section 3206.3.2.1, this provision allows for each class of commodity to be separated within the same building by 1-hour fire barriers constructed in accordance with IBC Section 707, which applies to fire barriers used for separating fire areas. To maintain integrity of the separation of fire areas, fire barriers must be continuous from the top of the floor below to the underside of the roof slab or deck above and be securely attached thereto. As with any fire-resistive barriers, consideration must be given to openings and penetrations. The number and size of openings in the fire barrier must comply with the provisions of IBC Section, and the opening protective assemblies must have a minimum fire-resistance rating of 1 hour. Note that IBC Section 716.5 allows an opening protection rating of  $\frac{3}{4}$  hour for nonexit-enclosure fire barriers; however, this section, with its specific requirement of a 1-hour opening protective assembly rating, would supersede that requirement. Penetrations of fire barriers must comply with IBC Section 714. Maintenance of the fire-resistance-rated

construction rests with the building owner or the tenant as described in Section 703. The use of separation allows the application of less-restrictive, active fire protection requirements in some areas containing lower hazard commodities. It also creates smaller areas that need to be applied to Table 3206.2. The exception permits the use of an accepted engineering analysis in accordance with Section 3204.2, which allows one to take advantage of the benefits of hydraulic design (see Section 3204.2).

**3206.4 Automatic sprinklers.** *Automatic sprinkler systems* shall be provided in accordance with Sections 3207, 3208 and 3209.

❖ This section refers the reader to Sections 3207, 3208 and 3209 for the specific sprinkler requirements based upon the type of high-piled storage. Sprinkler systems are discussed in Sections 3207.2, 3208.2 and 3209.2 for the various ways in which high-piled storage is configured.

**3206.4.1 Pallets.** Automatic sprinkler system requirements based upon the presence of pallets shall be in accordance with NFPA 13.

❖ The types of pallets used will alter the sprinkler protection provided for storage. NFPA 13 has extensive requirements for pallet use and storage based on the type of pallet that must be designed for and maintained during occupancy. Plastic pallets, when used, increase the fuel load to the commodity that is being stored on top of the pallet. NFPA 13 requires the commodity classification to be altered to address the additional hazard. There are specific adjustments for commodity class for unreinforced or reinforced polypropylene or unreinforced or reinforced high-density polyethylene plastic pallets. If a different type of plastic is used, the commodity shall either be adjusted by two classes or be tested to determine the classification. NFPA 13 does not specify a test.

**3206.4.1.1 Plastic pallets.** Plastic pallets listed and labeled in accordance with UL 2335 or FM 4996 shall be treated as wood pallets for determining required sprinkler protection.

❖ This section allows for plastic pallets that have passed UL 2335 or FM 4996 to be treated as wood pallets. UL 2335 and FM 4996 are tests specific to storage pallets and their associated flammability; those tests do not address smoke generation. The tests examine the comparative performance of the plastic pallet to a wood pallet.

**3206.5 Fire detection.** Where fire detection is required by Table 3206.2, an *approved* automatic fire detection system shall be installed throughout the *high-piled storage area*. The system shall be monitored and be in accordance with Section 907.

❖ Automatic fire detection systems are designed to increase the likelihood that the fire will be detected and the occupants given sufficient warning to allow area or building exit. The detectors must be smoke detectors approved for the particular use, as required

by Section 907.2. Table 3206.2 shows when a fire detection system is required to be installed in a storage area. Section 907 covers the application, installation, performance and maintenance of the fire alarm system and its components. Section 907.6.3 requires that the fire alarm system identify the specific initiation device address, location and device type. Several exceptions address issues such as small buildings where this is unnecessary, certain initiating devices and existing systems. Section 907.6.4 provides the minimum requirements for zoning the system, which limit the size of the zoned area to 22,500 square feet (2090 m<sup>2</sup>). Such systems are only required in some cases in Table 3206.2, primarily when the building is not sprinklered.

**3206.6 Building access.** Where building access is required by Table 3206.2, fire apparatus access roads in accordance with Section 503 shall be provided within 150 feet (45 720 mm) of all portions of the *exterior walls* of buildings used for high-piled storage.

**Exception:** Where fire apparatus access roads cannot be installed because of topography, railways, waterways, nonnegotiable grades or other similar conditions, the *fire code official* is authorized to require additional fire protection.

❖ This section contains the requirements for fire department access to a building. There are the same requirements found in Section 503.1.1. Section 503 discusses the minimum requirements for the location of such a roadway, additional access where required, minimum dimensions, minimum surface load tolerances, turning radii, grades, marking and overall access by the fire department. Additional measures are necessary when a road cannot be built on the property surrounding the building, including additional fire sprinkler protection, detection, building fire resistance, etc. This reliance on fire protection systems is necessary to compensate for the limited access available to fire department equipment.

**3206.6.1 Access doors.** Where building access is required by Table 3206.2, fire department access doors shall be provided in accordance with this section. Access doors shall be accessible without the use of a ladder.

❖ Building access requirements are summarized in Table 3206.2. The access requirements include the application of Sections 3206.6.1.1 through 3206.6.1.3. In addition, the provisions of Chapter 10, which address minimum clear width dimensions, allowable projections into the clear width, floor landings, door hardware, door identification, etc., must be considered. Section 504 states that an approved walkway must be provided from the fire apparatus access road, or from other approved fire apparatus access roadways, to an exterior door opening required for fire department access.

**3206.6.1.1 Number of doors required.** Not less than one access door shall be provided in each 100 linear feet (30 480 mm), or fraction thereof, of the exterior walls that face

required fire apparatus access roads. The required access doors shall be distributed such that the lineal distance between adjacent access doors does not exceed 100 feet (30 480 mm).

**Exception:** The linear distance between adjacent access doors is allowed to exceed 100 feet (30 480 mm) in existing buildings where no change in occupancy is proposed. The number and distribution of access doors in existing buildings shall be approved.

❖ In accordance with *International Fire Code*® (IFC®) Committee Interpretation No. 36-04, access door openings in exterior walls are to be located such that the distance between adjacent openings does not exceed 100 lineal feet (30 480 mm), providing the fire department short runs for quick access to assess, combat and control a fire in the high-piled storage areas of a building (see Commentary Figure 3206.6.1.1). The language is similar to that found in Section 903.2.11.1 for windowless stories or buildings. Table 3206.2 tends to require such doors for larger-sized, high-piled storage areas where fire fighting may be more difficult.

An exception is provided for existing buildings. This exception recognizes that there may be practical difficulties in adding doors to an existing building to meet the 100-foot limitations. The exception does not prescribe a specific number but instead requires the number and distribution to be approved. The current language limiting the distance to 100 feet first

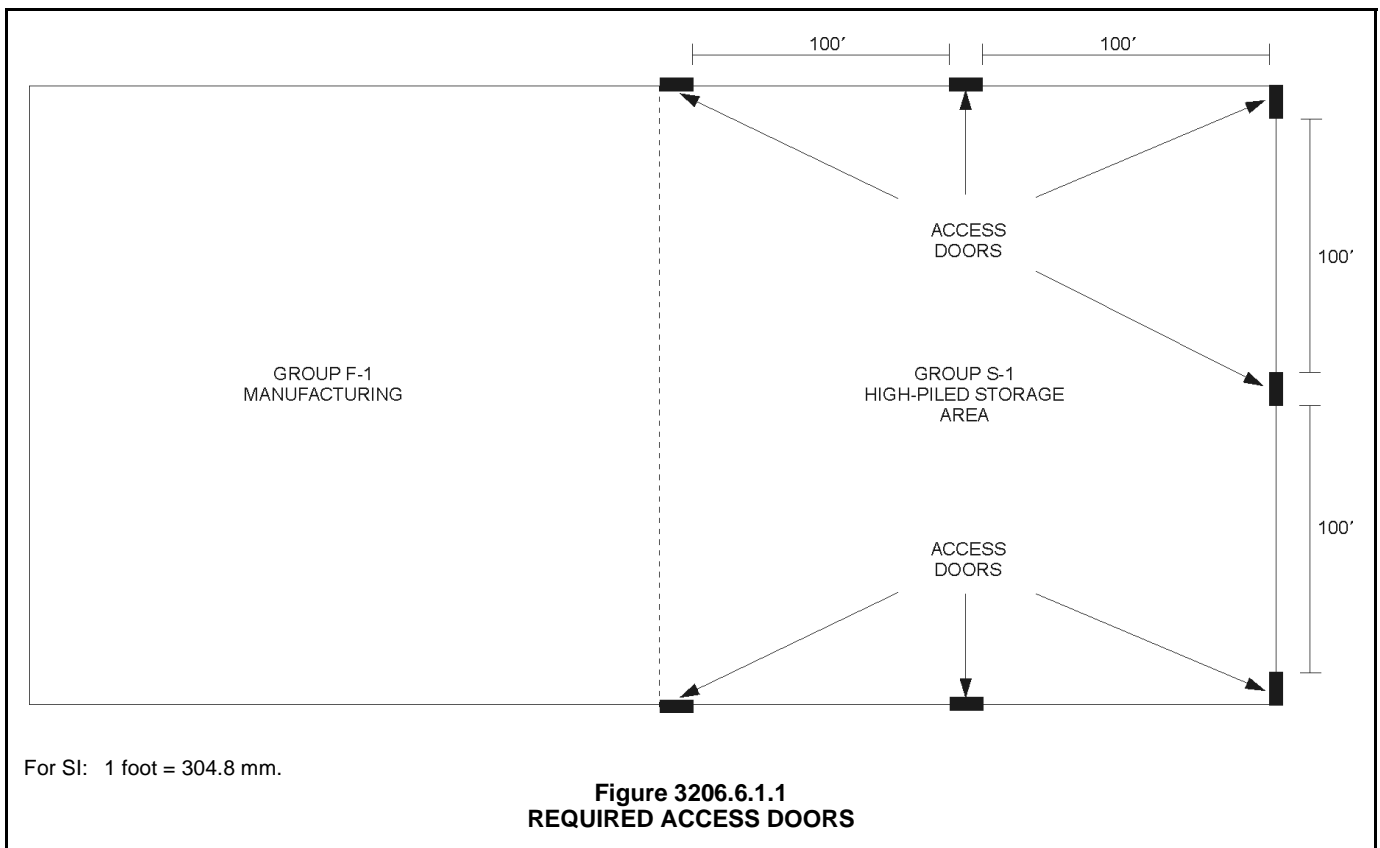

appeared in the 2009 edition of the code. Existing warehouses where one tenant moves out and a new tenant moves in will require a new high-piled storage permit. As part of the permit, the current/adopted edition of Chapter 32 is applied, often resulting in cutting holes in exterior walls, which are often concrete, and causing business restrictions as a result of adding doors where currently roll-up doors exist. This allows a small amount of flexibility for owners of existing buildings and the fire code official where adding doors appears costly or impractical.

**3206.6.1.2 Door size and type.** Access doors shall be not less than 3 feet (914 mm) in width and 6 feet 8 inches (2032 mm) in height. Roll-up doors shall not be used unless *approved*.

❖ Door sizes are the same as those in the means-of-egress door provisions of Chapter 10. The emphasis on the side-hinged type of door is to ensure that other door types, such as roll-up and sliding, are not used due to their historically poor reliability. The swing should be outward and no less than 90 degrees (1.75 rad). Section 1003.5, Exception 1, permits the door sill elevation to be above the outside grade if the door is not a required accessible route in accordance with the IBC. In some regions, the raised sill is preferred because of the potential buildup of snow and ice.

**3206.6.1.3 Locking devices.** Only *approved* locking devices shall be used.

❖ Locking mechanisms must be approved by the fire code official. The fire service must be able to open

the doors from the exterior side during an emergency. The locking mechanism must be designed to maintain the security of the building, to be readily openable from the egress side and to be openable by fire department personnel from the exterior.

**3206.7 Smoke and heat removal.** Where smoke and heat removal is required by Table 3206.2 it shall be provided in accordance with Section 910.

❖ Table 3206.2 identifies the requirements for smoke and heat removal based on the size and public accessibility of the high-piled storage area. If required, smoke and heat removal is to be designed and installed in accordance with Section 910. Smoke and heat removal would not be required if ESFR sprinklers or control mode special application sprinklers are installed in accordance with Note j of Table 3206.2. The concern addressed by Note j is that smoke and heat vents may affect sprinkler reliability and the general need for such features in sprinklered buildings. Also, these types of sprinkler systems are extremely successful in suppressing and extinguishing fires. They are also designed such that disruption from smoke and heat vents or even a mechanical smoke removal system would be detrimental to their successful operation. Smoke and heat vents and draft curtains were originally developed as a way to manage smoke in nonsprinklered large spaces. Draft curtains are no longer addressed in Chapter 32 or Section 910.

In addition, vent locations must reflect consideration of the temperature requirements of both the fusible link of the vent and the temperature rating range of the sprinkler heads. A vent opening could keep the temperature around nearby sprinkler heads low enough to prevent them from activating because of the cooler air passing to the opened vent; therefore, smoke and heat vents should have a higher temperature rating than the sprinklers. These concerns are addressed in more detail in standards UL793 and FM 4430.

**3206.8 Fire department hose connections.** Where *exit* passageways are required by the *International Building Code* for egress, a Class I standpipe system shall be provided in accordance with Section 905.

❖ An exit passageway is a means of continuing the exit enclosure protection horizontally to the exit discharge. Accordingly, an exit passageway may be used to connect an interior exit stairway to the exit discharge. Another use of an exit passageway is to bring an exit entrance within the allowable limit of exit access travel distance. This section states that when the IBC requires the installation of an exit passageway, a Class I standpipe system must be provided in accordance with Section 905. The intent is to recognize that the standpipe will provide a quick and convenient water source for fire department use where

fire hose lines would be in a protected area or would otherwise be impractical to use because of travel distance. The intent is to allow the fire department to initiate an attack on the fire more safely and quickly, thus reducing the possibility of loss of life or property.

**3206.9 Aisles.** Aisles providing access to *exits* and fire department access doors shall be provided in *high-piled storage areas* exceeding 500 square feet (46 m<sup>2</sup>), in accordance with Sections 3206.9.1 through 3206.9.3. Aisles separating storage piles or racks shall comply with NFPA 13. Aisles shall also comply with Chapter 10.

**Exception:** Where aisles are precluded by rack storage systems, alternate methods of access and protection are allowed when *approved*.

❖ Aisles in high-piled storage areas have multiple functions, which include the following:

- Exit access.
- Fire department access.
- Fire breaks.
- Everyday access to storage.

Under normal conditions, the aisles primarily serve people working in the building, and the design for minimum aisle width is based on the maneuvering capabilities of the commodity-handling methods and equipment. Under emergency situations, the aisle automatically becomes an egress pathway that must provide the required minimum width to accommodate the number of occupants that must use the aisles, and also serves to allow the water discharge from the sprinklers to penetrate the high-piled storage. Aisles also provide access for fire department personnel and serve as fire breaks between piles and racks.

Chapter 2 of both the code and the IBC define "Aisle" as an exit access component that defines and provides a path of egress travel. This is generally true when it comes to high-piled storage, but the aisles have other important functions as noted above.

This section differentiates between aisle requirements for fire department access and exit access for occupants from those required by NFPA 13. The aisle requirements in NFPA 13 are specific to rack storage and are based on the testing of specific commodity configurations. During tests of high-piled rack storage configurations, one of the criteria for success/failure has been whether the target array (commodity across the aisle) has been ignited. Therefore, as discussed in the definition of "High-piled storage areas" these aisle widths would be included in the area actually classified as high-piled combustible storage [see Commentary Figure 3206.9(2)]. Any of the aisles related solely to exit and access would be above and beyond the requirements in NFPA 13 and would not need to be included in the aggregate area. NFPA 13 does not address aisle widths for solid-piled or palletized storage; therefore, the aisle widths would not

need to be included as part of the high-piled storage area when applying Table 3206.2, but would be required by this section for egress and access. NFPA 13 does have a section that discusses the need for aisle widths in all high-piled storage areas as it relates to slowing the spread of fire, fire-fighter access, salvage and removal of storage but does not provide specific aisle widths (see also IFC Committee Interpretation No. 13-05 and the definition of “High-piled combustible storage” in Section 202).

Another scenario encountered when determining the high-piled storage area is high-piled storage surrounding other uses or low-piled storage. The aisle width when addressing rack storage should be included in the high-piled storage area determination [see Commentary Figure 3206.9(3)].

The exception to this section provides the ability to address situations where the required aisle width affects the ability of a facility to operate. Essentially, other strategies must be proposed. This may include the use of additional sprinkler protection within racks. The key is that egress and access for occupants and fire fighters be addressed appropriately. It should be noted that multiple-row racks specifically lack aisles, unlike single- and double-row racks. However, the increased hazard from such storage is already specifically addressed by NPFA 13 in the fire protection requirements.

**3206.9.1 Width.** Aisle width shall be in accordance with Sections 3206.9.1.1 and 3206.9.1.2.

**Exceptions:**

1. Aisles crossing rack structures or storage piles, that are used only for employee access, shall be not less than 24 inches (610 mm) wide.
2. Aisles separating shelves classified as shelf storage shall be not less than 30 inches (762 mm) wide.

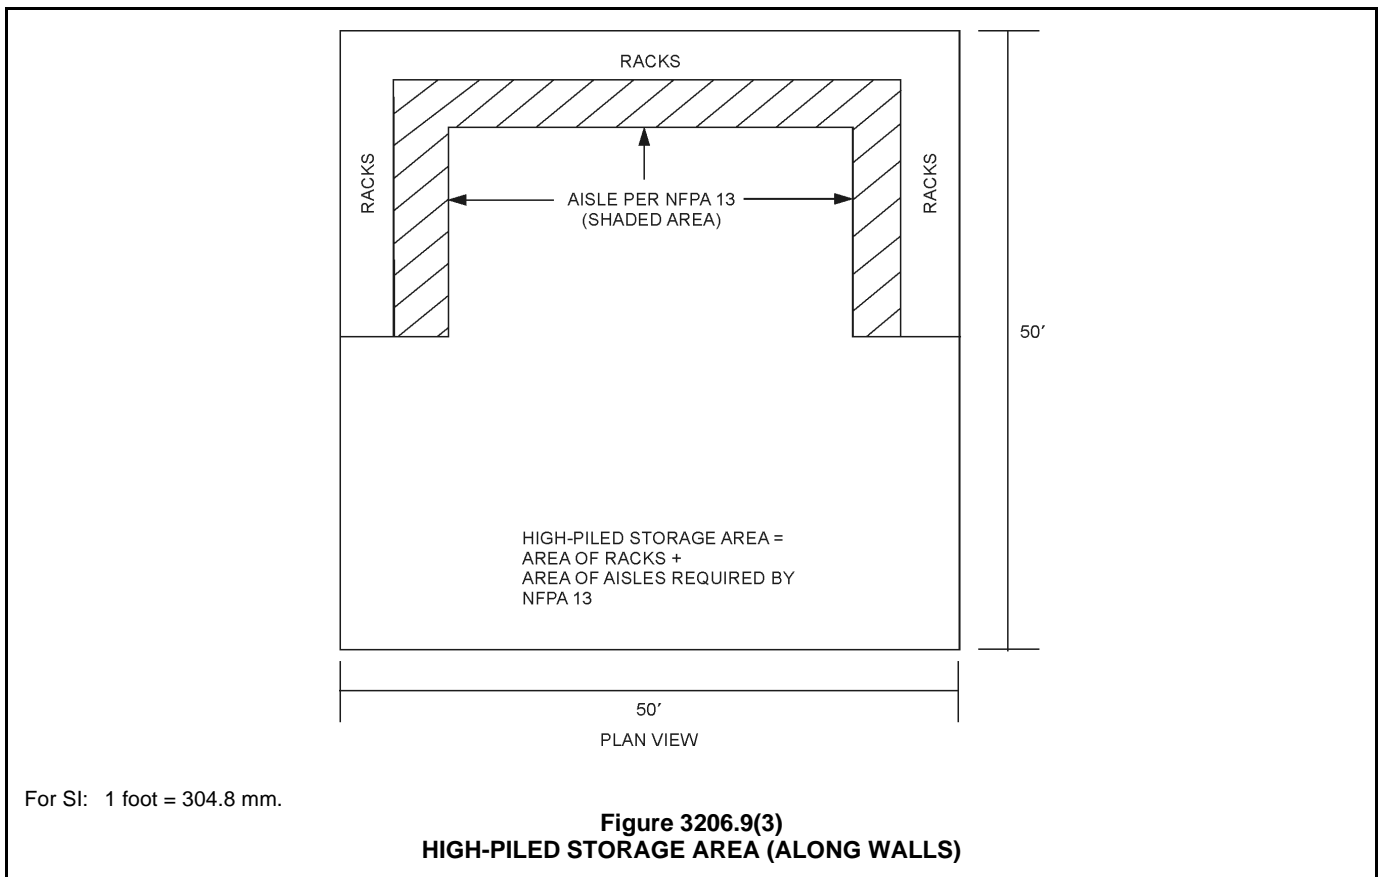

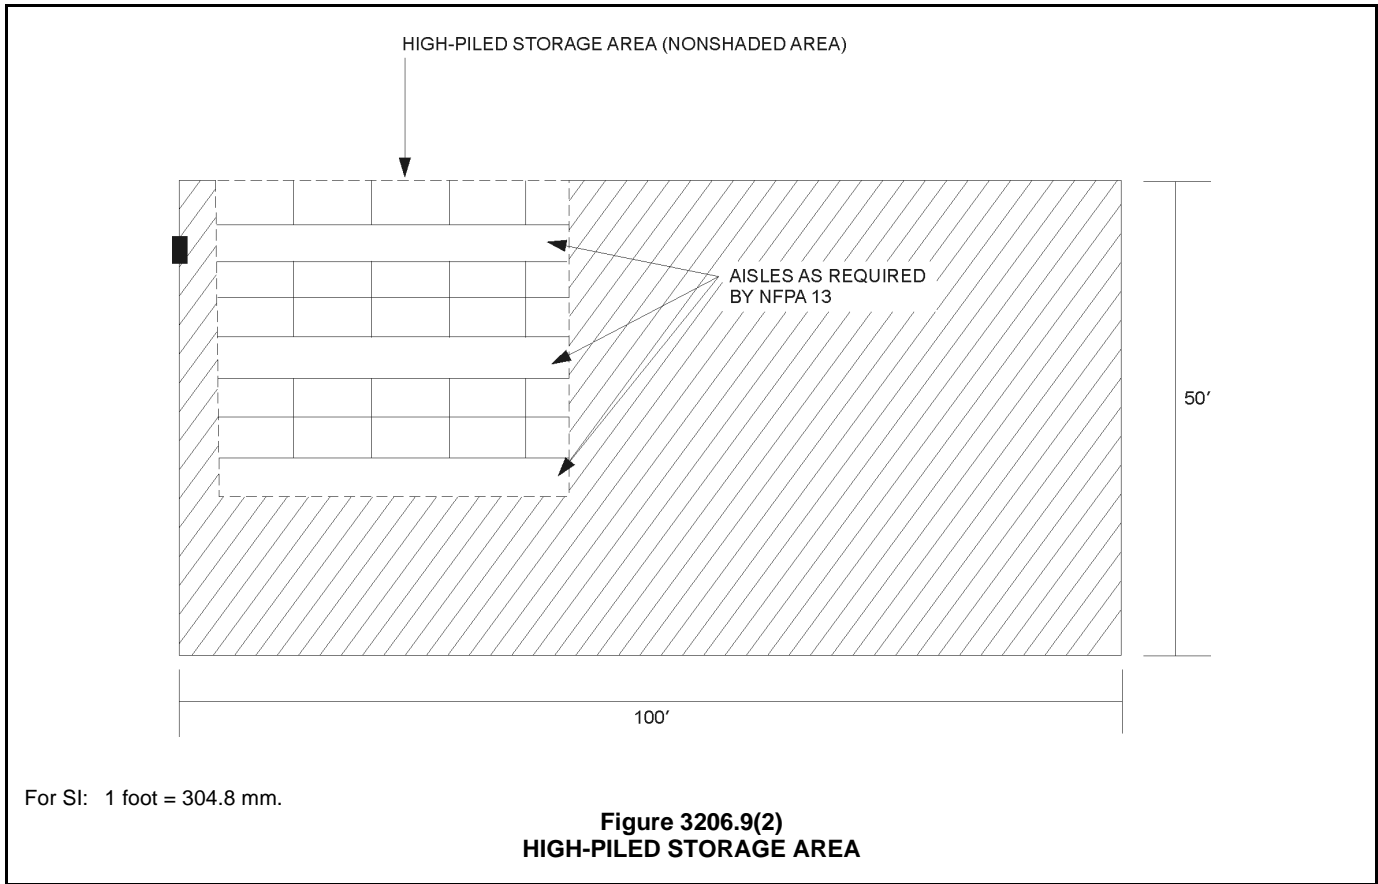

❖ This section alerts the code user to the various minimum aisle widths based on the commodity, commodity area and whether the building contains automatic sprinklers. It is important to note that for fire protection purposes, NFPA 13 defines “Aisle width” as “the horizontal dimension between the face of the loads in racks under consideration” (see Commentary Figure 3206.9.1).

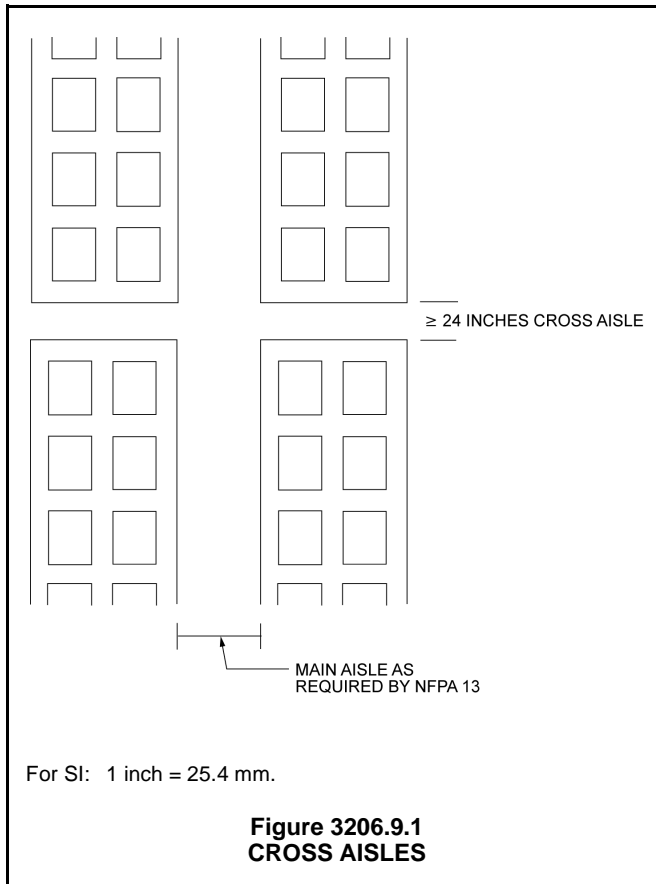

There are two exceptions to the aisle requirements. Exception 1 allows aisles that cross rack structures to be 24 inches (610 mm), the logic being that those aisles are not required (above and beyond egress, access and need for fire breaks) and are simply a convenience for building owners and users (see Commentary Figure 3206.9.1).

Exception 2 is for shelving that allows a 30-inch (762 mm) aisle. This is related to the requirements found in NFPA 13 for shelf storage that allows 30-inch (762 mm) aisles. Solid shelving in rack storage would not be addressed by this exception.

HIGH-PILED COMBUSTIBLE STORAGE

**3206.9.1.1 Sprinklered buildings.** Aisles in sprinklered buildings shall be not less than 44 inches (1118 mm) wide. Aisles shall be not less than 96 inches (2438 mm) wide in *high-piled storage areas* exceeding 2,500 square feet (232 m<sup>2</sup>) in area, that are accessible to the public and designated to contain high-hazard commodities.

**Exception:** Aisles in *high-piled storage areas* exceeding 2,500 square feet (232 m<sup>2</sup>) in area, that are accessible to the public and designated to contain high-hazard commodities, are protected by a sprinkler system designed for multiple-row racks of high-hazard commodities shall be not less than 44 inches (1118 mm) wide.

Aisles shall be not less than 96 inches (2438 mm) wide in areas accessible to the public where mechanical stocking methods are used.

- ❖ The 44-inch-minimum (1118 mm) aisle width allows two unimpeded parallel columns of occupants to travel in opposite directions in addition to anticipating other obstructions occurring during an emergency situation. These obstructions could be in the form of a lift truck, idle pallets, mercantile displays and even the results of unstable commodities falling into the aisle. In addition, the 96-inch (2438 mm) width further reduces the hazard of aisle jumps (radiant heat from a burning pile/rack causing the pile/rack across the aisle to ignite) in case of a fire and provides the fire

department with greater maneuvering capabilities during a fire, essentially providing an additional safety factor where more dangerous commodities are stored.

Aisles that provide access to exits and to the fire department access doors are required to comply with Section 3206.9.1. Therefore, where such exit access and fire department access doors are located, the aisles are required to be at least 44 inches. This would also require that single- or double-row racks have a minimum 44-inch aisle between racks when used as an aisle to provide access to exits and fire department access. This does not include cross aisles that are permitted to be 24 inches in width (Exception 1 to Section 3206.9.1). Note that NFPA 13 permits single- and double-row racks to have aisles as small as 3½ feet. This is slightly smaller than the minimum aisle width required by the code. Careful exit planning is needed in rack storage for single- and double-row racks.

This section would not require that all aisles within multirow rack installation be 44 inches. Again, only aisles necessary for egress and fire department access would need to meet these requirements. This may affect the layout of multirow rack systems to provide such access paths for egress and fire department access in some cases. Travel distance, common path of travel and dead ends may be limiting factors. This is similar to solid-piled storage which can take up large areas within a building without providing aisles within the storage pile itself.

The exception recognizes the increased safety provided by a higher level of sprinkler protection, such as using a multirow rack protection scheme in a single- or double-row rack system, an ESFR system or additional levels of in-rack sprinklers, by allowing for smaller aisle widths for high-hazard commodity areas exceeding 2,500 square feet (232 m<sup>2</sup>). If the sprinkler protection can protect multiple-row racks of high-hazard commodities, it should adequately protect small aisle displays between piles or racks.

It should be noted that NFPA 13 addresses two major configurations of rack storage. They include single- and double-row rack storage and multirow rack storage. The protection requirements are different and more stringent for multirow racks and are based specifically on test configurations with certain aisle spacings. NFPA considers any rack storage with less than 3½ foot (42 inches) aisles as multirow rack storage. NFPA 13 does not require aisles within multirow racks. NFPA 13 compensates for the increased fire hazard with more restrictive fire protection requirements. Therefore, within the multirow racking itself, aisles as required by Section 3206.9.1.1 are not required and small convenience aisles are appropriate. This is also consistent with Exception 1 to Section 3206.9.1 allowing 24-inch cross aisles for employee access.

## HIGH-PILED COMBUSTIBLE STORAGE

**3206.9.1.2 Nonsprinklered buildings.** Aisles in nonsprinklered buildings shall be not less than 96 inches (2438 mm) wide.

- ❖ The minimum 96-inch (2438 mm) aisle width for all aisles in nonsprinklered buildings recognizes the greater hazard caused by the lack of an automatic fire sprinkler system. This minimum width allows the building users a greater area for anticipating obstructions, as well as greater flexibility for the fire department personnel to assess, combat and control the fire.

**3206.9.2 Clear height.** The required aisle width shall extend from floor to ceiling. Rack structural supports and catwalks are allowed to cross aisles at a minimum height of 6 feet 8 inches (2032 mm) above the finished floor level, provided that such supports do not interfere with fire department hose stream trajectory.

- ❖ The clear ceiling height, or head room minimum [see Commentary Figure 3206.9(1)], is necessary for occupants to avoid an obstruction, to provide visibility to the occupants so that the path of travel can be planned and negotiated, and to allow sufficient area for effective use of the fire department's hose streams. The height is the vertical measurement above every point along the finished floor to a ceiling, to the underside of a rack storage catwalk or to the underside of a structural member. This requirement that aisles extend from floor to ceiling is for the primary aisles. Cross aisles are above and beyond that which is required for egress, access and the performance of fire protection systems. Though not specifically noted, it is within the intent of this code that cross aisles provide at least the minimum height of 6 feet 8 inches to be consistent with that required for structural supports and catwalks.

**3206.9.3 Dead-end aisles.** Dead-end aisles shall not exceed 20 feet (6096 mm) in length in Group M occupancies. Dead-end aisles shall not exceed 50 feet (15 240 mm) in length in all other occupancies.

**Exception:** Dead-end aisles are not limited where the length of the dead-end aisle is less than 2.5 times the least width of the dead-end aisle.

- ❖ Dead-end aisles can allow a single fire event to eliminate access to all the exits by trapping the occupants in the dead-end area. Dead ends, as they relate to high-piled storage, are similar to those formed by corridors. However, simply providing a reference back to Chapter 10 is somewhat confusing as to how the requirements would be intended to apply to warehouse configurations. This section provides two criteria specific to high-piled storage: one criterion for Group M occupancies of 20 feet; and, for all other occupancies, 50 feet. This is due to the fact that Group M occupancies are more likely to be open to the public where other occupancies, such as Group S, would not.

The exception recognizes aisles that are wide, which generally reduce the dangers of dead-end

aisles. The fire is less likely to completely block access to an exit in a larger space.

**3206.10 Portable fire extinguishers.** Portable fire extinguishers shall be provided in accordance with Section 906.

- ❖ Portable fire extinguishers provide the building occupants with an opportunity to suppress a fire in its incipient stage. In storage facilities, the fire extinguisher can contribute to the protection of occupants when there are evacuation difficulties or a specific hazard within that occupancy. For portable extinguishers to be effective, personnel must be properly trained in their use and maintenance (see Sections 3201.3 and 3201.4). Section 906 provides criteria for the location, installation, inspection and testing and maintenance of portable fire extinguishers. Section 906 also contains criteria for cabinets in which portable fire extinguishers may be stored, as well as the designated locations for wheeled portable fire extinguishers.

## SECTION 3207 SOLID-PILED AND SHELF STORAGE

**3207.1 General.** Shelf storage and storage in solid piles, solid piles on pallets and bin box storage in bin boxes not exceeding 5 feet (1524 mm) in any dimension, shall be in accordance with Sections 3206 and this section.

- ❖ Solid piling in piles or on pallets generally consists of commodities in cartons, boxes, bales or bags [see Commentary Figure 3207.1(1)] or which may be encapsulated in a plastic wrap for containment [see Commentary Figures 3207.1(2) and 3207.1(3)]. These commodities are usually stacked manually or with lift trucks. Palletized storage consists of commodities set onto pallets that are generally made of

wood or plastic, are square in shape and measure 3 to 4 feet (914 to 1219 mm) on each side. In this case, the cavity portion of the pallet is designed to accept the fork prongs of the lifting device for the commodity and pallet to be transported. The height limitations for stacking palletized storage are directly proportional to stackability of the commodity. Heights of palletized storage can reach 30 feet (9144 mm) in some cases.

**3207.2 Fire protection.** Where automatic sprinklers are required by Table 3206.2, an *approved automatic sprinkler system* shall be installed throughout the building or to 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code*. Openings in such *fire barriers* shall be protected by opening protectives having a 1-hour *fire protection rating*. The design and installation of the *automatic sprinkler system* and other applicable fire protection shall be in accordance with the *International Building Code* and NFPA 13.

❖ The provision for approved automatic sprinklers is based on the commodity class and the size of the storage area. Automatic sprinkler protection, when required, is to be provided throughout the area con-

taining the storage. For example, in a mixed-use occupancy, the area designated for storage would require an automatic sprinkler protection system throughout the storage area up to the fire barrier(s), whereas the other areas of the mixed-use occupancy may or may not require automatic sprinkler protection.

NFPA 13 is referenced for sprinkler protection and contains extensive requirements for high-piled storage, including the provisions that were originally found in NFPA 231 (NFPA 231C for rack storage). The development of these provisions was based on a number of large-scale fire tests conducted to determine the advantages and limitations of automatic sprinklers in various storage array configurations; however, test information was not available for all configurations. As a result, some of the protection criteria are based on extrapolation of the test information.

The automatic sprinkler system is expected to remain in operation as the fire fighters are attempting to control and extinguish the fire. As a result, design considerations for water supply must ensure that the water supply is not compromised by other operations. In no case should manual fire-fighting operations be substituted for automatic sprinklers. The sprinkler protection is to extend throughout the building containing the rack storage or to a fire barrier. The fire barrier is to comply with the provisions of IBC Section 707, which applies to fire barriers used for separating fire areas. To maintain integrity of fire area separations, fire barriers must be continuous from the top of the floor below to the underside of the roof slab or deck above and be securely attached thereto.

As with any fire-resistive barriers, consideration must be given to openings and penetrations. The number and size of openings in the fire barrier must comply with the provisions of IBC Section 707, and the opening protective assemblies must have a minimum fire-resistance rating of 1 hour. Note that IBC Section 716.5 allows an opening protection rating of  $\frac{3}{4}$  hour for nonexit-enclosure fire barriers; however, this section, with its specific requirement of a 1-hour rating, would supersede that requirement. Penetrations of fire barriers must comply with IBC Section 714. Maintenance of the fire-resistance-rated construction rests with the building owner or the tenant as described in Section 703.

**3207.2.1 Shelf storage.** Shelf storage greater than 12 feet (3658 mm) but less than 15 feet (4572 mm) in height shall be in accordance with the fire protection requirements set forth in NFPA 13. Shelf storage 15 feet (4572 mm) or more in height shall be protected in an *approved* manner with special fire protection, such as in-rack sprinklers.

❖ Storage on shelving presents a unique problem because it shields the fire from the sprinklers. This shielding can both delay activation of the sprinklers and make it difficult for the water to reach the fire. This section recognizes the provisions of NFPA 13 that apply to the height range in question because

## HIGH-PILED COMBUSTIBLE STORAGE

those provisions were developed based on full-scale tests of both unencapsulated and encapsulated products up to the 15-foot (4572 mm) height. Those provisions are found within NFPA 13 with the solid-piled and palletized storage requirements. As a result, the provisions related to solid shelving within the rack storage requirements of NFPA 13 should be used when addressing shelf storage of commodities above that height.

**3207.3 Pile dimension and height limitations.** Pile dimensions, the maximum permissible storage height and pile volume shall be in accordance with Table 3206.2.

❖ The commodity class and the size of the storage area directly regulate pile dimensions and height limitations. In Table 3206.2, these limitations include:

- Maximum pile dimension.
- Maximum permissible storage height.
- Maximum pile volume.

NFPA 13 only limits the pile height as it relates to the ceiling height and associated sprinkler requirements. The code takes it a step further and puts limits on the pile sizes. Specific aisle requirements are made in Section 3206.9, which the standard does not provide. The pile dimensions presented in Table 3206.2 are the same within each category of commodity class for the various high-piled storage area sizes except for height and volume limitations for the nonpublic accessible Option 2, which is not required to be sprinklered.

**3207.4 Array.** Where an *automatic sprinkler system* design utilizes protection based on a closed array, array clearances shall be provided and maintained as specified by the standard used.

❖ The closed array is defined in NFPA 13 as “a storage arrangement where air movement through a pile is restricted due to vertical flues 6 inches in width or narrower.” Since most protection requirements are based on full-scale testing using a specific method of storage (closed versus open array) the specific configuration must be maintained for the sprinkler system to be effective in controlling and suppressing a fire. A closed array does not let the water penetrate, but also does not allow the fire to grow as rapidly.

## SECTION 3208 RACK STORAGE

**3208.1 General.** Rack storage shall be in accordance with Section 3206 and this section. Bin boxes exceeding 5 feet (1524 mm) in any dimension shall be regulated as rack storage.

❖ Storage racks are commonly steel frames (see Commentary Figure 3208.1) able to store commodities in various configurations. There are numerous variations of rack storage, such as single-row, double-row and multiple-row racks. The rack structure may or may not be connected to the building superstructure,

which is governed by Chapters 16 and 22 of the IBC. The commodity is generally set on pallets for easy and economical transport using lift trucks or automated materials handling systems (automatic/unmanned). Manual rack storage operations require reasonably wide aisles to accommodate the lift trucks, whereas automated systems can operate in much narrower aisles.

**3208.2 Fire protection.** Where automatic sprinklers are required by Table 3206.2, an *approved automatic sprinkler system* shall be installed throughout the building or to 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code*. Openings in such *fire barriers* shall be protected by opening protectives having a 1-hour *fire protection rating*. The design and installation of the *automatic sprinkler system* and other applicable fire protection shall be in accordance with Section 903.3.1.1 and the *International Building Code*.

❖ The provision for approved automatic sprinklers is based on the commodity class and the size of the storage area. The automatic sprinkler protection, when required, is to be installed throughout the area containing the storage. For example, in a mixed-use occupancy, the area designated for storage would require an automatic sprinkler protection system throughout up to the fire barrier(s), whereas the other areas may or may not require automatic sprinkler protection. It should be noted that 15 feet (4572 mm) beyond the high-piled storage area a different type of sprinkler system can be used. It may be necessary to provide draft curtains to divide the two types of sys-

**Figure 3208.1  
TYPICAL RACK SYSTEM**

tems. An example is dividing an ESFR sprinkler system from a standard sprinkler system.

When the rack storage generally exceeds 25 feet (7620 mm) in height, in-rack automatic sprinkler systems should be incorporated into the design because ceiling sprinklers alone may not be able to provide protection for those commodities in the lower levels of the rack storage. There are some configurations involving systems such as ESFR sprinklers that would not require in-rack sprinklers. It depends on many factors and must be determined when applying NFPA 13. Factors include such things as whether the storage is single-, double- or multiple-row, storage height, ceiling height, type of sprinkler, flue spaces and other factors. In addition, the protection of the columns of a building by that same sprinkler may be necessary to satisfy the provisions of Section 3208.4 (see NFPA 13). NFPA 13 contains the protection requirements for rack storage. The provisions were incorporated into NFPA 13 from NFPA 231C, which was originally developed based on a number of large-scale fire tests conducted to determine the advantages and limitations of automatic sprinklers in various storage array configurations. However, test information was not available for all configurations. As a result, some of the protection criteria are based on extrapolation of the test information.

The automatic sprinkler system is expected to remain in operation as the fire fighters attempt to control and extinguish the fire. As a result, design considerations for water supply must ensure that the water supply is not compromised by other operations. In no case should manual fire-fighting operations be substituted for automatic sprinklers. The sprinkler protection is to extend throughout the building containing the rack storage or to a fire barrier. The fire barrier is to comply with the provisions of IBC Section 707, which applies to fire barriers used for separating fire areas. To maintain integrity of the separation of fire areas, fire barriers must be continuous from the top of the floor below to the underside of the roof slab or deck above and be securely attached thereto. As with any fire-resistance-rated barriers, consideration must be given to openings and penetrations. The number and size of openings in the fire barrier must comply with the provisions of IBC Section 707, and the opening protective assemblies must have a minimum fire-resistance rating of 1 hour. Note that IBC Section 716.5 allows an opening protection rating of  $\frac{3}{4}$  hour for nonexit-enclosure fire barriers; however, this section, with its specific requirement of a 1-hour rating, would supersede that requirement. Penetrations of fire barriers must comply with IBC Section 714. Maintenance of the fire-resistance-rated construction rests with the building owner or the tenant as described in Section 703.

**3208.2.1 Plastic shelves.** Storage on plastic shelves shall be protected by *approved* specially engineered *fire protection systems*.

❖ Plastic shelving, when used, increases the fuel load to the commodity that is being stored on top of the pallet or shelving. Specific requirements are not provided, but the code requires that special protection be provided as approved by the fire code official.

**3208.2.2 Racks with solid shelving.** Racks with solid shelving having an area greater than 20 square feet (1.9 m<sup>2</sup>), measured between *approved* flue spaces at all four edges of the shelf, shall be in accordance with this section.

**Exceptions:**

1. Racks with mesh, grated, slatted or similar shelves having uniform openings not more than 6 inches (152 mm) apart, comprising not less than 50 percent of the overall shelf area, and with *approved* flue spaces are allowed to be treated as racks without solid shelves.
  2. Racks used for the storage of combustible paper records, with solid shelving, shall be in accordance with NFPA 13.
- ❖ Racks with solid shelving provide a challenge to the fire protection system design (see Commentary Figure 3208.2.2). Ceiling-only automatic sprinkler protection will not provide sufficient suppression and protection of the neighboring commodities or the building. Additional sprinkler protection will be necessary to control and potentially suppress a fire. In this case, in-rack sprinklers have demonstrated that they can supplement the ceiling sprinklers for acceptable protection overall by reducing the fire's ability to develop a high rate of heat release. Designs for in-rack protection must consider necessary clearances, distance from structural components, flue space clearances and protection of the heads to allow the sprinklers to function properly.

In addition to Exception 1, NFPA 13 has provisions that allow slatted shelves to be considered equivalent to racks without solid shelves when certain criteria have been met. These criteria relate to restrictions on commodities (e.g., not allowing exposed expanded Group A plastics), certain types of sprinklers, minimum aisle widths, certain sprinkler configurations, flue spaces and other considerations (see NFPA 13).

**3208.2.2.1 Fire protection.** Fire protection for racks with solid shelving shall be in accordance with NFPA 13.

❖ The provisions of NFPA 13 stipulate the minimum requirements for the design and construction of an automatic fire suppression system within a building containing rack storage with solid shelving. Rack storage with solid shelving requires the installation of an in-rack automatic fire suppression system. Since

## HIGH-PILED COMBUSTIBLE STORAGE

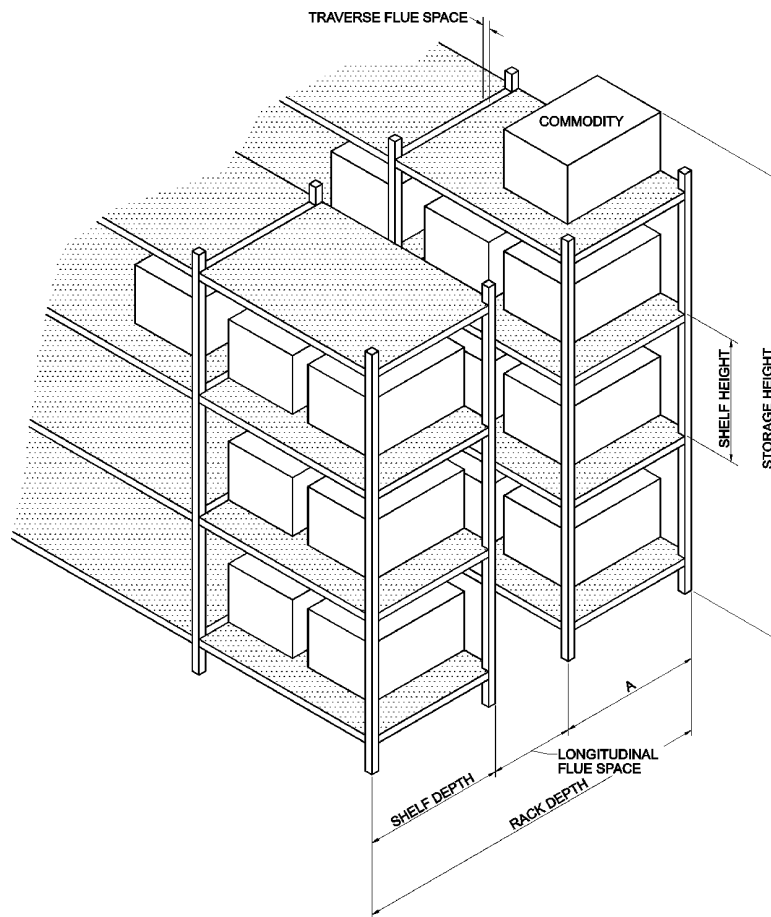

most rack storage systems are permanent, they can support the piping for the in-rack system. The in-rack fire suppression system provides an additional layer of protection that ceiling-only systems could not provide because the shelving prevents the water discharge from entering the individually shelved commodities. The in-rack sprinklers can contain the fire to a small area of the rack structure and wet the commodities adjacent to the fire, thus preventing the fire from spreading to other commodities located horizontally and vertically from the commodities involved in the fire. Important design considerations are the location and protection of supply lines from commodity storage and handling operations, protection of individual sprinkler heads and the separation of water supply to the in-rack fire suppression system from other systems, such as the ceiling-mounted fire suppression system.

**3208.3 Flue spaces.** Flue spaces shall be provided in accordance with Table 3208.3. Required flue spaces shall be maintained.

❖ This section refers to the requirements in Table 3208.3 for minimum longitudinal and transverse flue

dimensions and design for the automatic fire suppression system, in association with Table 3206.2. In high-piled combustible storage racks, flue spaces are an important component of the fire protection design. NFPA 13 categorizes flue spaces as either being longitudinal or transverse. Longitudinal flue spaces extend the length of the storage rack while transverse flue spaces extend the depth of the rack. Flue spaces permit water discharged from a ceiling sprinkler to penetrate into the rack system so it can begin to either control or suppress the fire, depending on the automatic sprinkler system design. When the sprinkler system is designed to control the fire, flue spaces allow the additional sprinkler discharge to prewet the storage commodities, which slows vertical and horizontal fire spread within the rack, thus limiting the number of sprinklers that may operate. Note that when in-rack sprinklers are provided or if the building is not sprinklered, flue spaces are not required.

Flue spaces in storage racks containing Class I through IV commodities greater than 12 feet (3658 mm) in height, high-hazard commodities greater than 6 feet (1829 mm) in height or bin box storage greater

**Figure 3208.2.2**  
**DOUBLE-ROW RACKS WITH SOLID SHELVES**

than 5 feet (1524 mm) in height must comply with all of the provisions in this section, which require longitudinal and transverse spaces to be maintained in accordance with Table 3208.3. Its requirements are dependent on the high-piled combustible storage area being unprotected or protected by an automatic sprinkler system, the height of rack storage, the type of storage rack system, and if partial or complete in-rack automatic sprinkler protection is provided. See Commentary Figures 3208.3(1-3) for the various flue space options based upon fire protection provided and storage height. Commentary Figure 3208.3(4) shows vertical alignment of flue spaces as required for storage over 25 feet in Table 3208.3.

Note that where proper maintenance of the flue spaces becomes a problem, Section 3208.3.1 may be applied by the fire code official. See also the commentary for the definitions of “Transverse” and “Longitudinal flue spaces” in Chapter 2.

**3208.3.1 Flue space protection.** Where required by the *fire code official*, flue spaces required by Table 3208.3, in single-, double- or multiple-row rack storage installations shall be equipped with *approved* devices to protect the required flue spaces. Such devices shall not be removed or modified.

❖ This section authorizes the fire code official to require installation of approved devices to maintain required flue spaces in storage rack systems. It is not the intent of this authority to require such devices in each instance, but rather when a business has an established history of poor flue space maintenance.

Available flue space protection devices that are designed to maintain transverse and longitudinal flue

spaces include but are not limited to brackets, cables or other elements that are securely fastened to the load-bearing columns of the rack system. The devices control the depth or width to which a product, pallet or similar material can be stored in the rack system, thereby preventing obstruction of the required flue space. However, device selection should consider if the rack tiers are designed for mechanized material handling equipment, such as forklifts, versus racks where hand picking is the preferred method of material handling, such as archive storage. Devices available for hand-picking operations may lack the mechanical strength to withstand the impact loads that can arise during movements of palletized unit loads.

Once approved devices are installed, most business owner confusion regarding flue space requirements is removed. Other benefits include: property loss reduction through quick activation of the fire protection system; improved penetration of sprinkler discharge through the rack system to the seat of the fire; faster activation of smoke and heat vent systems; and improved employee, public and fire fighter safety. See Commentary Figure 3208.3.1 for an example of flue space protection device.

**3208.4 Column protection.** Steel building columns shall be protected in accordance with NFPA 13.

❖ NFPA 13 provides steel-column protection criteria in areas used for the rack storage of Class I through IV commodities in Section 16.1.4, for rack storage of plastic and rubber products in Section 17.1.4 and for rack storage of rubber tires in Section 18.2.

**TABLE 3208.3  
REQUIRED FLUE SPACES FOR RACK STORAGE**

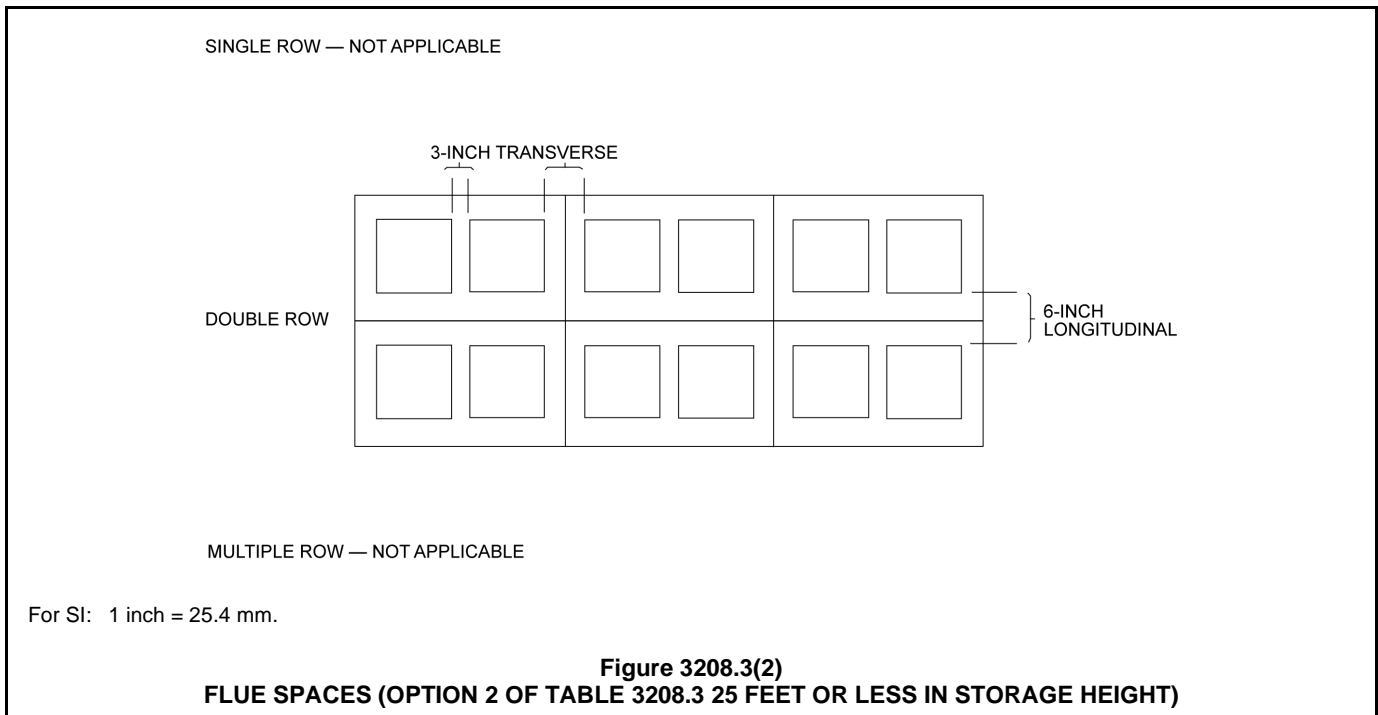

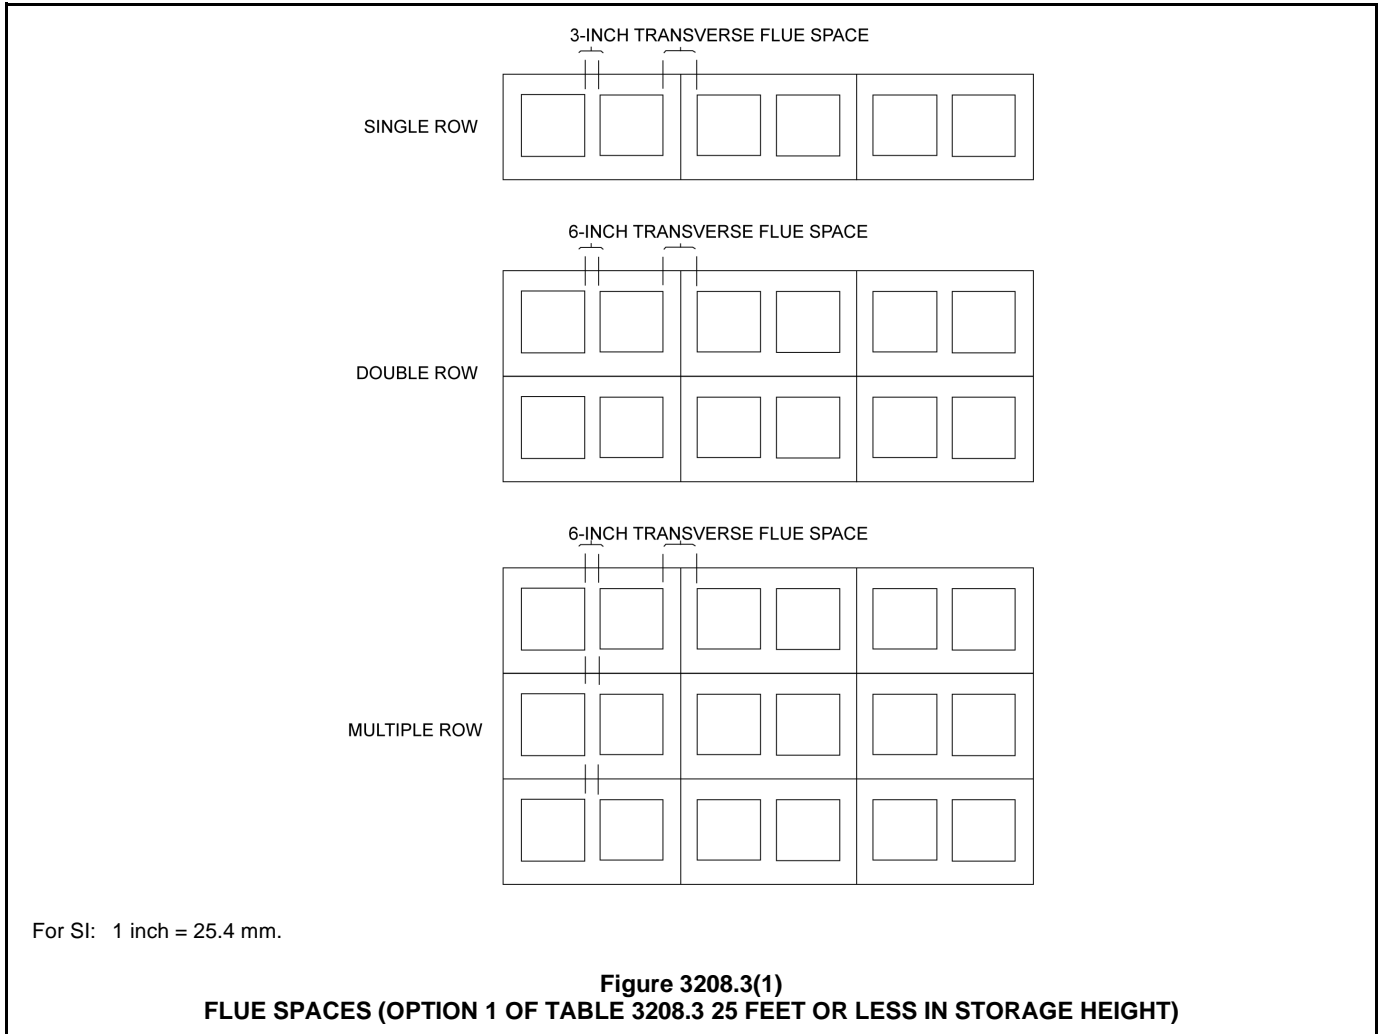

RACK CONFIGURATION	AUTOMATIC SPRINKLER PROTECTION		SPRINKLER AT THE CEILING WITH OR WITHOUT MINIMUM IN-RACK SPRINKLERS			IN-RACK SPRINKLERS AT EVERY TIER	NONSPRINKLERED
			≤ 25 feet		> 25 feet		
			Option 1	Option 2			
Single-row rack	Transverse flue space	Size <sup>b</sup>	3 inches	Not Applicable	3 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Applicable	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	Not Applicable	Not Required	Not Required	Not Required
Double-row rack	Transverse flue space	Size <sup>b</sup>	6 inches <sup>a</sup>	3 inches	3 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Required	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	6 inches	6 inches	Not Required	Not Required
Multirow rack	Transverse flue space	Size <sup>b</sup>	6 inches	Not Applicable	6 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Applicable	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	Not Applicable	Not Required	Not Required	Not Required

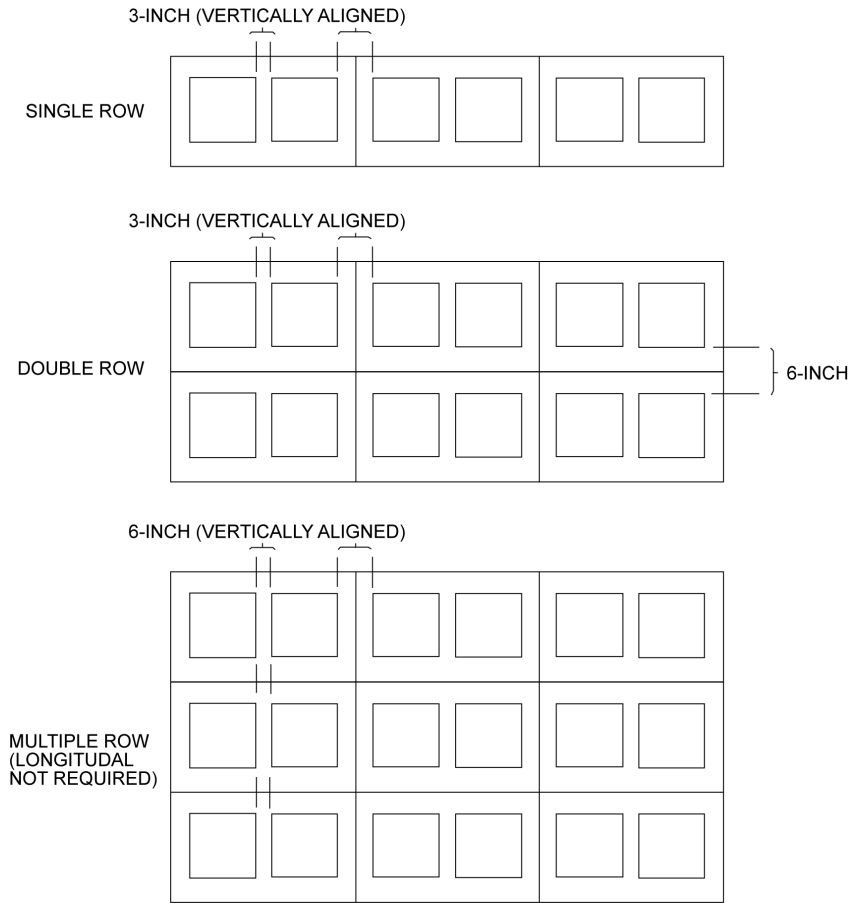

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Three-inch transverse flue spaces shall be provided not less than every 10 feet where ESFR sprinkler protection is provided.

b. Random variations are allowed, provided that the configuration does not obstruct water penetration.

**HIGH-PILED COMBUSTIBLE STORAGE**

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**Figure 3208.3(3)  
FLUE SPACES GREATER THAN 25 FEET IN STORAGE HEIGHT**

**Figure 3208.3(4)  
VERTICAL ALIGNMENT OF FLUE SPACES**

Figure 3208.3.1  
FLUE SPACE PROTECTION EXAMPLE

**3208.5 Extra-high-rack storage systems.** Approval of the *fire code official* shall be obtained prior to installing extra-high-rack combustible storage.

❖ In addition to the permit requirements contained in Section 105, the building owner, tenant or lessee is required to seek permission from the fire code official to construct an extra-high-rack storage system because of the higher challenge fire that such storage presents (see the commentary to Section 202 for the definition of “Extra-high-rack combustible storage”).

**3208.5.1 Fire protection.** Buildings with extra-high-rack combustible storage shall be protected with a specially engineered *automatic sprinkler system*. Extra-high-rack combustible storage shall be provided with additional special fire protection, such as separation from other buildings and additional built-in fire protection features and fire department access, where required by the *fire code official*.

❖ Extra-high-rack storage is considered to have additional risks that warrant the requirement for an automatic sprinkler system engineered with additional protection features. These features could include additional heads along the vertical axis, change in the type of sprinkler heads and the use of high-expansion foam systems. To further protect the building and neighboring buildings, the fire code official may require that additional fire protection measures be taken to increase the likelihood that, if a fire does occur, it will be contained to that building. These measures can include greater building separation requirements than required in Table 602 of the IBC, enhanced fire apparatus access, additional fire

hydrants and building openings. All additional fire protection and life safety systems require the approval of the fire code official.

## SECTION 3209 AUTOMATED STORAGE

**3209.1 General.** Automated storage shall be in accordance with this section.

❖ Automated storage is generally designed for operations in which the commodity storage necessary to serve the operation is large and where that facility may operate 24 hours a day, seven days a week. This type of storage is generally programmed for commodity stocking and retrieving, and contains a sufficient amount of commodity for the operation to continue working even if restocking may experience a slow period. Operations that commonly employ such facilities are automotive parts manufacturers, electronic parts manufacturers and even the food industry. One of the primary fire concerns with automated storage is the potential for the fire to be carried by the mechanism that transports the commodity. If such a fire were to occur while the commodity is in motion, it could reduce, if not overwhelm, the effectiveness of the automatic fire suppression system. As a result, additional measures are required in an attempt to compensate for that potential fire hazard.

**3209.2 Automatic sprinklers.** Where automatic sprinklers are required by Table 3206.2, the building shall be equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ The provisions requiring an automatic sprinkler system throughout the building housing the automatic storage system is an additional fire protection feature based on the concept that the area may be difficult for the fire service to suppress a fire manually. The reference to the provisions of Chapter 9 covers generally all types of sprinkler systems beyond those specific to high-piled storage. Not all areas would need a sprinkler system that is designed to protect high-piled storage commodities.

**3209.3 Carousel storage.** *High-piled storage areas* having greater than 500 square feet (46 m<sup>2</sup>) of carousel storage shall be provided with automatic shutdown in accordance with one of the following:

1. An automatic smoke detection system installed in accordance with Section 907, with coverage extending 15 feet (4575 mm) in all directions beyond unenclosed carousel storage systems and that sounds a local alarm at the operator’s station and stops the carousel storage system upon the activation of a single detector.
2. An automatic smoke detection system installed in accordance with Section 907 and within enclosed carousel storage systems, that sounds a local alarm at the operator’s station and stops the carousel storage system upon the activation of a single detector.

3. A single dead-man-type control switch that allows the operation of the carousel storage system only when the operator is present. The switch shall be in the same room as the carousel storage system and located to provide for observation of the carousel system.

❖ Carousel storage is used in large storage operations when the commodity must be protected (security), when the commodity requires strict environmental control or both. In addition, carousel storage is selected because it may provide an economic advantage to an operation or business by having the commodity come directly to the employee rather than the employee stocking and retrieving the commodity. The carousel area is normally not occupied. An exception to this may be when the carousel system is undergoing maintenance or repair or during an annual inspection of the fire protection features. Examples of commodities within carousel storage may include distribution centers that distribute pharmaceutical or refrigerated/frozen foods and beverages. The additional fire safety requirements are precautionary, directly resulting from the limited access to these types of storage areas and addressing the potential of a moving fire via the carousel mechanism. Because the area of the carousel is controlled by a mechanized, generally computer-controlled system, immediate access to the actual storage area is normally limited. These limits serve to protect both personnel and the commodity. The additional fire safety measures include provisions for an elaborate automatic detection system, which upon activation stops the carousel from operating (moving). This precaution prevents the fire from spreading throughout the entire storage area.

**3209.4 Automated rack storage.** *High-piled storage areas* with automated rack storage shall be provided with a manually activated emergency shutdown switch for use by emergency personnel. The switch shall be clearly identified and shall be in a location *approved* by the fire chief.

❖ This section requires that if an emergency occurs in an automated rack storage facility, the remotely controlled pallet moving equipment be manually shut down. This shutdown accomplishes two objectives. First, the potential to either move additional product into the fire or move burning product through the storage area is removed. Second, it is not safe to place emergency personnel within the automated storage area when the system is still active. Many of these automated devices move much faster than personnel can get out of the way, and there is a physical danger to personnel. This shutdown will eliminate danger to personnel and reduce property damage. Since the shutdown of such systems is a tactical maneuver, the fire chief is required to approve the location for the switch and ensure that it is properly identified. The switch should be in a readily accessible location outside of the boundaries of the automated rack storage area. See also the commentary to Section 202 for the definition of “Automated rack storage.”

## SECTION 3210 SPECIALTY STORAGE

**3210.1 General.** Records storage facilities used for the rack or shelf storage of combustible paper records greater than 12 feet (3658 mm) in height shall be in accordance with Sections 3206 and 3208 and NFPA 13. Palletized storage of records shall be in accordance with Section 3207.

❖ The storage of various types of records can have a relatively high intrinsic value. This is where protection of the actual documents is essential to any business to retrieve information or to reconstruct records. The provisions of this section specifically identify the fire and life safety requirements for records stored on pallets and in-rack or shelf storage systems. Although the provisions of this section set the minimum safeguards from the hazards of fire and explosion, it is up to the owners of the records to determine the actual protection that must be provided. NFPA 13, as with other high-piled storage, is the minimum referenced standard. NFPA 13 specifically deals with carton record storage in Section 20.5 and high-bay record storage in Section 20.7.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*High-piled Combustible Storage Application Guide, 2009 IFC.* Washington, DC: International Code Council, 2011.

# Chapter 33: Fire Safety During Construction and Demolition

## General Comments

This chapter outlines general fire safety precautions for all structures and all occupancies during construction and demolition operations. In general, these requirements seek to maintain required fire protection, limit fire spread, establish the appropriate operation of equipment and promote prompt response to fire emergencies.

There are 17 sections in Chapter 33. Section 3301 gives the general scope of the chapter and provides the basis for enforcement of its provisions. Section 3302 defines terms specifically relevant to the chapter. The listing, arrangement, fueling and supervision of temporary heating equipment is described in Section 3303. Section 3304 deals with precautions against fire that involve the control of smoking, waste disposal, open burning, spontaneous ignition and temporary electrical wiring. The storage, handling and classification of flammable and combustible liquids, flammable gases and explosive materials are addressed in Sections 3305, 3306 and 3307, respectively.

Sections 3308 and 3309 regulate the need for prefire planning, training and maintenance of fire protection systems and emergency notification means. Access for fire fighting is discussed in Section 3310. Escape by on-site personnel is covered under means of egress in Section 3311. The provision and maintenance of specific fire protection devices such as standpipes, automatic sprinkler systems and portable fire extinguishers is explained in Sections 3313, 3314 and 3315, respectively. The need to regulate heat sources, such as internal combustion engines and fuel-fired asphalt and tar kettles, is addressed in Sections 3316 and 3317.

## Purpose

This chapter contains requirements that are intended to safeguard people from injury or illness and protect property from damage during the construction or demolition processes.

## SECTION 3301 GENERAL

**3301.1 Scope.** This chapter shall apply to structures in the course of construction, *alteration* or demolition, including those in underground locations. Compliance with NFPA 241 is required for items not specifically addressed herein.

❖ Buildings are most vulnerable to fire when undergoing construction, demolition or alteration. Special measures are required to either minimize the potential for a fire or aid in fire control and suppression. These requirements amplify those of other sections of the code and prescribe maintenance of adequate means of egress and on-site incipient fire-fighting equipment. Temporary heating appliances are regulated to prevent ignition of combustible debris and structural elements. Fire apparatus access and maintenance of standpipes are also addressed [see also Chapter 33 of the *International Building Code*® (IBC®), NFPA 241 and the *NFPA Fire Protection Handbook*]. Note that, in accordance with Section 102.7.2 of the code, where both Chapter 33 of the code and NFPA 241 regulate a topic, the provisions of the code take precedence.

**3301.2 Purpose.** This chapter prescribes minimum safeguards for construction, *alteration* and demolition operations to provide reasonable safety to life and property from fire during such operations.

❖ This chapter is intended to regulate access by the responding fire department, fire protection systems, operations and maintenance of structures for precautions against fire and spread of fire during construction and demolition.

## SECTION 3302 DEFINITIONS

**3302.1 Terms defined in Chapter 2.** Words and terms used in this chapter and defined in Chapter 2 shall have the meanings ascribed to them as defined therein.

❖ This section directs the code user to Chapter 2 for the proper application of the terms used in this chapter. These terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentaries, Sections 201.1 through 201.4).

**SECTION 3303  
TEMPORARY HEATING EQUIPMENT**

**3303.1 Listed.** Temporary heating devices shall be *listed* and *labeled* in accordance with the *International Mechanical Code* or the *International Fuel Gas Code*. Installation, maintenance and use of temporary heating devices shall be in accordance with the terms of the listing.

❖ Listing and labeling are used to identify materials, assemblies and devices that are required to bear the identification of the manufacturer, as well as a third-party quality-control agency. The quality-control agency allows the use of its listing or label based on periodic audits and inspections of the manufacturer's facility. Not all testing laboratories, inspection agencies and other organizations concerned with product or program evaluation use the same means for identifying listed equipment, materials or agencies. Some do not recognize equipment or materials as listed unless they are also labeled. The fire code official must use the same system as the listing organization to identify listed equipment, materials or agencies.

**3303.2 Oil-fired heaters.** Oil-fired heaters shall comply with Section 603.

❖ The regulations for the devices that are likely to be used for temporary heat are delineated in Section 603.

**3303.3 LP-gas heaters.** Fuel supplies for liquefied-petroleum gas-fired heaters shall comply with Chapter 61 and the *International Fuel Gas Code*.

❖ Because propane gas is heavier than air, special attention must be given to the way the fuel tank is arranged and connected to the heating device. Tank location and protection are just two of the concerns addressed in the *International Fuel Gas Code*® (IFGC®).

**3303.4 Refueling.** Refueling operations for liquid-fueled equipment or appliances shall be conducted in accordance with Section 5705. The equipment or appliance shall be allowed to cool prior to refueling.

❖ This section addresses the refueling of liquid-fueled equipment, but Section 5705 addresses proper liquid transfer, container filling operations, filling locations, quantity limits and more. Because hot surfaces can cause ignition of flammable vapors and spills, the appliance must be allowed to cool before refueling.

**3303.5 Installation.** Clearance to combustibles from temporary heating devices shall be maintained in accordance with the *labeled* equipment. When in operation, temporary heating devices shall be fixed in place and protected from damage, dislodgement or overturning in accordance with the manufacturer's instructions.

❖ Because conditions change during construction or demolition, temporary heating devices must be monitored and maintained. Materials are constantly being moved, which may reduce the clearances to the device. It may be advantageous for the owner to hire

a fire watch to check operating conditions while work is in progress and at the end of work shifts. The fire code official may need to decide what is required.

**3303.6 Supervision.** The use of temporary heating devices shall be supervised and maintained only by competent personnel.

❖ Temporary installations must be as safe as permanent ones. Having qualified people do these installations is important.

**SECTION 3304  
PRECAUTIONS AGAINST FIRE**

**3304.1 Smoking.** Smoking shall be prohibited except in *approved* areas. Signs shall be posted in accordance with Section 310. In *approved* areas where smoking is permitted, *approved* ashtrays shall be provided in accordance with Section 310.

❖ This smoking prohibition is out of concern for fire safety, not health or the environment. Every effort must be made to keep hot smoking materials from igniting building materials or debris. Smoking in occupancies subject to ignition hazards from smoking materials should be approved by the fire code official, confined to spaces without significant amounts of combustibles and where approved ash trays or receptacles are provided. Signage indicating "smoking permitted in this area" will encourage the use of the limited area. "No Smoking" signs similar to Commentary Figure 3304.1 may be used.

**3304.2 Combustible debris, rubbish and waste.** Combustible debris, rubbish and waste material shall comply with the requirements of Sections 3304.2.1 through 3304.2.4.

❖ As a basic fire safety measure, work site housekeeping is often overlooked. This section introduces an orderly progression of procedures for managing the accumulation of combustible rubbish on construction and demolition sites. The subsections were formerly contained in a single paragraph but have been placed in separate sections to emphasize their importance in fire safety planning.

**3304.2.1 Combustible waste material accumulation.** Combustible debris, rubbish and waste material shall not be accumulated within buildings.

❖ Construction jobs must be kept reasonably free of accumulations of combustible waste inside of buildings undergoing construction or demolition where any number of ignition sources may exist.

**3304.2.2 Combustible waste material removal.** Combustible debris, rubbish and waste material shall be removed from buildings at the end of each shift of work.

❖ To help mitigate the hazards of accumulating combustible rubbish inside of buildings, this section requires that such materials be removed to outside of the building at the end of each work shift.

**3304.2.3 Rubbish containers.** Where rubbish containers with a capacity exceeding 5.33 cubic feet (40 gallons) (0.15 m<sup>3</sup>) are used for temporary storage of combustible debris, rubbish and waste material, they shall have tight-fitting or self-closing lids. Such rubbish containers shall be constructed entirely of materials that comply with either of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> when tested in accordance with ASTM E1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation.

❖ Large rubbish containers must be provided for temporary storage of combustible construction or demolition rubbish. The specific container size is consistent with the size criteria in Section 304.3 and the fire safety requirements are consistent with those for large rubbish containers found throughout the code. The use of containers with tight-fitting or self-closing lids provides a method to reduce the possibility that a fire can be started in the container by accident and prevent continued burning if ignition does occur. Such containers need not be constructed of metal but can be constructed of other noncombustible materials, including materials that have been shown to be safe by meeting a very severe fire test, similar to those required by Section 808 for Group I-1, I-2 and I-3 occupancies and Section 304.3.4 for general rubbish control. A key requirement is that the lids must be tight-fitting or self-closing. Note that this does not address materials susceptible to spontaneous ignition, such as oily rags, that are covered by Section 3304.2.4. The use of the phrase “combustible debris,

rubbish and waste” makes this section consistent with other sections of the code.

**3304.2.4 Spontaneous ignition.** Materials susceptible to spontaneous ignition, such as oily rags, shall be stored in a listed disposal container.

❖ Spontaneous ignition, also known as autoignition or self-ignition, is defined by Burklin and Purington as “ignition due to chemical reaction or bacterial action in which there is slow oxidation of organic compounds until the material ignites; usually there is sufficient air for oxidation but insufficient ventilation to carry heat away as it is generated.” A detailed treatment of the subject appears in the *NFPA Fire Protection Handbook*. The One Meridian Plaza office building fire in 1991 was allegedly started by spontaneous ignition of oil-soaked rags that were improperly stored during a remodeling operation. This high-rise building in the heart of Philadelphia was so seriously damaged in the fire that it was razed in 1999. A listed container for the storage of the oily rags was not used. The fire code official should determine the kinds of oils or solvents used and research their potential for spontaneous ignition (see commentary, Section 304.3.1).

**3304.3 Burning of combustible debris, rubbish and waste.** Combustible debris, rubbish and waste material shall not be disposed of by burning on the site unless approved.

❖ Combustible rubbish and construction waste must not be burned, unless local environmental and fire authorities are consulted on local open burning regulations.

**3304.4 Open burning.** *Open burning* shall comply with Section 307.

❖ Section 307 requires that a permit be obtained for open burning. Other areas of concern are burning location and monitoring. The owner should make documentation of the event available to the fire code official.

**3304.5 Fire watch.** Where required by the *fire code official* for building demolition, or building construction during working hours that is hazardous in nature, qualified personnel shall be provided to serve as an on-site fire watch. Fire watch personnel shall be provided with not less than one approved means for notification of the fire department and their sole duty shall be to perform constant patrols and watch for the occurrence of fire.

❖ Hazardous demolition or construction operations may need the services of qualified emergency response personnel, such as hazmat technicians or fire fighters, to stand by or actually patrol the area, especially when hazardous construction operations are being conducted in an occupied building. When such persons are needed, it is essential that they focus on that task only and have no other assignments. A lay person should not be used; it is within the authority of the fire code official to require that professionals be on site. It is critical that such watch personnel be able to contact the fire department immediately in case of an

emergency through a reliable means of communication approved by the fire code official. See the commentary to Sections 403.12.1 through and 403.12.1.2 for additional information on fire watch personnel and their duties.

**3304.6 Cutting and welding.** Operations involving the use of cutting and welding shall be done in accordance with Chapter 35.

❖ Cutting and welding operations account for 9 percent of fires in industrial operations. With accumulations of combustible materials that are common during construction and demolition, additional precautions must be taken. One of the most effective ways to prevent or promptly respond to fires caused by cutting and welding is to have a vigorous “hot work” permit system. Chapter 35 presents these precautions.

**3304.7 Electrical.** Temporary wiring for electrical power and lighting installations used in connection with the construction, *alteration* or demolition of buildings, structures, equipment or similar activities shall comply with NFPA 70.

❖ Temporary wiring used during construction is, by its very nature, of a lesser class or quality than that which would be installed as permanent building wiring and must, therefore, be monitored for damage, unfinished work or exposed connections. Demolition operations may leave exposed live wiring, so coordination between the on-site electrician and the power company is important. Section 590 of NFPA 70 contains requirements for temporary wiring in buildings, including provisions for overcurrent protection, lamp protection, wiring quality and installation, disconnects and time limitations, to name but a few (see also commentary, Section 605).

## SECTION 3305

### FLAMMABLE AND COMBUSTIBLE LIQUIDS

**3305.1 Storage of flammable and combustible liquids.** Storage of flammable and *combustible liquids* shall be in accordance with Section 5704.

❖ Storage and use of flammable and combustible liquids require the approval of the fire code official for the control of hazards and to provide the fire department with vital hazard data for preplanning for incidents involving such materials. A permit is required for storage. See Section 105.6.17 and the accompanying commentary for more information on permit requirements.

**3305.2 Class I and Class II liquids.** The storage, use and handling of flammable and *combustible liquids* at construction sites shall be in accordance with Section 5706.2. Ventilation shall be provided for operations involving the application of materials containing flammable solvents.

❖ Sections 5706.2 through 5706.2.8.1 contain comprehensive regulations on the proper storage, use and

handling of Class I and II liquids on construction sites. Areas of particular concern are: signage, storage location, ventilation, sources of ignition and dispensing. Class I liquids are more hazardous than Class II because of their lower flash points [less than 100°F (38°C)] (see commentaries, Sections 5706.2 through 5706.2.8.1).

**3305.3 Housekeeping.** Flammable and combustible liquid storage areas shall be maintained clear of combustible vegetation and waste materials. Such storage areas shall not be used for the storage of combustible materials.

❖ Housekeeping, in this case, concerns ignition sources and added fuel load in the liquid storage area. Easily ignited dry weeds, grass and paper are prohibited in the area. Access to the area by fire fighters can be hampered when combustibles in the storage area ignite.

**3305.4 Precautions against fire.** Sources of ignition and smoking shall be prohibited in flammable and *combustible liquid* storage areas. Signs shall be posted in accordance with Section 310.

❖ Sources of ignition, such as electric arcing, open-flame heating devices and static electricity, must be controlled. Smoking must also be controlled by posting “no smoking” signs, providing safe smoking areas and promoting on-the-job awareness of the smoking prohibition as stipulated in Section 310.

**3305.5 Handling at point of final use.** Class I and II liquids shall be kept in *approved* safety containers.

❖ This section mandates that only approved safety cans (as defined in Section 202) of not more than a 5-gallon (19 L) capacity with a spring-loaded, self-closing lid and spout covers, designed to safely relieve internal pressure under fire conditions, be used for the storage of Class I and II liquids at construction and demolition sites.

The key to the proper storage and handling of flammable and combustible liquids is to keep liquids and vapors away from ignition sources. Restrictions on flammable liquid container sizes, separation distances and active and passive fire protection are based on the extent of the hazard presented should an uncontrolled release occur.

**3305.6 Leakage and spills.** Leaking vessels shall be immediately repaired or taken out of service and spills shall be cleaned up and disposed of properly.

❖ Accidental liquid spills create a vapor release that can quickly travel from the spill point to an ignition source. Because spills need immediate attention to neutralize and remove the hazard, the local fire department should be notified; it is the agency best prepared to deal with the immediate hazards of a spill.

Leaks can indicate a developing problem with equipment or piping needing immediate repair. Until repairs are made, the equipment or piping must be

taken out of service. If the leak or spill is expected to spread beyond the property lines or contaminate water or air, environmental authorities should also be notified.

### SECTION 3306 FLAMMABLE GASES

**3306.1 Storage and handling.** The storage, use and handling of flammable gases shall comply with Chapter 58.

❖ Chapter 58 deals with quantity limits for indoor storage, storage containers, ignition sources and limits for the outdoor storage of flammable gases. Also refer to Chapter 53 for general requirements for compressed gases.

**3306.2 Cleaning with flammable gas.** Flammable gases shall not be used to clean or remove debris from piping open to the atmosphere.

❖ In the past several years, two explosions that killed a combined 10 people were attributed to workers using natural gas flowing at high velocities to clean/clear fuel gas piping during the commissioning of fuel gas piping at industrial plants. The flammable gas and debris from the piping were vented to the atmosphere and ignited by sparks, one of which was suspected to be caused by static electricity. For details on the incidents see the U.S. Chemical Safety Board report at: <http://www.csb.gov/assets/1/19/KleenUrgentRec.pdf>.

The dangerous practice of using flammable gases to clean or remove debris from fuel piping that is open to the atmosphere is prohibited by this section.

**3306.2.1 Pipe cleaning and purging.** The cleaning and purging of flammable gas piping systems, including cleaning new or existing piping systems, purging piping systems into service and purging piping systems out of service, shall comply with NFPA 56.

#### Exceptions:

1. Compressed gas piping systems other than fuel gas piping systems where in accordance with Chapter 53.
  2. Piping systems regulated by the *International Fuel Gas Code*.
  3. Liquefied petroleum gas systems in accordance with Chapter 61.
- ❖ The intent of this section is to address the fire and explosion hazards associated with the purging of flammable gas piping typically found in electric generating plants and in industrial, institutional, and commercial applications. NFPA 56 provides minimum safety requirements for the cleaning and purging of flammable gas piping systems, including cleaning new or existing piping systems, purging piping systems into service, and purging piping systems out of service. It includes the appropriate managerial and

operational requirements necessary to foster safe outcomes. NFPA 56 compliments this section and also does not allow flammable gases to be used for internal cleaning of piping open to the atmosphere.

As indicated by the exceptions, it is not the intent of this section to cover cleaning or purging of the three listed systems.

### SECTION 3307 EXPLOSIVE MATERIALS

**3307.1 Storage and handling.** *Explosive* materials shall be stored, used and handled in accordance with Chapter 56.

❖ Chapter 56 prescribes minimum requirements for the safe storage, handling and use of explosives, ammunition and blasting agents for commercial and industrial occupancies. Its provisions are intended to protect the general public, emergency responders and individuals who handle explosives in connection with construction or demolition operations.

**3307.2 Supervision.** Blasting operations shall be conducted in accordance with Chapter 56.

❖ Specific requirements dealing with local physical and governmental controls, blasting area security and post-blast procedures are found in Section 5607.

Security precautions for explosive materials must conform to the requirements of this chapter and the referenced standards. Any discrepancy that suggests the loss or theft of explosives must be reported to local law enforcement authorities and the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) within 24 hours of discovery (see DOTy 27 CFR, Part 55.30). The ATF hotline may be contacted 24 hours a day at (800) 800-3855. Abandoned explosives, including those not claimed by the consignee within 48 hours of their arrival at a terminal, should be returned to the control of the last licensee (manufacturer or distributor) to possess them before they were abandoned. Local law enforcement authorities and the ATF should be contacted if this is not possible.

**3307.3 Demolition using explosives.** *Approved* fire hoses for use by demolition personnel shall be maintained at the demolition site whenever *explosives* are used for demolition. Such fire hoses shall be connected to an *approved* water supply and shall be capable of being brought to bear on post-*detonation* fires anywhere on the site of the demolition operation.

❖ The code text does not stipulate the number, size or length of hoses needed; therefore, the involvement of the fire code official is essential to anticipate an incident. The competence of the demolition crew to properly use the hose for fire fighting is not addressed, which suggests that fire brigade training may be in order. Periodic inspections by the fire code official are imperative. As is the case throughout the code, fire protection methods and procedures must be acceptable to the fire code official.

## SECTION 3308 OWNER'S RESPONSIBILITY FOR FIRE PROTECTION

**3308.1 Program superintendent.** The *owner* shall designate a person to be the fire prevention program superintendent who shall be responsible for the fire prevention program and ensure that it is carried out through completion of the project. The fire prevention program superintendent shall have the authority to enforce the provisions of this chapter and other provisions as necessary to secure the intent of this chapter. Where guard service is provided, the superintendent shall be responsible for the guard service.

- ❖ Each project must have a fire prevention program superintendent who is in charge of all fire safety efforts, such as prefire planning, on-the-job training of personnel, guard service and the other areas covered in Sections 3308.1 through 3308.7. This person acts on behalf of the fire code official and can enforce the provisions of Chapter 33.

**3308.2 Prefire plans.** The fire prevention program superintendent shall develop and maintain an *approved* prefire plan in cooperation with the fire chief. The fire chief and the *fire code official* shall be notified of changes affecting the utilization of information contained in such prefire plans.

- ❖ Prefire plans are developed by the fire prevention program superintendent to assist the site personnel responding to a fire. This plan must be coordinated with the local fire chief and the fire code official. Changes in building operations or equipment that could affect the fire department's ground attack of a fire must be reported to the fire department responder immediately. For example, if an additional 1,000-gallon (3785 L) propane tank is located alongside an existing tank, the responder needs to know about this situation.

**3308.3 Training.** Training of responsible personnel in the use of fire protection equipment shall be the responsibility of the fire prevention program superintendent.

- ❖ The fire responder is expected to know what fire-fighting and fire protection equipment is on the site and how to operate it. The fire prevention program superintendent is responsible for training the job-site personnel in the proper use of hand-held fire extinguishers, hose lines, fire alarms and sprinkler systems.

**3308.4 Fire protection devices.** The fire prevention program superintendent shall determine that all fire protection equipment is maintained and serviced in accordance with this code. The quantity and type of fire protection equipment shall be *approved*.

- ❖ Fire protection and detection equipment must be maintained during construction and demolition. The fire prevention program superintendent must decide what is necessary to enforce maintenance as required by the code. Approval of the equipment and its maintenance is not, however, transferred to the

fire prevention program superintendent, but remains with the fire code official.

**3308.5 Hot work operations.** The fire prevention program superintendent shall be responsible for supervising the permit system for hot work operations in accordance with Chapter 35.

- ❖ This issue is also discussed in the commentary to Section 3304.6. Chapter 35 contains an in-depth treatment of hot work, especially Section 3503.3, which deals with hot work permits. The fire prevention program superintendent issues the permits to coordinate a response if a fire should occur in the known hot work permit area.

**3308.6 Impairment of fire protection systems.** Impairments to any *fire protection system* shall be in accordance with Section 901.

- ❖ Section 901.7 specifically deals with systems out of service because of planned, emergency or accidental impairment. During demolition, portions of the equipment must be kept in service as long as possible. Likewise, equipment on a construction site must keep pace with the new work and be kept in service as much as possible, especially at the end of the work day.

**3308.7 Temporary covering of fire protection devices.** Coverings placed on or over fire protection devices to protect them from damage during construction processes shall be immediately removed upon the completion of the construction processes in the room or area in which the devices are installed.

- ❖ Fire protection devices must be kept in service as much as possible during construction. An example would be that paper or plastic bags must be removed from the sprinkler heads as soon as the painting of the sprinkler piping or the adjacent ceiling is completed. Additional information can be obtained from standards, such as NFPA 13 and NFPA 72.

## SECTION 3309 FIRE REPORTING

**3309.1 Emergency telephone.** Readily accessible emergency telephone facilities shall be provided in an *approved* location at the construction site. The street address of the construction site and the emergency telephone number of the fire department shall be posted adjacent to the telephone.

- ❖ The construction site must have an emergency phone located in an approved location. Workers on the site are not expected to know the street address of the site or the fire department emergency number if it is a number other than 9-1-1. Therefore, the site address and fire department emergency number must be prominently posted. Typical customized signs are available from safety equipment suppliers or sign companies.

### SECTION 3310 ACCESS FOR FIRE FIGHTING

**3310.1 Required access.** *Approved* vehicle access for fire fighting shall be provided to all construction or demolition sites. Vehicle access shall be provided to within 100 feet (30 480 mm) of temporary or permanent fire department connections. Vehicle access shall be provided by either temporary or permanent roads, capable of supporting vehicle loading under all weather conditions. Vehicle access shall be maintained until permanent fire apparatus access roads are available.

❖ Fire-fighting vehicle access is the means by which fire fighters gain access to the construction or demolition site and building for fire suppression and rescue operations until the permanent fire apparatus access roads are constructed. Such access is an integral component of the fire prevention program. The site superintendent or other person responsible for construction and demolition operations is responsible for maintaining and policing fire-fighter access routes, as provided in Section 3308. Fire apparatus must be able to get within 100 feet (30 480 mm) of any installed fire department connection supplying water to temporary or permanent fire protection systems. Access roads must support the weight of the heaviest vehicle that might respond. The weight requirements are available from the local fire department. All-weather surfaces are required because the responding fire department should not waste time moving snow or trying to get out of mud (see also commentary, Section 503).

**3310.2 Key boxes.** Key boxes shall be provided as required by Chapter 5.

❖ As construction nears completion, some areas may not be accessible to the fire department without the use of a key. In those cases, the fire code official may require a key box as stipulated in Section 506.

### SECTION 3311 MEANS OF EGRESS

**[B] 3311.1 Stairways required.** Where a building has been constructed to a *building height* of 50 feet (15 240 mm) or four stories, or where an existing building exceeding 50 feet (15 240 mm) in *building height* is altered, not less than one temporary lighted *stairway* shall be provided unless one or more of the permanent *stairways* are erected as the construction progresses.

❖ Work crews will necessarily be in, and the fire department will need access to, buildings under construction or demolition at the same time that the means-of-egress elements are being built or destroyed. This situation requires diligence on the part of the fire code official and the construction managers to make sure a means of escape for workers and access for emergency forces is available at all times, and that construction of occupiable areas does not unnecessarily extend beyond the construction of the means of egress. By the time the building is substantially

enclosed, all required means of egress should be fully constructed and functional. For a building under construction, these precautions are triggered when the building exceeds 50 feet (15 240 mm) in height or four stories. Any temporary stairways must be lighted.

Similarly, the destruction of the means of egress should not precede the demolition of areas occupied by workers.

**3311.2 Maintenance.** Required *means of egress* shall be maintained during construction and demolition, remodeling or *alterations* and additions to any building.

**Exception:** *Approved* temporary *means of egress* systems and facilities.

❖ As in any building where people must egress, the required means of egress must be kept clear of construction materials and demolition debris so occupants can exit in an emergency.

Temporary means of egress may be provided when the permanent egress system cannot be maintained in accordance with this section.

### SECTION 3312 WATER SUPPLY FOR FIRE PROTECTION

**3312.1 When required.** An *approved* water supply for fire protection, either temporary or permanent, shall be made available as soon as combustible material arrives on the site.

❖ A water supply must be connected to the wet standpipe, and underground water supply and hydrants must be available for the dry standpipes as soon as combustible materials are on the job site. As previously stated in this commentary, the unfinished building is most vulnerable to fire and must be protected as much as possible.

### SECTION 3313 STANDPIPES

**3313.1 Where required.** In buildings required to have standpipes by Section 905.3.1, not less than one standpipe shall be provided for use during construction. Such standpipes shall be installed prior to construction exceeding 40 feet (12 192 mm) in height above the lowest level of fire department vehicle access. Such standpipe shall be provided with fire department hose connections at accessible locations adjacent to usable stairways. Such standpipes shall be extended as construction progresses to within one floor of the highest point of construction having secured decking or flooring.

❖ This section requires the installation of standpipes during construction for any building required by Chapter 9 and the IBC to be equipped with a standpipe system. The requirement for standpipe and hose connections is triggered when construction progresses to a height of not more than 40 feet (12 192 mm) above the lowest level of fire department access. While hoses need not be provided, the hose connection must be located adjacent to a stairway.

Although thread requirements are not stated here, the hose threads must be compatible with those of the responding fire department as required by Section 905.1. Standpipe hose connections must be ready for use on each floor before the installation of the floor deck on the story or level above in order to provide fire fighters with a means of bringing hose lines to bear on a fire on the highest floor level having access.

**3313.2 Buildings being demolished.** Where a building is being demolished and a standpipe is existing within such a building, such standpipe shall be maintained in an operable condition so as to be available for use by the fire department. Such standpipe shall be demolished with the building but shall not be demolished more than one floor below the floor being demolished.

❖ When a structure is being demolished and a standpipe system exists within that structure, the standpipe system must be operable and be available for use by the fire department. When a structure or a floor is to be demolished, its standpipe system must also be demolished with the structure; however, the system may not be demolished more than one floor below the floor being demolished.

The abundance of avenues for vertical fire spread make buildings undergoing partial or total demolition highly susceptible to damage from fire. Even more so than construction sites, demolition projects attract vandals and vagrants who may set fires on the property for warmth or criminal purposes. Further, cutting equipment and portable heating appliances may easily ignite combustible debris created during demolition. Once started, fire will spread rapidly through voids and vertical openings created to remove building service equipment. Standpipes provide fire fighters with a means of deploying hose lines quickly against these rapidly spreading fires.

**3313.3 Detailed requirements.** Standpipes shall be installed in accordance with the provisions of Section 905.

**Exception:** Standpipes shall be either temporary or permanent in nature, and with or without a water supply, provided that such standpipes comply with the requirements of Section 905 as to capacity, outlets and materials.

❖ Section 905 deals with installation; maintenance and supervision; building height and area; special occupancy application and type as related to standpipe systems in buildings under construction (see commentary, Section 905).

Temporary standpipes, whether dry or wet, are subject to the same requirements of Section 905 as permanent standpipes.

### SECTION 3314 AUTOMATIC SPRINKLER SYSTEM

**3314.1 Completion before occupancy.** In buildings where an *automatic sprinkler system* is required by this code or the *International Building Code*, it shall be unlawful to occupy

any portion of a building or structure until the *automatic sprinkler system* installation has been tested and *approved*, except as provided in Section 105.3.4.

❖ Section 105.3.4 is very clear in that when the sprinkler system is not tested and approved, the building cannot be occupied by the owner or tenants. In other words “no protection; no people” as one fire code official has put it. This is especially important in a building that has been given construction alternatives (i.e., increased travel distances, increased height and area, or reduced fire-resistance ratings) based on the installation of a sprinkler system, because the building is not safe for people when the system is not functional. Since the issuance of a Certificate of Occupancy is regulated by Section 111.1 of the IBC, the administration of this section should be coordinated with the building official.

**3314.2 Operation of valves.** Operation of sprinkler control valves shall be allowed only by properly authorized personnel and shall be accompanied by notification of duly designated parties. Where the sprinkler protection is being regularly turned off and on to facilitate connection of newly completed segments, the sprinkler control valves shall be checked at the end of each work period to ascertain that protection is in service.

❖ Closed control valves at the time of a fire are a major cause of sprinkler system failure. Only properly trained personnel should be operating these valves under the supervision of the fire prevention program superintendent, if available. The systems must be kept in service as much as possible and especially overnight or at the time of shift changes. If a fire watch is employed, duties should include monitoring these valves. The fire department must be notified when the system is out of service for an extended period of time because it responds to a sprinklered building differently than it does to an unsprinklered building.

### SECTION 3315 PORTABLE FIRE EXTINGUISHERS

**3315.1 Where required.** Structures under construction, *alteration* or demolition shall be provided with not less than one *approved* portable fire extinguisher in accordance with Section 906 and sized for not less than ordinary hazard as follows:

1. At each *stairway* on all floor levels where combustible materials have accumulated.
2. In every storage and construction shed.
3. Additional portable fire extinguishers shall be provided where special hazards exist including, but not limited to, the storage and use of flammable and *combustible liquids*.

❖ Portable extinguishers must be rated for the hazards protected. Section 906 and NFPA 10, the applicable standard for portable fire extinguishers, contain infor-

mation on fire extinguisher ratings. Other circumstances under which the fire code official may require additional extinguishers include workers using: open-flame devices; flammable or combustible liquids; welding or cutting equipment; or painting equipment for applying flammable or combustible finishes during both construction and demolition.

### SECTION 3316 MOTORIZED CONSTRUCTION EQUIPMENT

**3316.1 Conditions of use.** Internal-combustion-powered construction equipment shall be used in accordance with all of the following conditions:

1. Equipment shall be located so that exhausts do not discharge against combustible material.
  2. Exhausts shall be piped to the outside of the building.
  3. Equipment shall not be refueled while in operation.
  4. Fuel for equipment shall be stored in an *approved* area outside of the building.
- ❖ Motorized equipment, particularly equipment powered by an internal combustion engine, must be kept clear of combustibles, must have exhaust arranged so as not to create an environmental hazard, must not be fueled while hot and have fuel stored properly. These issues are similarly addressed in Sections 3303, 3304 and 3305.

### SECTION 3317 SAFEGUARDING ROOFING OPERATIONS

**3317.1 General.** Roofing operations utilizing heat-producing systems or other ignition sources shall be conducted in accordance with Sections 3317.2 and 3317.3 and Chapter 35.

- ❖ Although licensed and bonded contractors are often required for roofing operations by state or local laws or ordinances, the jurisdiction must establish who is authorized to conduct such activities. In addition to the requirements of Section 3317, the applicable hot work requirements of Chapter 35 also apply to certain roofing operations. Since the definition of “Hot work” in Section 202 specifically includes the installation of torch-applied roofing systems, permits for roofing operations utilizing such heat-producing systems that are ignition sources are required by Section 105.6.24. Additional permits for the use of combustible liquids and compressed gas may be also appropriate. Roofing permits are typically required by the IBC, as well.

**3317.2 Asphalt and tar kettles.** Asphalt and tar kettles shall be operated in accordance with Section 303.

- ❖ Section 303 regulates transportation, location, fueling, supervision, construction and fire protection of asphalt and tar kettles (see commentary, Section 303).

**3317.3 Fire extinguishers for roofing operations.** Fire extinguishers shall comply with Section 906. There shall be not less than one multipurpose portable fire extinguisher with a minimum 3-A 40-B:C rating on the roof being covered or repaired.

- ❖ Section 906 generally covers the location and requirements of portable fire extinguishers with a particular reference to asphalt kettles in Table 906.1. Section 303 also has requirements for extinguishers on the kettle, in the proximity of the kettle and on the roof. Fire extinguishers are to be fully charged and ready for service. Many construction sites are littered with building materials and debris. The kettle operator is responsible for maintaining an appropriate distance between the hot kettle and combustible materials.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 34: Tire Rebuilding and Tire Storage

## General Comments

Each year, over 270 million vehicle tires are disposed of in the United States. Recycling, reuse and energy recovery are having a major impact, but tire storage continues to present an environmental and fire safety hazard. The risk associated with tire fires demonstrates the need to address this problem. This chapter prescribes ways to prevent and control fires in tire rebuilding plants, tire storage and tire byproduct facilities.

Tire fires, although infrequent, are serious situations that are difficult to extinguish, expensive to clean up and often become major hazardous material incidents affecting entire communities, frequently requiring neighborhood evacuations and long, drawn-out fire-extinguishing operations. These fires threaten pollution of the air, soil and water. Federal and state agencies, municipalities and private companies have spent millions of dollars cleaning up tire fires across the country.

Scrap tires are not generally considered a hazardous waste; however, if a tire fire occurs, tires break down into hazardous compounds including gases, heavy metal and oil. The average passenger car tire is estimated to produce over 2 gallons (8 L) of oil when burned, according to the Rubber Manufacturers Association. Oil that exudes into ground and surface water as a result of tire fires is a significant environment pollutant. In some cases, this may trigger Environmental Protection Agency (EPA) Superfund cleanup status. For every million tires consumed by fire, about 55,000 gallons (208 175 L) of runoff oil can pollute the environment unless contained and collected. This oily material is also highly flammable.

Air pollution is also produced by tire fires. Air emissions may include polycyclic aromatic hydrocarbons (PAHs), benzene, styrene, phenols and butadiene. For more information on toxic air pollutants generated by tire fires, go to the U.S. EPA's Toxics Air Pollution website.

Notable tire fires include the following:

1. In 1983, 7 million tires burned in Rhinehart, Virginia, issuing a plume of smoke 3,000 feet (912 m) high and nearly 50 miles (80 km) long with air pollution emissions deposited in three states. The fire burned for nine months, polluting nearby water sources with lead and arsenic. The tire storage facility where the fire occurred is now being cleaned up as a Superfund site.
2. In 1999, a lightning strike ignited a tire fire in Westley, California. The tire dump contained millions of scrap tires located in a canyon in a coastal mountain range. The large smoke plume from the fire impacted nearby farming communities and caused widespread concern of potential health effects from exposure to the smoke emissions. The tire fire also produced large volumes of pyrolytic oil that flowed off the slope and into the drainage of an intermittent stream. This oil was ignited too, and the oil fire significantly increased the smoke emissions close to ground level. A response to the oil and tire fires was beyond the capabilities of local and state agencies. The EPA regional coordinator immediately responded using Oil Pollution Act of 1990 authority. It took 30 days to extinguish the fire. Total EPA response costs were \$3.5 million.

Waste tires are difficult to ignite, but once a tire fire starts, it is generally very hard to control and extinguish. Using water or foam to extinguish a tire fire is often futile. Water is best used to keep adjacent, unburned tires from igniting. Smothering a tire fire with dirt or sand is usually the best option for extinguishing fires. Typically, the sand or dirt is moved with heavy equipment to cover the burning tires. Putting out a tire fire can also be facilitated by removing unburned tires from the pile to lessen the fuel load.

## Purpose

The requirements of Chapter 34 are intended to prevent or control fires and explosions associated with the remanufacture and storage of tires. Additionally, these requirements are intended to minimize the impact of tire storage fires by segregating the various operations and controlling ignition sources. Although the finished product, the tire, is not an unusual hazard, once ignition occurs the fire is extremely difficult to extinguish. Facilities designed and constructed for tire remanufacture are regulated by the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) to reduce the impact of potential fires on buildings and the environment.

### SECTION 3401 GENERAL

**3401.1 Scope.** Tire rebuilding plants, tire storage and tire byproduct facilities shall comply with this chapter, other applicable requirements of this code and NFPA 13. Tire storage in buildings shall also comply with Chapter 32.

❖ In addition to the provisions of this chapter, NFPA 13 is referenced for sprinkler system design. Annex A of NFPA 13 also contains illustrations of various tire storage arrays. Spray operations using flammable or combustible solvents must also comply with Chapter 24. Sprinkler requirements for the bulk storage of rubber tires (defined in Section 202) may be found in Section 903.2.9.2. See the commentary to the above noted section for further discussion of fire protection for tire storage.

**3401.2 Permit required.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.6.46 for discussion of specific operational permits for tire rebuilding facilities and their operation and maintenance. The process also notifies the fire department of the need for pre-fire planning for the hazardous property.

### SECTION 3402 DEFINITIONS

**3402.1 Terms defined in Chapter 2.** Words and terms used in this chapter and defined in Chapter 2 shall have the meanings ascribed to them as defined therein.

❖ This section directs the code user to Chapter 2 for the proper application of the terms used in this chapter. Such terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (also see commentaries, Sections 201.1 through 201.4).

### SECTION 3403 TIRE REBUILDING

**3403.1 Construction.** Tire rebuilding plants shall comply with the requirements of the *International Building Code*, as to construction, separation from other buildings or other portions of the same building, and protection.

❖ This section requires that construction must comply with the IBC. At a minimum, tire rebuilding plants are

classified in Group F-1 (factory/industrial moderate hazard) in accordance with Section 306.2 of the IBC. Depending on an evaluation of the actual hazards presented by a given operation, which could include grinding, buffing or gluing of tires or tire components, the plant or portions of it might be classified in Group H.

**3403.2 Location.** Buffing operations shall be located in a room separated from the remainder of the building housing the tire rebuilding or tire recapping operations by a 1-hour *fire barrier*.

**Exception:** Buffing operations are not required to be separated where all of the following conditions are met:

1. Buffing operations are equipped with an *approved* continuous automatic water-spray system directed at the point of cutting action.
2. Buffing machines are connected to particle-collecting systems providing a minimum air movement of 1,500 cubic feet per minute (cfm) (0.71 m<sup>3</sup>/s) in volume and 4,500 feet per minute (fpm) (23 m/s) in-line velocity.
3. The collecting system shall discharge the rubber particles to an *approved* outdoor noncombustible or fire-resistant container that is emptied at frequent intervals to prevent overflow.

❖ This section specifies that the buffing operations must be separated from the other operations by a 1-hour fire barrier. The intent is identical to the intent regarding construction: to keep the higher hazard operations separate, thereby reducing the potential for a rapidly spreading fire.

The exception recognizes that meeting the three outlined conditions will afford protection equivalent to the 1-hour fire barrier required by this section.

**3403.3 Cleaning.** The buffing area shall be cleaned at frequent intervals to prevent the accumulation of rubber particles.

❖ This section recognizes the importance of keeping the buffing area clean to reduce the possibility of igniting waste material. A maintenance schedule should be developed for particle removal. Cleaning frequency should be determined by the amount of equipment in operation.

**3403.4 Spray rooms and booths.** Each spray room or spray booth where flammable or combustible solvents are applied, shall comply with Chapter 24.

❖ When flammable or combustible solvents are used, the room or spray booth must comply with the requirements of Chapter 24. This provision is intended to reduce the likelihood of igniting solvents used in this process and to keep the incident within manageable proportions if ignition should occur.

## SECTION 3404 PRECAUTIONS AGAINST FIRE

**3404.1 Open burning.** *Open burning* is prohibited in tire storage yards.

❖ Due to the stubborn nature of tire fires once they are ignited, this section prohibits open burning in tire storage areas where ignition of tires is a hazard.

**3404.2 Sources of heat.** Cutting, welding or heating devices shall not be operated in tire storage yards.

❖ Like the previous section, this section prohibits additional sources of ignition from welding or heating devices.

**3404.3 Smoking prohibited.** Smoking is prohibited in tire storage yards, except in designated areas.

❖ Except in smoking locations designated by the owner and approved by the fire code official, smoking is prohibited in tire storage yards. “No smoking” signs should be posted prominently in the yards and rigorously enforced. See the commentary to Section 310 for further information on smoking regulations.

**3404.4 Power lines.** Tire storage piles shall not be located beneath electrical power lines having a voltage in excess of 750 volts or that supply power to fire emergency systems.

❖ Should a fire occur in a tire storage yard, it could burn for some time before it is extinguished. Because these fires can be quite extensive and burn very hot, this precaution reduces the possibility that large electrical grids or emergency power supplies will be disabled for extended periods.

**3404.5 Fire safety plan.** The *owner* or individual in charge of the tire storage yard shall be required to prepare and submit to the *fire code official* a fire safety plan for review and approval. The fire safety plan shall include provisions for fire department vehicle access. Not less than one copy of the fire safety plan shall be prominently posted and maintained at the storage yard.

❖ This section requires that the owner develop a fire safety plan and submit it to the fire code official for approval. This plan should be as detailed as necessary, depending on the size and layout of the yard. This plan should also be coordinated with fire department pre-incident plans. The plan should include the size and composition of the storage material; layout of access and egress routes; the physical infrastructure of the roads and other possible access routes. Maps should include hydrant and water sources, interior access lanes, fuel load configurations and the location of utilities on the site. The composition of the storage pile should be indicated because shredded scrap or chip piles require a different fire-fighting approach than a pile of whole tires.

**3404.6 Telephone number.** The telephone number of the fire department and location of the nearest telephone shall be posted conspicuously in attended locations.

❖ This section requires posting of the fire department telephone number along with the location of the telephone in conspicuous locations.

## SECTION 3405 OUTDOOR STORAGE

**3405.1 Individual piles.** Tire storage shall be restricted to individual piles not exceeding 5,000 square feet (464.5 m<sup>2</sup>) of continuous area. Piles shall not exceed 50,000 cubic feet (1416 m<sup>3</sup>) in volume or 10 feet (3048 mm) in height.

❖ Whole tires (new, used or awaiting recycling), shredded tires or tire chip piles represent a fuel package of considerable volume and heat potential. To manage this hazard, the code places limitations on pile heights and sizes as a means of controlling the size of potential fires and facilitating fire-fighting operations.

**3405.2 Separation of piles.** Individual tire storage piles shall be separated from other piles by a clear space of not less than 40 feet (12 192 mm).

❖ The intent of this section is to create 40-foot (12 192 mm) clear firebreaks between piles of tire storage in all directions.

**3405.3 Distance between piles of other stored products.** Tire storage piles shall be separated by a clear space of not less than 40 feet (12 192 mm) from piles of other stored product.

❖ This section also requires a 40-foot (12 192 mm) clear firebreak from piles of other materials, not just other tire storage piles.

**3405.4 Distance from lot lines and buildings.** Tire storage piles shall be located not less than 50 feet (15 240 mm) from *lot lines* and buildings.

❖ This section requires increasing the firebreak to 50 feet (15 240 mm) from lot lines and buildings due to the potential exposure to buildings on the same property or on adjacent property.

**3405.5 Fire breaks.** Storage yards shall be maintained free from combustible ground vegetation for a distance of 40 feet (12 192 mm) from the stored material to grass and weeds; and for a distance of 100 feet (30 480 mm) from the stored product to brush and forested areas.

❖ Because dry grass and weeds represent a significant fuel accumulation and fire hazard, this section requires that all combustible vegetation (grasses and weeds) be kept at least 40 feet (12 192 mm) from storage piles. The distance is increased to 100 feet (30 480 mm) when next to brush or forested areas,

not only to protect the brush and forested area from a fire in a storage yard but also to protect the storage yard from a brush or forest fire. For additional information on the protection of such areas, see the *International Wildland-Urban Interface Code*<sup>®</sup> (IWUIC<sup>®</sup>). The clearances required by this section require a vegetation control program to reduce the hazards.

**3405.6 Volume more than 150,000 cubic feet.** Where the bulk volume of stored product is more than 150,000 cubic feet (4248 m<sup>3</sup>), storage arrangement shall be in accordance with the following:

1. Individual storage piles shall comply with size and separation requirements in Sections 3405.1 through 3405.5.
2. Adjacent storage piles shall be considered a group, and the aggregate volume of storage piles in a group shall not exceed 150,000 cubic feet (4248 m<sup>3</sup>).

Separation between groups shall be not less than 75 feet (22 860 mm) wide.

❖ This section correlates with the requirements in Section 3405.1, which allow storage piles up to 50,000 cubic feet (1416 m<sup>3</sup>) in volume. There is really no reason to limit the number of piles but rather to limit the volume of storage. This section limits the group volume to 150,000 cubic feet (4248 m<sup>3</sup>) and clarifies that the piles must still comply with Sections 3405.1 through 3405.5 on pile size and separations. Basically, with the 75-foot (22 860 mm) separation requirement between groups, unlimited amounts of storage would be allowed.

**3405.7 Location of storage.** Outdoor waste tire storage shall not be located under bridges, elevated trestles, elevated roadways or elevated railroads.

❖ This section restricts where waste tire storage may be located. As a result of past fire experiences that created extended disruption in transportation, storage is prohibited under elevated roadways and bridges.

### SECTION 3406 FIRE DEPARTMENT ACCESS

**3406.1 Required access.** New tire storage yards shall be provided with fire apparatus access roads in accordance with Section 503 and Section 3406.2. Existing tire storage yards shall be provided with fire apparatus access roads where required in Chapter 11.

❖ Fire apparatus access roads must be arranged to provide clear, unobstructed access to required yard hydrants, if provided, and all points of the yard storage area. Turn-arounds and turning radii must be sized so that the fire apparatus can maneuver to protect exposures as well as fire fighters. Access roads must also comply with Section 503. Fire department access for existing tire storage yards must comply with Sections 1106.1 through 1106.1.2. Appendix D, where adopted by the jurisdiction, covers design

guidelines for access roads. Note that the appendices are not considered as part of the code unless specifically adopted. See Section 1 of the sample adopting ordinance on page xxi of the code book.

**3406.2 Location.** Fire apparatus access roads shall be located within all pile clearances identified in Section 3405.4 and within all fire breaks required in Section 3405.5. Access roadways shall be within 150 feet (45 720 mm) of any point in the storage yard where storage piles are located, not less than 20 feet (6096 mm) from any storage pile.

❖ In order to provide adequate access for fire suppression operations in tire storage yard fires, fire apparatus access roads must be located within all pile clearances and within all firebreaks. No portion of a pile is to be more than 150 feet (45 720 mm) from an access road and no less than 20 feet (6096 mm) from any storage pile. Maintaining a 20-foot (6096 mm) clearance between storage piles and the edge of the fire apparatus access road reduces the likelihood that the collapse of a pile [limited to 10 feet (3048 mm) in height by Section 3405.1] will totally obstruct access.

### SECTION 3407 FENCING

**3407.1 Where required.** Where the bulk volume of stored material is more than 20,000 cubic feet (566 m<sup>3</sup>), a firmly anchored fence or other *approved* method of security that controls unauthorized access to the storage yard shall surround the storage yard.

❖ Perimeter fences for site security are required to limit access to stored materials and deter theft, vandalism and arson in storage yards where the volume of tire material stored exceeds 20,000 cubic feet (566 m<sup>3</sup>).

**3407.2 Construction.** The fence shall be constructed of *approved* materials and shall be not less than 6 feet (1829 mm) high and provided with gates at least 20 feet (6096 mm) wide.

❖ Owners should be encouraged to construct noncombustible fences. Chain-link fencing is an excellent choice because it can be firmly anchored and requires little maintenance. To accommodate fire apparatus, all gates must be at least 20 feet (6096 mm) wide. Depending on local security concerns, fences may be topped with barbed wire for intruder control to further enhance the level of security provided. Such an installation should be approved by the fire code official and the local administrative authority, since some communities have ordinances or a zoning code that prohibits the use of barbed wire on fences.

**3407.3 Locking.** Gates to the storage yard shall be locked when the storage yard is not staffed.

❖ This section states that access gates to the storage yard are to be locked when not staffed to deter unauthorized entry. Since the yard entrance is considered part of the fire apparatus road network required for

the yard, gates must also comply with the provisions of Section 503.6.

**3407.4 Unobstructed.** Gateways shall be kept clear of obstructions and be fully openable at all times.

- ❖ This section requires that gates be accessible and be fully openable at all times, which will allow full and quick access for fire apparatus.

### SECTION 3408 FIRE PROTECTION

**3408.1 Water supply.** A public or private fire protection water supply shall be provided in accordance with Section 508. The water supply shall be arranged such that any part of the storage yard can be reached by using not more than 500 feet (152 m) of hose.

- ❖ This section requires that a fire protection water supply, in accordance with Section 508, be provided to the storage yard. Open storage yards are often located substantial distances from public fire mains, which may mean that water must be delivered to the scene by fire department tankers. This requirement should be included in both the prefire plan and the facility fire safety plan required by Section 3404.5. Alternative water supplies, such as a stream, lake or other body of water in the vicinity, should be explored.

**3408.2 Fire extinguishers.** Buildings or structures shall be provided with portable fire extinguishers in accordance with Section 906. Fuel-fired vehicles operating in the storage yard shall be equipped with a minimum 2-A:20-B:C-rated portable fire extinguisher.

- ❖ This section and Section 906 require that fire extinguishers be available. Portable fire extinguishers are provided for incipient fire control. These appliances should be located where they are readily available. They are also required on fuel-fired vehicles operating in the yard.

### SECTION 3409 INDOOR STORAGE ARRANGEMENT

**3409.1 Pile dimensions.** Where tires are stored on-tread, the dimension of the pile in the direction of the wheel hole shall be not more than 50 feet (15 240 mm). Tires stored adjacent to or along one wall shall not extend more than 25 feet (7620 mm) from that wall. Other piles shall be not more than 50 feet (15 240 mm) in width.

- ❖ This section places further restrictions on tire storage to maintain fire-fighting access to the stored tires in case of a fire. When the tires are stored on their tread, storage piled against a wall (i.e., closed on one end) must not extend more than 25 feet (7620 mm) from the wall. Where the on-tread piles are open on both ends, the length of the pile must not exceed 50 feet (15 240 mm), measured in the direction of the wheel hole. These limitations enhance hose stream

access to the interior of the pile. Piles of any other configuration cannot exceed 50 feet in any dimension. Annex A to Chapter 3 of NFPA 13 includes example illustrations of tire storage arrays.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Prevention and Management of Scrap Tire Fires*. Washington, DC: Rubber Manufacturers Association.

# Chapter 35: Welding and Other Hot Work

## General Comments

Welding and other hot work are frequent ignition sources. Statistics from a major property insurance company for a recent 5-year period showed 290 hot-work-related ignitions that led to losses of \$407 million, or an average of \$1.4 million per incident. Of these 290 losses, 42 percent were caused by employees and 58 percent were caused by outside contractors. To compare the magnitude of these losses, this same insurance company saw 395 fires associated with housekeeping and 262 losses associated with smoking. The average poor housekeeping loss was \$902,000; the average smoking loss was about \$440,000.

Both hot work operations themselves and the equipment and materials associated with such work can create significant ignition and fire hazards. Hot work creates sparks and slag and gives off heat. Materials, such as acetylene and oxygen, are used in gas welding and an electrical current is used for arc welding. Additionally, these activities tend to occur in buildings that are not designed for these materials and hazards. Hot work often occurs within buildings undergoing renovations, which are even more susceptible to ignition. Hot work can be either temporary or ongoing. Permanent installations generally have the ability to address ignition hazards more consistently.

Several different types of hot work would fall under the requirements found in Chapter 35, including both gas and electric arc methods and any open-torch operations.

The important factor in avoiding ignition hazards is preparing for and monitoring hot-work activities. Primarily these precautions relate to basic fire prevention and fire control. Chapter 35 details a program that allows a facility to assign an employee to be the administrator of a hot-work program as defined in Section 202 of the code. This administrator would be allowed to issue permits for work on site, would be required to perform pre-work inspections and would be responsible for ensuring that the correct safety measures are taken. The fire code official has the authority to make periodic checks of these records, so they must be made available for at least 48 hours after the work ends. This chapter provides specific requirements for the protection of combustibles and for fire watches.

Personnel undertaking hot work will have varying levels of familiarity with the building or facility where the work is being done. Often, the person undertaking hot work is not an employee at the facility and may not be under the direct control of the hot work program manager. The qualifications of the hot work operator are discussed in Section 3503.4.

## Purpose

This chapter covers requirements for safety in welding and other types of hot work by reducing the potential for fire ignitions. Many of the activities of this chapter focus on the actions of occupants. As noted, welding and other hot work are responsible for a large percentage of fire ignitions that usually result in large losses.

## SECTION 3501 GENERAL

**3501.1 Scope.** Welding, cutting, open torches and other hot work operations and equipment shall comply with this chapter.

❖ Welding and cutting operations, whether electric or gas, are methods for joining or separating metals. In either case, a strong heat energy source is applied to the material, commonly known as the workpiece, to perform the required operation. Specific hazards associated with each type of welding or cutting apparatus and process may vary greatly, but, in each case, two elements are always present that may cause or contribute to the spread of fire—a heat energy source and air or oxygen. As a result, efforts

to control fuels and reduce the impact of fires if they occur are the focuses of these requirements.

**3501.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants must demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit. The process also notifies the fire department of the need for prefire planning for the hazardous property and helps to verify that proper procedures will be followed.

The actual permit requirements for hot work are in Section 105.6.24. This section lists several specific instances where a permit would be required for hot work operations. One of the items would allow a single permit to be issued to allow a hot work program. This program will be explained in more detail in this chapter, but essentially it allows a person on site to manage the hot work activities. This program has a number of safety requirements, including fire department review of documentation at the facility for a minimum of 48 hours after the work is completed. Generally, this type of permit provides much needed flexibility for facilities where hot work is a common occurrence.

**3501.3 Restricted areas.** Hot work shall only be conducted in areas designed or authorized for that purpose by the personnel responsible for a Hot Work Program. Hot work shall not be conducted in the following areas unless approval has been obtained from the *fire code official*:

1. Areas where the sprinkler system is impaired.
  2. Areas where there exists the potential of an explosive atmosphere, such as locations where flammable gases, liquids or vapors are present.
  3. Areas with readily ignitable materials, such as storage of large quantities of bulk sulfur, baled paper, cotton, lint, dust or loose combustible materials.
  4. On board ships at dock or ships under construction or repair.
  5. At other locations as specified by the *fire code official*.
- ❖ This section describes restrictions on the areas where hot work can take place. Normally hot work activities are restricted to designated areas; however, there are times when hot work may be needed in specific locations, such as in a building undergoing renovation. This section presents this list as a way to verify that when hot work is needed, notification of the activity is made and special precautions are taken. In addition, this section also authorizes the fire code official to add other areas where special approval would be necessary. The code cannot anticipate all potentially hazardous situations. For this reason, this section does not explicitly prohibit hot work in these areas; it simply requires special approval.

**3501.4 Cylinders and containers.** *Compressed gas* cylinders and fuel containers shall comply with this chapter and Chapter 53.

- ❖ This section is focused on any cylinders or containers used to store gases used in hot work operations, primarily oxygen and acetylene. Oxygen is an oxidizing gas and acetylene is a highly flammable gas and an unstable reactive Class 2. This section requires that any specific requirements within Chapter 35 be addressed along with the general requirements found in Chapter 53 regarding compressed gases.

**3501.5 Design and installation of oxygen-fuel gas systems.** An oxygen-fuel gas system with two or more manifolded cylinders of oxygen shall be in accordance with NFPA 51.

- ❖ This section references NFPA 51 for any oxygen-fuel gas systems where any number of oxygen containers are manifolded. The scope of this standard specifically states that it addresses only situations where two or more cylinders are manifolded.

## SECTION 3502 DEFINITIONS

**3502.1 Definitions.** The following terms are defined in Chapter 2:

**HOT WORK.**

**HOT WORK AREA.**

**HOT WORK EQUIPMENT.**

**HOT WORK PERMITS.**

**HOT WORK PROGRAM.**

**RESPONSIBLE PERSON.**

**TORCH-APPLIED ROOF SYSTEM.**

- ❖ Definitions of terms can help in the understanding and application of code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 3503 GENERAL REQUIREMENTS

**3503.1 General.** Hot work conditions and operations shall comply with this chapter.

- ❖ This section is generally applicable to all hot work activities, which would include welding and cutting, but also includes activities such as torch-applied roof systems. The requirements are primarily related to the hot work permit program, qualifications and general administrative provisions related to fire safety procedures.

**3503.2 Temporary and fixed hot work areas.** Temporary and fixed hot work areas shall comply with this section.

- ❖ These provisions are applicable to both temporary and permanent activities because the same fire hazard exists in both cases. Temporary situations generally pose a greater hazard, however, because they typically occur in areas not designed for such ignition hazards. For example, hot work is fairly common in buildings undergoing renovation.

**3503.3 Hot work program permit.** Hot work permits, issued by an *approved* responsible person under a hot work program, shall be available for review by the *fire code official* at the time the work is conducted and for 48 hours after work is complete.

❖ Because individual facilities are allowed to manage the process of issuing permits, permit information must be available to the fire code official for periodic review. As noted in the definition for “Hot work permits,” the records must be available for at least 48 hours following completion of work. The 48-hour period gives the fire code official the time necessary to verify that permitting was done according to established procedures if a fire should occur.

This section does not require that the permits be submitted to the fire code official; it asks only that they be available for review. This section, along with Section 3503.5, is part of the package that allows a periodic random check of the permitting and hot work administrative procedures.

**3503.4 Qualifications of operators.** A permit for hot work operations shall not be issued unless the individuals in charge of performing such operations are capable of performing such operations safely. Demonstration of a working knowledge of the provisions of this chapter shall constitute acceptable evidence of compliance with this requirement.

❖ The definitions for “Hot work program” and “Responsible person” in Section 202 are specifically aimed at the individual who coordinates issuing and managing permits. The qualifications of the operator and administrative follow-through are critical aspects in preventing hot work fires and are the subjects of this section.

Operators of welding and cutting apparatus must demonstrate understanding of, competence in and responsibility for their activities. A thorough understanding of proper welding and cutting safety precautions as outlined in this chapter and NFPA 51 is a minimum requirement. Operators should also be familiar with general industry standards, as well as federal and state Occupational Safety and Health Administration (OSHA) regulations, manufacturers’ recommendations regarding equipment being operated and standards of good practice as detailed by the American Welding Society (AWS), National Fire Protection Association (NFPA) or other professional safety organization. Operators must be capable of physically demonstrating their knowledge of proper safety practices when required by the fire code official. Written competency examinations are not required by this section.

**3503.5 Records.** The individual responsible for the hot work area shall maintain “prework check” reports in accordance with Section 3504.3.1. Such reports shall be maintained on the premises for not less than 48 hours after work is complete.

❖ This section is specific to the hot work program administrator and requires that the prework checks be available for review for at least 48 hours. This allows periodic checks by the fire code official and

would allow reasonable time for review of documentation after a fire to determine if welding or cutting was implicated in any fire situation during the previous permit period.

**3503.6 Signage.** Visible hazard identification signs shall be provided where required by Chapter 50. Where the hot work area is accessible to persons other than the operator of the hot work equipment, conspicuous signs shall be posted to warn others before they enter the hot work area. Such signs shall display the following warning:

CAUTION  
HOT WORK IN PROGRESS  
STAY CLEAR

❖ Signage, as with many other code applications, is used as a method to warn of hazards. This is especially critical in areas where people unfamiliar with the hazards may be present. For example, this may be more important during renovations in an occupied office building. The signage requirements apply to both temporary and fixed situations, and the visibility of the signs must be consistent with the requirements of Chapter 50.

## SECTION 3504 FIRE SAFETY REQUIREMENTS

**3504.1 Protection of combustibles.** Protection of combustibles shall be in accordance with Sections 3504.1.1 through 3504.1.9.

❖ This section deals with basic fire safety activities that should be addressed when undertaking hot work. Some of the requirements may be more applicable to certain types of hot work than others because of the specific hazards presented. The three specific issues addressed include the protection of the area and fire protection systems located in the vicinity of the hot work; requirements for fire watches during and after the hot work is undertaken; and the administrative procedures used to confirm that all the applicable safety steps have been taken. This section focuses primarily on the protection of combustibles through both passive and active means. More specifically, combustibles must either be removed or protected by fire protection systems that remain operational during hot work activities.

**3504.1.1 Combustibles.** Hot work areas shall not contain combustibles or shall be provided with appropriate shielding to prevent sparks, slag or heat from igniting exposed combustibles.

❖ This section requires that combustibles either be removed from the area or properly shielded from sparks or excessive heat that could ignite a fire. A shield may need to be both noncombustible and insulating. In the case of sparks that provide little heat, a metal shield may be allowable. If the hot work operation gives off large amounts of heat, such as the use

of a torch, the shield would also need to resist the transmission of heat.

**3504.1.2 Openings.** Openings or cracks in walls, floors, ducts or shafts within the hot work area shall be tightly covered to prevent the passage of sparks to adjacent combustible areas, or shielded by metal fire-resistant guards, or curtains shall be provided to prevent passage of sparks or slag.

❖ Openings or cracks in walls, floors, ducts or shafts within the hot work area shall be tightly covered to prevent the passage of sparks to adjacent combustible areas; shields constructed of metal fire-resistant guards or curtains shall be provided to prevent passage of sparks or slag.

Openings or cracks in walls are potential travel paths for sparks or slag from hot work operations. It is very common for a partition in an existing building to have penetrations for pipes or other utilities. Sparks that penetrate a partition or wall have the potential of starting a fire in adjoining rooms or areas.

**3504.1.3 Housekeeping.** Floors shall be kept clean within the hot work area.

❖ This section addresses a basic fire safety issue of keeping the floors in the hot work area clean. Accumulations of dust and other high-surface-area materials are highly susceptible to ignition, flash fires and explosions. This kind of housekeeping is doubly important for welding and similar hot work in a building under renovation because such buildings tend to have higher concentrations of dusts and other hazardous combustibles.

**3504.1.4 Conveyor systems.** Conveyor systems that are capable of carrying sparks to distant combustibles shall be shielded or shut down.

❖ Conveyor systems, particularly in industrial applications, constitute a hazard. More specifically, if a welding operation ignites a fire on a conveyor system, the fire can move throughout the parts of the building served by the conveyor and possibly ignite multiple fires. Generally, most fire protection features are not designed for multiple-fire ignitions, but instead are designed for a single event. For instance, a sprinkler system has a specific design density for a specified area of operation. If the fire demand is higher than what the sprinkler system was designed to handle, the water supply and pressure could be inadequate and the sprinkler system will likely be overcome. Also, because the fire is moving, it is more difficult for the sprinklers to activate because the sprinkler might not heat sufficiently. This results in the fire growing larger before intervention from the fire protection systems. Even if a sprinkler does activate, it may not be addressing the origin of the fire.

**3504.1.5 Partitions.** Partitions segregating hot work areas from other areas of the building shall be noncombustible. In fixed hot work areas, the partitions shall be securely con-

nected to the floor such that no gap exists between the floor and the partition. Partitions shall prevent the passage of sparks, slag, and heat from the hot work area.

❖ The partitions discussed in this section act as shields, as described in Section 3504.1.1. The requirements state that partitions must be installed so that there is no room for sparks, slag or heat to pass beyond the hot work area. These requirements are primarily geared toward fixed hot work areas where the conditions can be more permanently controlled. Hot work operations in temporary locations will likely not have partitions installed solely for the purpose of protecting combustible materials. Section 3504.1.1 would be more applicable to temporary hot work.

**3504.1.6 Floors.** Fixed hot work areas shall have floors with noncombustible surfaces.

❖ The requirement for noncombustible floor surfaces is specific to fixed hot work operations because a fixed location situation can be more easily controlled than a temporary hot work operation. In many cases, program administrators will have little control over the type of floor and the location of combustibles in the areas where temporary hot work occurs.

**3504.1.7 Precautions in hot work.** Hot work shall not be performed on containers or equipment that contain or have contained flammable liquids, gases or solids until the containers and equipment have been thoroughly cleaned, inerted or purged; except that "hot tapping" shall be allowed on tanks and pipe lines where such work is to be conducted by *approved* personnel. Hot work on flammable and *combustible liquid* storage tanks shall be conducted in accordance with Section 3510.

❖ The title of this section is somewhat misleading because the section pertains specifically to hot work on containers or equipment that may contain flammable or combustible liquids. Simply because a container is empty does not mean that it is safe to conduct hot work. In fact, the vapors are usually much more susceptible to ignition than the liquid itself; therefore, before any hot work can occur, the vapors and liquids must be purged.

This section does allow hot work on containers or piping without the specific removal of liquids. This is termed "hot tapping" and must be done by an experienced individual. Hot tapping is extremely dangerous since the piping or tank still contains flammable or combustible liquids and, therefore, the personnel performing this work must be aware of the hazards and be able to safeguard the operation. This section also points the user to Section 3510, which contains specific safeguards for hot work on flammable and combustible liquid storage tanks and references NFPA 326 for these hot work operations. Note that NFPA 326 does not cover hot tapping, therefore other industry standards and safeguards must be used.

**3504.1.8 Sprinkler protection.** Automatic sprinkler protection shall not be shut off while hot work is performed. Where hot work is performed close to automatic sprinklers, noncombustible barriers or damp cloth guards shall shield the individual sprinkler heads and shall be removed when the work is completed. If the work extends over several days, the shields shall be removed at the end of each workday. The *fire code official* shall approve hot work where sprinkler protection is impaired.

❖ One of the major sources of losses related to hot work occurs either at buildings under construction or under renovation where an installed automatic sprinkler system has been shut off. In many cases, there is a concern that the automatic sprinkler system will be damaged or will accidentally activate during construction so the system is temporarily shut off. Unfortunately, this is the most likely time for an ignition to occur. Frequently, large manufacturing, storage and institutional occupancies intentionally perform much of their heavy maintenance work during slow periods to reduce service disruptions. Under such circumstances, care must be exercised so that sprinkler outages do not coincide with welding or cutting operations.

To reduce the likelihood of accidental operation of sprinklers if welding or cutting operations must be performed in close proximity to sprinklers or sprinkler piping, this section includes some methods of protecting the sprinkler without shutting the system down. It is important to note that any protection placed onto or near the sprinklers is to be removed at the end of each workday. Field welding or cutting operations performed on sprinkler piping is prohibited by NFPA 13.

**3504.1.9 Fire detection systems.** *Approved* special precautions shall be taken to avoid accidental operation of automatic fire detection systems.

❖ As with sprinkler systems, there is a concern for false alarms. This section does not give a methodology for protecting against false alarms but does state that precautions must be taken. There are many different technologies and approaches for fire detection systems in addition to the building-specific applications. Each situation should be looked at individually. One possible scenario would be to shut down smoke detectors in a hot work area and put a fire watch in place. As soon as the hot work is complete, those detectors are placed back on line.

**3504.2 Fire watch.** Fire watches shall be established and conducted in accordance with Sections 3504.2.1 through 3504.2.6.

❖ This section is critical to avoiding ignition as a result of hot work operations. The six subsections list criteria for establishing and conducting a fire watch.

**3504.2.1 When required.** A fire watch shall be provided during hot work activities and shall continue for not less than 30 minutes after the conclusion of the work. The *fire code official*, or the responsible manager under a hot work pro-

gram, is authorized to extend the fire watch based on the hazards or work being performed.

**Exception:** Where the hot work area has no fire hazards or combustible exposures.

❖ Fire watches are required any time hot work is undertaken and are to extend a minimum of 30 minutes beyond completion of the work. The time may need to be extended, depending on the specific hazards present, such as a large amount of combustibles or the facility being open to the public. There is an exception for those situations when combustibles are simply not present. The combustibility of the floor should also be considered.

**3504.2.2 Location.** The fire watch shall include the entire hot work area. Hot work conducted in areas with vertical or horizontal fire exposures that are not observable by a single individual shall have additional personnel assigned to fire watches to ensure that exposed areas are monitored.

❖ This section states that a fire watch is required in all hot work areas. The term “hot work area” is defined but is necessarily a general definition because many things will affect the extent of the area. These factors include the type and application of hot work, the configuration and layout of the space and the types of materials in the area. Also, where, for example, many pieces of equipment act as obstructions or the shape of the room or placement of partitions blocks a line of sight, the fire watch may need to consist of more than one person.

**3504.2.3 Duties.** Individuals designated to fire watch duty shall have fire-extinguishing equipment readily available and shall be trained in the use of such equipment. Individuals assigned to fire watch duty shall be responsible for extinguishing spot fires and communicating an alarm.

❖ The individuals who undertake a fire watch have specific duties. They not only need to watch for and notify of an ignition of combustibles, they also need to be prepared to extinguish spot fires with portable extinguishers. Intervention when fires are small is the best line of defense in extinguishing and controlling fires. Waiting until the fire department or fire brigade arrives will allow a fire to increase dramatically in size and intensity.

**3504.2.4 Fire training.** The individuals responsible for performing the hot work and individuals responsible for providing the fire watch shall be trained in the use of portable fire extinguishers.

❖ A person conducting a fire watch must be trained to operate fire extinguishers located in the watch area. As noted previously, intervention in the incipient stages of a fire is extremely effective.

**3504.2.5 Fire hoses.** Where hoselines are required, they shall be connected, charged and ready for operation.

❖ This section states that when a hoseline is required, it should be properly charged and ready for use during a fire watch. Otherwise, the effectiveness is much lower. As already noted, fires are more likely to be

extinguished or controlled when intervention occurs early. An uncharged hoseline will defeat the purpose of the equipment.

**3504.2.6 Fire extinguisher.** Not less than one portable fire extinguisher complying with Section 906 and with a minimum 2-A:20-B:C rating shall be readily accessible within 30 feet (9144 mm) of the location where hot work is performed.

❖ This section specifies that the fire extinguishers required for a fire watch must be all-purpose extinguishers for all fire types; the potential fire type will vary with the type of hot work and the surrounding combustibles. The 30-foot (9144 mm) travel distance specified here is more restrictive than what is required for similar ratings of extinguishers in Section 906. Table 906.3(2) would allow a maximum travel distance of 50 feet (15 240 mm) for other applications with the same rating of extinguisher.

**3504.3 Area reviews.** Before hot work is permitted and not less than once per day while the permit is in effect, the area shall be inspected by the individual responsible for authorizing hot work operations to ensure that it is a fire safe area. Information shown on the permit shall be verified prior to signing the permit in accordance with Section 105.6.

❖ This section is part of the hot work program. It requires the person administering the program to check the area where hot work has been permitted. A specific checklist is contained within Section 3504.3.1 to provide guidance as to what is to be inspected. Because the authority is given to those other than the fire department to issue permits and manage the safety of hot work operations, documentation of the inspections is a mechanism for review by the fire department to verify that operations are proceeding safely.

**3504.3.1 Pre-hot-work check.** A pre-hot-work check shall be conducted prior to work to ensure that all equipment is safe and hazards are recognized and protected. A report of the check shall be kept at the work site during the work and available upon request. The pre-hot-work check shall determine all of the following:

1. Hot work equipment to be used shall be in satisfactory operating condition and in good repair.
2. Hot work site is clear of combustibles or combustibles are protected.
3. Exposed construction is of noncombustible materials or, if combustible, then protected.
4. Openings are protected.
5. Floors are kept clean.
6. No exposed combustibles are located on the opposite side of partitions, walls, ceilings or floors.
7. Fire watches, where required, are assigned.
8. *Approved* actions have been taken to prevent accidental activation of suppression and detection equipment in accordance with Sections 3504.1.8 and 3504.1.9.

9. Fire extinguishers and fire hoses (where provided) are operable and available.

❖ As noted in Section 3504.3, this section includes a list of items to be reviewed in hot work areas. These checks confirm that the requirements in Sections 3504.1 and 3504.2 are actually being met.

## SECTION 3505 GAS WELDING AND CUTTING

**3505.1 General.** Devices or attachments mixing air or oxygen with combustible gases prior to consumption, except at the burner or in a standard torch or blow pipe, shall not be allowed unless *approved*.

❖ The materials used for gas cutting and welding are generally materials such as acetylene and oxygen. Acetylene is a flammable gas and oxygen is an oxidizer. Together, these gases produce an intense high-temperature flame. The high temperature of combustion is excellent for welding and cutting and, at the same time, is a significant ignition hazard. Acetylene is the preferred gas because it burns at high temperatures, but other flammable gases, such as methyl acetylene-propadiene and propylene, are also sometimes used. The other major type of welding is electric arc welding, which is discussed in Section 3506.

Because of the enriched combustion process created by pure oxygen, this section prohibits mixing oxygen and air prior to use with the flammable gas of choice for welding or cutting.

**3505.2 Cylinder and container storage, handling and use.** Storage, handling and use of *compressed gas* cylinders, containers and tanks shall be in accordance with this section and Chapter 53.

❖ A major hazard with gas welding and cutting is not necessarily the hot work operation itself, but instead the materials used in the operation. These gases are stored in cylinders and manifolded into systems for use. The storage, handling and use of such gases is specifically regulated by Chapter 53, which addresses issues such as security, valve protection, separation from hazardous materials and container and cylinder marking (see commentary, Chapter 53). Note that oxygen-fuel gas systems where two or more cylinders of oxygen are manifolded must meet the requirements of NFPA 51.

**3505.2.1 Cylinders connected for use.** The storage or use of a single cylinder of oxygen and a single cylinder of fuel gas located on a cart shall be allowed without requiring the cylinders to be separated in accordance with Section 5003.9.8 or 5003.10.3.6 when the cylinders are connected to regulators, ready for service, equipped with apparatus designed for cutting or welding and all of the following:

1. Carts shall be kept away from the cutting or welding operation in accordance with Section 3505.5 or fire-resistant shields shall be provided.

2. Cylinders shall be secured to the cart to resist movement.
  3. Carts shall be in accordance with Section 5003.10.3.
  4. Cylinder valves not having fixed hand wheels shall have keys, handles or nonadjustable wrenches on valve stems while the cylinders are in service.
  5. Cylinder valve outlet connections shall conform to the requirements of CGA V-1.
  6. Cylinder valves shall be closed when work is finished.
  7. Cylinder valves shall be closed before moving the cart.
- ❖ The use of “welding carts” has been common practice as a means to secure cylinders of oxygen and fuel-gas used in cutting and welding operations. The carts serve as a means to safely secure cylinders, as well as a means to hold flexible hose, torches and, in some cases, safety equipment such as goggles or eye shields and welding rods (see Commentary Figure 3505.2.1).

This section was added to the code because a number of fire code officials were considering a compressed gas cylinder containing a fuel gas located adjacent to a cylinder of compressed or cryogenic oxygen on a cart to be incompatible hazardous materials based on the definition of “Incompatible materials” in Section 202.

The requirements for separation of incompatible materials under Sections 5003.9.8 and 5003.10.3.6 present a practical difficulty when the quantity of materials is limited. Allowing single cylinders of oxygen and fuel-gas, with additional controls to address the typical use condition, provides a more rational and comprehensive approach to safe use than outright prohibition that is out of convention with a common practice.

This section correctly treats a single cylinder of fuel gas adjacent to a cylinder of oxygen as being available for service as a closed use system rather than being considered storage. It requires that both the oxygen and fuel gas cylinder be equipped with a pressure regulator, which is a valve that reduces the pressure of a gas to safe levels for use and consumption. Section 3505.4 requires acetylene gas cylinders be equipped with a pressure regulator that limits the pressure to 15 pounds per square inch gauge (psig) (103 kPa) or less. For other fuel gases such as liquefied petroleum gas (LP-gas) and MAPP gas (an LP-gas mixed with methylacetylene-propadiene to yield a higher combustion temperature in oxygen), Section 3509.1 requires that fuel gas hose systems comply with NFPA 51, which has requirements for pressure regulators. Regulators for oxygen and fuel gas are required by NFPA 51 to be listed for use with the particular gases being used.

In addition to the requirements in NFPA 51, this section also specifies requirements for the protection of the cylinders and their contents. Cylinders must be adequately secured on the cart to limit their movement. Prior to moving the cart, the cylinder valves

must be closed. Fuel gas cylinder valves that utilize square-head keys or similar valves that are not equipped with fixed hand wheels are required to be provided with their operating device on the cylinder to facilitate prompt and easy operation of the cylinder valve during use. Cylinders must also be protected from hot slag and sparks by being located away from the hot work activity or by protection using fire-resistant shields.

As an additional safety feature to prevent the connection of a fuel gas pressure regulator to an oxygen cylinder (or vice-versa), Item 5 requires that cylinder fittings comply with Compressed Gas Association (CGA) Standard V-1. Flammable gas cylinder valves are normally constructed using left-handed threaded connections and the outlet diameter is sized so a pressure regulator designed for oxygen cannot be accidentally connected to a cylinder containing a fuel gas.

In further substantiation of this new section, it should be pointed out that the CGA performed an extensive survey of its member companies who reported that in 75 years of experience, no regulator failures, hose fires or other incidents were attributable to single cylinders of oxygen and acetylene located next to each other and that most accidents associated with the use of oxygen regulators are failures and explosions caused by contamination.

It should also be noted that nothing in this section exempts or waives the requirements of Chapter 50 for maximum allowable quantities (MAQs), and the storage, handling and use of hazardous materials, or the requirements in Chapters 53, 58 and 63 for compressed gases, flammable gases and oxidizing

**Figure 3505.2.1**  
**TYPICAL WELDING CART**

gases, respectively. A building in which oxygen and fuel gas supplies are stored and used must maintain quantities below the MAQs for indoor control areas. If the amount in storage and closed use exceeds the MAQ in one or more control areas the building must be constructed as a Group H-2 occupancy.

**3505.2.1.1 Individual cart separation.** Individual carts shall be separated from each other in accordance with Section 5003.9.8.

❖ In buildings housing more than one cart containing oxygen and fuel gas used for cutting and welding, this section requires that individual carts be separated from one another in accordance with Section 5003.9.8. For cutting and welding carts, this requires a minimum 20-foot (6096 mm) separation between each cart or the construction of noncombustible line-of-sight barriers that extend a minimum of 18 inches (457.2 mm) above and to the sides of each cart.

This section also recognizes the allowance created by Section 3505.2.1 to allow a single cylinder of oxidizing gas and a single cylinder of fuel gas to be located on an individual cart, and addresses the possible concern over multiple carts stored in close proximity to one another. If the number of carts were to grow, the quantity controls imposed by the MAQs per control area would trigger the use of a Group H occupancy when the MAQ of 1,000 cubic feet (23.32 m<sup>3</sup>) of flammable gas was exceeded (three or four carts, depending on the fuel gas). However, using MAQ as a quantity control was not the intent of Section 3505.2.1.

**3505.3 Precautions.** Cylinders, valves, regulators, hose and other apparatus and fittings for oxygen shall be kept free from oil or grease. Oxygen cylinders, apparatus and fittings shall not be handled with oily hands, oily gloves, or greasy tools or equipment.

❖ Oxygen, which is an oxidizer, will increase the intensity of combustion; therefore, traces of combustibles, such as oils or greases, that normally pose a moderate hazard will be a higher hazard when found on cylinders of oxygen. Keeping gas cylinders free of grease and oil is especially important because gas-welding operations use flammable gases in combination with oxygen.

**3505.4 Acetylene gas.** Acetylene gas shall not be piped except in *approved* cylinder manifolds and cylinder manifold connections, or utilized at a pressure exceeding 15 pounds per square inch gauge (psig) (103 kPa) unless dissolved in a suitable solvent in cylinders manufactured in accordance with DOTn 49 CFR Part 178. Acetylene gas shall not be brought in contact with unalloyed copper, except in a blowpipe or torch.

❖ Acetylene is the preferred gas for welding because it burns at very high temperatures, which is more conducive to welding and cutting operations. This also creates a high fire hazard. Therefore, this section limits the piping of acetylene to approved cylinder manifolds and manifold connections, which can be

accomplished in a variety of ways. The pressure of piped acetylene is limited to 15 pounds per square inch gauge (psig) (103 kPa) to avoid large releases of acetylene. There is an exception when acetylene is dissolved in a solvent, such as acetone, which reduces its volatility hazard.

Acetylene (CH = CH) is an extremely volatile compressed gas that is usually dissolved in a solvent, such as acetone or dimethylformamide, because of its volatility, and is normally stored and shipped in cylinders at a pressure of 250 pounds per square inch (psi) (1724 kPa). These solvents are Class IB flammable and Class II combustible liquids, respectively. However, in practice it is the flammable gas hazard that is regulated; the solvent into which the gas is absorbed has not been independently assessed. The established reason for doing this is that the control strategy for the compressed gas hazard is suitable for that of the solvent hazard. Acetone will dissolve approximately 425 times its volume of acetylene at 250 psi (1724 kPa).

Acetylene gas reacts vigorously with some metals, including copper and some copper alloys, to produce metallic acetylides that are shock-sensitive explosive compounds. Copper acetylide is an extremely shock-sensitive explosive and, if detonated, even in very small quantities, can initiate acetylene decomposition, cause hose or tank rupture and potentially cause catastrophic detonations or deflagrations, especially when tanks are manifolded.

**3505.5 Remote locations.** Oxygen and fuel-gas cylinders and acetylene generators shall be located away from the hot work area to prevent such cylinders or generators from being heated by radiation from heated materials, sparks or slag, or misdirection of the torch flame.

❖ Because of the hazards of using gases for welding and cutting, the cylinders and generators must be located away from the hot work operation itself. This means that the connection must be a sufficient length to allow locating the cylinders a safe distance from the hot work. Generally, only a short distance is required; a distance of only a few feet may be sufficient under ordinary conditions. A greater distance may be more prudent when welding or cutting operations involve a highly reflective surface or material. Where space is limited, a suitable barrier may be erected to protect cylinders from heat, provided such a barrier does not impair the operation of regulating equipment.

**3505.6 Cylinders shutoff.** The torch valve shall be closed and the gas supply to the torch completely shut off when gas welding or cutting operations are discontinued for a period of 1 hour or more.

❖ Good practice dictates shutting off gas cylinders when equipment is not in use; however, it is common practice for welding and cutting operators who must use a torch intermittently to shut off only the torch. Care must be taken in these instances to check the system to see that it has been properly shut down when work

is discontinued for a longer duration and at the end of the work period. This limits the amount of flammable or oxidizing gases that can be emitted to the atmosphere if the torch or hose is damaged in any way or if a valve at the torch head is not tightly closed.

**3505.7 Prohibited operation.** Welding or cutting work shall not be held or supported on *compressed gas* cylinders or containers.

❖ Section 3505.5 addresses physical separation of the welding and cutting gas cylinders from the hot work. This section goes a step further and prohibits welding operations on top of compressed gas containers or cylinders. This requirement would apply to any compressed gas cylinders or containers, whether they contain flammable gases or not. The concern is explosion caused by overpressure in the compressed gas cylinders when they are heated.

**3505.8 Tests.** Tests for leaks in piping systems and equipment shall be made with soapy water. The use of flames shall be prohibited for leak testing.

❖ This section requires that piping and equipment subjected to hot work be tested using soapy water rather than a flame to recognize any leaks. This is important because the piping may contain some residual flammable or oxidizing materials. Soapy water will produce harmless bubbles at the leak site even at very low pressures.

## SECTION 3506 ELECTRIC ARC HOT WORK

**3506.1 General.** The frame or case of electric hot work machines, except internal-combustion-engine-driven machines, shall be grounded. Ground connections shall be mechanically strong and electrically adequate for the required current.

❖ The following sections are specific to welding and cutting using an electrical arc. This process produces enough heat to join metals together or cut metals. There are several variations of arc welding and cutting. More specifically, in some arc welding processes a shielding gas is used to protect the weld from contaminants and prevent metal oxidation. Also, the electrode is either nonconsumable or consumable, which dictates whether additional materials are needed in the process.

Electric arc hot work poses some potential hazards because the process is working with electric power and current. Therefore, unless the welder is powered using an internal combustion engine, the frame or case of the welding piece must be grounded.

**3506.2 Return circuits.** Welding current return circuits from the work to the machine shall have proper electrical contact at joints. The electrical contact shall be periodically inspected.

❖ The current for welding must be able to loop back to the power source from the item being welded or cut. Cable movement may loosen contacts, causing poor conduction and interruption of ground continuity. At

the high voltages used in welding and cutting operations, high-resistance arcs may occur at loose contacts, resulting in a fire. Similarly, loose contacts may create a ground path, exposing the operator or others in the vicinity to the danger of electrocution.

**3506.3 Disconnecting.** Electrodes shall be removed from the holders when electric arc welding or cutting is discontinued for any period of 1 hour or more. The holders shall be located to prevent accidental contact and the machines shall be disconnected from the power source.

❖ The intent of this section is to prevent materials and machinery used as part of the electric arc-welding process from becoming a source of ignition after the hot work operations have been discontinued for 1 hour or more by requiring the disconnection of the electrodes and the power supply. Poorly supervised arc-welding machines may be subject to tampering or misuse even when properly maintained, and could become a fire hazard if left unattended and energized for long durations. Accidental contact with unsupervised welding electrodes or machine contacts may result in electrocution. This is similar to the intent of Section 3505.6 for gas hot work, which requires the supply gas valves to be shut off when an extended interruption occurs.

**3506.4 Emergency disconnect.** A switch or circuit breaker shall be provided so that fixed electric welders and control equipment can be disconnected from the supply circuit. The disconnect shall be installed in accordance with NFPA 70.

❖ When an electric arc-welding or cutting operation is in a permanent location, it is important that the particular operation be isolated onto a single disconnect switch. This makes it easier to verify that operations are in fact disconnected from the power supply during an emergency. NFPA 70 will have the specific requirements for this disconnect.

**3506.5 Damaged cable.** Damaged cable shall be removed from service until properly repaired or replaced.

❖ Damaged cable increases the likelihood of ignition hazards because wires may be exposed, resulting in resistance heating or potential electric shock hazards.

## SECTION 3507 CALCIUM CARBIDE SYSTEMS

**3507.1 Calcium carbide storage.** Storage and handling of calcium carbide shall comply with Chapter 50 of this code and Chapter 9 of NFPA 51.

❖ Calcium carbide gas is used for the creation of acetylene gas used in gas welding and cutting. Acetylene gas, as discussed earlier in this commentary, is extremely flammable and burns at very high temperatures. Calcium carbide itself is considered water reactive and will form acetylene upon contact with moisture. This section increases the likelihood that the gas is handled to avoid a hazardous situation.

Compliance with Chapter 50 of the code and Chapter 9 of NFPA 51 is required. Chapter 9 of NFPA 51 specifically relates to storage requirements for calcium carbide gas. These requirements focus on keeping the calcium carbide dry and separated from other areas when it is stored in large quantities.

### SECTION 3508 ACETYLENE GENERATORS

**3508.1 Use of acetylene generators.** The use of acetylene generators shall comply with this section and Chapter 6 of NFPA 51A.

❖ Acetylene generators essentially use calcium carbide gas and moisture to generate acetylene. Because acetylene is extremely flammable, the equipment must be handled with care.

Detailed requirements for acetylene generators are left to Chapter 4 of NFPA 51A, which is specific to such generators. These provisions deal with issues such as the construction requirements of generator rooms or houses and detailed installation requirements for the generators themselves.

There are several types of generators, including those with automatic water feed and manual water feed.

**3508.2 Portable generators.** The minimum volume of rooms containing portable generators shall be 35 times the total gas-generating capacity per charge of all generators in the room. The gas-generating capacity in cubic feet per charge shall be assumed to be 4.5 times the weight of carbide per charge in pounds. The minimum ceiling height of rooms containing generators shall be 10 feet (3048 mm). An acetylene generator shall not be moved by derrick, crane or hoist while charged.

❖ When generators are portable, they are generally at a greater risk for damage and are more likely to be in a location that may not have been specifically designed for this equipment. Therefore, this section provides some minimum volume requirements to make sure that a particular space can handle the volume of gases produced. The 35-to-1 volume requirement is intended to prevent formation of an explosive atmosphere in rooms or spaces where portable acetylene generators are employed. Assuming there is no leakage from the compartment, and that perfect efficiency in the generation of acetylene is achieved, this volume produces an atmosphere only slightly above the lower explosive limit (LEL). These provisions will reduce the likelihood of the formation of an explosive acetylene-air mixture if the required ventilation is maintained and acetylene production is not vented directly to the atmosphere in the room. To assist the code user in determining how much acetylene could be generated, this section includes a conservative approach to calculating the generation capacity.

Because acetylene is slightly lighter than air, the high ceiling is intended to provide space above the top of wall openings for containment of any combusti-

ble mixture that may form. The high ceiling is also important because acetylene is considered an asphyxiant, and having the high ceiling will allow the gas to rise, giving any occupants a longer escape time without being exposed to the gas.

Finally, this section prohibits the relocation of charged acetylene generators. Moving an acetylene generator while charged is likely to cause an uncontrolled gas release if it is dropped or damaged.

**3508.3 Protection against freezing.** Generators shall be located where water will not freeze. Common salt such as sodium chloride or other corrosive chemicals shall not be utilized for protection against freezing.

❖ Because acetylene generators use calcium carbide and moisture to create acetylene, freezing temperatures may cause water in the system to expand, thus damaging generator components. Additionally, corrosive materials, such as salt used to thaw ice on walkways, should not be used near the generators since they may have a damaging effect on generator components and potentially lead to failure.

### SECTION 3509 PIPING MANIFOLDS AND HOSE SYSTEMS FOR FUEL GASES AND OXYGEN

**3509.1 General.** The use of piping manifolds and hose systems shall be in accordance with Section 3509.2 through 3509.7, Chapter 53 and Chapter 5 of NFPA 51.

❖ Quite often, manifolding of several cylinders is desirable to decrease the amount of time taken to disconnect spent cylinders and reconnect new ones. When cylinders are manifolded, the potential hazard increases because the amount of material that can be released in one event is much larger. Special care and specific requirements are necessary to address these hazards. Compliance with Chapter 5 of NFPA 51 and Chapter 53 of the code for compressed gases is referenced. Although manifolded cylinders may create a higher risk for a large release, numerous disconnections and connections using a single cylinder may increase the likelihood of a failure.

**3509.2 Protection.** Piping shall be protected against physical damage.

❖ When cylinders are manifolded, the potential size of a gas release increases. Manifold piping is more likely to be damaged than the cylinders themselves. This section requires that piping associated with manifolded cylinders be installed in a manner minimizing the likelihood of mechanical and physical damage from collision or abrasion. When piping must be run in an area where mechanical and physical hazards cannot be eliminated, barriers or other suitable protection must be provided to absorb or deflect the impact of such damage without affecting the compressed gas piping.

Though not specifically listed in this section, physical damage resulting from corrosion should be con-

sidered when providing piping protection. Corrosion is the enemy of any piping system and can be caused by weather exposure, burial in the soil or construction materials that are in contact with the pipe. Protection is usually provided by a factory-applied coating or by field-wrapping the pipe with a protective covering, such as a coal-tar-based or plastic wrapping. Where possible, a piping material should be chosen that is not subject to the type of corrosion of the application. Acceptable fuel gas piping materials are regulated by Chapter 4 of the *International Fuel Gas Code*® (IFGC®).

Corrosion can also be caused by galvanic action that takes place where dissimilar metals are joined together in a current-carrying medium, such as soil or water. For example, if steel and copper pipe are joined in a medium that conducts electrical current, the steel pipe will corrode at an accelerated rate because of the electrochemical process between the dissimilar metals. To protect against galvanic corrosion, dielectric fittings and couplings are used to join the piping.

**3509.3 Signage.** Signage shall be provided for piping and hose systems as follows:

1. Above-ground piping systems shall be marked in accordance with ASME A13.1.
  2. Station outlets shall be marked to indicate their intended usage.
  3. Signs shall be posted, indicating clearly the location and identity of section shutoff valves.
- ❖ Signage for piping and hosing associated with manifolded cylinders must indicate the content of the system, gas flow direction, intended use of the gas outlets and location of shutoff valves. This information helps to quickly assess emergencies and take corrective action.

**3509.4 Manifolding of cylinders.** Oxygen manifolds shall not be located in an acetylene generator room. Oxygen manifolds shall be located not less than 20 feet (6096 mm) away from combustible material such as oil or grease, and gas cylinders containing flammable gases, unless the gas cylinders are separated by a *fire partition*.

❖ Manifolds are groups of cylinders connected to one another in a series in a gas supply system. As a general rule throughout the code, oxidizing and flammable materials must be kept physically separated from each other, either by space or fire-resistance-rated construction. Acetylene is a flammable gas with an explosive range of 2.5 to 100 percent and needs very little oxygen to burn. Excess oxygen may only make an explosion worse; therefore, separation is required. Other materials found in shop areas, such as solvents, oils and lubricants, must be kept clear of oxygen cylinders for similar reasons and may either be separated by distance or fire-resistive shielding. The fire partitions required by this section must be constructed in accordance with Section 708 of the *International Building Code*® (IBC®).

**3509.5 Identification of manifolds.** Signs shall be posted for oxygen manifolds with service pressures not exceeding 200 psig (1379 kPa). Such signs shall include the words:

LOW-PRESSURE MANIFOLD

DO NOT CONNECT HIGH-PRESSURE CYLINDERS

MAXIMUM PRESSURE 250 PSIG

❖ The signage required by this section is intended to prevent high-pressure oxygen cylinders from being connected to a low-pressure manifold. A high-pressure cylinder may cause a rupture of the system, resulting in an instantaneous release of large volumes of oxygen. The maximum 250-psig (1723 kPa) working pressure is approximately one-half the customary minimum safety margin of  $1\frac{1}{2}$  times the working pressure.

**3509.6 Clamps.** Hose connections shall be clamped or otherwise securely fastened.

❖ Hoses are potentially less reliable than a pipe if they do not receive proper care. This section requires clamps or other methods of securing to provide stability and prevent an inadvertent disconnection during use. Hose connections may fail because of an improper connection, damage or overpressurization. An unrestrained hose can become a deadly weapon if it becomes disconnected.

**3509.7 Inspection.** Hoses shall be inspected frequently for leaks, burns, wear, loose connections or other defects rendering the hose unfit for service.

❖ Many places where welding or cutting operations are performed pose distinct hazards to welding and cutting hoses. Excessive abrasions, cuts, dry rot, cracking or discoloration are all signs that a hose needs to be replaced. Any hose sustaining burn damage or having a damaged or deformed connection should be replaced immediately. When in doubt about the condition of a hose, it should be taken out of service and hydrostatically tested by qualified personnel in accordance with the manufacturer's recommendations before being returned to service or replaced. Discarding defective lengths of hose improves the likelihood that it will not be reused.

## SECTION 3510 HOT WORK ON FLAMMABLE AND COMBUSTIBLE LIQUID STORAGE TANKS

**3510.1 General.** Hot work performed on the interior or exterior of tanks that hold or have held flammable or *combustible liquids* shall be in accordance with Section 3510.2 and Chapters 4, 5, 6, 7 and 10 of NFPA 326.

❖ Annually, there are numerous documented incidents involving loss of life, injury and property damage where hot work was conducted on tanks containing or that had contained flammable or combustible liquids and industry-specific precautions were not followed or personnel did not understand the hazard or risk.

## WELDING AND OTHER HOT WORK

This section improves the general guidelines in the code and references the appropriate standard to safely conduct hot work on tanks that contain or had contained flammable or combustible liquids. Other references to hot work on flammable and combustible tanks are in Section 3504.1.7 and in 5704.2.7.6 of the code, as well as Section 6.5.3 of NFPA 30.

**3510.2 Prevention.** The following steps shall be taken to minimize hazards where hot work must be performed on a flammable or *combustible liquid* storage container:

1. Use alternative methods to avoid hot work where possible.
  2. Analyze the hazards prior to performing hot work, identify the potential hazards and the methods of hazard control.
  3. Hot work shall conform to the requirements of the code or standard to which the container was originally fabricated.
  4. Test the immediate and surrounding work area with a combustible gas detector and provide for a means of continuing monitoring while conducting the hot work.
  5. Qualified employees and contractors performing hot work shall use an industry-approved hot work permit system to control the work.
  6. Personnel shall be properly trained on hot work policies and procedures regarding equipment, safety, hazard controls and job-specific requirements.
  7. On-site safety supervision shall be present where hot work is in progress to protect the personnel conducting the hot work and provide additional overview of site-specific hazards.
- ❖ The United States Chemical Safety Board (CSB) has published general guidelines applicable to almost every situation where welding or cutting on flammable, combustible or toxic chemical tanks occurs. Those general safety guidelines are listed in this section.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Complete Revision History to the 2015 I-Codes.* Washington, DC: International Code Council, 2014.

Manz, A. "Welding, Cutting and Other Hotwork," Section 6, Chapter 14. *Fire Protection Handbook*, 19<sup>th</sup> ed. Quincy, MA: National Fire Protection Association, 2003.

# Chapter 36: Marinas

## General Comments

Chapter 36 addresses fire protection and prevention requirements for marinas. This chapter was developed in response to complications encountered by a number of fire departments responsible for protecting marinas, as well as fire loss history in marinas that lacked fire protection. Fire-fighting operations at marinas are more of a challenge from the perspectives of access, hose stream deployment and the proximity of exposures. These factors are compounded because personal marine craft are typically constructed of rigid thermoplastics or wood, do not burn as shielded fires when compared to fires involving passenger vehicles, and have flammable and combustible liquids on board in varying amounts.

Part of the basis for the approval of these requirements was the United States' fire loss history for marina fires from 2003 through 2006, wherein marina fires

caused the complete loss of 272 boats and houseboats for a total loss of more than \$67 million. Excluding the scoping section, Chapter 36 is divided into four sections:

Section 3602—Definitions

Section 3603—General Precautions

Section 3604—Fire Protection Equipment

Section 3605—Marine Motor Fuel-dispensing Stations

## Purpose

Compliance with this chapter is to establish safe practices in marina areas, provide an identification method for mooring spaces in the marina, provide fire fighters with safe operational areas and provide fire protection methods to extend hose lines in a safe manner.

---

## SECTION 3601 SCOPE

**3601.1 Scope.** Marina facilities shall be in accordance with this chapter.

❖ This section identifies that marina facilities are covered in this chapter. It is possible to find and utilize the provisions found in this chapter among other sections of the code. However, it was felt that, for ease of use, a chapter specific to this special use would be beneficial to those fire code officials with marinas in their jurisdictions.

**3601.2 Plans and approvals.** Plans for marina fire protection facilities shall be *approved* prior to installation. The work shall be subject to final inspection and approval after installation.

❖ Plan approval prior to installation enables the jurisdiction to review the marina layout, the required fire protection features and general safety precautions for the public, property and fire fighters. The inspection process verifies that the general safety precautions are met and that the required fire protection features are practiced.

## SECTION 3602 DEFINITIONS

**3602.1 Definitions.** The following terms are defined in Chapter 2:

FLOAT.

MARINA.

PIER.

VESSEL.

WHARF.

❖ Definitions of terms can help in the understanding and application of code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentaries, Sections 201.1 through 201.4).

## SECTION 3603 GENERAL PRECAUTIONS

**3603.1 Combustible debris.** Combustible debris and rubbish shall not be deposited or accumulated on land beneath marina structures, piers or wharves.

❖ Due to the combustible nature of most piers and wharves, the code requires that combustible debris not be deposited or allowed to accumulate under them. Consistent with the provisions found in Section 304.1.1, this section prohibits disorderly, unkempt storage or accumulation of trash, waste rags, waste-paper, litter and other combustible materials. Litter and trash represent serious fire hazards because of their ease of ignition and rapid heat release once

ignited. The importance of maintaining property and buildings in good order seems obvious, but sloppy housekeeping still occurs and can be the cause of serious fires.

**3603.2 Sources of ignition.** Open-flame devices used for lighting or decoration on the exterior of a vessel, float, pier or wharf shall be *approved*.

- ❖ Similar to Section 308.1.1, this section requires that open-flame devices used in marina areas—including the wharf, pier, float or aboard a vessel—be approved. Fire code official approval ensures the device is appropriate for the intended use and that any needed precautions will be followed.

**3603.3 Flammable or combustible liquid spills.** Spills of flammable or *combustible liquids* at or upon the water shall be reported immediately to the fire department or jurisdictional authorities.

- ❖ Spills of flammable and combustible liquids in a marina create significant hazards due to the fact that these materials have a specific gravity less than that of water and will float on the water, spreading the liquid quickly around the many combustible materials found in vessels, floats, piers and wharves. The vapors that are released from these materials may easily find an ignition source with the resulting fire covering a large area. In addition to the fire problem, rapid response can help mitigate issues that affect the environment, marine animals and birds.

**3603.4 Rubbish containers.** Containers with tight-fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material. The rubbish containers shall be constructed entirely of materials that comply with any one of the following:

1. Noncombustible materials.
  2. Materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> where tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation.
- ❖ The use of containers with tight-fitting or self-closing lids reduces the possibility that an accidental container fire can be started and prevents continued burning if ignition does occur. Rubbish containers need not be constructed of metal or other noncombustible material. Other materials, including materials that have been shown to be safe by meeting a very severe fire test similar to those required by Section 808 for Group I-1, I-2 and I-3 occupancies and Section 304.3.4 for general rubbish control, may be used. Note that the requirement covers all types of rubbish and is not intended to address spills of combustible or flammable liquids. The use of the phrase “combustible debris, rubbish and waste material” makes this section consistent with other sections of the code. This section should be applied in conjunction with Section 304.3.

**3603.5 Electrical equipment.** Electrical equipment shall be installed and used in accordance with its listing, Section 605 of this code and Chapter 5 of NFPA 303 as required for wet, damp and hazardous locations.

- ❖ Section 605 provides the basic requirements for the use of electrical cords, appliances, motors and space heaters. Chapter 5 of NFPA 303 covers the same information and specifies requirements for new installations. It also requires an annual inspection of the marina’s electrical wiring and equipment. The inspection must include all electrical grounds, verification of the polarity of circuits and an inspection of all flexible cords and cables, including shore power cable sets that supply electricity to docked marine craft. Other elements include requirements that address the introduction of hazards or uses that are greater than those for which the electrical system was originally designed.

**3603.6 Berthing and storage.** Berthing and storage shall be in accordance with Chapter 7 of NFPA 303.

- ❖ When vessels are either berthed or stored on land, this section requires these activities be performed in accordance with the requirements in NFPA 303. The requirements are based on whether the storage is wet or dry, indoor or outdoor and rack storage. Berthing involves locating a marine craft or vessel in a space between piers, wharves or docks. The berth is the area that is occupied by the water.

When wet berthed, the boat must be stored so that it can be removed in an emergency without moving other boats, and fire department access is required around piers, wharves and floats. When dry storage is used, the standard has extensive requirements for the use of heaters and open flame-producing devices, such as torches, on-board batteries, fuel tanks and types of equipment to access and remove the vessels, in an emergency.

**3603.7 Slip identification.** Slips and mooring spaces shall be individually identified by an *approved* numeric or alphabetic designator. Space designators shall be posted at the space. Signs indicating the space designators located on finger piers and floats shall be posted at the base of all piers, finger piers, floats and finger floats.

- ❖ A slip is a berthing space located between two adjacent piers. The term “mooring space” can also refer to a slip or an anchored space where the vessel is simply secured to a mooring buoy. Large marinas can have many hundreds of slips or mooring spaces on site.

Similar to the premises identification provisions in Section 505, this section provides for an approved system of signs indicating how the marina is laid out to enable emergency responders to quickly identify the location of a fire or other emergency. The provision not only provides for a marina layout, but also requires that individual float and slip identification be provided.

## SECTION 3604 FIRE PROTECTION EQUIPMENT

**3604.1 General.** Piers, marinas and wharves with facilities for mooring or servicing five or more vessels, and marine motor fuel-dispensing facilities shall be equipped with fire protection equipment in accordance with Sections 3604.2 through 3604.6.

❖ Marinas have a significant potential for a fire emergency. Therefore, the fire protection to be provided must be properly established, installed and identified for use in an emergency.

**3604.2 Standpipes.** Marinas and boatyards shall be equipped throughout with standpipe systems in accordance with NFPA 303. Systems shall be provided with hose connections located such that no point on the marina pier or float system exceeds 150 feet (15 240 mm) from a standpipe hose connection.

❖ Standpipe systems in marinas are basically a horizontal standpipe to reach all parts of the float system, piers and buildings with no more than 150 feet (15 240 mm) of travel distance from a fire hose connection. This section requires a Class I standpipe system that provides 2½-inch (64 mm) hose connections for fire department use. The system is allowed to be a manual dry system in accordance with Section 6.4 of NFPA 303, meaning that the only required water supply is a connection for fire apparatus and that piping is not required to contain water at all times. In addition, NFPA 303 permits the omission of hose racks, hoses and standpipe cabinets at marinas and boatyards, recognizing that these would be subject to misuse in such venues.

**3604.2.1 Identification of standpipe outlets.** Standpipe hose connection locations shall be clearly identified by a flag or other *approved* means designed to be readily visible from the pier accessing the float system.

❖ To provide emergency responders with a visual cue in locating standpipe hose connections, each connection must have an approved identification marker readily visible from the wharf or pier to which the floats are attached.

**3604.3 Access and water supply.** Piers and wharves shall be provided with fire apparatus access roads and water-supply systems with on-site fire hydrants where required by the *fire code official*. Such roads and water systems shall be provided and maintained in accordance with Sections 503 and 507.

❖ So that emergency responders can quickly access the floats, fire apparatus access roads are to be provided in close proximity to the gangways and standpipe inlets that serve the marina. The access roads may be part of the parking lot system for the marina; however, they must meet the minimum width, load-bearing capability and turning radius criteria for the responding apparatus set forth in Section 503. In addition to the access roads, a fire hydrant system complying with the requirements of Section 508 may be required. Note that such systems are to be pro-

vided when it is determined by the fire code official that they are needed to properly protect the marina.

**3604.4 Portable fire extinguishers.** One portable fire extinguisher of the ordinary (moderate) hazard type shall be provided at each required standpipe hose connection. Additional portable fire extinguishers, suitable for the hazards involved, shall be provided and maintained in accordance with Section 906.

❖ A 2-A:10-B-C-rated portable fire extinguisher placed adjacent to each standpipe hose connection would meet the general requirement for this section. In addition, to meet the requirements of Table 906.3(1), a sufficient number of extinguishers must be provided throughout the marina with a maximum travel distance of 75 feet (22 860 mm) from any point along the piers, wharves or floats to an extinguisher.

**3604.5 Communications.** A telephone not requiring a coin to operate or other *approved*, clearly identified means to notify the fire department shall be provided on the site in a location *approved* by the *fire code official*.

❖ This section requires a public telephone to be provided at locations approved by the fire code official. The phone is to have the capability of coinlessly dialing 911 or other means of notifying the fire department. A sign identifying the location of the emergency phone must be provided. When a telephone is provided, NFPA 303 requires a sign at the telephone indicating the address of the marina so that callers may clearly and promptly communicate the location of any emergency.

**3604.6 Emergency operations staging areas.** Space shall be provided on all float systems for the staging of emergency equipment. Emergency operation staging areas shall provide a minimum of 4 feet wide by 10 feet long (1219 mm by 3048 mm) clear area exclusive of walkways and shall be located at each standpipe hose connection. Emergency operation staging areas shall be provided with a curb or barrier having a minimum height of 4 inches (102 mm) and maximum space between the bottom edge and the surface of the staging area of 2 inches (51 mm) on the outboard sides of the staging area.

An *approved* sign reading FIRE EQUIPMENT STAGING AREA—KEEP CLEAR shall be provided at each staging area.

❖ Adjacent to each standpipe there is to be an open space at least 4 feet wide by 10 feet long (1219 mm by 3048 mm) in addition to the walkway width. This area is for the purpose of providing storage and working space around the standpipe for equipment that must be transported to the area for operational needs. To ensure the equipment does not slide, roll or otherwise fall into the water, a minimum 4-inch-high (102 mm) curb or barrier is to be provided. A maximum 2-inch (51 mm) space between the surface of the float deck and the bottom of the 4-inch-high (102 mm) barrier is permitted on the water side of the staging area to allow for drainage of the surface of

## MARINAS

the pier, float or dock. A sign is required to identify the area as a dedicated fire department staging area and to keep it clear of other items that may be placed there by those who use the floats.

### SECTION 3605 MARINE MOTOR FUEL-DISPENSING FACILITIES

**3605.1 Fuel dispensing.** Marine motor fuel-dispensing facilities shall be in accordance with Chapter 23.

- ❖ Fuel-dispensing facilities in marinas are required to be in accordance with Sections 2303 and 2310. Section 2303 provides general requirements for all fuel-dispensing facilities. Section 2310 contains the specific requirements for the marine fuel-dispensing facilities, which are similar to other fuel-dispensing facilities. Section 2310.1 also references the *International Building Code*® (IBC®) and NFPA 30A for construction requirements of these fueling facilities and Chapter 57 for fuel storage requirements.

#### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Fire Protection Handbook,* 20<sup>th</sup> ed. Quincy, MA: National Fire Protection Association, 2008.

# Chapter 37: Combustible Fibers

## General Comments

Operations involving combustible fibers are typically associated with salvage, paper milling, recycling, cloth manufacturing, carpet and textile mills and agricultural operations, among others.

The primary hazard associated with these operations is the abundance of materials and their ready ignitability. These so-called “rag districts,” where cloth scrap and clippings are collected and separated for reuse in paper manufacturing, have been associated with catastrophic conflagrations as recently as the 1970s.

Because of these hazards, occupancies storing or handling more than 100 cubic feet (3 m<sup>3</sup>) of loose, or 1,000 cubic feet (28 m<sup>3</sup>) of baled, combustible fibers are classified as Group H-3 (high hazard) by the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>).

## Purpose

Chapter 37 establishes the requirements for the storage and handling of combustible fibers, including animal, vegetable and synthetic fibers, whether woven into textiles, baled, packaged or loose.

---

## SECTION 3701 GENERAL

**3701.1 Scope.** The equipment, processes and operations involving *combustible fibers* shall comply with this chapter.

❖ Fibers and textiles are an integral part of our daily lives. Almost all fibers are combustible. This characteristic is a problem when the fibers are manufactured, made into fabrics and collected as waste.

**3701.2 Applicability.** Storage of *combustible fibers* in any quantity shall comply with this section.

❖ Fibers stored as raw material or finished product must comply with this section.

**3701.3 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.8 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous properties.

## SECTION 3702 DEFINITIONS

**3702.1 Definitions.** The following terms are defined in Chapter 2:

**BALED COTTON.**

**BALED COTTON, DENSELY PACKED.**

**COMBUSTIBLE FIBERS.**

**SEED COTTON.**

❖ Definitions of terms can help in the understanding and application of code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 3703 GENERAL PRECAUTIONS

**3703.1 Use of combustible receptacles.** Ashes, waste, rubbish or sweepings shall not be placed in wood or other combustible receptacles and shall be removed daily from the structure.

❖ The regular and proper disposal of ashes, waste, rubbish and sweepings is of the utmost importance. Not giving a fire a place of origin is the main objective.

## COMBUSTIBLE FIBERS

The waste containers cannot be combustible. Routine and regular handling and disposal of waste products are integral parts of housekeeping.

**3703.2 Vegetation.** Grass or weeds shall not be allowed to accumulate at any point on the premises.

❖ Tall grass, dry weeds and bushes around buildings and on and alongside roadways, highways and streets present a definite fire hazard. Controlling or clearing grass, weeds and bushes reduces this hazard.

**3703.3 Clearances.** A minimum clearance of 3 feet (914 mm) shall be maintained between automatic sprinklers and the top of piles.

❖ Although a 3-foot (914 mm) clearance is required by this section, other sections of the code and NFPA 13 allow less clearance. Sprinkler clearances are intended to provide room for the fire plume to develop, thus ensuring sprinkler activation and preventing obstruction of the sprinkler spray pattern.

**3703.4 Agricultural products.** Hay, straw, seed cotton or similar agricultural products shall not be stored adjacent to structures or combustible materials unless a clear horizontal distance equal to the height of a pile is maintained between such storage and structures or combustible materials. Storage shall be limited to stacks of 100 tons (91 metric tons) each. Stacks shall be separated by not less than 20 feet (6096 mm) of clear space. Quantities of hay, straw, seed cotton and other agricultural products shall not be limited where stored in or near farm structures located outside closely built areas. A permit shall not be required for agricultural storage.

❖ Farm and other agricultural buildings are exempt from the requirements of this section. Agricultural outbuildings probably represent the single largest class of buildings used for combustible fiber storage; however, despite the hazards associated with the spontaneous combustion of green hay, these occupancies generally pose little threat to life or adjacent property.

**3703.5 Dust collection.** Where located within a building, equipment or machinery that generates or emits *combustible fibers* shall be provided with an *approved* dust-collecting and exhaust system. Such systems shall comply with Chapter 22 of this code and Section 511 of the *International Mechanical Code*.

❖ Dust may create a considerable explosion when displaced from a surface on which it rests, and it may also be ignited by static sparks. For this reason, a dust-collecting hood and exhaust system is required.

**3703.6 Portable fire extinguishers.** Portable fire extinguishers shall be provided in accordance with Section 906 as required for extra-hazard occupancy protection as indicated in Table 906.3(1).

❖ Section 906 gives the requirements for portable fire extinguishers. Such extinguishers must be selected and installed for an extra-hazard occupancy because of the high possibility of ignition of combustible fibers or dust.

**3703.7 Sources of ignition.** Sources of ignition shall comply with Sections 3703.7.1 and 3703.7.2.

❖ This section introduces the provisions for ignition control. A form of heat is required to ignite combustible fibers. By limiting the sources of ignition in the storage or use area, one can reduce the possibility of a fire.

**3703.7.1 Smoking.** Smoking shall be prohibited and “No Smoking” signs provided as follows:

1. In rooms or areas where materials are stored or dispensed or used in open systems.
2. Within 25 feet (7620 mm) of outdoor storage or open use areas.
3. Facilities or areas within facilities that have been designated as totally “no smoking” shall have “No Smoking” signs placed at all entrances to the facility or area. Designated areas within such facilities where smoking is permitted either permanently or temporarily shall be identified with signs designating that smoking is permitted in these areas only.

Signs required by this section shall be in English as a primary language or in symbols allowed by this code and shall comply with Section 310.

❖ The three areas listed in this section, because of their hazard characteristics, have been designated to receive “No Smoking” signs, in accordance with Section 310 of the code.

**3703.7.2 Open flames.** Open flames and high-temperature devices shall not be used in a manner that creates a hazardous condition and shall be listed for use with the materials stored or used. High-temperature devices and those devices utilizing an open flame shall be listed for use with the materials stored or used.

❖ Processes that use open flames must be installed and safeguarded in accordance with the manufacturer’s specifications. Safety is further enhanced by the requirement for certain devices to be listed for use in proximity to hazardous materials.

## SECTION 3704 LOOSE FIBER STORAGE

**3704.1 General.** Loose combustible fibers, not in suitable bales or packages and stored outdoors in the open, shall comply with Section 2808 of this code. Occupancies involving the indoor storage of loose combustible fibers in amounts exceeding the *maximum allowable quantity per control area* as set forth in Section 5003.1 shall comply with Sections 3704.2 through 3704.6.

❖ This section identifies Section 2808 of the code as the appropriate standard for the exterior storage of combustible fibers. The material hazards presented by combustible fibers are similar to the wood chips, hogged materials, fines, compost, raw materials and solid biomass feedstock regulated by Section 2808. This section further indicates that the more restrictive

indoor storage of combustible fibers regulated by Sections 3704.2 through 3704.6 is for those facilities that have amounts exceeding the maximum allowable quantity per control area (MAQ) as set forth in Section 5003.1. If the hazards are controlled so as to eliminate the application of Table 5003.1.1 of the code [IBC Table [F]307.1(1)] and IBC Section 307.5, the increased protection levels for a Group H-3 occupancy would not be necessary.

**3704.2 Storage of 100 cubic feet or less.** Loose *combustible fibers* in quantities of not more than 100 cubic feet (3 m<sup>3</sup>) located in a structure shall be stored in a metal or metal-lined bin equipped with a self-closing cover.

- ❖ Small amounts of material may be stored inside a building in approved containers. Acceptable receptacles include metal or metal-lined containers with self-closing lids that help prevent the loose fibers from being ignited by outside sources such as cigarettes, candles, friction, sparks, etc. The term “self-closing” means that the lid is equipped with an approved device or is otherwise arranged to operate in a manner that will ensure its closing after having been opened. In many cases, these types of bins are top-opening and need nothing more than gravity to meet this requirement. See the commentary to the definition of “Self-closing” in Chapter 2.

**3704.3 Storage of more than 100 cubic feet to 500 cubic feet.** Loose *combustible fibers* in quantities exceeding 100 cubic feet (3 m<sup>3</sup>) but not exceeding 500 cubic feet (14 m<sup>3</sup>) shall be stored in rooms enclosed with 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both, with openings protected by an *approved* opening protective assembly having a *fire protection rating* of  $\frac{3}{4}$  hour in accordance with the *International Building Code*.

- ❖ Moderate quantities of material must be stored in 1-hour fire-resistance-rated rooms. Openings in floors, walls and ceilings must be protected with self-closing or automatic-closing  $\frac{3}{4}$ -hour fire doors or windows in approved frames. Section 707 of the IBC deals with the construction of and fire-resistance ratings for fire barriers and with fire barriers used for separation of incidental use areas.

**3704.4 Storage of more than 500 cubic feet to 1,000 cubic feet.** Loose *combustible fibers* in quantities exceeding 500 cubic feet (14 m<sup>3</sup>) but not exceeding 1,000 cubic feet (28 m<sup>3</sup>) shall be stored in rooms enclosed with 2-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both, with openings protected by an *approved* opening protective assembly having a *fire protection rating* of 1½ hours in accordance with the *International Building Code*.

- ❖ Large amounts of material require a 2-hour fire-resistance-rated enclosure. Openings in floors, walls and ceilings require self-closing or automatic-closing, 1½-

hour fire doors or windows in approved frames. Again, the IBC establishes the requirements for the construction of fire barriers and required opening protectives.

**3704.5 Storage of more than 1,000 cubic feet.** Loose *combustible fibers* in quantities exceeding 1,000 cubic feet (28 m<sup>3</sup>) shall be stored in rooms enclosed with 2-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both, with openings protected by an *approved* opening protective assembly having a *fire protection rating* of 1½ hours in accordance with the *International Building Code*. The storage room shall be protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.

- ❖ The enclosure requirements in this section are the same as in Section 3704.4; however, if the storage quantity exceeds 1,000 cubic feet (28 m<sup>3</sup>), the storage room must be sprinklered for extra protection.

**3704.6 Detached storage structure.** Not more than 2,500 cubic feet (70 m<sup>3</sup>) of loose *combustible fibers* shall be stored in a detached structure suitably located, with openings protected against entrance of sparks. The structure shall not be occupied for any other purpose.

- ❖ Separate, special-purpose structures are required for the storage of extremely large volumes of loose material. Only loose fiber material may be stored in the structure, and openings must restrict the entrance of sparks. These occupancies must be classified in Group H-3, and must be constructed and protected in accordance with the IBC.

## SECTION 3705 BALED STORAGE

**3705.1 Bale size and separation.** Baled *combustible fibers* shall be limited to single blocks or piles not more than 25,000 cubic feet (700 m<sup>3</sup>) in volume, not including aisles or clearances. Blocks or piles of baled fiber shall be separated from adjacent storage by aisles not less than 5 feet (1524 mm) wide, or by flash-fire barriers constructed of continuous sheets of noncombustible material extending from the floor to a minimum height of 1 foot (305 mm) above the highest point of the piles and projecting not less than 1 foot (305 mm) beyond the sides of the piles.

- ❖ Bulk restrictions and aisle requirements for piles or blocks of combustible fibers are established in this section. These restrictions provide access for fire fighting and limit the fuel load of piles and blocks. Aisles or flash-fire barriers must be provided between piles and blocks. Aisles must be a minimum of 5 feet (1524 mm) wide to reduce the likelihood of horizontal fire spread between blocks or piles of stored material; and to provide fire fighters access to fires. In place of aisles, protection in the form of flash-fire barriers constructed of noncombustible materials is considered equivalent and may be used as specified in this sec-

## COMBUSTIBLE FIBERS

tion. Depending upon the height and array of the baled storage, the provisions of Chapter 32 may also apply to these materials.

Note that these provisions do not apply to densely packed baled cotton based on its exclusion from the definition of "Combustible fibers" in Section 202. See the commentary to the various cotton definitions in Section 202 for a discussion of the hazards of various cotton processing and storage operations.

**3705.2 Special baling conditions.** Sisal and other fibers in bales bound with combustible tie ropes, jute and other fibers that swell when wet, shall be stored to allow for expansion in any direction without affecting building walls, ceilings or columns. A minimum clearance of 3 feet (914 mm) shall be required between walls and sides of piles, except that where the storage compartment is not more than 30 feet (9144 mm) wide, the minimum clearance at side walls shall be 1 foot (305 mm), provided that a center aisle not less than 5 feet (1524 mm) wide is maintained.

❖ Allowances or clearances must be provided for the expansion of combustible fibers susceptible to swelling when wet. In addition to the lateral forces that these piles may create if placed against structural elements, their contribution to the building live load should be considered. This section prescribes clearances from building elements. Structural loading concerns should be referred to the building official or to a qualified structural engineer. As an example of special baling conditions, rolled paper is commonly stored on its side rather than on its end to promote water runoff. Structural damage has resulted from the expansion of wet paper rolls or bales of rags when minimum clearances were not provided.

## Part V—Hazardous Materials

# Chapter 50: Hazardous Materials—General Provisions

### General Comments

The requirements of this chapter apply to all hazardous chemicals. Hazardous chemicals are defined as those that pose an unreasonable risk to the health and safety of operating or emergency personnel, the public and the environment if not properly controlled during handling, storage, manufacture, processing, packaging, use, disposal or transportation. The requirements of this chapter and associated chapters are considered the

minimum safety requirements for the use, production and storage of hazardous chemicals.

### Purpose

This chapter contains the general requirements for hazardous chemicals in all occupancies. The general provisions of this chapter are intended to be companion provisions with the specific requirements of Chapters 51 and 53 through 67 regarding a given hazardous material.

### SECTION 5001 GENERAL

**5001.1 Scope.** Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that where specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

#### Exceptions:

1. In retail or wholesale sales occupancies, the quantities of medicines, foodstuff or consumer products and cosmetics containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solutions not being flammable shall not be limited, provided such materials are packaged in individual containers not exceeding 1.3 gallons (5 L).
2. Quantities of alcoholic beverages in retail or wholesale sales occupancies shall not be limited providing the liquids are packaged in individual containers not exceeding 1.3 gallons (5 L).
3. Application and release of pesticide and agricultural products and materials intended for use in weed abatement, erosion control, soil amendment or similar applications where applied in accordance with the manufacturers' instructions and label directions.

4. The off-site transportation of hazardous materials where in accordance with Department of Transportation (DOTn) regulations.
5. Building materials not otherwise regulated by this code.
6. Refrigeration systems (see Section 606).
7. Stationary storage battery systems regulated by Section 608.
8. The display, storage, sale or use of fireworks and *explosives* in accordance with Chapter 56.
9. *Corrosives* utilized in personal and household products in the manufacturers' original consumer packaging in Group M occupancies.
10. The storage of distilled spirits and wines in wooden barrels and casks.
11. The use of wall-mounted dispensers containing alcohol-based hand rubs classified as Class I or II liquids where in accordance with Section 5705.5.

❖ The purpose of Exception 1 is to address consumer products, foodstuffs and cosmetics that are not formulated with flammable constituents and are stored and displayed in Group M occupancies, provided the individual package is limited to a volume of 1.3 gallons (5 L) or less. In the event of a leak or broken package, the amount of hazardous material lost would be small and present a smaller spill cleanup problem. This is limited to products containing no more than 50 percent by volume of water-miscible liquids and with the remaining content not being flammable, based on the code's definition of "Flammable liquid." This percentage limitation further reduces the

hazard of a material spill due to the difficult ignitability of such materials. This exception would not apply to any Level 2 or 3 aerosol as defined in Chapter 2, because these consumer products are formulated with either a flammable propellant or a flammable base product. It also would not apply to many paints, coatings, adhesives or lubricants formulated with flammable or combustible liquids. Consumer products, such as household bleach (which is typically a mixture of less than 12.5-percent sodium hypochlorite by volume and water) or window cleaners (typically formulated with 3 to 6 percent by volume of ammonium hydroxide) would be exempted by this exception, as would a 1-gallon (3.9 L) bottle containing a solution of 37-percent hydrochloric acid and water used for disinfecting swimming pool water or for cleaning concrete surfaces.

Similar to Exception 1, Exception 2 deals with the amount of storage allowed in Group M occupancies where individual containers of alcoholic beverages do not exceed 1.3 gallons (5 L) in wholesale and retail stores. In the event of a leak or broken consumer package, the amount of flammable or combustible beverage lost would be small and present a smaller spill cleanup problem. This exception parallels Section 5701.2, Exception 3.

Exception 3 states that the application of pesticides and agricultural products is not considered a hazardous process if done in accordance with the manufacturer's instructions and label directions, since those products and pesticides have been tested in these application methods.

Exception 4 states that any time hazardous materials are transported over public highways or by public transportation, U.S. Department of Transportation (DOTn) requirements must be enforced. The code intends that when a material, good or commodity is transported off site, it is within the domain of the DOTn while the material is in transit. In the case of hazardous materials, DOTn has ruled that the activities associated with preparing the material for shipment, such as selection of the type of shipping container, placarding the container to identify its hazards and the preparation of shipping papers, are within the domain of DOTn and that local codes [e.g., the *International Fire Code*<sup>®</sup> (IFC<sup>®</sup>)] are preempted by the Hazardous Materials Transportation Act. Commonly, this includes storing goods and materials at a railroad siding for several months before they are consigned for shipment. The code has no authority when the material is in transit, including while shipping papers are being prepared or are in effect. Note, however, that while the code exempts hazardous materials in transportation, it does not exempt the facility where these materials are packaged and prepared for shipment.

Once the material reaches the point where it has been delivered and the shipping papers have been received by the consignee (e.g., the party responsible for the material), the goods or commodity are no longer

within the domain of DOTn and the applicable regulatory requirements are those adopted fire and building codes of the jurisdiction whose enforcement and interpretation is the responsibility of the fire code official.

Exception 5 exempts commonly used building materials that may exhibit some hazardous properties, but do not fall into the realm of a hazardous materials as defined in the code, from being regulated as hazardous material. Without this exception, the storage of certain building materials could result in a Group H occupancy classification.

Exception 6 states that refrigeration systems are governed by Section 606, which has specific requirements that would be enforced over any general requirements of the hazardous material chapters of the code.

Exception 7 notes that stationary storage battery systems are governed by Section 608, which has specific requirements that would be enforced over any general requirements of the hazardous material chapters of the code. Note that the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) considers this an incidental storage area. See Table 509 of the IBC for incidental use area requirements.

Exception 8 refers to Chapter 56 for specific requirements concerning fireworks and explosives. Those specific requirements would be enforced over any general requirements of the hazardous material chapters of the code.

Exception 9 states that corrosives used in personal and household products, such as certain cleaners or detergents, are not considered hazardous when maintained in their original packaging in Group M areas. Note that this is specific to Group M use areas only. However, this exception does not apply to small containers of flammable aerosols or liquids in retail display areas where they are regulated in Chapter 51 or 57, respectively. Without this exception, many common products in mercantile display areas could be classified as hazardous materials resulting in grocery stores and other mercantile occupancies being inappropriately classified in occupancy classification Group H.

Exception 10 covers the storage of distilled spirits and wines in wooden barrels and casks. This statement may appear to exempt all requirements for these products from being a Group H occupancy. However, the IBC will still classify the storage area as a Group H occupancy if the amounts exceed the maximum allowable quantities (MAQs) per control area listed in Table 307.1(1) of that code for flammable or combustible liquids. All requirements for a Group H occupancy in the IBC are still applicable; however, any requirements from the code are not.

Exception 11 provides a necessary cross reference to provisions in Section 5705.5 to prevent alcohol-based hand rub dispensers from being considered the same as other flammable liquids and exempting them from the limitations of Table 5003.1.1(1).

**5001.1.1 Waiver.** The provisions of this chapter are waived where the *fire code official* determines that such enforcement is preempted by other codes, statutes or ordinances. The details of any action granting such a waiver shall be recorded and entered in the files of the code enforcement agency.

❖ If the fire code official determines that the requirements of this chapter are preempted by other codes, statutes or ordinances, he or she has the authority to waive the requirements of this chapter. Documentation must be placed into the files of the code enforcement agency stating the reasons for the waiver.

**5001.2 Material classification.** Hazardous materials are those chemicals or substances defined as such in this code. Definitions of hazardous materials shall apply to all hazardous materials, including those materials regulated elsewhere in this code.

❖ Hazardous materials are chemicals or substances defined in the code as such. Be sure to view the Material Safety Data Sheets (MSDS) for information on the properties of the material.

**5001.2.1 Mixtures.** Mixtures shall be classified in accordance with hazards of the mixture as a whole. Mixtures of hazardous materials shall be classified in accordance with nationally recognized reference standards; by an *approved* qualified organization, individual, or Material Safety Data Sheet (MSDS); or by other *approved* methods.

❖ Mixtures are to be classified to their specific blend of chemicals, i.e., as a whole, not as to their component ingredients. The MSDS are required sources of information on the properties of the chemical mixtures.

**5001.2.2 Hazard categories.** Hazardous materials shall be classified according to hazard categories. The categories include materials regulated by this chapter and materials regulated elsewhere in this code.

❖ The properties of the chemical will mandate the hazard categories under which the chemical is listed. These properties are found in the MSDS.

**5001.2.2.1 Physical hazards.** The material categories listed in this section are classified as *physical hazards*. A material with a primary classification as a *physical hazard* can also pose a *health hazard*.

1. *Explosives* and blasting agents.
2. *Combustible liquids*.
3. Flammable solids, liquids and gases.
4. Organic peroxide solids or liquids.
5. Oxidizer, solids or liquids.
6. Oxidizing gases.
7. Pyrophoric solids, liquids or gases.
8. Unstable (reactive) solids, liquids or gases.
9. Water-reactive materials solids or liquids.
10. *Cryogenic fluids*.

❖ This section lists those hazardous materials regulated in Chapters 51 and 53 through 67 that are clas-

sified as a physical hazard. The definition for the term “physical hazard” is located in Section 202. Because of their potential detonation or fire hazard, buildings containing more than the MAQ of hazardous materials listed in this section are classified as Group H-1, H-2 or H-3. Materials posing multiple hazards must be classified as both a health hazard and physical hazard, and meet the requirements of both classifications.

**5001.2.2.2 Health hazards.** The material categories listed in this section are classified as *health hazards*. A material with a primary classification as a *health hazard* can also pose a *physical hazard*.

1. Highly toxic and toxic materials.
2. *Corrosive* materials.

❖ This section lists those hazardous materials regulated in Chapters 51 and 53 through 67 that are classified as a health hazard. When hazardous chemicals pose more of a health problem than a fire, explosion or reactivity hazard, buildings containing more than the MAQ of hazardous materials listed in this section are classified as Group H-4. This section also notes that a hazardous material may pose multiple hazards and thus be considered both a physical hazard and health hazard. For example, a material classified as toxic or corrosive may also be a Class 2 or 3 oxidizer. Requirements for each material classification are applicable where a multiple hazard exists.

**5001.3 Performance-based design alternative.** Where *approved* by the *fire code official*, buildings and facilities where hazardous materials are stored, used or handled shall be permitted to comply with this section as an alternative to compliance with the other requirements set forth in this chapter and Chapters 51 through 67.

❖ The purpose of performance-based design criteria is to promote innovative, flexible and responsive solutions that optimize the expenditure and consumption of resources while preserving social and economic value. The model codes, including the *International Codes*® (I-Codes®), have traditionally incorporated alternative materials, designs and methods of construction provisions, such as those found in Section 104.9. This section provides a framework and opportunity to use new materials and methods when design equivalence to the prescriptive requirements of the code is demonstrated to and approved by the fire code official.

Large chemical manufacturing and production facilities are typically required to comply with federal risk management plans (RMP) and process safety management (PSM) requirements, which require a level of safety that generally exceeds current hazardous materials regulations in the code. This section is intended to be compatible with federal RMP and PSM programs, so it would reduce the burden on businesses in having to comply with duplicative or conflicting local and federal regulations. Yet, compliance with these provisions will yield a level of safety that

should equal or exceed the prescriptive code requirements.

Based on the fact that performance-based approaches are already in widespread use in federal laws regulating chemical storage and handling facilities, the topic of hazardous materials regulation stands out as a good place to start phasing performance-based concepts into the code. While a casual glance through the text of Section 5001.3 might lead one to conclude that the proposed section represents a huge loophole for the industry to jump through to avoid compliance with the code's prescriptive requirements, a closer investigation will reveal that this is not the case. This text, duplicated from Chapter 22 of the *ICC Performance Code® for Buildings and Facilities* (ICCPC®), was developed by trying to incorporate federal RMP and PSM regulations and then looking through the code's prescriptive hazardous materials regulations to pick up any topics that appeared to have been overlooked.

The text of this section was developed through a cooperative effort of fire officials and industry representatives in the IFC Performance Code Development Forum. Those who worked on the text believed that compliance with the proposed provisions would yield a facility that would be at least as safe, if not safer, than a facility constructed in accordance with the code's prescriptive requirements.

It is absolutely true that use of this approach would require a tremendous amount of time, money and effort on the part of a permit applicant to demonstrate code compliance to local fire code officials, and clearly, the approach will not be for everyone; however, even for those who might not use the approach in its entirety, the performance objectives would greatly assist code users and enforcers when dealing with alternative methods by better defining the intent of the code.

See the ICCPC and its "User's Guide" for a more comprehensive discussion of performance-based design concepts and philosophy.

**5001.3.1 Objective.** The objective of Section 5001.3 is to protect people and property from the consequences of unauthorized discharge, fires or explosions involving hazardous materials.

❖ The intent and scope of this section is to protect the occupants of the building, people in the surrounding area, emergency response personnel and property from acute consequences associated with unintended or unauthorized releases of hazardous materials. These performance-based design requirements encourage the use of both accident prevention and control measures to reduce risk.

It is not the intent of this section or the prescriptive requirements of the code to regulate all hazardous materials. Within the scopes of building and fire codes, hazardous materials are generally defined as those materials that are acutely dangerous to people or property. Building and fire codes in the United

States usually defer regulation of materials that present only a risk of chronic or environmental effects to other regulatory agencies, such as the Occupational Safety and Health Administration (OSHA) or the Environmental Protection Agency (EPA). Exposure of workers to hazardous materials in the normal course of their jobs is also beyond the scope of building and fire codes. Such workplace safety issues are instead regulated by occupational safety and health codes, which in the United States fall under the jurisdiction of OSHA.

When developing a performance-based design involving hazardous materials concerns, consideration should be given not only to the hazardous materials categories in Section 5001.2.2, but also to the quantity, state, situation (storage/use), arrangement and location of materials and processes.

**5001.3.2 Functional statements.** Performance-based design alternatives are based on the following functional statements:

1. Provide safeguards to minimize the risk of unwanted releases, fires or explosions involving hazardous materials.
2. Provide safeguards to minimize the consequences of an unsafe condition involving hazardous materials during normal operations and in the event of an abnormal condition.

❖ This section includes two functional statements that serve the overall objective of Section 5001.3. These two statements focus on reducing the probability of unsafe conditions involving hazardous materials and minimizing the consequences of an unsafe condition, if one occurs. The concepts can be summarized as prevention and control. Specific means by which these functional statements can be accommodated are listed in Section 5001.3.3.

**5001.3.3 Performance requirements.** Where safeguards, systems, documentation, written plans or procedures, audits, process hazards analysis, mitigation measures, engineering controls or construction features are required by Sections 5001.3.3.1 through 5001.3.3.18, the details of the design alternative shall be subject to approval by the *fire code official*. The details of actions granting the use of the design alternatives shall be recorded and entered in the files of the jurisdiction.

❖ Section 5001.3 allows the use of this section of the code based on the approval of the fire code official; however, the specifics of the design alternatives selected by designers, evaluators and operators should also be subject to review by a third party representing the public. The fire code official has the responsibility to verify that the performance alternatives provided by Section 5001.3 will protect from conditions hazardous to life, property or public welfare, as required by Section 101.2. When acceptance for the use of the design is granted, a record of the approval should be made in the public record to document acceptance of the design alternative.

**5001.3.3.1 Properties of hazardous materials.** The physical- and health-hazard properties of hazardous materials on site shall be known and shall be made readily available to employees, neighbors and the *fire code official*.

❖ This section correlates with the reporting requirements set forth in the Superfund Amendments and Reauthorization Act of 1986 (SARA Title III) and to some degree with the prescriptive reporting requirements set forth in the code. Compliance with these reporting requirements can be accomplished through the use of MSDS; inventory reports; SARA Title III reporting documents, which are typically mandatory under federal law; and Section 5001.5.2. This section ensures that interested parties will have access to information about the characteristics of hazardous materials that are located on site.

**5001.3.3.2 Reliability of equipment and operations.** Equipment and operations involving hazardous materials shall be designed, installed and maintained to ensure that they reliably operate as intended.

❖ Equipment and operations at facilities regulated by federal PSM rules should have little difficulty demonstrating compliance with the requirements of this section. The PSM rules generally address this topic area.

At facilities that are not required to comply with PSM rules, the selection of equipment and design of operations would have to go through a great deal of scrutiny by qualified individuals. In addition, equipment manuals and operational protocols would need to be developed and followed, as applicable.

**5001.3.3.3 Prevention of unintentional reaction or release.** Safeguards shall be provided to minimize the risk of an unintentional reaction or release that could endanger people or property.

❖ Facilities regulated by federal RMP rules are required to evaluate the potential consequences of various release scenarios on the surrounding area; therefore, many such facilities provide safety systems to reduce these potential consequences, recognizing that the consequence analysis information must be made available to the public.

Depending on the classification and state (solid, liquid or gas) of hazardous materials stored or used at a given site, a variety of mitigation measures may be provided to comply with this provision. Such measures might include process controls, spill control and containment systems, and ventilation controls.

**5001.3.3.4 Spill mitigation.** Spill containment systems or means to render a spill harmless to people or property shall be provided where a spill is determined to be a plausible event and where such an event would endanger people or property.

❖ This requirement is primarily derived from the prescriptive provisions in the code. As a general rule, storage facilities are regarded as less likely candidates for dangerous spills than facilities that involve dispensing or processing operations. In addition, dangerous spill conditions are probably more likely to occur in facilities with large quantity vessels or sys-

tems than those with only small containers. Information that may be useful in determining whether a spill is plausible and whether dangerous conditions would result includes the following:

- Specific material and process hazards involved.
- A block flow diagram for the facility.
- Piping and instrument drawings.
- A list of all safety devices showing their location, design basis and capacity, date of installation, etc.
- Equipment manufacturers' operational instructions, including safe operating limits for the equipment.
- Equipment drawings and specifications that reflect built and installed equipment.

**5001.3.3.5 Ignition hazards.** Safeguards shall be provided to minimize the risk of exposing combustible hazardous materials to unintended sources of ignition.

❖ The primary design and operating intent is to ensure that flammable and combustible materials are always completely controlled, in accordance with process design parameters; however, where flammable and combustible hazardous materials are present, a degree of redundancy is sometimes necessary to provide an additional level of safety. Where there is a plausible risk of spills or leaks, such as in loading and unloading or packaging operations, additional measures, such as ignition source controls, are prudent. To that end, process design and operation should ensure to the greatest degree possible that ignition sources are kept away from areas where flammable or combustible hazardous materials are present. Where separation is not feasible, ignition source controls may be warranted. Such controls may involve the following:

- Electrical classification of areas where flammable hazardous materials might be present.
- Classification of mobile equipment that might operate in areas where flammable hazardous materials might be present.
- The use of grounding systems and equipment to minimize the potential for sparking in areas where flammable hazardous materials might be present.

**5001.3.3.6 Protection of hazardous materials.** Safeguards shall be provided to minimize the risk of exposing hazardous materials to a fire or physical damage whereby such exposure could endanger or lead to the endangerment of people or property.

❖ This section directs the designer and operator to review and ensure that vessels or systems containing hazardous materials are not exposed to or are protected from damage by external fire. The design should focus, first, on reducing the possibility for fire or other hazards, such as vehicular impact, and, sec-

ond, on isolating hazardous materials from exposure to unsafe conditions, such as a fire.

All storage areas and systems should be formally reviewed to find and correct any sources of exposure to fire, including the following:

- Nearby storage of combustibles.
- Nearby hot work operation.
- Nearby vehicular operation.

All systems subject to fire exposure should be formally reviewed to ensure adequate protection, including the following:

- Sprinkler installation.
- Insulation of equipment.
- Fire-resistance-rated barriers.

**5001.3.3.7 Exposure hazards.** Safeguards shall be provided to minimize the risk of and limit damage from a fire or explosion involving explosive hazardous materials whereby such fire or explosion could endanger or lead to the endangerment of people or property.

❖ This section directs the designer and operator to review and ensure that vessels or systems containing hazardous materials are not subject to damage from internal fire, chemical reaction or explosion. The design criteria should be, first, to reduce the risk of an internal fire or explosion and, second, where the first is not feasible, to design vessels and systems in such a manner that loss of integrity will not occur in an overpressure situation.

All systems should be formally reviewed to identify and correct any sources of internal fire, explosion or overpressure. The review should include the following:

- The potential for inadvertent or improper mixing of reactive components.
- The potential for overheating of unstable materials.
- The potential for inadequate venting of unstable reaction byproducts.
- The potential for inadequate diluent material supply.

Where overpressure or explosion conditions cannot be reasonably ruled out, the design should consider overpressure protection, containment and explosion control systems.

**5001.3.3.8 Detection of gas or vapor release.** Where a release of hazardous materials gas or vapor would cause immediate harm to persons or property, means of mitigating the dangerous effects of a release shall be provided.

❖ This section increases the likelihood that hazardous vapor releases are detected and mitigated before they can harm individuals or property. In occupied areas, detection of a vapor release may be by sight, smell or an automatic detection system. For many hazardous materials, such as chlorine or ammonia, vapor releases are readily evident before concentra-

tions are truly hazardous based on the presence of vapor fog or a noxious odor. Where this is not the case, automatic detection systems and alarms may be warranted. Sensors can take the form of ambient sampling devices at strategic area locations, sampling devices in key vent streams or specially designed leak-detection systems, such as acoustic emission systems. The performance measurement is based on the ability of the sensing equipment or operators to provide adequate warning so that safety precautions can be taken before unsafe conditions are present.

Mitigation-based solutions can range from special process equipment designs to elaborate ventilation and air-scrubbing systems. Where practical, the simplest mitigation consists of overdesign of the process system so that the likelihood of release is extremely low. The performance measurement of a ventilation or treatment system is based on the reduction of the concentration of the hazardous materials in the workplace and nearby environment to levels that are not acutely hazardous.

**5001.3.3.9 Reliable power source.** Where a power supply is relied upon to prevent or control an emergency condition that could endanger people or property, the power supply shall be from a reliable source.

❖ This section is derived from the prescriptive requirements of the code. It is essential to ensure that a reliable power supply is provided for systems that are critical to safety. Some examples of systems that may require a reliable power supply include mechanical ventilation systems; treatment systems; gas detection and alarm systems; and emergency shutdown systems. The reliability needs of the system are related to the potential risks associated with system failure.

A reliable power source does not necessarily equate to a generator or battery system. The type of system to be used depends on the relative level of hazard that might result in the event of a power failure. In some cases, such as those where hazardous processes shut down upon loss of power, a connection ahead of the building's main disconnect switch may be adequate to qualify as a reliable source. Guidance on the selection and performance requirements for power supply systems providing an alternative source of electrical power can be found in NFPA 110.

**5001.3.3.10 Ventilation.** Where ventilation is necessary to limit the risk of creating an emergency condition resulting from normal or abnormal operations, means of ventilation shall be provided.

❖ In many cases involving hazardous materials, ventilation must be provided to limit the risk of creating an emergency condition. Ventilation might be necessary during both normal and abnormal operating conditions. Some examples of operations that may require ventilation are storage or processing of flammable and combustible liquids or gases inside buildings;

drum-filling operations inside buildings; laboratory use of chemicals and dust-handling systems. Ventilation may also be used as a means for reducing vapor concentrations below lower flammable limits (LFL) in areas where ignition sources are present or for pressurization of areas to isolate hazardous vapors.

Guidance on the performance requirements for ventilation systems can be found in a number of sources, including the OSHA Process Safety Management (PSM) regulations, DOL 29 CFR Part 1910.119; NFPA 30; NFPA 45; NFPA 69; and NFPA 497.

**5001.3.3.11 Process hazard analyses.** Process hazard analyses shall be conducted to ensure reasonably the protection of people and property from dangerous conditions involving hazardous materials.

❖ This section establishes an administrative safety control plan addressing process hazard analysis. Guidance on process hazard analysis techniques can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. The process hazard analysis must be appropriate to the complexity of the process and must identify, evaluate and control the hazards involved in the process. The analysis can be accomplished through various methods. Some of these are “what-if” scenarios, process hazard analysis, fault tree, etc. A person trained in these and other hazard evaluation techniques should be employed to complete this analysis.

**5001.3.3.12 Pre-startup safety review.** Written documentation of pre-startup safety review procedures shall be developed and enforced to ensure that operations are initiated in a safe manner. The process of developing and updating such procedures shall involve the participation of affected employees.

❖ This section establishes an administrative safety control plan addressing prestartup safety review procedures. Guidance on techniques for written documentation of prestartup safety review procedures can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. Prestartup safety reviews are typically necessary when new facilities are prepared for operation and where existing facilities are modified to a degree that is significant enough to require a change in the process safety information.

A prestartup safety review should confirm that, prior to the introduction of highly hazardous chemicals to a process, the following verifications have been accomplished at a minimum:

- Construction and equipment is in accordance with design specifications.
- Safety, operating, maintenance and emergency procedures are in place and are adequate.
- For new facilities, a process hazard analysis has been performed and recommendations have been resolved or implemented before startup; for modified facilities, requirements contained in

management of change documents have been met.

- Training of each employee involved in operating a process has been completed.

**5001.3.3.13 Operating and emergency procedures.** Written documentation of operating procedures and procedures for emergency shut down shall be developed and enforced to ensure that operations are conducted in a safe manner. The process of developing and updating such procedures shall involve the participation of affected employees.

❖ This section establishes an administrative safety control plan addressing written documentation of operating and emergency shutdown procedures. Guidance on developing written documentation for operating procedures and emergency shutdown techniques can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. Overall, there are 14 elements that employers covered by PSM are required to complete to meet the federal PSM regulations. Two elements that relate to this section are as follows:

- DOL 29 CFR Part 1910.119(c): This element requires that employees and their representatives be consulted on the development and conduct of hazard assessments and the development of chemical accident prevention plans, and provide access to these and other records required under the federal law.
- DOL 29 CFR Part 1910.119(f): This element requires that written operating procedures for the chemical process, including procedures for each operating phase, operating limitations, and safety and health considerations, must be developed and implemented.

**5001.3.3.14 Management of change.** A written plan for management of change shall be developed and enforced. The process of developing and updating the plan shall involve the participation of affected employees.

❖ This section establishes an administrative safety control plan addressing management of change. Guidance on developing written documentation for management of change can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. The PSM element that relates to this section is DOL 29 CFR, Part 1910.119 (l), which states that this element requires a review of the technical basis for the proposed change; the impact of change on safety and health; possible modifications to operating procedures and process safety information; the necessary time period for the change; and authorization requirements for the proposed change.

Employees involved in operating a process, and maintenance and contract employees whose job tasks will be affected by a change in the process, should be informed of and trained in the change prior to startup of the process or the affected part of the process.

**5001.3.3.15 Emergency plan.** A written emergency plan shall be developed to ensure that proper actions are taken in the event of an emergency, and the plan shall be followed if an emergency condition occurs. The process of developing and updating the plan shall involve the participation of affected employees.

❖ This section establishes an administrative safety control plan addressing emergency response planning. Guidance on developing written documentation for an emergency response plan can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. The PSM element that relates to this section is 29 CFR, Part 1910.119(n), which references other portions of the federal regulations. Such plans may include identification of actions to be taken by employees in the event of an emergency and the assignment of a staff liaison who can assist emergency response personnel.

**5001.3.3.16 Accident procedures.** Written procedures for investigation and documentation of accidents shall be developed, and accidents shall be investigated and documented in accordance with these procedures.

❖ This section establishes an administrative safety control plan addressing accident investigation and reporting. Guidance on accident investigation and reporting can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. The PSM element that relates to this section is DOL 29 CFR, Part 1910.119(m).

Some of the guidelines specified in the federal regulations include the following:

- The need for an incident investigation team to be established, consisting of at least one person knowledgeable in the process involved, a contract employee if the incident involved contractor work and other persons with appropriate knowledge and experience to thoroughly investigate and analyze the incident.
- The need for a report to be prepared at the conclusion of each investigation, including, at a minimum, the date of the incident and when the investigation began; description of the incident; factors that contributed to the incident and recommendations resulting from the investigation.
- The need for the establishment of a system to promptly address and resolve the incident report findings and recommendations, and to document resolutions and corrective actions.
- The need for accident investigation reports to be reviewed by all affected persons whose job tasks are relevant to the incident findings, including contract employees, where applicable.

**5001.3.3.17 Consequence analysis.** Where an accidental release of hazardous materials could endanger people or property, either on or off-site, an analysis of the expected consequences of a plausible release shall be performed and

utilized in the analysis and selection of active and passive hazard mitigation controls.

❖ This section establishes an administrative safety control plan addressing an analysis of off-site consequences. Guidance on accident investigation and reporting can be found in the EPA RMP regulation, 40 CFR, Part 68. These regulations amend the accident release prevention requirements under Section 112(r) of the Clean Air Act.

EPA's RMP rules are a good source of examples for alternative release scenarios for a particular site, and, through the identification and analysis of plausible release scenarios, changes can be implemented to minimize the probability and consequences of a release. A plausible release is one that has occurred in the past or could occur under reasonable single-system failures.

Devices that normally use some kind of motion or energy to prevent or minimize the release represent active mitigation controls. Active mitigation controls might include valves, switches, pumps and blowers. Passive mitigation controls include devices that are permanently in place and have an inherently safe design that allows them to be used at all times. Passive mitigation controls might include dikes, walls, ponds and sumps.

The off-site consequence analysis can be accomplished through various methods. Those methods include "what-if" scenarios, process hazard analysis, Hazard and Operability Analysis (HAZOP) and fault tree. A person trained in these and other hazard evaluation techniques should be used to complete this analysis.

**5001.3.3.18 Safety audits.** Safety audits shall be conducted on a periodic basis to verify compliance with the requirements of this section.

❖ This section establishes an administrative safety control plan addressing safety compliance audits. Guidance on safety audits can be found in the OSHA PSM regulation, DOL 29 CFR, Part 1910.119. The PSM element that relates to this section is DOL 29 CFR, Part 1910.119(o). On a routine basis, each facility must review its continuing compliance with each of the subsections in Section 5001.3 and other related provisions of the code. The word "periodic" reflects a need for adequate frequency to check that safety programs, features and systems will perform as intended. Recognizing that many code sections contain issues that change very little over time, compliance audit frequencies will not be the same for all programs, features and systems. Depending on the particular safety element, the audit frequency may range to as much as 5-year intervals under the PSM regulations.

**5001.4 Retail and wholesale storage and display.** For retail and wholesale storage and display of nonflammable solid and nonflammable or noncombustible liquid hazardous materials

in Group M occupancies and storage in Group S occupancies, see Section 5003.11.

- ❖ This section deals only with nonflammable solid and nonflammable or noncombustible liquid hazardous materials in Group M and S occupancies. For flammable or combustible liquids, see Section 5704.3.4 of the code.

**5001.5 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

When required by the *fire code official*, permittees shall apply for approval to permanently close a storage, use or handling facility. Such application shall be submitted not less than 30 days prior to the termination of the storage, use or handling of hazardous materials. The *fire code official* is authorized to require that the application be accompanied by an *approved* facility closure plan in accordance with Section 5001.6.3.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for the hazardous property.

**5001.5.1 Hazardous Materials Management Plan.** Where required by the *fire code official*, an application for a permit shall include a Hazardous Materials Management Plan (HMMP). The HMMP shall include a facility site plan designating the following:

1. Access to each storage and use area.
  2. Location of emergency equipment.
  3. Location where liaison will meet emergency responders.
  4. Facility evacuation meeting point locations.
  5. The general purpose of other areas within the building.
  6. Location of all above-ground and underground tanks and their appurtenances including, but not limited to, sumps, vaults, below-grade treatment systems and piping.
  7. The hazard classes in each area.
  8. Locations of all control areas and Group H occupancies.
  9. Emergency exits.
- ❖ This section requires information that allows emergency responders to understand the basic construction and access features of a building or premises to be presented. Such features include emergency exits that can be used for access; the physical and health hazards of hazardous materials stored and used

within particular areas; where emergency responders will meet the fire department liaison; and the location of all above-ground and underground tanks, sumps, vaults or any other below-grade processes. This information is extremely beneficial to emergency responders because it identifies locations where confined space entries may need to be performed. A Hazardous Materials Management Plan (HMMP) must also identify which areas are constructed as control areas and Group H occupancies.

HMMPs have commonly been used as tools to help facilitate tactical preplanning of Group H occupancies or facilities storing and handling large amounts of hazardous materials, such as petroleum storage terminals. HMMPs can be beneficial when preparing tactical preplans, but can be cumbersome if actually used as a tactical preplan. For example, consider a water treatment plant. Such a plant could have large amounts of anhydrous chlorine, sulfur dioxide, sodium hydroxide and hydrofluorosilic acid. To comply with all of the requirements of an HMMP for the various storage and process piping drawings, plant layout and process details could easily result in over 100 pages of information that would need to be read and understood. This level of information has not always been beneficial to emergency responders, especially given that Section 5003.9.1.1 requires the permit holder to designate responsible persons to serve as fire department liaisons in the event of an incident. It is expected that these responsible persons have a good understanding of the hazardous materials and the processes involving their storage and use.

All plans must be legible and should be drawn to scale or dimensioned and be kept updated. The fire code official may waive the requirement for an HMMP. By themselves, approvals of the building or site may suffice for the HMMP when dealing with small quantities of hazardous materials not posing a complex storage, use or maintenance problem.

Appendix H [Hazardous Materials Management Plan (HMMP) and Hazardous Materials Inventory Statement (HMIS) Instructions] was developed to provide a standard reporting format for businesses submitting an HMMP to the fire or building code official. Appendix H is not a mandatory appendix unless it is adopted by the jurisdiction. Some jurisdictions have already developed standard formats for submission of HMMPs, and Appendix H can be amended to provide this information to the regulated community.

**5001.5.2 Hazardous Materials Inventory Statement (HMIS).** Where required by the *fire code official*, an application for a permit shall include an HMIS, such as Superfund Amendments and Reauthorization Act of 1986 (SARA) Title III, Tier II Report or other *approved* statement. The HMIS shall include the following information:

1. Product name.
2. Component.
3. Chemical Abstract Service (CAS) number.

4. Location where stored or used.
  5. Container size.
  6. Hazard classification.
  7. Amount in storage.
  8. Amount in use-*closed systems*.
  9. Amount in use-*open systems*.
- ❖ HMIS requirements provide information that will prove beneficial to building and fire code officials, plans examiners and fire code inspectors who are attempting to determine that the amount of hazardous materials in storage and use complies with the applicable requirements of the code and the IBC. An HMIS must document the product's name, its chemical constituents along with its respective Chemical Abstract Service (CAS) numbers, the volume of containers or tanks, the product's hazard classification and the amount in storage, use-open systems and use-closed systems. This type of information is beneficial for plans examiners to confirm the correct occupancy classification, if the mechanical ventilation system should comply with Section 510 of the *International Mechanical Code*<sup>®</sup>, (IMC<sup>®</sup>), as well as to verify that the design of the process(es) complies with the applicable requirements of the code.

To provide the necessary information for proper occupancy classification, IBC Section 414.1.3 requires that information similar to the requirements for an HMIS be provided to the building code official. This section now requires that plans reflect where hazardous materials will be stored and used in multiple-story buildings, which is necessary to verify compliance with Table 5003.8.3.2 and IBC Table 414.2.2.

SARA Title III, known as the Emergency Planning and Right to Know Act, established requirements for emergency planning and reporting on hazardous materials. SARA Title III, Tier II reports are representative of a typical HMIS as required by this section. The exception, which is listed in SARA and is similar to Section 5001.4.1, leaves the requirement for submission of the HMIS up to the discretion of the fire code official for circumstances in which hazards can be managed without the need for HMIS.

A new Appendix H [Hazardous Materials Management Plan (HMMP) and Hazardous Materials Inventory Statement (HMIS) Instructions] was developed to provide a standard reporting format for businesses submitting an HMIS to the fire or building code official. Appendix H is not a mandatory appendix unless it is adopted by the jurisdiction. Some jurisdictions have already developed standard formats for submittal of HMISs, and Appendix H can be amended to provide this information to the regulated community.

**5001.6 Facility closure.** Facilities shall be placed out of service in accordance with Sections 5001.6.1 through 5001.6.3.

- ❖ This section contains requirements for handling and disposing of hazardous materials prior to a facility's closure. The 30-day notice prior to the facility's clo-

sure is intended to enable proper measures to be taken for disposing of or eliminating all hazardous materials before the building owner vacates the premises.

**5001.6.1 Temporarily out-of-service facilities.** Facilities that are temporarily out of service shall continue to maintain a permit and be monitored and inspected.

- ❖ Facilities warranting a closure plan are considered to be either temporarily or permanently out of service. Although a facility may not be closed permanently, this section recognizes the need to regulate hazardous materials in buildings that may be temporarily out of service. Because the out-of-service condition may be temporary, the storage or presence of any hazardous materials in a facility must be monitored and inspected, as required by the fire code official.

**5001.6.2 Permanently out-of-service facilities.** Facilities for which a permit is not kept current or is not monitored and inspected on a regular basis shall be deemed to be permanently out of service and shall be closed in an *approved* manner. Where required by the *fire code official*, permittees shall apply for approval to close permanently storage, use or handling facilities. The *fire code official* is authorized to require that such application be accompanied by an *approved* facility closure plan in accordance with Section 5001.6.3.

- ❖ Facilities warranting a closure plan are considered to be either temporarily or permanently out of service. A facility is to be classified as permanently out of service if approval is not kept current as required for a temporarily out-of-service facility or it is not properly monitored or inspected, as required by the fire code official.

**5001.6.3 Facility closure plan.** Where a facility closure plan is required in accordance with Section 5001.5 to terminate storage, dispensing, handling or use of hazardous materials, it shall be submitted to the *fire code official* not less than 30 days prior to facility closure. The plan shall demonstrate that hazardous materials that are stored, dispensed, handled or used in the facility will be transported, disposed of or reused in a manner that eliminates the need for further maintenance and any threat to public health and safety.

- ❖ This plan is used to document the timetable for the proper transportation, disposal or approved reuse of all chemicals that are on site. It is important to note that this could include any contaminated soils or dike facilities in the area.

## SECTION 5002 DEFINITIONS

**5002.1 Definitions.** The following terms are defined in Chapter 2:

**BOILING POINT.**

**CEILING LIMIT.**

**CHEMICAL.**

**CHEMICAL NAME.**

CLOSED CONTAINER.  
 CONTAINER.  
 CONTROL AREA.  
 CYLINDER.  
 DAY BOX.  
 DEFLAGRATION.  
 DESIGN PRESSURE.  
 DETACHED BUILDING.  
 DISPENSING.  
 EXCESS FLOW CONTROL.  
 EXHAUSTED ENCLOSURE.  
 EXPLOSION.  
 FLAMMABLE VAPORS OR FUMES.  
 GAS CABINET.  
 GAS ROOM.  
 HANDLING.  
 HAZARDOUS MATERIALS.  
 HEALTH HAZARD.  
 IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).  
 INCOMPATIBLE MATERIALS.  
 LIQUID.  
 LOWER EXPLOSIVE LIMIT (LEL).  
 LOWER FLAMMABLE LIMIT (LFL).  
 MATERIAL SAFETY DATA SHEET (MSDS).  
 MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA.  
 NORMAL TEMPERATURE AND PRESSURE (NTP).  
 OUTDOOR CONTROL AREA.  
 PERMISSIBLE EXPOSURE LIMIT (PEL).  
 PESTICIDE.  
 PHYSICAL HAZARD.  
 PRESSURE VESSEL.  
 SAFETY CAN.  
 SECONDARY CONTAINMENT.  
 SEGREGATED.  
 SOLID.  
 STORAGE, HAZARDOUS MATERIALS.  
 SYSTEM.  
 TANK, ATMOSPHERIC.  
 TANK, PORTABLE.  
 TANK, STATIONARY.  
 TANK VEHICLE.  
 UNAUTHORIZED DISCHARGE.  
 USE (MATERIAL).

## VAPOR PRESSURE.

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 5003 GENERAL REQUIREMENTS

**5003.1 Scope.** The storage, use and handling of all hazardous materials shall be in accordance with this section.

- ❖ Once a chemical is considered a hazardous chemical that is not exempt under the exceptions of Section 5001.1, it is expected to meet the general requirements listed in Section 5003 and any of the referenced codes or standards.

**5003.1.1 Maximum allowable quantity per control area.** The *maximum allowable quantity per control area* shall be as specified in Tables 5003.1.1(1) through 5003.1.1(4).

For retail and wholesale storage and display in Group M occupancies and Group S storage, see Section 5003.11.

- ❖ This section references Tables 5003.1.1(1) through 5003.1.1(4) for the maximum quantities allowed in a control area (see Section 5003.8.2 for design and protection requirements). If the quantity of chemicals used in a building does not exceed the maximum allowed per control area and the number of control areas does not exceed the number and percentage of chemicals allowed by Table 5003.8.3.2, those areas are considered part of the main use and do not have to meet all of the requirements for a hazardous occupancy.

**TABLE 5003.1.1(1).** See page 50-17.

- ❖ Table 5003.1.1(1) is subdivided based on whether the material is in storage or in use in a closed or open system. Definitions of both “Closed” and “Open” systems are found in Section 202. Within these subdivisions, the appropriate MAQ is listed in accordance with the physical state (solid, liquid or gas) of the material. A column for gas in open systems is not indicated because gaseous hazardous materials should not be allowed in a system that is continuously open to the atmosphere. Note that the third column of the table, “Group When the Maximum Allowable Quantity Is Exceeded,” is informational only, since occupancy group determination is within the scope of the IBC, not the code.

Note also that the MAQ values for gases are indicated (at the head of each gas column) as being “at NTP,” i.e., at a “normal” temperature of 70°F (21°C) and a pressure of one atmosphere, or 14.7 pounds per square inch absolute (psia) (101 kPa). In other

words, the MAQs for gases are based on a certain volume of free gas, not gas under pressure in its cylinder.

This table and Table 5003.1.1(3) for outdoor storage include a row for inert gases and inert cryogenics, thus clarifying that the amount of inert gases and inert cryogenics in storage or use is unlimited. There is also a definition in Section 202 for “Inert gas” that provides a means of classifying gases considered inert under conditions most commonly encountered by fire code officials. This definition ensures that inert compressed gases, inert cryogenic fluids or gas mixtures containing cryogenic fluid are properly classified. See the commentary to that definition in Section 202.

Even though the quantity of inert gases and cryogenics is not limited inside of a building, they are still subject to regulation. For example, storage of inert gases and cryogenic fluids requires an operational permit in accordance with Sections 105.6.9 and 105.6.11, respectively. In addition, Section 5307 has requirements for a mechanical ventilation system designed and operated in accordance with Section 5004.3 for storage and Section 5005.1.9 for use when a room or building contains inert compressed gases. Rooms containing inert cryogenic compressed gases are required to comply with the construction and mechanical ventilation requirements in Section 5504.2.

The unit of measure for liquefied gases has historically been incorporated into the MAQ tables in terms of gallons (L) because that has been the conventional thinking. From a practical standpoint, the use of gallons (L) as a unit of measure for liquefied gases introduces an inconsistency into the concept due to the fact that, unlike most liquids, the density of liquefied gases varies widely.

In commerce, liquefied gases are packaged and distributed based on weight as the unit of measure. The table has been revised to reflect threshold quantities in terms of the units of measure that are readily available from the commercial market and greatly simplifies the use of the code, thereby making it more user friendly. The revision required that a model be used as the basis for comparison. This approach was taken when thresholds were revised to base certain health-hazard threshold levels using a “chlorine index” as the model. A similar approach was used as a means to simplify the use of the table.

In the case of liquefied flammable gases, probably the most commonly encountered liquefied gas is LP-gas (LPG). LPG as defined can consist of propane, butane, propylene or others either in a mixed or pure form. NFPA 58, Table B.1.2(a), lists the approximate densities of commercial propane and butane at 60°F (16°C) as 4.20 and 4.81 pounds per gallon, respectively. Converting the 30-gallon (114 L) quantity to pounds and rounding up to the closest 5 pounds (2.3 kg) yields a quantity of 150 pounds (68 kg) on a weight basis. The density of butane is greater than

that of propane, therefore representing the worst case where mixtures of propane and butane are involved. The result of converting the 30-gallon (114 L) threshold to a 150-pound (68 kg) threshold is in keeping with the philosophical approach used with gases, such as ammonia and chlorine, as they appear in Table 5003.1.1(2).

The threshold level of 15 gallons (57 L) for oxidizing gases is now expressed in terms of weight based on using any of a number of oxidizing gases as the baseline. However, given the fact that a single cylinder of chlorine (an oxidizing, corrosive and toxic gas) has been used as the baseline in Table 5003.1.1(2), it is reasonable to use a single cylinder of chlorine as the baseline for the establishment of quantity in Table 5003.1.1(1), as well. To test the assumption, a comparison was made to the 1,500-cubic-foot (42 m<sup>3</sup>) baseline maximum quantity for a nonliquefied gas using oxygen as the model. Using a specific volume for oxygen of 12.1 cubic feet per pound translates the 1,500 cubic feet (42 m<sup>3</sup>) allowed for the baseline MAQ to 125 pounds (57 kg) if this gas was considered on a weight basis. The use of 150 pounds (68 kg) as a baseline quantity for liquefied oxidizing gases resolves the problem where a single cylinder of chlorine would not trip the Group H-4 occupancy threshold, but would trip the Group H-3 occupancy threshold where arguably the inherent health hazards of the gas may represent a greater concern for public safety than do the physical hazards of the same gas.

It is recognized that this approach may appear to represent a major increase in the threshold for liquefied oxidizing gases; however, it brings the threshold levels into parity with those of liquefied flammable gases, which may represent the greater hazard given the potential for fire and/or explosion. The example using oxygen as the baseline shows that an increase is justified and establishes a clear rationale that is based on practical examples of materials commonly found in commerce, which have generally been accepted for use as the threshold for an increased level of control. In addition, the use of weight as a unit of measure brings the code into correlation with units typically used by the suppliers of these products, thereby mitigating the need for elaborate conversions into units of measure not found in common use.

Note a refers the user to Section 5003.8.3 to determine if a design strategy using the control area concept is needed for a building to avoid being classified in Group H.

Note b clearly indicates that the aggregate quantity of hazardous materials in use and storage, within a given control area, cannot exceed the quantity listed in the table for storage.

Without Note c, many common alcoholic beverages and household products containing a negligible amount of a hazardous material could result in a Group M occupancy being classified as a high hazard. Note c also recognizes the reduced hazard of the materials based on their water miscibility and limited

container size. A similar exception is indicated in Table 5003.1.1(2), and in IBC Tables 307.1(1) and 307.1(2).

Notes d and e of the table are significant in that, for certain materials, the MAQ may be increased due to the use of approved special hazardous material storage methods as listed in the note, an approved automatic sprinkler system, or both. The notes are intended to be cumulative in that up to four times the base MAQ may be allowed per control area, if the building is sprinklered and approved special storage methods are used, without classifying the building as Group H. While the use of approved special storage methods is not always a feasible or practical method of storage, they do provide sufficient additional protection to warrant an increase if utilized to contain the entire MAQ (not just the increase amount). For example, the tabular MAQ for the storage of Class IA flammable liquid is 30 gallons (114 L) and both Notes d and e apply. Applying the notes accumulatively, the increased MAQ becomes  $30 \times 2 = 60 \times 2 = 120$  gallons (454 L). Note e also requires that a safety can, when used for increasing the MAQ of flammable and combustible liquids stored or used indoors, be a listed metal safety can meeting the requirements of UL 30, as required by Section 5003.9.10 (also see the commentary to that section).

The code recognizes the relative lower hazard of Class IIIB liquids as compared to that of other flammable and combustible liquids by classifying them as Group H-3 and by establishing a base MAQ of 13,200 gallons (49 962 L). As indicated in Note f, the quantity of Class I oxidizers and Class IIIB liquids, without classifying the occupancy as Group H-3, would not be limited, provided the building is fully sprinklered in accordance with NFPA 13. The hazard presented by Class I oxidizers is that they slightly increase the burning rate of combustible materials that they may come into contact with during a fire. Class IIIB combustible liquids have flash points at or above 200°F (93°C). Motor oil is a typical example of a Class IIIB combustible liquid.

Note g recognizes that the hazard presented by certain materials is such that they may be stored or used only inside buildings that are fully sprinklered.

Note h clarifies for the user that while there is a combination MAQ for flammable liquids, no individual class of liquid (Class IA, IB or IC) may exceed its own individual MAQ.

Note i allows for a special quantity of inside combustible liquid storage in tanks that are connected to a fuel-oil piping system in accordance with Section 603.3.2. This would apply to most oil-fired stationary equipment, whether in industrial, commercial or residential occupancies. Oil-fired heating equipment and diesel engine-driven generator sets and their fuel supplies are indicative of the types of fuel-oil piping systems to which this note would apply.

Note k permits a larger amount of Class III oxidizers in a building when used for maintenance and

health purposes. The quantities proposed are reasonable for occupancies such as the health care industry where Class III oxidizers are used for maintenance purposes, sterilization and sanitation of equipment and operation sanitation. The method used to store the oxidizers is subject to the evaluation and approval of the fire code official.

Note l clarifies that the 125 pounds (57 kg) of storage permitted for consumer fireworks represents the net weight of the pyrotechnic composition of the fireworks in a nonsprinklered building. This amount represents approximately 12½ shipping cases (less than one and one-half pallet loads) of fireworks in a nonsprinklered storage condition. In cases where the net weight of the pyrotechnic composition of the fireworks is unknown, 25 percent of the gross weight of the fireworks is to be used. The gross weight is to include the weight of the packaging.

Note n provides an exception when the amount of hazardous material in storage and display in Group M and S occupancies meets the requirements of Section 5003.11.

While cotton is included in the definition of combustible fibers, Note o recognizes the lesser hazard of cotton when it is stored in densely packed bales. See the commentary to the Section 202 definitions of “Baled cotton, densely packed” and “Combustible fibers” for further information.

Note p clarifies that vehicles and appliances with closed fuel systems should be treated no differently than machinery or equipment when applying the provisions of the table. The fuel contained within the fuel tanks of vehicles or motorized equipment is not to be considered when calculating the aggregate quantity of hazardous materials within a control area of a building. For example, when evaluating a parking garage with several hundred cars parked inside, the capacity of their fuel tanks is not counted. Also, when motorized equipment, such as a floor buffer or forklift, is stored or used, those fuels are not included as long as the other code requirements are followed. This note also allows a reasonable amount of alcohol-based hand rub for infection control and patient safety located in Group I-2 occupancies in appropriately sized dispensers to be located in control areas and permits the amounts not to be included in determining the MAQ. Section 5705.5 addresses the specifics regarding these amounts and locations.

Note q draws attention to the particularly challenging hazards of combustible dusts. This note specifies that where combustible dusts are manufactured, generated or used, and the concentration of dust or operating conditions creates a fire or explosion hazard, the building or space must be classified as a Group H-2 occupancy. To avoid this occupancy classification, the analysis needs to demonstrate why such a classification is not warranted. It should include an analysis of the material’s characteristics, and the type of engineering and administrative controls that will be employed in the process to quantitatively mitigate the

risk of a dust deflagration. The basis for this determination must be documented in a technical report and opinion in accordance with Section 104.7.2 (or IBC Section 414.1.3). See also the commentary to the definition of “Combustible dust” in Chapter 2 and the commentary to Chapter 22.

**TABLE 5003.1.1(2).** See page 50-20.

❖ Table 5003.1.1(2), similar to Table 5003.1.1(1), specifies the MAQs of hazardous materials, liquids or chemicals allowed per control area before having to classify a part of the building (or the entire building) as a Group H occupancy and is subdivided based on whether the material is in storage or in use in a closed or open system. Definitions of both “Closed system” and “Open system” are found in Section 202. Within these subdivisions, the appropriate MAQ is listed in accordance with the physical state (solid, liquid or gas) of the material. A column for gas in open systems is not indicated because hazardous gaseous materials should not be allowed in a system that is continuously open to the atmosphere. This table contains health-hazard materials classified as Group H-4, in accordance with IBC Section 307.6.

While the materials listed in this table are considered health hazards, some of the materials may also possess physical hazard characteristics more indicative of materials classified as Group H-1, H-2 or H-3 (see IBC Section 5001.1). The MAQs listed in the table are indicative of industry practice and assume the materials are properly stored and handled, in accordance with the code. Group H-4 materials, while indeed hazardous, are primarily considered a handling problem and do not possess the same fire, explosion or reactivity potential associated with other hazardous materials.

Note that the MAQ values for gases are indicated (at the head of each gas column) as being “at NTP,” i.e., at a “normal” temperature of 70°F (21°C) and pressure of one atmosphere, or 14.7 psia (101 kPa). In other words, the MAQs for gases are based on a certain volume of free gas, not gas under pressure in its cylinder.

The MAQ of 810 cubic feet (23 m<sup>3</sup>) for corrosive and toxic gases established in the table was based on a single cylinder of chlorine. Historically, Note g to the table that existed in previous editions of the code (but which was deleted in 2009) recognized that a single cylinder of ammonia should be allowed; however, the use of 810 cubic feet (23 m<sup>3</sup>) did not allow for this given the fact that, by comparison, a 150-pound (68 kg) cylinder of ammonia contains over 3,300 cubic feet (93 m<sup>3</sup>) of gas. The preferred solution in lieu of trying to justify or create a series of footnotes to address individual gases was to use an index system that created a standardized approach to establish the unit of measure by using a widely distributed gas, such as chlorine, as an index. However, the unit of measure in terms of weight was not carried into the table when it was formulated, thereby creat-

ing the need for the use of footnotes to address ammonia. Compressed gases may be in liquid form or they may be gaseous. Maintaining the use of chlorine as the index to the table for toxic and corrosive properties and listing the threshold for liquefied gases (as well as those that are nonliquefied) eliminates the need for elaborate conversions in units of measure using data that in many cases is not readily available. The index used to establish the weight threshold is based on the use of arsine, a highly toxic gas with a specific volume of 5.0 cubic feet per pound.

It may be argued that recognizing the common forms of gases, e.g., liquefied and nonliquefied, allows a de facto increase in the threshold levels applied. It is possible that one could have a toxic gas that is liquefied and also one that is nonliquefied in the same area, therefore doubling the aggregate quantity of gas if all was considered. While this is theoretically possible, it is not considered to be the norm. In addition, there is precedent in using the approach as established in Table 5003.1.1(1) for flammable and oxidizing gases. Also see the commentary to Table 5003.1.1(1) for further discussion of liquefied gas MAQ units of measure.

Note b clearly indicates that the aggregate quantity of hazardous materials in use and storage, within a given control area, cannot exceed the quantity listed in the table for storage.

Without Note c, many common household products containing a negligible amount of a hazardous material could result in a Group M occupancy being classified as a high hazard. Note c recognizes the reduced hazard of the materials based on their water miscibility and limited container size. A similar exception is indicated in Table 5003.1.1(1), and IBC Tables 307.1(1) and 307.1(2).

Where applicable, Notes d and e provide an increase in the base maximum allowable amount similar to that in Table 5003.1.1(1) [see commentary, Table 5003.1.1(1)].

Note f provides an exception when the amount of hazardous material in storage and display in Group M and S occupancies meets the requirements of Section 5003.11.

Note g of the table is significant in that, for certain materials, their hazard is so great that their MAQ may be stored in the building only when approved exhausted enclosures or gas cabinets complying with Sections 5003.8.5 and 5003.8.6, respectively, are utilized.

**TABLE 5003.1.1(3).** See page 50-21.

❖ Table 5003.1.1(3) specifies the MAQs of hazardous materials, liquids or chemicals allowed per outdoor control area before being subject to additional regulations contained in Chapters 51 and 53 through 67, and is subdivided based on whether the material is in storage or in use in a closed or open system. Definitions of both “Closed system” and “Open system” are found in Section 202. Within these subdivisions, the

appropriate MAQ is listed in accordance with the physical state (solid, liquid or gas) of the material. A column for gas in open systems is not indicated because hazardous gaseous materials should not be allowed in a system that is continuously open to the atmosphere. This table contains physical-hazard materials, as defined in Section 202. While the materials listed in this table are considered physical hazards, some of the materials may also possess health-hazard characteristics, as defined in Section 202. The MAQs per outdoor control area listed in the table are indicative of industry practice and assume the materials are properly stored and handled in accordance with the code. The base MAQ per outdoor control area of 810 cubic feet (23 m<sup>3</sup>) for gases that are either corrosive or toxic is based on a standard-size chlorine cylinder. Note that the MAQ values for gases are indicated (at the head of each gas column) as being “at NTP,” i.e., at a “normal” temperature of 70°F (21°C) and pressure of one atmosphere, or 14.7 psia (101 kPa). In other words, the MAQs for gases are based on a certain volume of free gas, not gas under pressure in its cylinder.

Historically, the concept of “outdoor control areas” was introduced into the code as a means to establish a threshold where the general provisions of Chapter 50 would apply. When this table was created, the logic for assignment of threshold values was primarily based on the use of multipliers representing a multiple increase of the basic tabular values shown in Table 5003.1.1(1). In the first draft of the code, this table limited the MAQ of gaseous and liquefied flammable gases to 1,500 cubic feet (42 m<sup>3</sup>) and 15 gallons (57 L), respectively. The result was that the threshold level for liquefied flammable gases in interior areas was greater than that allowed for the same commodity when stored in outdoor areas. Assuming that the threshold level of 30 gallons (114 L) for indoor areas was correct, the value of 15 gallons (57 L) shown for outdoor areas is believed to have been in error. Code change F1324-98 increased the threshold quantities for flammable and oxidizing gases, as well as a number of other commodities, in storage in outdoor areas by a factor of 2 resulting in the increase for liquefied flammable gases from 15 to 30 gallons (57 to 114 L), furthering the inconsistency.

The table corrects the MAQ inconsistency for liquefied flammable gases and, as in Table 5003.1.1(1), changes the MAQ unit of measure to units of weight rather than those of volume. This eliminates confusing and elaborate calculations, thereby bringing the code closer into harmony with the commercial environment. The index system used to obtain a unit of measure for weight is based on multiples for a single 150-pound (68 kg) cylinder of butane for flammable gases and a single 150-pound (68 kg) cylinder for chlorine. The row for oxidizing gases provides consistency and correlates in concept with conversion to a weight basis [also see commentary, Table 5003.1.1(1)].

While hazardous materials within a closed or open system are considered to be “in use,” Note b clearly indicates that the aggregate quantity of hazardous materials in use and storage within a given outdoor control area cannot exceed the quantity listed in the table for storage.

Note c provides an exception when the amount of hazardous materials in outdoor storage in conjunction with a retail or wholesale Group M occupancy meets the requirements of Section 5003.11. The outside storage area must be under the same ownership as the Group M occupancy.

**TABLE 5003.1.1(4).** See page 50-22.

❖ Table 5003.1.1(4), similar to Table 5003.1.1(3), specifies the MAQs of hazardous materials, liquids or chemicals allowed per outdoor control area before being subject to additional regulations contained in Chapters 51 and 53 through 67. It is also subdivided based on whether the material is in storage or in use in a closed or open system. Definitions of both “Closed system” and “Open system” are found in Section 202. Within these subdivisions, the appropriate MAQ is listed in accordance with the physical state (solid, liquid or gas) of the material. A column for gas in open systems is not indicated because hazardous gaseous materials should not be allowed in a system that is continuously open to the atmosphere. This table contains health-hazard materials, as defined in Section 202.

While the materials listed in this table are considered health hazards, some of the materials may also possess physical-hazard characteristics, as defined in Section 202. The MAQs per outdoor control area listed in the table are indicative of industry practice and assume the materials are properly stored and handled in accordance with the code. These materials, while indeed hazardous, are primarily considered a handling problem and do not possess the same fire, explosion or reactivity hazard associated with other hazardous materials.

As in Tables 5003.1.1(1) through 5003.1.1(3), a weight unit of measure has been established for liquefied gas MAQs and the table has been revised to recognize that these materials may exist in liquid, as well as gaseous form. The index system used to establish the quantity for toxics and corrosives is based on multiples of a single 150-pound (68 kg) cylinder of chlorine. The index system used to establish the threshold quantity for highly toxic liquefied gases is based on arsine, a highly toxic gas with a specific volume of 5.0 cubic feet per pound [also see commentary, Table 5003.1.1(1)].

Note b clearly indicates that the aggregate quantity of hazardous materials in use and storage within a given outdoor control area cannot exceed the quantity listed in the table for storage.

Note c provides an exception when the amount of hazardous material in outdoor storage in conjunction with a retail or wholesale Group M occupancy meets the requirements of Section 5003.11. The outside

storage area must be under the same ownership as the Group M occupancy.

Note d of the table is significant in that, for certain materials, the hazard is so great that their MAQ may be stored only when approved exhausted enclosures or gas cabinets complying with Sections 5003.8.5 and 5003.8.6, respectively, or laboratory fume hoods are utilized.

Note e states that when toxic liquids with a vapor pressure in excess of 1 psia (7 kPa) at 77°F (25°C) are stored, the MAQ is limited to the amount listed for highly toxic materials.

**5003.1.2 Conversion.** Where quantities are indicated in pounds and where the weight per gallon of the liquid is not provided to the *fire code official*, a conversion factor of 10 pounds per gallon (1.2 kg/L) shall be used.

❖ If the weight of a liquid is not given either in the MSDS or in other documentation on the material, the fire code official is allowed to use a conversion rate of 10 pounds of liquid to 1 gallon of material (Note: 1 U.S. gallon = 0.1336805 cubic foot).

**5003.1.3 Quantities not exceeding the maximum allowable quantity per control area.** The storage, use and handling of hazardous materials in quantities not exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(1) through 5003.1.1(4) shall be in accordance with Sections 5001 and 5003.

❖ See the commentary to Section 5003.1.1.

**5003.1.4 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of hazardous materials in quantities exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(1) through 5003.1.1(4) shall be in accordance with this chapter.

❖ Once the amounts of chemicals exceed the maximum allowed in Tables 5003.1.1(1) through 5003.1.1(4) per control area, the area or building is considered a hazardous occupancy and must meet the general requirements and specific requirements in both the code and the IBC, based on the chemicals being used.

**5003.2 Systems, equipment and processes.** Systems, equipment and processes utilized for storage, dispensing, use or handling of hazardous materials shall be in accordance with Sections 5003.2.1 through 5003.2.8.

❖ Devices used in the process and storage or dispensing of hazardous materials are to meet the requirements of Sections 5003.1 through 5003.2.8.

**5003.2.1 Design and construction of containers, cylinders and tanks.** Containers, cylinders and tanks shall be designed and constructed in accordance with *approved* standards. Containers, cylinders, tanks and other means used for containment of hazardous materials shall be of an *approved* type. Pressure vessels not meeting DOTn requirements for transportation shall comply with the ASME *Boiler and Pressure Vessel Code*.

❖ This section sets forth requirements for the construction of containers, cylinders and tanks used for the storage of hazardous materials. It requires that pressure vessels be constructed in accordance with the ASME *Boiler and Pressure Vessel Code* (BPVC) where hazardous materials are stored, used or handled inside of vessels designed to be operated at pressures greater than 15 pounds per square inch gauge (psig) (103.4 kPa). This is consistent with the requirements for pressure vessels used for other than hazardous materials purposes, as set forth in Section 1003.1 of the IMC.

The reference to the BPVC is in response to an incident investigated by the United States Chemical Safety Board (USCSB) involving an improperly modified pressure vessel at the Marcus Oil Company in Houston, Texas. The 12-foot-diameter (305 mm), 50-foot-long (15 240 mm) pressure vessel, which had an empty weight of approximately 50,000 pounds (22 680 kg), lacked any evidence of being constructed in accordance with the BPVC. The pressure vessel was not equipped with a pressure relief device. The pressure vessel was modified by the company by using an oxygen-acetylene torch to add a steam line that was used to melt polyethylene wax. The cut section of the head was reinstalled and welded into place by welders who were not qualified to perform work on pressure vessels. After the vessel was modified, it was not subjected to a hydrostatic pressure test to determine if it would remain closed when subjected to its operating pressure.

The vessel was returned to service and was pressurized by a nitrogen/air mixture while heating the polyethylene wax at a temperature of 300°F (149°C). On the day of the incident, the vessel catastrophically failed and was propelled more than 150 feet (45 720 mm) into an adjacent business. A 900-pound (408 kg) section of the vessel was propelled 900 feet (274 m) away and a 2-pound (0.9 kg) steel plate was found in the front yard of a residence one-quarter mile from the explosion. Shattered glass and building structural damage occurred one-quarter mile away from the explosion.

For SI: 1 cubic foot = 0.02832 m<sup>3</sup>, 1 pound = 0.454 kg, 1 gallon = 3.785 L.

NA = Not Applicable, NL = Not Limited, UD = Unclassified Detonable.

a. For use of control areas, see Section 5003.8.3.

b. The aggregate quantity in use and storage shall not exceed the quantity listed for storage.

c. The quantities of alcoholic beverages in retail and wholesale sales occupancies shall not be limited providing the liquids are packaged in individual containers not exceeding 1.3 gallons. In retail and wholesale sales occupancies, the quantities of medicines, foodstuff or consumer products and cosmetics containing not more than 50 percent by volume of water-miscible liquids with the remainder of the solutions not being flammable shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.

d. Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Where Note e also applies, the increase for both notes shall be applied accumulatively.

(continued)

**TABLE 5003.1.1(1)—continued**  
**MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING A PHYSICAL HAZARD<sup>a, i, m, n, p</sup>**

- e. Maximum allowable quantities shall be increased 100 percent where stored in approved storage cabinets, day boxes, gas cabinets, gas rooms, exhausted enclosures or in listed safety cans in accordance with Section 5003.9.10. Where Note d also applies, the increase for both notes shall be applied accumulatively.
- f. Quantities shall not be limited in a building equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.
- g. Allowed only in buildings equipped throughout with an approved automatic sprinkler system.
- h. Containing not more than the maximum allowable quantity per control area of Class IA, Class IB or Class IC flammable liquids.
- i. The maximum allowable quantity shall not apply to fuel oil storage complying with Section 603.3.2.
- j. Quantities in parenthesis indicate quantity units in parenthesis at the head of each column.
- k. A maximum quantity of 200 pounds of solid or 20 gallons of liquid Class 3 oxidizers is allowed where such materials are necessary for maintenance purposes, operation or sanitation of equipment where the storage containers and the manner of storage are approved.
- l. Net weight of pyrotechnic composition of the fireworks. Where the net weight of the pyrotechnic composition of the fireworks is not known, 25 percent of the gross weight of the fireworks including packaging shall be used.
- m. For gallons of liquids, divide the amount in pounds by 10 in accordance with Section 5003.1.2.
- n. For storage and display quantities in Group M and storage quantities in Group S occupancies complying with Section 5003.11, see Table 5003.11.1.
- o. Densely-packed baled cotton that complies with the packing requirements of ISO 8115 shall not be included in this material class.
- p. The following shall not be included in determining the maximum allowable quantities:
1. Liquid or gaseous fuel in fuel tanks on vehicles.
  2. Liquid or gaseous fuel in fuel tanks on motorized equipment operated in accordance with this code.
  3. Gaseous fuels in piping systems and fixed appliances regulated by the *International Fuel Gas Code*.
  4. Liquid fuels in piping systems and fixed appliances, regulated by the *International Mechanical Code*.
  5. Alcohol-based hand rubs classified as Class I or II liquids in dispensers that are installed in accordance with Sections 5705.5 and 5705.5.1. The location of the alcohol-based hand rub (ABHR) dispensers shall be provided in the construction documents.
- q. Where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 104.7.2.

TABLE 5003.1.1(2) MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIAL POSING A HEALTH HAZARD<sup>a, c, f, h, i</sup>

MATERIAL	STORAGE		USE-CLOSED SYSTEMS			USE-OPEN SYSTEMS		
	Solid pounds	Liquid gallons (pounds)	Gas cubic feet at NTP (pounds)	Solid pounds	Liquid gallons (pounds)	Gas cubic feet at NTP (pounds)	Solid pounds	Liquid gallons (pounds)
Corrosives	20,000	2,000	Gaseous 1,620 Liquefied (300)	10,000	1,000	Gaseous 810 Liquefied (150)	1,000	100
Highly toxics	20	(20)	Gaseous 40 <sup>d</sup> Liquefied (8) <sup>d</sup>	10	(10)	Gaseous 20 <sup>d</sup> Liquefied (4) <sup>d</sup>	3	(3)
Toxics	1,000	(1,000) <sup>e</sup>	Gaseous 1,620 Liquefied (300)	500	50 <sup>e</sup>	Gaseous 810 Liquefied (150)	125	(125) <sup>e</sup>

For SI: 1 cubic foot = 0.02832 m<sup>3</sup>, 1 pound = 0.454 kg, 1 gallon = 3.785 L, 1 pound per square inch absolute = 6.895 kPa, °C = [(°F)-32]/1.8].

- a. For gallons of liquids, divide the amount in pounds by 10 in accordance with Section 5003.1.2.
- b. The aggregate quantities in storage and use shall not exceed the quantity listed for storage.
- c. The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials allowed in outdoor storage per single property under the same ownership or control used for retail or wholesale sales is allowed to exceed the maximum allowable quantity per control area where such storage is in accordance with Section 5003.1.1.
- d. Allowed only where used in approved exhausted gas cabinets, exhausted enclosures or under fume hoods.
- e. The maximum allowable quantity per control area for toxic liquids with vapor pressures in excess of 1 psia at 77°F shall be the maximum allowable quantity per control area listed for highly toxic liquids.
- f. Quantities in parentheses indicate quantity units in parentheses at the head of each column.

**5003.2.2 Piping, tubing, valves and fittings.** Piping, tubing, valves, and fittings conveying hazardous materials shall be designed and installed in accordance with ASME B31 or other approved standards, and shall be in accordance with Sections 5003.2.2.1 and 5003.2.2.2.

❖ The design and construction of piping, tubing, valves and fittings must meet the requirements listed in Chapters 50 through 67, and the referenced standard or other approved standards acceptable to the fire code official. ASME B31 is the primary code for pressure piping. It is divided into nine sections, each regulating a different type of piping, and it has detailed requirements for installation, inspection and testing. Including ASME B31 in this general section on hazardous material piping will assist designers in referencing the correct standard in project specifications.

**5003.2.2.1 Design and construction.** Piping, tubing, valves, fittings and related components used for hazardous materials shall be in accordance with the following:

1. Piping, tubing, valves, fittings and related components shall be designed and fabricated from materials that are compatible with the material to be contained and shall be of adequate strength and durability to withstand the pressure, structural and seismic stress and exposure to which they are subject.
2. Piping and tubing shall be identified in accordance with ASME A13.1 to indicate the material conveyed.
3. Readily accessible manual valves or automatic remotely activated fail-safe emergency shutoff valves shall be installed on supply piping and tubing at the following locations:
  - 3.1. The point of use.
  - 3.2. The tank, cylinder or bulk source.
4. Manual emergency shutoff valves and controls for remotely activated emergency shutoff valves shall be identified and the location shall be clearly visible, accessible and indicated by means of a sign.
5. Backflow prevention or check valves shall be provided where the backflow of hazardous materials could create a hazardous condition or cause the unauthorized discharge of hazardous materials.
6. Where gases or liquids having a hazard ranking of:
  - Health Class 3 or 4
  - Flammability Class 4
  - Instability Class 3 or 4

in accordance with NFPA 704 are carried in pressurized piping above 15 pounds per square inch gauge (psig) (103 kPa), an *approved* means of leak detection and emergency shutoff or excess flow control shall be provided. Where the piping originates from within a hazardous material storage room or area, the excess flow control shall be located within the storage room or area. Where the piping originates from a

bulk source, the excess flow control shall be located as close to the bulk source as practical.

**Exceptions:**

1. Piping for inlet connections designed to prevent backflow.
  2. Piping for pressure relief devices.
- ❖ This section specifies minimum design requirements for any piping system handling hazardous materials. All associated piping, valves and fittings should also be compatible with the material to be used. As may be required by industry standards and OSHA regulations, piping and tubing conveying hazardous materials must be properly identified. Identification could include color-coded piping and permanent labeling on the piping and tubing. The method of operation of accessible manual shutoff valves must be identified as to what they control, as well. Backflow protection must be provided as necessary to protect potable water supplies and the environment, as required by local health departments, environmental agencies and fire code officials. This section mandates that a means of leak detection and either an emergency shutoff valve or excess flow control are to be provided.

**5003.2.2.2 Additional regulations for supply piping for health-hazard materials.** Supply piping and tubing for gases and liquids having a health-hazard ranking of 3 or 4 in accordance with NFPA 704 shall be in accordance with ASME B31.3 and the following:

1. Piping and tubing utilized for the transmission of highly toxic, toxic or highly volatile *corrosive* liquids and gases shall have welded, threaded or flanged connections throughout except for connections located within a ventilated enclosure if the material is a gas, or an *approved* method of drainage or containment is provided for connections if the material is a liquid.
2. Piping and tubing shall not be located within *corridors*, within any portion of a *means of egress* required to be enclosed in fire-resistance-rated construction or in concealed spaces in areas not classified as Group H occupancies.

**Exception:** Piping and tubing within the space defined by the walls of *corridors* and the floor or roof above or in concealed spaces above other occupancies where installed in accordance with Section 415.11.6.4 of the *International Building Code* for Group H-5 occupancies.

❖ Requirements of this section are dependent on whether the hazardous material involved has a health-hazard ranking of 3 or 4 based on the hazard classification system in NFPA 704. This section is not applicable to materials with a flammability or reactivity rating of 3 or 4; rather, it addresses piping systems handling highly toxic or toxic liquids and gases.

Leaks or piping failures are most common around threaded connections in the piping or tubing. Therefore, a means of containment is required around connections unless metallic piping or tubing with welded connections is used.

Hazardous material piping may not be located in an exit access corridor, exit or areas not classified as high hazard so that the required means of egress are available. The exception in this section recognizes specific design provisions for existing hazardous production materials facilities, which commonly transport hazardous materials through service passages or corridors. Also required are excess-flow control valves (to regulate the rate of flow of hazardous materials within the piping system) and emergency shutoff valves (to stop the flow of hazardous materials from possibly deteriorating further in an emergency scenario).

**5003.2.3 Equipment, machinery and alarms.** Equipment, machinery and required detection and alarm systems associated with the use, storage or handling of hazardous materials shall be listed or *approved*.

❖ Equipment associated with the use or storage of hazardous materials must be listed or approved by a third-party testing agency.

**5003.2.4 Installation of tanks.** Installation of tanks shall be in accordance with Sections 5003.2.4.1 through 5003.2.4.2.1.

❖ The installation of tanks shall be in accordance with Chapter 57, the referenced standards in Chapter 80 and Sections 5003.2.4.1 through 5003.2.4.2.1.

**5003.2.4.1 Underground tanks.** Underground tanks used for the storage of liquid hazardous materials shall be provided with secondary containment. In lieu of providing secondary containment for an underground tank, an above-ground tank in an underground vault complying with Section 5704.2.8 shall be permitted.

❖ This section requires that all new underground tanks for the storage of hazardous materials comply with applicable code requirements regarding the hazardous material in the tank. Secondary containment provides an additional measure of confining hazardous materials at their point of generation in case of a tank failure. As an alternative to providing secondary containment, an above-ground tank installed in an underground vault for flammable or combustible liquids in accordance with Section 5704.2.8 is allowed as being equivalent. Note that the requirement for secondary containment is a general requirement subject to the limitations and exclusions of Section 5001.1.

**5003.2.4.2 Above-ground tanks.** Above-ground stationary tanks used for the storage of hazardous materials shall be located and protected in accordance with the requirements for outdoor storage of the particular material involved.

**Exception:** Above-ground tanks that are installed in vaults complying with Section 5303.16 or 5704.2.8 shall not be

required to comply with location and protection requirements for outdoor storage.

❖ Requirements for above-ground tanks depend on the hazards associated with the material being stored. Tank requirements can be found in Sections 2306, 5404 and 5704.2. The exception allows the use of an above-ground tank in a below-grade tank vault in lieu of an underground tank. Installation of a tank in a vault is regarded as equivalent in safety to an underground tank by Chapter 57, and it is a superior method with regard to environmental safety. When such an installation is provided, requirements for location on site and similar provisions should be regarded as an underground installation.

**5003.2.4.2.1 Marking.** Above-ground stationary tanks shall be marked as required by Section 5003.5.

❖ This section requires that NFPA 704 hazard identification signs in accordance with Section 5003.5 be provided for above-ground tanks to assist emergency responders in identifying the hazards of the tanks' contents in case of a spill or fire incident.

**5003.2.5 Empty containers and tanks.** Empty containers and tanks previously used for the storage of hazardous materials shall be free from residual material and vapor as defined by DOTn, the Resource Conservation and Recovery Act (RCRA) or other regulating authority or maintained as specified for the storage of hazardous material.

❖ Tanks must be purged and cleaned of all residual hazardous chemicals before reuse for storage. Containers and tanks that have not been cleaned must be stored in areas meeting the requirements for a hazardous use area. Under the Resource Conservation and Recovery Act (RCRA), the EPA issues "cradle-to-grave" regulations for storing, using and disposing of hazardous waste. The act, enacted by Congress in 1976, established a uniform national policy for hazardous and solid waste disposal. This section requires that containers, cylinders and tanks, if still in use, either be properly maintained as required or comply with the EPA or other state and local environmental regulations.

**5003.2.6 Maintenance.** In addition to the requirements of Section 5003.2.3, equipment, machinery and required detection and alarm systems associated with hazardous materials shall be maintained in an operable condition. Defective containers, cylinders and tanks shall be removed from service, repaired or disposed of in an *approved* manner. Defective equipment or machinery shall be removed from service and repaired or replaced. Required detection and alarm systems shall be replaced or repaired where defective.

❖ Equipment, machinery and required detection and alarm equipment must be maintained in an operable condition at all times.

**5003.2.6.1 Tanks out of service for 90 days.** Stationary tanks not used for a period of 90 days shall be properly safe-

guarded or removed in an *approved* manner. Such tanks shall have the fill line, gauge opening and pump connection secured against tampering. Vent lines shall be properly maintained.

❖ This section places a time limitation on out-of-service storage tanks of hazardous materials. Within 90 days, proper steps should be taken to address any potential hazard with the storage tank. Without a time limitation for safeguarding the out-of-service storage tank, it is likely that the tank will not be properly monitored or inspected as necessary and, consequently, the risk of the tank becoming defective increases. Care shall be taken to prevent tampering with all associated equipment. Vent lines must be kept clear and be properly maintained during this time.

**5003.2.6.1.1 Return to service.** Tanks that are to be placed back in service shall be tested in an *approved* manner.

❖ Tanks must be tested as a new installation before being placed back in service.

**5003.2.6.2 Defective containers and tanks.** Defective containers and tanks shall be removed from service, repaired in accordance with approved standards or disposed of in an *approved* manner.

❖ Damaged containers, cylinders and tanks pose the potential hazard of content release. Care must be taken to determine that disposal does not present a greater hazard than the damaged container, cylinder or tank.

Small containers usually cannot be repaired easily. Large containers and fixed tank installations often cannot be easily replaced and must be repaired. Temporary storage of hazardous materials during container repair must comply with code requirements.

**5003.2.7 Liquid-level limit control.** Atmospheric tanks having a capacity greater than 500 gallons (1893 L) and that contain hazardous material liquids shall be equipped with a liquid-level limit control or other *approved* means to prevent overfilling of the tank.

❖ Overfilling of tanks has been a problem over the years. This section requires atmospheric tanks with a capacity greater than 500 gallons (1893 L) containing hazardous materials to be equipped with an approved method of fill control.

**5003.2.8 Seismic protection.** Machinery and equipment utilizing hazardous materials shall be braced and anchored in accordance with the seismic design requirements of the *International Building Code* for the seismic design category in which the machinery or equipment is classified.

❖ In areas listed in IBC Chapter 16 as requiring seismic protection, machinery and equipment containing hazardous materials must be protected against seismic activity. The IBC assigns importance factors in classifying buildings. Buildings containing sufficient quantities of toxic or explosive substances that are considered to be dangerous to the public if release occurs carry an importance factor of 1.25 and struc-

tures containing highly toxic materials where the storage or use exceeds the MAQ have an importance factor of 1.50.

**5003.2.9 Testing.** The equipment, devices and systems listed in Section 5003.2.9.1 shall be tested at the time of installation and at one of the intervals listed in Section 5003.2.9.2. Records of the tests conducted or maintenance performed shall be maintained in accordance with the provisions of Section 107.2.1.

**Exceptions:**

1. Periodic testing shall not be required where *approved* written documentation is provided stating that testing will damage the equipment, device or system and the equipment, device or system is maintained as specified by the manufacturer.
2. Periodic testing shall not be required for equipment, devices and systems that fail in a fail-safe manner.
3. Periodic testing shall not be required for equipment, devices and systems that self-diagnose and report trouble. Records of the self-diagnosis and trouble reporting shall be made available to the *fire code official*.
4. Periodic testing shall not be required if system activation occurs during the required test cycle for the components activated during the test cycle.
5. *Approved* maintenance in accordance with Section 5003.2.6 that is performed not less than annually or in accordance with an *approved* schedule shall be allowed to meet the testing requirements set forth in Sections 5003.2.9.1 and 5003.2.9.2.

❖ This section establishes that the critical life safety and property protection systems and equipment listed in Section 5003.2.9.1 associated with the storage, handling and use of hazardous materials must undergo regular, documented maintenance to verify that they will perform as designed when needed. The section also requires that, as with any other safeguard required by the code, maintenance records must be maintained and be available to the fire code official (see commentary, Section 107.2).

Exception 1 recognizes that certain equipment, devices or systems are designed to function when needed but could be damaged by periodic testing. This fact must be documented in writing by an authority on the equipment, device or system that is acceptable to the fire code official. This would most likely be the equipment, device or system manufacturer since it is most familiar with its product. In addition to the written documentation, the manufacturer's maintenance specifications must be followed in order to take this exception.

Exception 2 recognizes that some equipment, devices or systems are designed with a feature for automatically counteracting the effect of an anticipated failure and eliminating or mitigating a hazardous condition caused by that failure by compensating for it. The term "fail-safe" is defined in Chapter 2.

Exception 3 recognizes the reliability of technology that allows equipment, devices or systems to self-monitor, diagnose and report any problems that could lead to a failure. Many fire alarm systems have this capability. In order to take the exception, records of the self-diagnosis and reporting must be kept and be available to the fire code official in accordance with Section 107.2.1.

Exception 4 states that, in the unlikely (but possible) event that an actual activation of the equipment, device or system occurs during a scheduled test of the equipment, device or system, the actual activation can be accepted in lieu of the scheduled test of the affected components.

Exception 5 states that the maintenance required by Section 5003.2.6 of equipment, devices or systems can be conducted in accordance with Section 5003.2.9.2, Item 1 or 4.

**5003.2.9.1 Equipment, devices and systems requiring testing.** The following equipment, systems and devices shall be tested in accordance with Sections 5003.2.9 and 5003.2.9.2.

1. Gas detection systems, alarms and automatic emergency shutoff valves required by Section 6004.2.2.10 for highly toxic and toxic gases.
  2. Limit control systems for liquid level, temperature and pressure required by Sections 5003.2.7, 5004.8 and 5005.1.4.
  3. Emergency alarm systems and supervision required by Sections 5004.9 and 5005.4.4.
  4. Monitoring and supervisory systems required by Sections 5004.10 and 5005.1.6.
  5. Manually activated shutdown controls required by Section 6403.1.1.1 for *compressed gas* systems conveying pyrophoric gases.
- ❖ This section lists the equipment, devices and systems that are subject to the provisions of Sections 5003.2.9 and 5003.2.9.2.

**5003.2.9.2 Testing frequency.** The equipment, systems and devices listed in Section 5003.2.9.1 shall be tested at one of the frequencies listed below:

1. Not less than annually.
  2. In accordance with the *approved* manufacturer's requirements.
  3. In accordance with *approved* recognized industry standards.
  4. In accordance with an *approved* schedule.
- ❖ This section provides a list of suggested testing frequencies for equipment, devices and systems required by Section 5003.2.9.1 to be tested. The party responsible for compliance with the testing requirements can choose one of the four testing frequencies that meets its needs. Note that Section 5003.2.3 requires that equipment, devices or systems associated with the storage, handling and use of hazardous materials be listed or approved. When the fire

code official determines that listing is required, the choice of testing frequency must be correlated with the manufacturer's testing requirements, which are often included as an integral part of the listing of the product.

**5003.3 Release of hazardous materials.** Hazardous materials in any quantity shall not be released into a sewer, storm drain, ditch, drainage canal, creek, stream, river, lake or tidal waterway or on the ground, sidewalk, street, highway or into the atmosphere.

**Exceptions:**

1. The release or emission of hazardous materials is allowed where in compliance with federal, state or local governmental agencies, regulations or permits.
2. The release of pesticides is allowed where used in accordance with registered label directions.
3. The release of fertilizer and soil amendments is allowed where used in accordance with manufacturer's specifications.

❖ Because of the toxic and hazardous nature of chemicals governed by this section, no amount of release is allowed, unless it is in compliance with federal, state or local regulations. The release of pesticides is allowed when they are used in compliance with the manufacturer's instructions. Fertilizer and soil amendments are also allowed when they are used as the manufacturer specifies.

**5003.3.1 Unauthorized discharges.** Where hazardous materials are released in quantities reportable under state, federal or local regulations, the *fire code official* shall be notified and the following procedures required in accordance with Sections 5003.3.1.1 through 5003.3.1.4.

❖ As stated above, release of hazardous chemicals is prohibited; however, when a release does occur in quantities that exceed the requirements of federal, state and local regulations, the fire code official must be notified.

**5003.3.1.1 Records.** Records of the unauthorized discharge of hazardous materials by the permittee shall be maintained.

❖ The amounts released, the cause of the release, containment efforts, cleanup efforts and environmental impact are items that should be included in the records submitted and kept on the incident.

**5003.3.1.2 Preparation.** Provisions shall be made for controlling and mitigating unauthorized discharges.

❖ A facility preplan for controlling and mitigating a release is recommended. After a release, this plan should be immediately implemented.

**5003.3.1.3 Control.** Where an unauthorized discharge caused by primary container failure is discovered, the involved primary container shall be repaired or removed from service.

❖ Once the cause of the release has been determined, repair of defective equipment or changes in operating procedures must begin immediately.

**5003.3.1.4 Responsibility for cleanup.** The person, firm or corporation responsible for an unauthorized discharge shall institute and complete all actions necessary to remedy the effects of such unauthorized discharge, whether sudden or gradual, without cost to the jurisdiction. Where deemed necessary by the *fire code official*, cleanup can be initiated by the fire department or by an authorized individual or firm. Costs associated with such cleanup shall be borne by the *owner*, operator or other person responsible for the unauthorized discharge.

❖ Cleanup is the responsibility of the person, firm or corporation responsible for an unauthorized release. Cleanup must begin immediately once the incident is stable.

**5003.4 Material Safety Data Sheets.** Material Safety Data Sheets (MSDS) shall be readily available on the premises for hazardous materials regulated by this chapter. Where a hazardous substance is developed in a laboratory, available information shall be documented.

**Exception:** Designated hazardous waste.

❖ Both the number and the diversity of industrial chemicals are constantly increasing. The inventory of chemicals at modern industrial operations is sometimes quite variable. These factors make accurate and timely information more important to emergency responders. This section specifies requirements for submitting MSDS and other emergency response information. Regardless of quantity, MSDS are required for all hazardous materials regulated by the code, even if the intended quantities do not require a permit or exceed the maximum quantities allowed per control area relative to a high-hazard occupancy classification. Preincident planning is essential for buildings containing hazardous materials, regardless of quantity. See the commentary to the definition of “Material safety data sheet” in Section 202.

The exception recognizes that the information contained in the Uniform Hazardous Waste Manifest (EPA Form 870022A) required by DOTn 49 CFR regulations contains sufficient information on the hazards of the waste material. Because EPA shipping rules for hazardous waste require that the manifest be with the waste material at all times, the manifest serves the same purpose as an MSDS.

The following is the minimum information needed from the MSDS to assist in determining the hazardous occupancy. The special consideration area will tell when items such as emergency showers, eye wash centers, acid piping and special ventilation are required. The MSDS will have the following information:

- The chemical name.
- The boiling point.
- The flash point.
- The UFL.
- The LFL.

- The solubility of the chemical.
- The IDLH.
- The LD50.
- The NFPA 704 classification.
- Any special consideration with the chemical.

Note that as part of OSHA’s planned conversion to the Globally Harmonized System of Classification and Labeling of Chemicals (GHS/HC) by 2016, the MSDS will be reformatted to 16 sections and renamed as “Safety Data Sheets” (SDS). The format of the new SDS is expected to include the following information:

- Section 1. Identification
- Section 2. Hazard(s) identification
- Section 3. Composition/information on ingredients
- Section 4. First-aid measures
- Section 5. Fire-fighting measures
- Section 6. Accidental release measures
- Section 7. Handling and storage
- Section 8. Exposure controls/personal protection
- Section 9. Physical and chemical properties
- Section 10. Stability and reactivity
- Section 11. Toxicological information
- Section 12. Ecological information
- Section 13. Disposal considerations
- Section 14. Transport information
- Section 15. Regulatory information
- Section 16. Other information, including date of preparation or last revision

The purpose of the GHS/HC system is rooted in the agencies that will administer the regulations, i.e., OSHA and the United Nations. Neither agency is exclusively focused on emergency responder notifications but, rather, they focus on worker/workplace regulations and global transportation and shipping of hazardous materials.

**5003.5 Hazard identification signs.** Unless otherwise exempted by the *fire code official*, visible hazard identification signs as specified in NFPA 704 for the specific material contained shall be placed on stationary containers and above-ground tanks and at entrances to locations where hazardous materials are stored, dispensed, used or handled in quantities requiring a permit and at specific entrances and locations designated by the *fire code official*.

❖ This section contains requirements for identification signage and labeling of containers with hazardous materials. Signs are required to alert occupants who may unknowingly enter an area containing hazardous materials.

The hazard identification symbol (see Commentary Figure 5003.5) is a color-coded array of four numbers or letters arranged in a diamond shape. This symbol appears on the label of many chemicals acquired from commercial vendors.

The **blue diamond**, appearing on the left side of

the label, conveys **health hazard** information. A number from 0 to 4 appears in the blue diamond indicating the degree of the hazard. The higher the number, the higher the hazard, as follows:

- 0—No hazard.
- 1—Can cause irritation if not treated.
- 2—Can cause injury. Requires prompt treatment.
- 3—Can cause serious injury despite medical treatment.
- 4—Can cause death or major injury despite medical treatment.

The **red diamond**, appearing at the top of the label, conveys **flammability hazard** information. Again, the numbers 0 to 4 are used to rate the flammability hazard as follows:

- 0—No hazard.
- 1—Ignites after considerable heating.
- 2—Ignites if moderately heated.
- 3—Can be ignited at all normal temperatures.
- 4—Very flammable gases or very volatile flammable liquid.

The **yellow diamond**, appearing on the right side of the label, conveys **reactivity hazard** information. The numbers 0 to 4 are used to rank reactivity hazards as follows:

- 0—Normally stable. Not reactive with water.
- 1—Normally stable. Unstable at high temperatures and pressure. Reacts with water.
- 2—Normally unstable but will not detonate.
- 3—Can detonate or explode but requires strong initiating force or heating under confinement.
- 4—Readily detonates or explodes.

The **white diamond**, appearing at the bottom of the label, conveys **special hazard** information. This information is conveyed by the use of symbols that

represent the special hazard. Two of the common symbols are:

W—The material is water reactive.

OX—An oxidizing agent.

Some labels use the white diamond to convey personal protective equipment or engineering controls required to work with the material safely. You may see a picture of gloves, safety glasses or a fume hood in the white diamond.

NFPA hazard ratings can be found on the MSDS for a given chemical. Also, this symbol, or a form of this symbol, often appears on the label of commercial chemical products.

**5003.5.1 Markings.** Individual containers, cartons or packages shall be conspicuously marked or labeled in an approved manner. Rooms or cabinets containing *compressed gases* shall be conspicuously labeled: COMPRESSED GAS.

❖ DOTn 49 CFR requires labels on all containers, cartons and packages of hazardous materials during transportation. Many manufacturers also post comprehensive labels on all containers and packages. These labels often include hazard information beyond that required by DOTn 49 CFR. The international pictorial symbols likely to be found on these labels are shown in Commentary Figure 5003.5.1.

**5003.6 Signs.** Signs and markings required by Sections 5003.5 and 5003.5.1 shall not be obscured or removed, shall be in English as a primary language or in symbols allowed by this code, shall be durable, and the size, color and lettering shall be *approved*.

❖ Signs must be in English as the primary language, or in symbols allowed by the code, and be made of a durable material with the size, color and lettering approved by the fire code official or other sections of the I-Codes.

**5003.7 Sources of ignition.** Sources of ignition shall comply with Sections 5003.7.1 through 5003.7.3.

❖ This section introduces the provisions for ignition control. A form of heat is required to ignite the vapors of flammable and combustible liquids. By limiting the sources of ignition in the storage or use area, one can reduce the possibility of a fire.

**5003.7.1 Smoking.** Smoking shall be prohibited and “No Smoking” signs provided as follows:

1. In rooms or areas where hazardous materials are stored or dispensed or used in *open systems* in amounts requiring a permit in accordance with Section 5001.5.

2. Within 25 feet (7620 mm) of outdoor storage, dispensing or open use areas.
3. Facilities or areas within facilities that have been designated as totally “no smoking” shall have “No Smoking” signs placed at all entrances to the facility or area. Designated areas within such facilities where smoking is permitted either permanently or temporarily, shall be identified with signs designating that smoking is permitted in these areas only.
4. In rooms or areas where flammable or combustible hazardous materials are stored, dispensed or used.

Signs required by this section shall be in English as a primary language or in symbols allowed by this code and shall comply with Section 310.

- ❖ The four areas listed in this section, because of their hazard characteristics, have been designated to receive “No Smoking” signs, in accordance with Section 310.

**5003.7.2 Open flames.** Open flames and high-temperature devices shall not be used in a manner that creates a hazardous condition and shall be *listed* for use with the hazardous materials stored or used.

- ❖ Processes that use open flames must be installed and safeguarded in accordance with the manufacturer’s specifications. It should be noted that a chemical that is preheated can change from a nonhazardous classification to a hazardous classification or move from a lower hazard to a higher hazard. Safety is further enhanced by the requirement for devices to be listed for use in proximity to hazardous materials.

**5003.7.3 Industrial trucks.** Powered industrial trucks used in areas designated as hazardous (classified) locations in accordance with NFPA 70 shall be *listed* and *labeled* for use in the environment intended in accordance with NFPA 505.

- ❖ Powered industrial trucks used in hazardous locations defined in accordance with NFPA 70 must meet the requirements of NFPA 505 (see also Section 309).

**5003.8 Construction requirements.** Buildings, *control areas*, enclosures and cabinets for hazardous materials shall be in accordance with Sections 5003.8.1 through 5003.8.6.3.

- ❖ Both the code and the IBC have requirements for construction of hazardous use areas. Each of these codes must be consulted for the specific and general requirements based on the chemicals being protected.

**5003.8.1 Buildings.** Buildings, or portions thereof, in which hazardous materials are stored, handled or used shall be constructed in accordance with the *International Building Code*.

- ❖ Buildings must meet the construction requirements of the IBC. Note that IBC Section 414 is a good starting point for this review.

**5003.8.2 Required detached buildings.** Group H occupancies containing quantities of hazardous materials in excess of

those set forth in Table 5003.8.2 shall be in detached buildings.

- ❖ The definition of a “Detached building” is found in Section 202. As defined, a detached storage building is a separate single-story building, without a basement or crawl space, that is used for the storage of hazardous materials and located an approved distance from all other structures.

The manufacture and storage of hazardous materials are frequently integrated into a single building. Additionally, it is not unusual for certain manufacturing buildings to contain multiple Group H uses where the threshold quantities are exceeded. Limiting the uses of identified hazardous materials to separate buildings containing only Group H uses maintains the intent of the code, which is to isolate large quantities of certain physical hazardous materials from uses other than those in Group H.

**TABLE 5003.8.2.** See page 50-30.

- ❖ Table 5003.8.2 gives the MAQs of materials that can be stored in Group H occupancies without detached storage.

**5003.8.3 Control areas.** *Control areas* shall comply with Sections 5003.8.3.1 through 5003.8.3.5.

- ❖ As defined in Section 202, a “Control area” is a space within a building where quantities of hazardous materials not exceeding the MAQs per control area are stored, dispensed, used or handled.

This section, in conjunction with the MAQ tables in Section 5003.1, utilizes a density concept for hazardous materials through the use of control areas. The intent of the control area concept is to provide an alternative method for the handling of hazardous materials without classifying the occupancy as Group H. In order to not be considered Group H, the amount of hazardous materials within any single control area bounded by fire barriers, horizontal assemblies, fire walls or exterior walls cannot exceed the MAQ for a specific material listed in Table 5003.1.1(1) or 5003.1.1(2) [see Commentary Figure 5003.8.3(1)]. A control area may be an entire building or a portion thereof. Where a building is not compartmented as required by the code for control areas, the entire building would be considered a single control area, in which case the entire MAQ of material from Table 5003.1.1(1) or 5003.1.1(2) located on any story would be subject to the limitations of Table 5003.8.3.2 based on IFC Committee Interpretations 51-07 and 52-07 of the table. Note that MAQs are based on the physical state, situation and hazard classification of materials and that up to the MAQ of each state of each class of material is permitted in each control area, subject to material incompatibility issues (see Section 5003.9.8).

As noted above, application of the control area provisions is intended only as a means for a building to avoid classification as Group H. It is not intended in

all cases to result in adequate separation of certain hazardous materials storage. For example, a control area for the storage of flammable liquids not exceeding the MAQ indicated in Table 5003.1.1(1) and constructed in accordance with these sections may require a fire-resistance rating of 1 hour for a building to avoid classification in Group H. However, the provisions of Chapter 57 or the referenced standard on flammable liquids, NFPA 30, may require a higher fire-resistance rating to provide proper separation based on the hazards of the flammable liquid being stored. In such a case, the provisions requiring the higher rating would apply.

**5003.8.3.1 Construction requirements.** *Control areas* shall be separated from each other by *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ This section requires that control areas be separated both vertically and horizontally, from one another as well as the rest of the building in which they are located, by the same type of construction as is used for occupancy separations. The fire barriers and horizontal assemblies thus required must be constructed in accordance with IBC Sections 707 and 711, respectively. Requiring fire-resistance-rated compartmentation of control areas minimizes the possibility of simultaneous involvement of multiple control areas in

a single fire incident. A fire in a single control area would involve only the amount of hazardous materials in that control area, which would not exceed the MAQ.

**5003.8.3.2 Percentage of maximum allowable quantities.**

The percentage of maximum allowable quantities of hazardous materials per *control area* allowed at each floor level within a building shall be in accordance with Table 5003.8.3.2.

❖ See the commentary to Table 5003.8.3.2.

**TABLE 5003.8.3.2.** See page 50-31.

❖ Table 5003.8.3.2 establishes the maximum quantity of hazardous materials permitted in a building and the required fire-resistance-rated separation for control areas. The overall maximum quantity of hazardous materials that can be present in the entire building is established based on the number of permitted control areas in Table 5003.8.3.2 and the maximum quantity of materials allowed in each control area per floor.

Based on the table, the first floor level could contain four control areas with up to 100 percent of the MAQ of each hazardous material per control area. For example, a single control area in a one-story, nonsprinklered building could contain up to 30 gallons (114 L) of Class 1A flammable liquids [see Table 5003.1.1(1)], 125 pounds (57 kg) of Class III organic peroxides [see Table 5003.1.1(1)], 250 pounds (114

**TABLE 5003.8.2  
DETACHED BUILDING REQUIRED**

A DETACHED BUILDING IS REQUIRED WHERE THE QUANTITY OF MATERIAL EXCEEDS THAT LISTED HEREIN			
Material	Class	Solids and liquids (tons) <sup>a, b</sup>	Gases (cubic feet) <sup>a, b</sup>
Explosives	Division 1.1	Maximum Allowable Quantity	Not Applicable
	Division 1.2	Maximum Allowable Quantity	
	Division 1.3	Maximum Allowable Quantity	
	Division 1.4	Maximum Allowable Quantity	
	Division 1.4 <sup>c</sup>	1	
	Division 1.5	Maximum Allowable Quantity	
	Division 1.6	Maximum Allowable Quantity	
Oxidizers	Class 4	Maximum Allowable Quantity	Maximum Allowable Quantity
Unstable (reactives) detonable	Class 3 or 4	Maximum Allowable Quantity	Maximum Allowable Quantity
Oxidizer, liquids and solids	Class 3	1,200	Not Applicable
	Class 2	2,000	
Organic peroxides	Detonable	Maximum Allowable Quantity	Not Applicable
	Class I	Maximum Allowable Quantity	
	Class II	25	
	Class III	50	
Unstable (reactives) nondetonable	Class 3	1	2,000
	Class 2	25	10,000
Water reactives	Class 3	1	Not Applicable
	Class 2	25	
Pyrophoric gases	Not Applicable	Not Applicable	2,000

For SI: 1 pound = 0.454 kg, 1 cubic foot = 0.02832 m<sup>3</sup>, 1 ton = 2000 lbs. = 907.2 kg.

- a. For materials that are detonable, the distance to other buildings or lot lines shall be as specified in the *International Building Code*. For materials classified as explosives, the required separation distances shall be as specified in Chapter 56.
- b. “Maximum Allowable Quantity” means the maximum allowable quantity per control area set forth in Table 5003.1.1(1).
- c. Limited to Division 1.4 materials and articles, including articles packaged for shipment, that are not regulated as an explosive under Bureau of Alcohol, Tobacco, Firearms and Explosives regulations, or unpackaged articles used in process operations that do not propagate a detonation or deflagration between articles, providing the net explosive weight of individual articles does not exceed 1 pound.

kg) of Class 2 oxidizers [see Table 5003.1.1(1)] and 500 gallons (1892 L) of corrosive liquids [see Table 5003.1.1(2)]. These quantities could be contained in four different control areas if they are separated from one another by a minimum 1-hour fire-resistance-rated fire barrier.

The amount of hazardous materials per control area and the number of control areas per floor are reduced if hazardous materials are stored or used above the first floor. Difficulty in gaining access for fire fighting or other emergency response purposes and potential hazard to building occupants who must egress that area are increased above the first floor. The use of control areas on upper floors can be advantageous for multistory research and laboratory-type facilities that often have a functional need to use limited amounts of hazardous materials throughout

various portions of the building. Without control areas, the MAQ for a hazardous material would be limited to an entire building area regardless of the overall size or height of the building. For example, if control areas are not used, a 50,000-square-foot (4645 m<sup>2</sup>) multistory building would be limited to the same MAQ of hazardous materials as a single-story building of 5,000 square feet (465 m<sup>2</sup>), subject to the per-floor limitations of the table based on IFC Committee Interpretations of Chapter 50.

Note a clarifies that the MAQ is based on Table 5003.1.1(1) or 5003.1.1(2) including the increases allowed by an automatic sprinkler system in accordance with NFPA 13, approved hazardous material storage cabinets or both where applicable.

Note b clarifies the fire barrier separation needed to establish the boundaries of the control area that

**TABLE 5003.8.3.2  
DESIGN AND NUMBER OF CONTROL AREAS**

FLOOR LEVEL		PERCENTAGE OF THE MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA <sup>a</sup>	NUMBER OF CONTROL AREAS PER FLOOR	FIRE-RESISTANCE RATING FOR FIRE BARRIERS IN HOURS <sup>b</sup>
Above grade plane	Higher than 9	5	1	2
	7-9	5	2	2
	6	12.5	2	2
	5	12.5	2	2
	4	12.5	2	2
	3	50	2	1
	2	75	3	1
	1	100	4	1
Below grade plane	1	75	3	1
	2	50	2	1
	Lower than 2	Not Allowed	Not Allowed	Not Allowed

a. Percentages shall be of the maximum allowable quantity per control area shown in Tables 5003.1.1(1) and 5003.1.1(2), with all increases allowed in the footnotes to those tables.

b. Separation shall include fire barriers and horizontal assemblies as necessary to provide separation from other portions of the building.

include not only the vertical wall assemblies but also the floor/ceiling assemblies in order to be adequately separated from all adjacent interior spaces.

Example: Determine the maximum amount of Class IB flammable liquids that can be stored within a single-story, 10,000-square-foot (929 m<sup>2</sup>) nonsprinklered Group F-1 occupancy [see Commentary Figure 5003.8.3(2)] of Type IIB construction without classifying the storage area Group H-2.

Based on a MAQ of 120 gallons (454 L) for Class IB flammable liquids from Table 5003.1.1(1), a maximum of 120 gallons (454 L) can be stored in each of the four control areas; therefore, while the building may actually contain a total of 480 gallons (1817 L), a maximum of 120 gallons (454 L) is permitted in each control area that is separated from all adjacent control areas by minimum 1-hour fire barriers constructed in accordance with IBC Section 707.

The building, in this case, could still be classified as Group F-1. An automatic fire suppression system would not be required, since the 12,000-square-foot (1115 m<sup>2</sup>) threshold for suppression of Group F-1 fire areas is not exceeded (see Section 903.2.3) and there are no control areas containing hazardous materials that exceed the MAQ. Notes d and e of Table 5003.1.1(1) would allow the base quantity of Class IB flammable liquids to be increased 100 percent in buildings protected with an automatic sprinkler system or when the material is stored in approved hazardous material storage cabinets. In this example, this would result in increasing the MAQ of Class IB flammable liquids by a factor of two; therefore, the building could now contain a total of 960 gallons (3634 L) with a maximum of 240 gallons (908 L) in

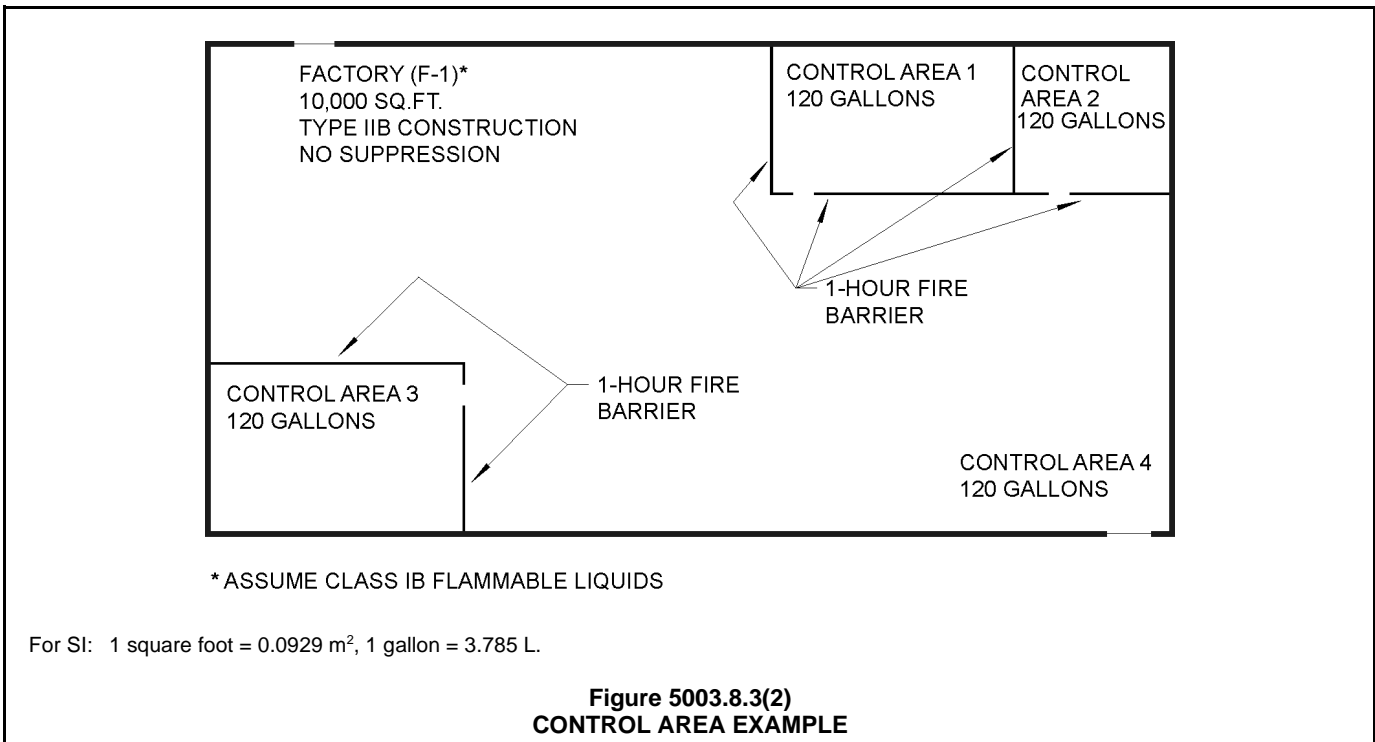

each of the four control areas, separated as required by the code, and still maintain a Group F-1 classification.

If both an automatic sprinkler system and hazardous material storage cabinets are used to protect the Class IB flammable liquids, then the base quantity of Table 5003.1.1(1) could be increased by a factor of four. The building in this example, therefore, with both sprinkler protection and approved cabinets, could contain a total of 1,920 gallons (7267 L) with a maximum of 480 gallons (1817 L) in each of the four control areas, separated as required by the code, and still maintain a Group F-1 classification.

The allowable increase in the MAQ is offset by the additional level or levels of protection. The use of control areas provides a tradeoff based on building compartmentation. Fire protection (automatic sprinkler systems) and controlled storage through the use of approved hazardous material storage cabinets also adds a degree of protection, justifying the increased allowable quantities. See IFC Committee Interpretations 51-07 and 52-07 in Commentary Figure 5003.8.3.2.

**5003.8.3.3 Number.** The maximum number of *control areas* per floor within a building shall be in accordance with Table 5003.8.3.2.

❖ It is not the code's intent to require multiple control areas. As previously indicated, in a building that is entirely one control area, if the total quantity of hazardous materials does not exceed the MAQ, the building would not be classified as Group H. Similarly, if the owner is satisfied with an occupancy classification of Group H, multiple control areas would not be required. Therefore, control areas are characterized

**COMMITTEE INTERPRETATION NO. 51-07**

Section 5003.8.3.2

Issued on 2006 edition – Issued 04-29-08

Q: Given a nonsprinklered, multistory building of Type IIB construction. The building is used for the storage of hazardous materials that do not exceed the maximum allowable quantity per control area in accordance with Tables 5003.1.1(1) and 5003.1.1(2) of the *International Fire Code*. The building contains no fire walls, interior fire barriers or fire-resistance-rated horizontal assemblies. The entire building is defined as a single control area.

Are the provisions of Section 5003.8.3.2 of the *International Fire Code*, which limit the percentage of the maximum allowable quantity of hazardous materials for any floor, applicable to a multistory building consisting of a single control area?

A: Yes. When the quantity of hazardous material stored in the building is equal to or less than the maximum allowable quantity per control area in Tables 5003.1.1(1) and 5003.1.1(2), the entire building would be considered the control area. When the entire building is the control area, the maximum allowable quantity of material may be located anywhere in the building subject to the per-floor limitations of Table 5003.8.3.2.

**COMMITTEE INTERPRETATION NO. 52-07**

Section 5003.8.3.2

Issued on 2006 edition – Issued 04-29-08

Q: Given a nonsprinklered multistory building of Type IIB construction. The building is used for the storage of hazardous materials that exceeds the maximum allowable quantity permitted for a single control area in accordance with Tables 5003.1.1(1) and 5003.1.1(2) of the *International Fire Code*. An interior fire barrier is constructed that spans from the foundation to the roof for the entire height of the building. There are no fire-resistance-rated horizontal assemblies provided between floors. Therefore, the entire building is defined as having two independent multistory control areas.

Are the provisions of Section 5003.8.3.2 of the *International Fire Code*, which limit the percentage of the maximum allowable quantity of hazardous materials for any floor, applicable to a multistory building consisting of multiple control areas?

A: Yes. When the quantity of hazardous material being stored in each control area is equal to or less than the maximum allowable quantity per control area in Tables 5003.1.1(1) and 5003.1.1(2), the maximum allowable quantity of material per control area may be located anywhere within a multistory control area, subject to the per-floor limitations of Table 5003.8.3.2.

**Figure 5003.8.3.2**  
**COMMITTEE INTERPRETATIONS**

as an alternative means by which a building can be classified as other than Group H. Again, the provisions are applicable only when control areas are chosen as a design alternative to classification of the occupancy as Group H (see commentary, Table 5003.8.3.2).

**5003.8.3.4 Fire-resistance-rating requirements.** The required *fire-resistance rating* for *fire barriers* shall be in accordance with Table 5003.8.3.2. The floor assembly of the *control area* and the construction supporting the floor of the

*control area* shall have a *fire-resistance rating* of not less than 2 hours.

**Exception:** The floor assembly of the *control area* and the construction supporting the floor of the *control area* is allowed to be 1-hour *fire-resistance* rated in buildings of Type IIA, IIIA and VA construction, provided that both of the following conditions exist:

1. The building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

2. The building is three stories or less above grade plane.

- ❖ The fire separation requirements for control areas, both horizontal and vertical, are dependent on their location in a building in accordance with Table 5003.8.3.2. The amount of hazardous materials per control area, as well as the number of control areas per floor, are reduced if stored or used above the first floor.

Where the control area is located above the first floor, the floor assembly and all supporting construction for the control area would require a minimum 2-hour fire-resistance rating. The required 2-hour fire-resistance rating of the floor construction only refers to the floor of the control area. The increased fire-resistance rating and reduced quantities are intended to aid the fire department and other emergency response personnel in overcoming the difficulties associated with dealing with hazardous materials incidents above the level of fire department access (see commentary, Table 5003.8.3.2). The use of control areas on upper floors provides an alternative method for multistory research and laboratory-type facilities that may need to use a limited amount of hazardous materials throughout various portions of the building. Without control areas, the MAQ for a hazardous material would be limited to a single building area regardless of the overall size or height of the building. For example, if control areas are not utilized, a 50,000-square-foot (4645 m<sup>2</sup>) single-story building would be limited to the same quantity of hazardous materials as a two-story building with 5,000 square feet (464 m<sup>2</sup>) per floor.

Buildings of Type IIA, IIIA and VA construction are required to have floor construction with a minimum fire-resistance rating of 1 hour as indicated in IBC Table 601. The exception recognizes the combination of a 1-hour horizontal assembly in conjunction with sprinkler protection as a reasonable alternative for the noted construction types. The three-story limitation is consistent with the fire-resistant-rating requirements for fire barriers in Table 5003.8.3.2.

**5003.8.3.5 Hazardous material in Group M display and storage areas and in Group S storage areas.** The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials allowed within a single control area of a Group M display and storage area or a Group S storage area is allowed to exceed the *maximum allowable quantities per control area* specified in Tables 5003.1.1(1) and 5003.1.1(2) without classifying the building or use as a Group H occupancy, provided that the materials are displayed and stored in accordance with Section 5003.11.

- ❖ This section addresses an option for control areas containing certain nonflammable or noncombustible hazardous materials that are stored in mercantile and storage occupancies, including outdoor control areas. This option would allow Group H-4 materials, which present a health hazard rather than a physical hazard, as well as limited Group H-2 and H-3 materials

such as oxidizers, to be stored in both retail display and stock areas of regulated mercantile occupancies and in storage-related occupancies in excess of the MAQs of Tables 5003.1.1(1) and 5003.1.1(2) without classifying the building as Group H. Without this option, many mercantile and storage occupancies could be classified technically as Group H. The increased quantities of certain hazardous materials are based on the recognition that while there is limited risk in these occupancies, the packaging and storage arrangements can be controlled. For further information on the storage limitations required for these types of materials, see Section 5003.11.3.

This section, in conjunction with Table 5003.11.1, establishes the maximum quantity of the indicated hazardous materials permitted within a single control area of a mercantile occupancy. As indicated in Table 5003.11.1, this section only applies to certain nonflammable solids and nonflammable or noncombustible liquids. Note that this option is not applicable to mercantile and storage occupancies containing hazardous materials other than those indicated in Table 5003.11.1.

**5003.8.4 Gas rooms.** Where a gas room is used to increase the *maximum allowable quantity per control area* or provided to comply with the provisions of Chapter 60, the gas room shall be in accordance with Sections 5003.8.4.1 and 5003.8.4.2.

- ❖ Where gas rooms are provided as required by Chapter 60 or where they are used in accordance with Table 5003.1.1(1), Note e to increase the maximum allowable quantity per control area (MAQ) of hazardous materials, they must meet the requirements stated in the subsections that follow. Gas rooms are required to be protected by automatic sprinklers, separated based on the occupancy, and have ventilation designed to operate at a negative pressure. These requirements are similar to those that apply to exhausted enclosures that allow the quantity increase. This section will bring consistency between the requirements for gas cabinets, exhausted enclosures and gas rooms with respect to application and MAQ.

**5003.8.4.1 Construction.** Gas rooms shall be protected with an *automatic sprinkler system*. Gas rooms shall be separated from the remainder of the building in accordance with the requirements of the *International Building Code* based on the occupancy group into which it has been classified.

- ❖ Construction shall be based on the occupancy separation requirements of IBC Table 302.3.3. A gas room would typically be a Group H-4 occupancy; therefore, the separation requirements would be from a Group H-4 occupancy to the other occupancy (i.e., business, institutional, storage, etc.).

**5003.8.4.2 Ventilation system.** The ventilation system for gas rooms shall be designed to operate at a negative pressure in relation to the surrounding area. Highly toxic and toxic gases shall also comply with Section 6004.2.2.6. The ventila-

tion system shall be installed in accordance with the *International Mechanical Code*.

- ❖ The gas room exhaust ventilation system must be designed to operate at a negative pressure to the area in which it is located in order to maintain a safe atmosphere outside the gas room in the event of a leak. Section 6004.2.2.6 also has specific ventilation requirements for highly toxic and toxic gases. Ventilation systems must comply with the IMC.

**5003.8.5 Exhausted enclosures.** Where an exhausted enclosure is used to increase *maximum allowable quantity per control area* or where the location of hazardous materials in exhausted enclosures is provided to comply with the provisions of Chapter 60, the exhausted enclosure shall be in accordance with Sections 5003.8.5.1 through 5003.8.5.3.

- ❖ When exhausted enclosures are provided as required by Chapter 60, they must meet the requirements of the following subsections.

**5003.8.5.1 Construction.** Exhausted enclosures shall be of noncombustible construction.

- ❖ See IBC Section 202 for the definition of “Noncombustible construction.”

**5003.8.5.2 Ventilation.** Exhausted enclosures shall be provided with an exhaust ventilation system. The ventilation system for exhausted enclosures shall be designed to operate at a negative pressure in relation to the surrounding area. Ventilation systems used for highly toxic and toxic gases shall also comply with Items 1, 2 and 3 of Section 6004.1.2. The ventilation system shall be installed in accordance with the *International Mechanical Code*.

- ❖ The exhausted enclosure exhaust ventilation system must be designed to operate at a negative pressure to the area in which it is located in order to maintain a safe atmosphere in the area in the event of a leak. Section 6004.2.2.6 also has specific ventilation requirements for highly toxic and toxic gases. Ventilation systems must comply with the IMC.

**5003.8.5.3 Fire-extinguishing system.** Exhausted enclosures where flammable materials are used shall be protected by an approved automatic fire-extinguishing system in accordance with Chapter 9.

- ❖ Special care is required in selecting the correct type of automatic fire suppression system. The MSDS should be consulted for compatibility of the suppression system and the chemicals being used.

**5003.8.6 Gas cabinets.** Where a gas cabinet is used to increase the *maximum allowable quantity per control area* or where the location of *compressed gases* in gas cabinets is provided to comply with the provisions of Chapter 60, the gas cabinet shall be in accordance with Sections 5003.8.6.1 through 5003.8.6.3.

- ❖ When gas cabinets are provided as required by Chapter 60, they must meet the requirements of the following subsections.

**5003.8.6.1 Construction.** Gas cabinets shall be constructed in accordance with the following:

1. Constructed of not less than 0.097-inch (2.5 mm) (No. 12 gage) steel.
2. Be provided with self-closing limited access ports or noncombustible windows to give access to equipment controls.
3. Be provided with self-closing doors.
4. Gas cabinet interiors shall be treated, coated or constructed of materials that are compatible with the hazardous materials stored. Such treatment, coating or construction shall include the entire interior of the cabinet.

- ❖ This section itemizes four requirements for the construction of gas cabinets. Listed and labeled gas cabinets can be assumed to meet these minimum requirements when they have been tested by an approved third-party testing agency.

**5003.8.6.2 Ventilation.** Gas cabinets shall be provided with an exhaust ventilation system. The ventilation system for gas cabinets shall be designed to operate at a negative pressure in relation to the surrounding area. Ventilation systems used for highly toxic and toxic gases shall also comply with Items 1, 2 and 3 of Section 6004.1.2. The ventilation system shall be installed in accordance with the *International Mechanical Code*.

- ❖ The gas cabinet exhaust ventilation system must be designed to operate at a negative pressure to the area in which it is located in order to maintain a safe atmosphere in the area in the event of a leak. Section 6004.2.2.6 also has specific ventilation requirements for highly toxic and toxic gases. Ventilation systems must comply with the IMC.

**5003.8.6.3 Maximum number of cylinders per gas cabinet.** The number of cylinders contained in a single gas cabinet shall not exceed three.

- ❖ This section limits the number of cylinders of compressed gases within a gas cabinet for quantity control purposes in an effort to reduce the potential involvement of other gas cylinders in a fire.

**5003.8.7 Hazardous materials storage cabinets.** Where storage cabinets are used to increase *maximum allowable quantity per control area* or to comply with this chapter, such cabinets shall be in accordance with Sections 5003.8.7.1 and 5003.8.7.2.

- ❖ This section recognizes that the use of approved storage cabinets is an acceptable alternative to increase the MAQ of certain hazardous materials. For example, the base MAQ in each control area for storage of Class IB flammable liquids is 120 gallons (454 L) as indicated in Table 5003.1.1(1). However, if Class IB flammable liquids are stored in an approved storage cabinet, the base MAQ could be increased to 240 gallons (908 L). Therefore, a building could contain 240 gallons (908 L) of Class IB liquids in each control

area without classifying the building as a high-hazard occupancy if all flammable liquids are stored in an approved storage cabinet. These types of storage cabinets are sometimes known as flammable liquid cabinets or acid storage cabinets.

**5003.8.7.1 Construction.** The interior of cabinets shall be treated, coated or constructed of materials that are nonreactive with the hazardous material stored. Such treatment, coating or construction shall include the entire interior of the cabinet. Cabinets shall either be *listed* in accordance with UL 1275 as suitable for the intended storage or constructed in accordance with the following:

1. Cabinets shall be of steel having a thickness of not less than 0.0478 inch (1.2 mm) (No. 18 gage). The cabinet, including the door, shall be double walled with a 1½-inch (38 mm) airspace between the walls. Joints shall be riveted or welded and shall be tight fitting. Doors shall be well fitted, self-closing and equipped with a self-latching device.
2. The bottoms of cabinets utilized for the storage of liquids shall be liquid tight to a minimum height of 2 inches (51 mm).

Electrical equipment and devices within cabinets used for the storage of hazardous gases or liquids shall be in accordance with NFPA 70.

❖ This section gives two methods of acceptance. Either the cabinet is listed in accordance with UL 1275 or construction meets the requirements of this section.

This section specifies minimum construction requirements for hazardous material storage cabinets similar to those cabinets required for flammable and combustible liquids in NFPA 30. While both this section and NFPA 30 require the door of the cabinet to be equipped with a latching device, this section does not specifically require a three-point latch arrangement on all cabinet doors. The three-point latch arrangement is recommended to enhance the integrity of the cabinet in a fire. The door sill of hazardous material storage cabinets used for storing liquids must be raised 2 inches (51 mm) above the bottom of the cabinet. The 2-inch (51 mm) raised sill is intended to retain any spilled liquid within the cabinet. The surface of the cabinets must be compatible with the material stored in the cabinets. Any electrical equipment must comply with NFPA 70.

**5003.8.7.2 Warning markings.** Cabinets shall be clearly identified in an approved manner with red letters on a contrasting background to read:

HAZARDOUS—KEEP FIRE AWAY.

❖ To warn the general public and employees of potential exposure to hazardous materials within storage cabinets, appropriate warning labels are required. Cabinets shall be clearly identified with the wording given in this section.

**5003.9 General safety precautions.** General precautions for the safe storage, handling or care of hazardous materials shall be in accordance with Sections 5003.9.1 through 5003.9.10.

❖ The following subsections deal with the safe handling and storage of hazardous materials.

**5003.9.1 Personnel training and written procedures.** Persons responsible for the operation of areas in which hazardous materials are stored, dispensed, handled or used shall be familiar with the chemical nature of the materials and the appropriate mitigating actions necessary in the event of fire, leak or spill.

❖ Each tenant or owner should develop a mitigation plan. This plan should be posted and be familiar to all workers. In the event of a release, this plan should be immediately placed into effect.

**5003.9.1.1 Fire department liaison.** Responsible persons shall be designated and trained to be liaison personnel to the fire department. These persons shall aid the fire department in preplanning emergency responses and identifying the locations where hazardous materials are located, and shall have access to Material Safety Data Sheets and be knowledgeable in the site's emergency response procedures.

❖ It goes without saying that an emergency is not the time to wonder who, what, when or where. The code section recommends that a working relationship be established with the emergency services prior to the emergency. A plant engineer or chemist who knows the type of materials, methods of storage, location of storage in the structure and chemical makeup would typically be the best person for this liaison work.

**5003.9.2 Security.** Storage, dispensing, use and handling areas shall be secured against unauthorized entry and safeguarded in a manner *approved* by the *fire code official*.

❖ Safeguards must be in place to assist in the prevention of unauthorized entry into the building or the removal of hazardous chemicals.

**5003.9.3 Protection from vehicles.** Guard posts or other *approved* means shall be provided to protect storage tanks and connected piping, valves and fittings; dispensing areas; and use areas subject to vehicular damage in accordance with Section 312.

❖ Storage, piping or other process equipment that could be damaged by vehicular traffic must be protected with barriers designed to meet the requirements of Section 312.

**5003.9.4 Electrical wiring and equipment.** Electrical wiring and equipment shall be installed and maintained in accordance with NFPA 70.

❖ Article 500 of NFPA 70 is the applicable article for classified locations.

**5003.9.5 Static accumulation.** Where processes or conditions exist where a flammable mixture could be ignited by

static electricity, means shall be provided to prevent the accumulation of a static charge.

- ❖ NFPA 77 gives some guidance into the methods of protection against static electricity. NFPA 70 also provides guidance on the requirements.

**5003.9.6 Protection from light.** Materials that are sensitive to light shall be stored in containers designed to protect them from such exposure.

- ❖ Light-sensitive chemicals must be protected from UV lights or other spectrum patterns that may be damaging. See the MSDS for additional information and requirements for chemicals.

**5003.9.7 Shock padding.** Materials that are shock sensitive shall be padded, suspended or otherwise protected against accidental dislodgement and dislodgement during seismic activity.

- ❖ Several explosive chemicals are shock sensitive and must be protected against accidents that could knock them from their shelves. If the building in which they are stored or used is in a seismic zone, they must also be protected.

**5003.9.8 Separation of incompatible materials.** *Incompatible materials* in storage and storage of materials that are incompatible with materials in use shall be separated where the stored materials are in containers having a capacity of more than 5 pounds (2 kg) or 0.5 gallon (2 L). Separation shall be accomplished by:

1. Segregating *incompatible materials* in storage by a distance of not less than 20 feet (6096 mm).
2. Isolating *incompatible materials* in storage by a non-combustible partition extending not less than 18 inches (457 mm) above and to the sides of the stored material.
3. Storing liquid and solid materials in hazardous material storage cabinets.
4. Storing *compressed gases* in gas cabinets or exhausted enclosures in accordance with Sections 5003.8.5 and 5003.8.6. Materials that are incompatible shall not be stored within the same cabinet or exhausted enclosure.

- ❖ Materials that are incompatible with each other must be separated. This section gives four methods of separation. If cabinets or exhausted enclosures are used, only compatible chemicals can be stored in any one cabinet or enclosure.

**5003.9.9 Shelf storage.** Shelving shall be of substantial construction, and shall be braced and anchored in accordance with the seismic design requirements of the *International Building Code* for the seismic zone in which the material is located. Shelving shall be treated, coated or constructed of materials that are compatible with the hazardous materials

stored. Shelves shall be provided with a lip or guard where used for the storage of individual containers.

**Exceptions:**

1. Storage in hazardous material storage cabinets or laboratory furniture specifically designed for such use.
2. Storage of hazardous materials in amounts not requiring a permit in accordance with Section 5001.5.

Shelf storage of hazardous materials shall be maintained in an orderly manner.

- ❖ Where hazardous chemicals are stored on shelves, the shelves must have a lip or guard at the edges. The shelving must be treated or otherwise protected to be compatible with the chemicals stored.

**5003.9.10 Safety cans.** Safety cans shall be *listed* in accordance with UL 30 where used to increase the *maximum allowable quantities per control area* of flammable or *combustible liquids* in accordance with Table 5003.1.1(1). Safety cans *listed* in accordance with UL 1313 are allowed for flammable and *combustible liquids* where not used to increase the *maximum allowable quantities per control area* and for other hazardous material liquids in accordance with the listing.

- ❖ This section specifically prescribes the use of metallic safety cans listed in accordance with UL 30 when increasing the MAQ of flammable and combustible liquids in Table 5003.1.1(1). For all other physical hazard classes of hazardous material, a listed safety can constructed of either metal or nonmetallic material can be used to increase the MAQ provided that the safety can is suitable and listed for the particular hazardous material.

It should be noted that metal safety cans listed under UL 30 are "...primarily intended to store and handle flammable and combustible liquids, such as gasoline, naphtha, kerosene, acetone, MEK and similar liquids..." according to the scope statement of that standard. As such, a listed safety can constructed of metal may not always be the appropriate container for hazardous materials presenting multiple hazards. Consider acetic acid, which is not only a Class II combustible liquid, but also a corrosive liquid. Galvanized steel is an inappropriate construction material because the acid will corrode the steel. However, a material like polyethylene, which is used in the manufacturing of nonmetallic safety cans, is chemically compatible with acetic acid. Once again, however, the caution is raised that the scope statement of UL 1313 states that nonmetallic safety cans "...are primarily intended to store and handle fuel oil, gasoline, kerosene. Nonmetallic safety cans that are intended to store and handle liquid fuels other than those specified...may be subjected to additional

requirements not covered in the Standard.” Also see the commentary to Section 5002.1 for the definition of “Safety can” and Table 5003.1.1(1), Note e.

**5003.10 Handling and transportation.** In addition to the requirements of Section 5003.2, the handling and transportation of hazardous materials in *corridors* or enclosures for stairways and ramps shall be in accordance with Sections 5003.10.1 through 5003.10.3.6.

❖ This section deals with the handling and transportation of hazardous chemicals in corridors or exit enclosures.

**5003.10.1 Valve protection.** Hazardous material gas containers, cylinders and tanks in transit shall have their protective caps in place. Containers, cylinders and tanks of highly toxic or toxic *compressed gases* shall have their valve outlets capped or plugged with an *approved* closure device in accordance with Chapter 53.

❖ Whenever a cylinder or tank of hazardous gases is transported, it can have a protective cover on the outlet valves or be plugged with an approved closure valve as stated in Section 5303.4.

**5003.10.2 Carts and trucks required.** Liquids in containers exceeding 5 gallons (19 L) in a *corridor* or enclosure for a stairway or ramp shall be transported on a cart or truck. Containers of hazardous materials having a hazard ranking of 3 or 4 in accordance with NFPA 704 and transported within *corridors* or interior exit stairways and ramps, shall be on a cart or truck. Where carts and trucks are required for transporting hazardous materials, they shall be in accordance with Section 5003.10.3.

**Exceptions:**

1. Two hazardous material liquid containers that are hand carried in acceptable safety carriers.
  2. Not more than four drums not exceeding 55 gallons (208 L) each that are transported by suitable drum trucks.
  3. Containers and cylinders of *compressed gases* that are transported by *approved* hand trucks, and containers and cylinders not exceeding 25 pounds (11 kg) that are hand carried.
  4. Solid hazardous materials not exceeding 100 pounds (45 kg) that are transported by *approved* hand trucks, and a single container not exceeding 50 pounds (23 kg) that is hand carried.
- ❖ This section limits the amount of hazardous liquid that can be transported by hand in approved containers to 5 gallons (19 L) or less. Containers with hazardous liquids exceeding 5 gallons (19 L) must be transported using approved carts or trucks that meet the construction requirements of Section 5003.10.3. This section addresses not only hand push-type carts and trucks, but also gas carts, motorized hand trucks and specialized industrial trucks. Additional guidance on the approved use and construction of motorized hand trucks and electrical industrial trucks can be found in

NFPA 505. This section prohibits the transportation of more than the MAQ of any material within an exit. The movement of hazardous materials through exit enclosures within a building is undesirable. However, it may also be unavoidable in multistory buildings. This section is intended to limit the amount of hazardous materials within an exit at any time.

Exception 1 recognizes that two safety carriers can be hand carried.

Exception 2 recognizes that a maximum of four drums with a capacity of 55 gallons (208 L) or less can be transported using an approved drum truck.

Exception 3 recognizes that some containers and cylinders of compressed gases can be transported if they are secured on approved hand trucks. Also, the hand carrying of containers and cylinders is approved when they weigh no more than 25 pounds (11 kg).

Exception 4 recognizes that solid hazardous materials not exceeding 100 pounds (45 kg) can be transported using approved hand trucks. Single containers weighing no more than 50 pounds (23 kg) may be hand carried.

**5003.10.3 Carts and trucks.** Carts and trucks required by Section 5003.10.2 to be used to transport hazardous materials shall be in accordance with Sections 5003.10.3.1 through 5003.10.3.6.

❖ Where carts and trucks are required, they must be designed in accordance with Sections 5003.10.3.1 through 5003.10.3.6.

**5003.10.3.1 Design.** Carts and trucks used to transport hazardous materials shall be designed to provide a stable base for the commodities to be transported and shall have a means of restraining containers to prevent accidental dislodgement. *Compressed gas* cylinders placed on carts and trucks shall be individually restrained.

❖ Carts and trucks must be of an inherently stable design to minimize tipping, rolling or other uncontrolled movement. They must also be equipped with a means to restrain cylinders or other containers from falling, tipping or rolling.

**5003.10.3.2 Speed-control devices.** Carts and trucks shall be provided with a device that will enable the operator to control safely movement by providing stops or speed-reduction devices.

❖ Carts and trucks must be equipped with speed control devices, brakes, steering stops or other controls for use when uncontrolled movements occur.

**5003.10.3.3 Construction.** Construction materials for hazardous material carts or trucks shall be compatible with the material transported. The cart or truck shall be of substantial construction.

❖ The surface of the cart or truck must be compatible with the material transported. Although this section only clarifies that the cart or truck be made of substantial construction, trucks are built of noncombustible materials. The cart or truck should not be a contributing factor in a fire.

**5003.10.3.4 Spill control.** Carts and trucks transporting liquids shall be capable of containing a spill from the largest single container transported.

❖ Each cart or hand truck used must be able to control the spill of the largest container it transports.

**5003.10.3.5 Attendance.** Carts and trucks used to transport materials shall not obstruct or be left unattended within any part of a *means of egress*.

❖ When transporting material through a corridor or exit enclosure, the material must not be left unattended.

**5003.10.3.6 Incompatible materials.** *Incompatible materials* shall not be transported on the same cart or truck.

❖ As has been stated throughout the code, incompatible materials must not be mixed during transport.

**5003.11 Group M storage and display and Group S storage.** The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials stored and displayed within a single *control area* of a Group M occupancy, or an outdoor *control area*, or stored in a single *control area* of a Group S occupancy, is allowed to exceed the *maximum allowable quantity per control area* indicated in Section 5003.1 where in accordance with Sections 5003.11.1 through 5003.11.3.11.

❖ This section names three specific use or storage areas in which limits on nonflammable solid and nonflammable or noncombustible liquid chemicals may be exceeded:

1. When they are being stored or displayed in a Group M occupancy.
2. When they are being stored in a single control area of a Group S occupancy.
3. When they are in an outdoor control area.

MAQs can be exceeded when the area is protected as required by Sections 5003.11.1 through 5003.11.3.10.

**5003.11.1 Maximum allowable quantity per control area in Group M or S occupancies.** The aggregate amount of nonflammable solid and nonflammable or noncombustible liquid hazardous materials stored and displayed within a single *control area* of a Group M occupancy or stored in a single *control area* of a Group S occupancy shall not exceed the amounts set forth in Table 5003.11.1.

❖ The amounts of nonflammable solid and nonflammable or noncombustible liquid hazardous material stored and displayed in inside areas may not exceed the MAQs shown in Table 5003.11.1 unless a footnote allows an increase.

**TABLE 5003.11.1.** See page 50-40.

❖ Table 5003.11.1 lists the hazardous materials eligible for the mercantile and storage occupancy option and the corresponding MAQs depending on the extent of protection provided. The permitted quantities of each listed material are independent of each other, as well

as the various classes or physical state of a specific material. For example, a given control area could contain up to the permitted maximum quantity of Class 2 solid oxidizers, Class 3 solid oxidizers and Class 2 liquid oxidizers, in addition to the permitted quantities of corrosive materials.

Notes b and c would allow the listed maximum quantity in Table 5003.11.1 to be increased due to the use of sprinklers or approved hazardous materials storage cabinets, or both. The notes are intended to be cumulative in that up to four times the listed amount may be allowed per control area, if the building is fully sprinklered and approved cabinets are utilized, without classifying the building as Group H.

Note d simply refers to Table 5003.8.3.2 for the design and permitted number of control areas. Note b of Table 5003.8.3.2 limits mercantile and storage occupancies utilizing this option to two control areas.

The 100-percent increase in MAQs for outdoor control areas permitted by Note f is based on the reduced exposure hazard to the building and its occupants. The increase encourages exterior storage applications without mandating sprinkler protection or approved hazardous material storage cabinets.

Notes g and h recognize that Class 2 and 3 solid oxidizers include several disinfectants that are commonly used in recreational, potable and waste water treatment. Without these exceptions, the tabular MAQs allowed in Group M and S occupancies would not be sufficient to sustain trade demand during times of peak usage. Because small containers of these materials have not been involved in losses, the exceptions permit additional containers of 10 pounds (5 kg) or less. Note that Section 5003.11.3.6 limits the tabular quantities to individual containers of 100 pounds (45 kg) or less, whereas these exceptions give the retailer/wholesaler the option of increasing quantities on the shelves when the packaging sizes are limited to 10 pounds (5 kg) or less.

Note i recognizes the inherently higher level of protection and safety afforded by a sprinkler system and that, by definition, the only hazard presented by Class 1 oxidizers is they slightly increase the burning rate of combustible materials they may contact with during a fire. Materials with such properties present nowhere near the level of hazard of many ordinary commodities that might be found in a Group M or S occupancy, such as foam plastics. To put this matter into perspective, Class 1 oxidizers are materials with a degree of hazard similar to that of toilet bowl cleaner crystals. Note i also provides correlation with Note f of Table 5003.1.1(1).

Note j further recognizes the lesser hazard of Class 1 oxidizers and the inherent safety of storing hazardous materials outdoors by allowing quantities to be unlimited in outdoor control areas. Note j also provides correlation with Table 5003.1.1(3).

**5003.11.2 Maximum allowable quantity per outdoor control area in Group M or S occupancies.** The aggregate

**HAZARDOUS MATERIALS—GENERAL PROVISIONS**

amount of nonflammable solid and nonflammable or non-combustible liquid hazardous materials stored and displayed within a single outdoor *control area* of a Group M occupancy shall not exceed the amounts set forth in Table 5003.11.1.

❖ The amounts of storage of nonflammable solid and nonflammable or noncombustible liquid hazardous material stored and displayed in outside areas may not exceed the MAQs given in Table 5003.11.1.

**5003.11.3 Storage and display.** Storage and display shall be in accordance with Sections 5003.11.3.1 through 5003.11.3.11.

❖ Storage and display of nonflammable solid and nonflammable or noncombustible liquid chemicals must comply with Sections 5003.11.3.1 through 5003.11.3.10.

**5003.11.3.1 Density.** Storage and display of solids shall not exceed 200 pounds per square foot (976 kg/m<sup>2</sup>) of floor area actually occupied by solid merchandise. Storage and display

of liquids shall not exceed 20 gallons per square foot (0.50 L/m<sup>2</sup>) of floor area actually occupied by liquid merchandise.

❖ The key element to this section is the phrase “floor area actually occupied by solid or liquid merchandise.” As an example, if 10 square feet (0.9 m<sup>2</sup>) of floor area is to be used for storage or display, the limit allowed would be 2,000 pounds (908 kg) (200 pounds × 10 square feet) of solid material or 200 gallons (757 L) (20 gallons × 10 square feet) of liquid material.

**5003.11.3.2 Storage and display height.** Display height shall not exceed 6 feet (1829 mm) above the finished floor in display areas of Group M occupancies. Storage height shall not exceed 8 feet (2438 mm) above the finished floor in storage areas of Group M and Group S occupancies.

❖ This section limits Group M display height to 6 feet (1829 mm). In storage areas of Group M occupancies and Group S occupancies, the storage height is increased to 8 feet (2438 mm) in recognition of the fact that these areas are not normally open to the

**TABLE 5003.11.1  
MAXIMUM ALLOWABLE QUANTITY PER INDOOR AND OUTDOOR CONTROL AREA IN GROUP M  
AND S OCCUPANCIES—NONFLAMMABLE SOLIDS, NONFLAMMABLE AND NONCOMBUSTIBLE LIQUIDS<sup>d, e, f</sup>**

CONDITION		MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA	
Material <sup>a</sup>	Class	Solids pounds	Liquids gallons
<b>A. HEALTH-HAZARD MATERIALS—NONFLAMMABLE AND NONCOMBUSTIBLE SOLIDS AND LIQUIDS</b>			
1. Corrosives <sup>b, c</sup>	Not Applicable	9,750	975
2. Highly Toxics	Not Applicable	20 <sup>b, c</sup>	2 <sup>b, c</sup>
3. Toxics <sup>b, c</sup>	Not Applicable	1,000	100
<b>B. PHYSICAL-HAZARD MATERIALS—NONFLAMMABLE AND NONCOMBUSTIBLE SOLIDS AND LIQUIDS</b>			
1. Oxidizers <sup>b, c</sup>	4	Not Allowed	Not Allowed
	3	1,150 <sup>e</sup>	115
	2	2,250 <sup>h</sup>	225
	1	18,000 <sup>i, j</sup>	1,800 <sup>i, j</sup>
2. Unstable (Reactives) <sup>b, c</sup>	4	Not Allowed	Not Allowed
	3	550	55
	2	1,150	115
	1	Not Limited	Not Limited
3. Water Reactives	3 <sup>b, c</sup>	550	55
	2 <sup>b, c</sup>	1,150	115
	1	Not Limited	Not Limited

For SI: 1 pound = 0.454 kg, 1 gallon = 3.785 L, 1 cubic foot = 0.02832 m<sup>3</sup>.

- a. Hazard categories are as specified in Section 5001.2.2.
- b. Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Where Note c also applies, the increase for both notes shall be applied accumulatively.
- c. Maximum allowable quantities shall be increased 100 percent where stored in approved storage cabinets in accordance with Section 5003.8. Where Note b also applies, the increase for both notes shall be applied accumulatively.
- d. See Table 5003.8.3.2 for design and number of control areas.
- e. Maximum allowable quantities for other hazardous material categories shall be in accordance with Section 5003.1.
- f. Maximum allowable quantities shall be increased 100 percent in outdoor control areas.
- g. Maximum allowable quantities shall be increased to 2,250 pounds where individual packages are in the original sealed containers from the manufacturer or packager and do not exceed 10 pounds each.
- h. Maximum allowable quantities shall be increased to 4,500 pounds where individual packages are in the original sealed containers from the manufacturer or packager and do not exceed 10 pounds each.
- i. Quantities are unlimited where protected by an automatic sprinkler system.
- j. Quantities are unlimited in an outdoor control area.

public. These areas are also subject to the density requirements of Section 5003.11.3.1.

**5003.11.3.3 Container location.** Individual containers less than 5 gallons (19 L) or less than 25 pounds (11 kg) shall be stored or displayed on pallets, racks or shelves.

❖ When the capacity of individual containers is less than either 5 gallons (19 L) or 25 pounds (11 kg), they must be displayed on pallets, racks or shelves.

**5003.11.3.4 Racks and shelves.** Racks and shelves used for storage or display shall be in accordance with Section 5003.9.9.

❖ The design of racks and shelves must meet the requirements of Section 5003.9.9. See also Chapter 32 for high-piled combustible storage and rack storage over 12 feet in height.

**5003.11.3.5 Container type.** Containers shall be *approved* for the intended use and identified as to their content.

❖ Containers must be approved for the storage or display conditions.

**5003.11.3.6 Container size.** Individual containers shall not exceed 100 pounds (45 kg) for solids or 10 gallons (38 L) for liquids in storage and display areas.

❖ The individual containers may not exceed 10 gallons (38 L) for liquids or 100 pounds (45 kg) for solids.

**5003.11.3.7 Incompatible materials.** *Incompatible materials* shall be separated in accordance with Section 5003.9.8.

❖ Incompatible materials may not be stored together unless separated in accordance with Section 5003.9.8.

**5003.11.3.8 Floors.** Floors shall be in accordance with Section 5004.12.

❖ Floors in storage and display areas must meet the requirements of Section 5004.12. See the commentary for that section.

**5003.11.3.9 Aisles.** Aisles 4 feet (1219 mm) in width shall be maintained on three sides of the storage or display area.

❖ The storage or display area must be surrounded on at least three sides with an aisle that is at least 4 feet (1219 mm) wide.

**5003.11.3.10 Signs.** Hazard identification signs shall be provided in accordance with Section 5003.5.

❖ Signs meeting the requirements of NFPA 704 and Section 5003.5 must be installed.

**5003.11.3.11 Storage plan.** A storage plan illustrating the intended storage arrangement, including the location and dimensions of aisles, and storage racks shall be provided.

❖ This section makes it clear that all racks and other arrays for merchandise and storage must be shown in order to do a complete and accurate plan review, especially with respect to verifying the adequacy of the means of egress and arrangement of aisles for fire protection of rack systems. These types of plans are often part of the fixture plan prepared after the

construction documents have been submitted but are no less important in the plan review process.

**5003.12 Outdoor control areas.** Outdoor *control areas* for hazardous materials in amounts not exceeding the maximum allowable quantity per outdoor *control area* shall be in accordance with the following:

1. Outdoor *control areas* shall be kept free from weeds, debris and common combustible materials not necessary to the storage. The area surrounding an outdoor *control area* shall be kept clear of such materials for not less than 15 feet (4572 mm).
2. Outdoor control areas shall be located not closer than 20 feet (6096 mm) from a lot line that can be built upon, public street, public alley or public way.

**Exceptions:**

1. For solid and liquid hazardous materials, a 2-hour fire-resistance-rated wall without openings extending not less than 30 inches (762 mm) above and to the sides of the storage area shall be allowed in lieu of such distance.
  2. For compressed gas hazardous materials, unless otherwise specified, the minimum required distances shall not apply where *fire barriers* without openings or penetrations having a minimum *fire-resistance rating* of 2 hours interrupt the line of sight between the storage and the exposure. The configuration of the *fire barrier* shall be designed to allow natural ventilation to prevent the accumulation of hazardous gas concentrations.
  3. Where a property exceeds 10,000 square feet (929 m<sup>2</sup>), a group of two outdoor *control areas* is allowed where *approved* and where each *control area* is separated by a minimum distance of 50 feet (15 240 mm).
  4. Where a property exceeds 35,000 square feet (3252 m<sup>2</sup>), additional groups of outdoor *control areas* are allowed where *approved* and where each group is separated by a minimum distance of 300 feet (91 440 mm).
- ❖ This section lists four requirements for an outdoor control area:

Item 1 requires that outdoor control areas be kept clear of combustible materials for a minimum of 15 feet (4572 mm) around the control area.

Item 2 requires the control area to either be 20 feet (6096 mm) from the lot lines, street, alley or public way or have a 2-hour blank wall extending a minimum of 30 inches (762 mm) above and to either side of the storage area, if the distance requirement cannot be met. Exception 1 allows encroachment on lot lines, public streets, public alleys or public ways through the use of a protective 2-hour fire-resistance-rated wall, which acts as a shield between the storage and the exposure. Recognition of the protection thus provided can also be found in Section 5904.2.1, which contains comparable provisions for flammable solids identifying the use of a protective structure as a

means to allow encroachment on lot lines, public streets, public alleys or public ways. For gases, Exception 2 allows encroachment on property lines, public streets, public ways, etc., through the use of an unpenetrated protective 2-hour fire barrier (constructed as required by IBC Section 707), which acts as a shield between the storage and the exposure. This recognizes that a 2-hour fire-barrier provides an equivalent means of achieving the objective of spatial separation. Where a separation assembly is used instead of a physical separation distance, the wall must interrupt the line of sight between storage and exposure and be configured so as to prevent a hazardous accumulation of gas.

Item 3 allows two control areas on properties larger than 10,000 square feet (929 m<sup>2</sup>) when they are separated by at least 50 feet (15 240 mm). The 20-foot (6096 mm) distance from the lot lines, street, alley or public way is still in effect.

Item 4 allows for more than two control areas when the property exceeds 35,000 square feet (3252 m<sup>2</sup>). Each group must be separated by a minimum distance of 300 feet (91 440 mm) to reduce the likelihood of simultaneous involvement of multiple outdoor control areas in a single incident.

## SECTION 5004 STORAGE

**5004.1 Scope.** Storage of hazardous materials in amounts exceeding the *maximum allowable quantity per control area* as set forth in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5004. Storage of hazardous materials in amounts not exceeding the *maximum allowable quantity per control area* as set forth in Section 5003.1 shall be in accordance with Sections 5001 and 5003. Retail and wholesale storage and display of nonflammable solid and nonflammable and noncombustible liquid hazardous materials in Group M occupancies and Group S storage shall be in accordance with Section 5003.11.

❖ This scope paragraph considers four storage situations: storage of quantities exceeding the maximum, storage of quantities within the allowable limits, retail and wholesale storage and display in Group M occupancies and storage areas in Group S occupancies. Section references are given for each of the four storage and use situations.

**5004.2 Spill control and secondary containment for liquid and solid hazardous materials.** Rooms, buildings or areas used for the storage of liquid or solid hazardous materials shall be provided with spill control and secondary containment in accordance with Sections 5004.2.1 through 5004.2.3.

**Exception:** Outdoor storage of containers on approved containment pallets in accordance with Section 5004.2.3.

❖ This section introduces the specific requirements for spill control and secondary containment for solid and liquid hazardous materials. The exception recognizes the innovation of containment pallets and their suit-

ability for preventing the spread of hazardous materials spills in outdoor control areas (see commentary, Section 5004.2.3).

### 5004.2.1 Spill control for hazardous material liquids.

Rooms, buildings or areas used for the storage of hazardous material liquids in individual vessels having a capacity of more than 55 gallons (208 L), or in which the aggregate capacity of multiple vessels exceeds 1,000 gallons (3785 L), shall be provided with spill control to prevent the flow of liquids to adjoining areas. Floors in indoor locations and similar surfaces in outdoor locations shall be constructed to contain a spill from the largest single vessel by one of the following methods:

1. Liquid-tight sloped or recessed floors in indoor locations or similar areas in outdoor locations.
2. Liquid-tight floors in indoor locations or similar areas in outdoor locations provided with liquid-tight raised or recessed sills or dikes.
3. Sumps and collection systems.
4. Other *approved* engineered systems.

Except for surfacing, the floors, sills, dikes, sumps and collection systems shall be constructed of noncombustible material, and the liquid-tight seal shall be compatible with the material stored. Where liquid-tight sills or dikes are provided, they are not required at perimeter openings having an open-grate trench across the opening that connects to an approved collection system.

❖ The requirement for spill control in a room or area is based on two items. The first is that the storage container(s) have a capacity of more than 55 gallons (208 L). The second is that the aggregate capacity of multiple vessels be more than 1,000 gallons (3785 L). The area, once determined to require spill control, must be protected so that the containment area will handle the release from the largest container in the area. This section recommends four methods of containment:

1. Liquid-tight sloped or recessed floors. The chemicals being stored or used in the area must be evaluated to ensure that the method of making the floor liquid tight will not cause a reaction with the chemicals.
2. Liquid-tight floors with a containment sill or trench around the area. To determine the volume of the containment sill or dike, the following procedure is recommended:
  - Determine the greatest amount of liquid that can be released from the largest tank or container within the containment area.
  - If more than one tank or group of containers are in the containment area, the volume of the tank or group of containers below the height of the containment sill or dike can be subtracted from the volume of the containment sill or dike.

- The following is the equation for determining the volumetric capacity of a tank:

$$V = \frac{3.1416(d)^2h}{4}$$

where:

$V$  = Tank capacity, in gallons.

$d$  = Diameter of tank, in feet.

$h$  = Height of tank, in feet.

- Determine whether the containment sill or dike is of sufficient size to control the spill.
- The following is the equation for determining the volumetric capacity of the containment sill or dike:

$$V = a \cdot h$$

where:

$V$  = Volumetric capacity of dike, in gallons.

$a$  = Area of storage floor, in square feet.

$h$  = Height of sill, in feet.

#### Example:

There is a sprinklered first-floor inside storage room that is 20 feet by 15 feet (6096 mm by 4572 mm). Storage consists of 32 drums [55 gallon (208 L)] of a Class II combustible liquid stacked two pallets high. The containment sill is 4 inches (102 mm) high. Is this height adequate for spill containment?

The largest tank is 55 gallons (208 L). It is 36 inches (914 mm) tall and 22 inches (559 mm) wide, and has a volumetric capacity of:

$$V = \frac{3.1416(22/12)^2(36/12)}{4}$$

(Convert inches to feet)

$V = 7.91$  cubic feet (0.22 m<sup>3</sup>) of spill from a 55-gallon (208 L) drum.

There are four pallets that are 54 inches by 54 inches square (1372 mm by 1372 mm) and 4 inches (102 mm) tall.

$$V = (54/12) \times (54/12) \times 4/12 \text{ inches}$$

$$V = 6.68 \text{ cubic feet (0.2 m}^3\text{) per pallet.}$$

$6.68 \times 4$  (pallets) = 26.73 cubic feet (0.76 m<sup>3</sup>) of space taken up in the containment area.

The room has a containment area of 20 feet by 15 feet by 4/12 or 99 cubic feet (3 m<sup>3</sup>).

When the volume of the pallets is subtracted, there is 72.27 cubic feet (0.2

m<sup>3</sup>) of containment. The largest container [55-gallon (208 L) drum] would produce a spill volume of 7.91 cubic feet (0.2 m<sup>3</sup>). Thus, the secondary containment of a 20-foot by 15-foot (6096 mm by 4572 mm) room with a 4-inch (102 mm) curb would contain the spill from the largest container.

- Sumps and collection systems that can consist of floor drains to a remote collection tank. Oil/water separators would also be required by Section 1003.4 of the *International Plumbing Code*<sup>®</sup> (IPC<sup>®</sup>) for floor drains that discharge into the building drainage system or other point of disposal.
- Any other approved engineered systems. Any system that has been engineered and evaluated for the hazards present can be accepted by the fire code official.

**5004.2.2 Secondary containment for hazardous material liquids and solids.** Where required by Table 5004.2.2 buildings, rooms or areas used for the storage of hazardous materials liquids or solids shall be provided with secondary containment in accordance with this section where the capacity of an individual vessel or the aggregate capacity of multiple vessels exceeds both of the following:

- Liquids: Capacity of an individual vessel exceeds 55 gallons (208 L) or the aggregate capacity of multiple vessels exceeds 1,000 gallons (3785 L).
- Solids: Capacity of an individual vessel exceeds 550 pounds (250 kg) or the aggregate capacity of multiple vessels exceeds 10,000 pounds (4540 kg).

❖ Table 5004.2.2 specifies requirements for secondary containment according to the type of material and method of storage. In addition, the capacity of an individual container must exceed 55 gallons (208 L) of liquid or the aggregate capacity of multiple containers must exceed 1,000 gallons (3785 L). If the chemical is in solid form and the capacity of an individual container exceeds 550 pounds (250 kg) or the cumulative capacity of multiple containers exceeds 10,000 pounds (4540 kg), secondary containment is required when called for in Table 5004.2.2.

**TABLE 5004.2.2.** See page 50-44.

❖ This table is divided into three main columns: material, indoor storage and outdoor storage. Indoor and outdoor storage is further divided into two subcolumns: solids and liquids. This table indicates when secondary containment is required.

**5004.2.2.1 Containment and drainage methods.** The building, room or area shall contain or drain the hazardous materials and fire protection water through the use of one of the following methods:

- Liquid-tight sloped or recessed floors in indoor locations or similar areas in outdoor locations.

**HAZARDOUS MATERIALS—GENERAL PROVISIONS**

2. Liquid-tight floors in indoor locations or similar areas in outdoor locations provided with liquid-tight raised or recessed sills or dikes.
  3. Sumps and collection systems.
  4. Drainage systems leading to an *approved* location.
  5. Other *approved* engineered systems.
- ❖ The five methods of containment and drainage for secondary containment in this section are similar to those of spill control.

Method 1 consists of liquid-tight sloped or recessed floors. The chemicals being stored or used in the area must be evaluated to ensure that the method of making the floor liquid tight will not cause a reaction

with the chemicals.

Method 2 consists of liquid-tight floors with a containment sill or trench around the area.

To determine the height of the containment sill or dike, the following procedure is recommended:

- Determine the greatest amount of liquid that can be released from the largest tank or container within the containment area.
- If more than one tank or group of containers are in the containment area, the volume of the tank or group of containers below the height of the containment sill or dike must be subtracted from the volume of the containment sill or dike.

**TABLE 5004.2.2  
REQUIRED SECONDARY CONTAINMENT—HAZARDOUS MATERIAL SOLIDS AND LIQUIDS STORAGE**

MATERIAL		INDOOR STORAGE		OUTDOOR STORAGE	
		Solids	Liquids	Solids	Liquids
<b>1. Physical-hazard materials</b>					
Combustible liquids	Class II	Not Applicable	See Chapter 57	Not Applicable	See Chapter 57

Highly toxics		Required	Required	Required	Required
Toxics					

- The following is the equation for determining the volumetric capacity of a tank:

$$V = \frac{3.1416(d)^2h}{4}$$

- Determine whether the containment sill or dike is of sufficient size to control a spill and the fire-fighting water, as required.

The following is the equation for determining the volumetric capacity of a containment sill or dike:

$$V = (a) (h)$$

where:

$V$  = Volume of the containment, in cubic feet.

$a$  = Area of the containment, in square feet.

$h$  = Height of the sill or dike, in feet.

#### Example:

There is a sprinklered first floor inside storage room that is 20 feet by 15 feet (6096 mm by 4572 mm). Stored in this area are 32 drums [55 gallons (208 L)] of a Class II combustible liquid stacked two pallets high. The containment sill is 4 inches (102 mm) high. Will this provide secondary containment?

The largest tank is 55 gallons (208 L). It has dimensions of 36 inches (914 mm) tall and 22 inches (539 mm) wide, and has a volumetric capacity of:

$$V = \frac{3.1416(22/12)^2(36/12)}{4}$$

(Convert inches to feet)

$$V = 7.91 \text{ cubic feet (0.2 m}^3\text{) of spill from a 55-gallon (208 L) drum.}$$

There are four pallets with a size of 54 inches by 54 inches (1372 mm by 1372 mm) and 4 inches (102 mm) tall.

$$V = (54/12)(54/12) (4/12)$$

$$V = 6.68 \text{ cubic feet (0.2 m}^3\text{) per pallet}$$

$6.68 \times 4$  (pallets) = 26.73 cubic feet (0.76 m<sup>3</sup>) of space taken up in the containment area.

The room has a containment area of 20 feet by 15 feet by 4 inches (6096 mm by 4572 mm by 102 mm) or 99 cubic feet (3 m<sup>3</sup>).

When the volume of the pallets is subtracted, there is 72.27 cubic feet (2 m<sup>3</sup>) of containment. The largest container [55-gallon (208 L) drum] would produce a spill of 7.91 cubic feet (0.2 m<sup>3</sup>). Thus, the secondary containment of a 20-foot by 15-foot (6096 mm by 4572 mm) room with a 4-inch (102 mm) curb would contain the spill from the largest container. Now the requirements of the fire-fighting water from the

sprinkler system as required by Section 5004.2.2.3 must be factored in. From NFPA 13 Chapter 11, the design density is 0.2. This design density of 0.2 times the fire area of 300 square feet (28 m<sup>2</sup>) equals 60 gallons (227 L) per minute discharge. The sprinkler discharge will be 60 gallons (227 L) × 20 minutes (as required by Section 5004.2.2.3) or 1,200 gallons (4542 L) of fire-fighting water.

The conversion factor from gallon to cubic foot is 0.1335805. Therefore, 1,200 gallons (4542 L) of fire-fighting water × 0.1335805 = 167.79 cubic feet (5 m<sup>3</sup>) of containment area required.

The largest tank volume is 7.91 cubic feet (0.2 m<sup>3</sup>).

The volume of the pallets is 26.73 cubic feet (0.8 m<sup>3</sup>).

The volume for fire-fighting water is 167.79 cubic feet (5 m<sup>3</sup>).

Total cubic feet required for secondary containment is 202.43 cubic feet (6 m<sup>3</sup>).

In this case, the secondary containment does not have enough capacity. Although the 4-inch (102 mm) sill does give enough capacity for spill containment, with the requirement of fire-fighting water there is now no proper secondary containment.

Method 3 recommends sumps and collection systems, which can consist of floor drains to remote collection tanks. It is important to remember that oil/water separators are required by IPC Section 1003.4 for floor drains that discharge into the building drainage system or other point of disposal.

Method 4 is a drainage system leading to an approved location. If water is being used as the automatic extinguishing agent for the area, a large containment area will be required to hold the runoff of the sprinkler water and the spill.

Method 5 is any other approved engineered system. Any system that has been engineered and evaluated for the hazards present can be accepted by the fire code official.

**5004.2.2.2 Incompatible materials.** *Incompatible materials* used in *open systems* shall be separated from each other in the secondary containment system.

- ❖ Different containment areas cannot be manifolded if the products in the different areas are incompatible. Even in containment of a spill in a single area, incompatible materials must be kept separated.

**5004.2.2.3 Indoor design.** Secondary containment for indoor storage areas shall be designed to contain a spill from the largest vessel plus the design flow volume of fire protection water calculated to discharge from the fire-extinguishing system over the minimum required system design area or area of the room or area in which the storage is located, whichever is

smaller. The containment capacity shall be designed to contain the flow for a period of 20 minutes.

- ❖ Secondary containment must be sized to hold the release of the largest container in the area plus the design flow volume of the fire protection for a 20-minute period.

For example, there is a 500-square-foot (46 m<sup>2</sup>) flammable liquid storage area that is sprinklered. Section 5004.5 states that the minimum design of the sprinkler system is an ordinary hazard Group 2 with the minimum design area of 3,000 square feet (279 m<sup>2</sup>). From NFPA 13 Chapter 11, the design density is 0.2. This design density of 0.2 times the fire area of 500 square feet (46 m<sup>2</sup>) equals 100-gallon-per-minute (6 L/s) discharge.

The largest tank in the fire area is 100 gallons (379 L). The secondary containment must be sized to hold the 100 gallons (379 L) plus the sprinkler discharge of 100 gallons (379 L) for 20 minutes, or 2,100 gallons (7949 L). This must be the minimum capacity of the secondary containment.

**5004.2.2.4 Outdoor design.** Secondary containment for outdoor storage areas shall be designed to contain a spill from the largest individual vessel. If the area is open to rainfall, secondary containment shall be designed to include the volume of a 24-hour rainfall as determined by a 25-year storm and provisions shall be made to drain accumulations of groundwater and rainwater.

- ❖ In addition to holding the volume of the largest container, if the area is open to rainfall, the secondary containment must include the volume of a 24-hour rainfall, as determined by a 25-year storm. Drains must be sized to carry off accumulations of ground water and rainwater. See IPC Section 1106.1 for information on rainfall maps.

**5004.2.2.5 Monitoring.** An *approved* monitoring method shall be provided to detect hazardous materials in the secondary containment system. The monitoring method is allowed to be visual inspection of the primary or secondary containment, or other *approved* means. Where secondary containment is subject to the intrusion of water, a monitoring method for detecting water shall be provided. Where monitoring devices are provided, they shall be connected to *approved* visual or audible alarms.

- ❖ Visual inspection of the primary or secondary containment system is permitted; otherwise, an electronic monitoring system must be installed. These electronic systems must be connected to both audible and visual alarms.

**5004.2.2.6 Drainage system design.** Drainage systems shall be in accordance with the *International Plumbing Code* and all of the following:

1. The slope of floors to drains in indoor locations, or similar areas in outdoor locations shall be not less than 1 percent.

2. Drains from indoor storage areas shall be sized to carry the volume of the fire protection water as determined by the design density discharged from the automatic fire-extinguishing system over the minimum required system design area or area of the room or area in which the storage is located, whichever is smaller.
3. Drains from outdoor storage areas shall be sized to carry the volume of the fire flow and the volume of a 24-hour rainfall as determined by a 25-year storm.
4. Materials of construction for drainage systems shall be compatible with the materials stored.
5. *Incompatible materials* used in *open systems* shall be separated from each other in the drainage system.
6. Drains shall terminate in an *approved* location away from buildings, valves, *means of egress*, fire access roadways, adjoining property and storm drains.

- ❖ Drainage systems for hazardous materials must meet the requirements of IPC Section 1003, in addition to the six elements listed in this section:

1. The slope of the floor may not be more than 1 percent.
2. The drains for an indoor storage area must be sized to carry the automatic fire-extinguishing agent from the room. If an agent other than a liquid is used, no additional volume will be needed for calculations.
3. The drains for outdoor storage must be sized to carry the volume of fire flow and the volume of a 24-hour rainfall.
4. The piping and other elements of the system must be chosen to be compatible with the chemicals and extinguishing agents that will be flowing through the drainage system.
5. Incompatible materials pose a great hazard both in use and when an emergency occurs. This section requires that incompatible materials, when used in open systems, be separated into different drainage systems.
6. Drains must terminate in safe locations so that they do not pose additional threats to lives and property.

**5004.2.3 Containment pallets.** Where used as an alternative to spill control and secondary containment for outdoor storage in accordance with the exception in Section 5004.2, containment pallets shall comply with all of the following:

1. A liquid-tight sump accessible for visual inspection shall be provided.
2. The sump shall be designed to contain not less than 66 gallons (250 L).
3. Exposed surfaces shall be compatible with material stored.

4. Containment pallets shall be protected to prevent collection of rainwater within the sump.

❖ Another option now available is the use of containment pallets. This type of pallet is designed to contain a leak should one occur. This section specifies the minimum design for the pallet.

**5004.3 Ventilation.** Indoor storage areas and storage buildings shall be provided with mechanical exhaust ventilation or natural ventilation where natural ventilation can be shown to be acceptable for the materials as stored.

**Exception:** Storage areas for flammable solids complying with Chapter 59.

❖ Indoor storage areas and buildings must be ventilated either mechanically or naturally so that the level of vapors is maintained below the LFL or PEL. Keeping the area/building at these levels maintains a level of safety for the area. Storage areas for flammable solids that meet the requirements of Chapter 59 are exempted from this requirement.

**5004.3.1 System requirements.** Exhaust ventilation systems shall comply with all of the following:

1. Installation shall be in accordance with the *International Mechanical Code*.
2. Mechanical ventilation shall be at a rate of not less than 1 cubic foot per minute per square foot [ $0.00508 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of floor area over the storage area.
3. Systems shall operate continuously unless alternative designs are *approved*.
4. A manual shutoff control shall be provided outside of the room in a position adjacent to the access door to the room or in an *approved* location. The switch shall be a break-glass or other *approved* type and shall be *labeled*: VENTILATION SYSTEM EMERGENCY SHUTOFF.
5. Exhaust ventilation shall be designed to consider the density of the potential fumes or vapors released. For fumes or vapors that are heavier than air, exhaust shall be taken from a point within 12 inches (305 mm) of the floor. For fumes or vapors that are lighter than air, exhaust shall be taken from a point within 12 inches (305 mm) of the highest point of the room.
6. The location of both the exhaust and inlet air openings shall be designed to provide air movement across all portions of the floor or room to prevent the accumulation of vapors.
7. Exhaust air shall not be recirculated to occupied areas if the materials stored are capable of emitting hazardous vapors and contaminants have not been removed. Air contaminated with explosive or flammable vapors, fumes or dusts; flammable, highly toxic or toxic gases; or radioactive materials shall not be recirculated.

❖ The exhaust ventilation system must comply with all of the seven requirements of this section:

1. Systems must be installed as required by IMC Chapter 5.

2. The minimum rate for mechanical ventilation is listed here; however, the MSDS must also be reviewed. The ventilation needed to maintain a safe environment could require a much higher flow rate.
3. The exhaust system must provide continuous ventilation in the area.
4. The entry door into the area must be equipped with an emergency shutoff that can be used to disable the ventilation system in case of a fire.
5. The system design must consider the vapor density of the chemicals being stored. The vapor density for the chemicals can be found in the MSDS.
6. The system must provide air movement across the entire area being protected.
7. Item 7 recognizes the possibility for contaminant control and energy conservation for hazardous exhaust systems through air-recovery systems. Some energy conservation opportunities use the exhausted air for heat recovery, makeup air, or recirculation to occupied areas. Those systems incorporate a variety of contaminant control strategies, including water mist sprays, activated carbon filters and oxidizing pellet filters.

Air contaminated with explosive or flammable vapors, fumes or dusts; flammable or toxic gases; or radioactive material must be exhausted to the outdoors and, therefore, cannot be recirculated or transferred to any other space. Note that the recirculation of exhaust in any form is in direct conflict with IMC Section 510.1, which requires hazardous exhaust to discharge to the outdoors.

**5004.4 Separation of incompatible hazardous materials.** *Incompatible materials* shall be separated in accordance with Section 5003.9.8.

❖ Incompatible materials must be kept separated so that accidental mixing of chemicals in an emergency does not create a more dangerous incident.

**5004.5 Automatic sprinkler systems.** Indoor storage areas and storage buildings shall be equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. The design of the sprinkler system shall be not less than that required for Ordinary Hazard Group 2 with a minimum design area of 3,000 square feet (279 m<sup>2</sup>). Where the materials or storage arrangement are required by other regulations to be provided with a higher level of sprinkler system protection, the higher level of sprinkler system protection shall be provided.

❖ This section requires a sprinkler system for indoor storage areas and buildings. The system must comply with NFPA 13 and provide a minimum density as required for an Ordinary Hazard Group 2. The MSDS should be consulted for compatibility with water. If the

materials are incompatible, other methods of automatic extinguishing should be used.

**5004.6 Explosion control.** Indoor storage rooms, areas and buildings shall be provided with explosion control in accordance with Section 911.

❖ Storage rooms and use areas must be provided with explosion control in accordance with Table 911.1. The design of the explosion control must meet the requirements of Section 911.

**5004.7 Standby or emergency power.** Where mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are required, such systems shall be provided with an emergency or standby power in accordance with Section 604.

For storage areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2.

❖ A backup emergency power source is considered essential for required systems monitoring and serving hazardous materials; therefore, when limit controls, detection systems or mechanical ventilation is required for a specific hazardous material, an emergency electrical system or standby power system is required.

**5004.7.1 Exempt applications.** Standby or emergency power is not required for mechanical ventilation systems for any of the following:

1. Storage of Class IB and Class IC flammable and *combustible liquids* in closed containers not exceeding 6½ gallons (25 L) capacity.
2. Storage of Class 1 and 2 oxidizers.
3. Storage of Class II, III, IV and V organic peroxides.
4. Storage of asphyxiant, irritant and radioactive gases.

❖ Exempt application 1 correlates with industry treatment of portable container storage. Notably, storage of small, closed containers does not pose a risk that warrants ventilation for these materials. FM Data Sheet 7-29, *Ignitable Liquid Storage in Portable Containers*, does not require mechanical ventilation for flammable liquids in closed containers of not greater than 6½-gallon (25 L) individual capacity, with a flash point of not greater than 100°F (38°C) and a boiling point equal to or greater than 100°F (38°C). NFPA 30 also recognizes that closed container storage does not pose a risk that warrants ventilation (ventilation is required if there is open dispensing). These materials are in sealed containers in storage. Any loss of power would require an immediate cessation of operations, which would eliminate spill risk. By limiting the container size, the potential for accidental spills is significantly reduced.

Exempt applications 2 and 3 address low-hazard oxidizers and organic peroxides that do not present a severe fire or reactivity hazard. Highly toxic and toxic materials (see Exception 5) must conform to applicable requirements of Chapter 37. For example, emergency power may be required for treatment systems

utilized to process the accidental release of highly toxic or toxic compressed gases caused by a leak or rupture in storage cylinders or tanks. Without emergency power, all required monitoring systems, including the treatment system for neutralizing potential leaking gas, would be rendered inoperative if a power failure or other electrical system failure occurred.

Exempt application 4 exempts storage areas for asphyxiant, irritant or radioactive gases because, unlike the requirements for other hazard categories, which use the MAQ as a trigger threshold, the requirement for ventilation in storage areas containing these gases is not quantity based. The construction of compressed gas containers is robust compared to the containers used for other materials that may be of glass, plastic or paper. The integrity of the containers alone represents a major safeguard against likely failure. While leakage from containers is a consideration, the concern over reestablishing power to the ventilation system within 60 seconds is not warranted given the facts that the requirement could be imposed for insignificant quantities of the gas, and that occupancy of a storage area during power outage is not the norm.

**5004.7.2 Fail-safe engineered systems.** Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an *approved* fail-safe engineered system is installed..

❖ This section recognizes the use of an engineered system designed to always fail in the appropriate design mode without human intervention in lieu of the emergency power system. The intent of the exception is to permit alternative systems that are not subject to power interruptions. Note that this exception does not apply to detection and alarm systems, but addresses those systems essential to the removal of hazardous fumes and vapors from potentially occupied areas.

**5004.8 Limit controls.** Limit controls shall be provided in accordance with Sections 5004.8.1 and 5004.8.2.

❖ Based on the MSDS, limit controls may be required to protect the chemicals.

**5004.8.1 Temperature control.** Materials that must be kept at temperatures other than normal ambient temperatures to prevent a hazardous reaction shall be provided with an approved means to maintain the temperature within a safe range. Redundant temperature control equipment that will operate on failure of the primary temperature control system shall be provided. Where *approved*, alternative means that prevent a hazardous reaction are allowed.

❖ When a chemical is temperature sensitive, a temperature control system with a redundant backup is required.

**5004.8.2 Pressure control.** Stationary tanks and equipment containing hazardous material liquids that can generate pressures exceeding design limits because of exposure fires or internal reaction shall have some form of construction or other *approved* means that will relieve excessive internal

pressure. The means of pressure relief shall vent to an *approved* location or to an exhaust scrubber or treatment system where required by Chapter 60.

- ❖ Emergency vents must be installed when the vapor density of a chemical could cause a boiling liquid expanding vapor explosion (BLEVE) during a fire.

**5004.9 Emergency alarm.** An *approved* manual emergency alarm system shall be provided in buildings, rooms or areas used for storage of hazardous materials. Emergency alarm-initiating devices shall be installed outside of each interior *exit* or *exit access* door of storage buildings, rooms or areas. Activation of an emergency alarm-initiating device shall sound a local alarm to alert occupants of an emergency situation involving hazardous materials.

- ❖ A manual emergency alarm system that meets the requirements of Section 908 must be installed (see commentary, Sections 908.1 through 908.6).

**5004.10 Supervision and monitoring.** Emergency alarm, detection and automatic fire-extinguishing systems required by Section 5004 shall be electrically supervised and monitored by an *approved* supervising station or, where approved, shall initiate an audible and visual signal at a constantly attended on-site location.

- ❖ Emergency alarm systems, detection systems and automatic extinguishing systems must be supervised by an approved central, proprietary or remote station system. Where a facility has an on-site, “constantly attended location” (as defined in Chapter 2) staffed by qualified personnel who can respond to signals in a timely fashion, the fire code official may approve the monitoring of audible and visual signals by such an attended location in lieu of off-site transmission to an approved supervising station.

**5004.11 Clearance from combustibles.** The area surrounding an outdoor storage area or tank shall be kept clear of combustible materials and vegetation for a minimum distance of 25 feet (7620 mm).

- ❖ Vegetation and other combustible materials must be cut back for a distance of at least 25 feet (7620 mm) from outdoor storage to minimize the exposure to the storage area in the event of a fire in the combustible materials. Note that Section 5005.3.8 requires an additional 5 feet (1524 mm) of clearance due to the fact that in use, dispensing and handling scenarios, vapors may be present, whereas in storage, containers or tanks are closed and vapors are contained.

**5004.12 Noncombustible floor.** Except for surfacing, floors of storage areas shall be of noncombustible construction.

- ❖ The floor of hazardous occupancies must be of noncombustible construction.

**5004.13 Weather protection.** Where overhead noncombustible construction is provided for sheltering outdoor hazardous material storage areas, such storage shall not be considered indoor storage where the area is constructed in accordance

with the requirements for weather protection as required by the *International Building Code*.

**Exception:** Storage of *explosive* materials shall be considered as indoor storage.

- ❖ This section allows for the construction of noncombustible covers over outdoor storage areas for weather protection. This area is not considered inside storage, except when explosive materials are stored under the noncombustible roof. IBC Section 414.6.1 contains the specific requirements for weather-protection construction.

## SECTION 5005 USE, DISPENSING AND HANDLING

**5005.1 General.** Use, dispensing and handling of hazardous materials in amounts exceeding the *maximum allowable quantity per control area* set forth in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5005. Use, dispensing and handling of hazardous materials in amounts not exceeding the *maximum allowable quantity per control area* set forth in Section 5003.1 shall be in accordance with Sections 5001 and 5003.

- ❖ The section references two conditions: when the amount of chemicals exceeds the MAQ; and when the amount of chemicals is within the MAQ.

**5005.1.1 Separation of incompatible materials.** Separation of *incompatible materials* shall be in accordance with Section 5003.9.8.

- ❖ When using, dispensing or handling incompatible materials, care must be taken to ensure that the chemicals do not mix.

**5005.1.2 Noncombustible floor.** Except for surfacing, floors of areas where liquid or solid hazardous materials are dispensed or used in *open systems* shall be of noncombustible, liquid-tight construction.

- ❖ When chemicals are used in an open system, the floors must be both liquid tight and of noncombustible construction.

**5005.1.3 Spill control and secondary containment for hazardous material liquids.** Where required by other provisions of Section 5005, spill control and secondary containment shall be provided for hazardous material liquids in accordance with Section 5004.2.

- ❖ If required by Section 5005, the spill control and secondary containment must meet the requirements of Section 5004.2.

**5005.1.4 Limit controls.** Limit controls shall be provided in accordance with Sections 5005.1.4.1 through 5005.1.4.4.

- ❖ Limit controls required in use, dispensing and handling areas are described in the four subsections to this section.

**5005.1.4.1 High-liquid-level control.** Open tanks in which liquid hazardous materials are used shall be equipped with a

liquid-level limit control or other means to prevent overflowing of the tank.

- ❖ When there is a danger of overflowing a tank, especially in open systems, liquid-level controls are required.

**5005.1.4.2 Low-liquid-level control.** *Approved* safeguards shall be provided to prevent a low-liquid level in a tank from creating a hazardous condition, including but not limited to, overheating of a tank or its contents.

- ❖ If the method of storage can allow for the collapse of the tank or other types of failure as a result of a low level of chemicals, low-liquid-level controls are required.

**5005.1.4.3 Temperature control.** Temperature control shall be provided in accordance with Section 5004.8.1.

- ❖ See Section 5004.8.1 for requirements for temperature controls.

**5005.1.4.4 Pressure control.** Pressure control shall be provided in accordance with Section 5004.8.2.

- ❖ See Section 5004.8.2 for requirements for pressure control systems.

**5005.1.5 Standby or emergency power.** Where mechanical ventilation, treatment systems, temperature control, manual alarm, detection or other electrically operated systems are required by this code, such systems shall be provided with emergency or standby power in accordance with Section 604.

- ❖ Mechanical ventilation, treatment systems, temperature controls or other important safety controls must be connected to an emergency electrical system or standby power as required by Section 604 to enhance their reliability in emergency situations.

**5005.1.5.1 Exempt applications.** Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an *approved* fail-safe engineered system is installed.

- ❖ This section recognizes the use of an engineered system that is designed to always fail in the appropriate design mode without human intervention in lieu of the emergency power system. The exception is intended to permit alternative systems that are not subject to power interruptions. Note that this exception does not apply to detection and alarm systems, but addresses those systems essential to the removal of hazardous fumes and vapors from potentially occupied areas.

**5005.1.6 Supervision and monitoring.** Manual alarm, detection and automatic fire-extinguishing systems required by other provisions of Section 5005 shall be electrically supervised and monitored by an *approved* supervisory service or, where *approved*, shall initiate an audible and visual signal at a constantly attended on-site location.

- ❖ Manual fire alarm systems, detection systems and automatic extinguishing systems must be supervised by an approved central, proprietary or remote station

system. Where a facility has an on-site, “constantly attended location” (as defined in Chapter 2) staffed by qualified personnel who can respond to signals in a timely fashion, the fire code official may approve the monitoring of audible and visual signals by such a location in lieu of off-site transmission to an approved supervising station.

**5005.1.7 Lighting.** Adequate lighting by natural or artificial means shall be provided.

- ❖ All areas must be adequately lighted.

**5005.1.8 Fire-extinguishing systems.** Indoor rooms or areas in which hazardous materials are dispensed or used shall be protected by an automatic fire-extinguishing system in accordance with Chapter 9. Sprinkler system design shall be not less than that required for Ordinary Hazard, Group 2, with a minimum design area of 3,000 square feet (279 m<sup>2</sup>). Where the materials or storage arrangement are required by other regulations to be provided with a higher level of sprinkler system protection, the higher level of sprinkler system protection shall be provided.

- ❖ An automatic sprinkler system is required in use, dispensing and handling areas. Special attention must be paid to chemical/water compatibility.

**5005.1.9 Ventilation.** Indoor dispensing and use areas shall be provided with exhaust ventilation in accordance with Section 5004.3.

**Exception:** Ventilation is not required for dispensing and use of flammable solids other than finely divided particles.

- ❖ Exhaust ventilation meeting the requirements of Section 5004.3 must be installed in indoor use and dispensing areas so that the level of vapors is maintained below the LFL or the PEL. Keeping the area/building at these levels provides a level of safety for the area.

**5005.1.10 Liquid transfer.** Liquids having a hazard ranking of 3 or 4 in accordance with NFPA 704 shall be transferred by one of the following methods:

1. From safety cans complying with UL 30.
2. Through an *approved* closed piping system.
3. From containers or tanks by an approved pump taking suction through an opening in the top of the container or tank.
4. From containers or tanks by gravity through an approved self-closing or automatic-closing valve where the container or tank and dispensing operations are provided with spill control and secondary containment in accordance with Section 5004.2. Highly toxic liquids shall not be dispensed by gravity from tanks.
5. *Approved* engineered liquid transfer systems.

**Exceptions:**

1. Liquids having a hazard ranking of 4 where dispensed from approved containers not exceeding 1.3 gallons (5 L).

2. Liquids having a hazard ranking of 3 or 4 dispensed from approved containers not exceeding 5.3 gallons (20 L).

❖ Liquids having a hazard rating of 3 or 4 in NFPA 704 must be transferred using one of the five methods listed in this section. Exceptions include liquids having a hazard ranking of 4 being dispensed from approved containers not exceeding 1.3 gallons (5 L) and liquids having a hazard ranking of 3 when dispensed from approved containers not exceeding 5.3 gallons (20 L).

**5005.1.11 Design.** Systems shall be suitable for the use intended and shall be designed by persons competent in such design. Controls shall be designed to prevent materials from entering or leaving the process or reaction system at other than the intended time, rate or path. Where failure of an automatic control could result in a dangerous condition or reaction, the automatic control shall be fail-safe.

❖ This section provides requirements that govern the use and dispensing of hazardous materials in quantities that exceed the MAQ by relocating a provision that previously only applied to indoor dispensing and use activities to the general provisions. This is a significant improvement because it now requires process design and safety controls to be considered for outdoor processes using quantities of hazardous materials that exceed the outdoor control area MAQs. A variety of hazardous processes are performed outside of buildings because of the physical size of the process or to avoid constructing a building to the IBC and code requirements for a Group H occupancy. By locating this provision as a general requirement, outdoor hazardous materials processes are now subject to design requirements that ensure process variables, such as time, rate, pressure, temperature, flow rate or sequencing the order of chemicals being blended, are considered.

This section requires that automatic process controls be “fail-safe,” as defined in Section 202. A fail-safe design can include an automatic emergency shutoff valve that is designed to close upon loss of power or a process upset condition. It may include an excess flow control valve or feature, which is designed to stop the flow of a gas or liquid when a preset flow rate is exceeded. In most cases, the fail-safe condition would stop the movement or processing of hazardous materials. However, some processes require staged shutdown to be safely stopped, and in these cases, a process hazard analysis is necessary to determine the true fail-safe mode.

**5005.2 Indoor dispensing and use.** Indoor dispensing and use of hazardous materials shall be in buildings complying with the *International Building Code* and in accordance with Section 5005.1 and Sections 5005.2.1 through 5005.2.2.4.

❖ Indoor dispensing and use areas must be constructed to meet the requirements of the IBC along

with Section 5005.1 and Sections 5005.2.1 through 5005.2.2.4 of the code.

**5005.2.1 Open systems.** Dispensing and use of hazardous materials in open containers or systems shall be in accordance with Sections 5005.2.1.1 through 5005.2.1.4.

❖ See the commentary to the definition of “Open systems” in Chapter 2.

**5005.2.1.1 Ventilation.** Where gases, liquids or solids having a hazard ranking of 3 or 4 in accordance with NFPA 704 are dispensed or used, mechanical exhaust ventilation shall be provided to capture gases, fumes, mists or vapors at the point of generation.

**Exception:** Gases, liquids or solids that can be demonstrated not to create harmful gases, fumes, mists or vapors.

❖ Areas where gases, liquids or solids having a ranking of 3 or 4 in accordance with NFPA 704 are used or dispensed must have a mechanical exhaust system to capture vapors at the point of generation unless the chemicals do not produce harmful fumes, mists or vapors.

**5005.2.1.2 Explosion control.** Explosion control shall be provided in accordance with Section 5004.6 where an explosive environment can occur because of the characteristics or nature of the hazardous materials dispensed or used, or as a result of the dispensing or use process.

❖ Based on the requirements of Section 5004.6, explosion control must be provided when the dispensing or use of a chemical could cause an explosion.

**5005.2.1.3 Spill control for hazardous material liquids.** Buildings, rooms or areas where hazardous material liquids are dispensed into vessels exceeding a 1.3-gallon (5 L) capacity or used in *open systems* exceeding a 5.3-gallon (20 L) capacity shall be provided with spill control in accordance with Section 5004.2.1.

❖ When dispensing hazardous materials into containers larger than 1.3 gallons (5 L) or in an open system with a capacity of 5.3 gallons (20 L), spill control must be provided.

**5005.2.1.4 Secondary containment for hazardous material liquids.** Where required by Table 5005.2.1.4, buildings, rooms or areas where hazardous material liquids are dispensed or used in *open systems* shall be provided with secondary containment in accordance with Section 5004.2.2 where the capacity of an individual vessel or system or the capacity of multiple vessels or systems exceeds the following:

1. Individual vessel or system: greater than 1.3 gallons (5 L).
2. Multiple vessels or systems: greater than 5.3 gallons (20 L).

❖ Table 5005.2.1.4 lists conditions where secondary spill containment is required. The containment must meet the requirements of Section 5004.2.2 where the capacity of a single vessel exceeds 1.3 gallons (5 L) or multiple vessels exceed 5.3 gallons (20 L).

**TABLE 5005.2.1.4.** See below.

❖ This table specifies when secondary containment is required. The table is divided into three columns: material, indoor use and outdoor use. Subcolumns of solids and liquids further divide the table. By finding the type of material in question, the physical state and the method of use, one can determine whether secondary containment is required.

**5005.2.2 Closed systems.** Use of hazardous materials in closed containers or systems shall be in accordance with Sections 5005.2.2.1 through 5005.2.2.4.

❖ See the definition of “Closed systems” in Chapter 2.

**5005.2.2.1 Ventilation.** Where *closed systems* are designed to be opened as part of normal operations, ventilation shall be provided in accordance with Section 5005.2.1.1.

❖ See Section 5005.2.1.1 for requirements on ventilation of areas with closed systems.

**5005.2.2.2 Explosion control.** Explosion control shall be provided in accordance with Section 5004.6 where an explosive environment exists because of the hazardous materials dispensed or used, or as a result of the dispensing or use process.

**Exception:** Where process vessels are designed to contain fully the worst-case explosion anticipated within the ves-

**TABLE 5005.2.1.4  
REQUIRED SECONDARY CONTAINMENT—HAZARDOUS MATERIAL LIQUIDS USE**

MATERIAL	INDOOR LIQUIDS USE	OUTDOOR LIQUIDS USE	
<b>1. Physical-hazard materials</b>

sel under process conditions based on the most likely failure.

- ❖ If the use or process could produce an explosion and the vessels are not rated as explosionproof, explosion control must meet the requirements of Section 5004.6. The exception covers process vessels designed to contain potential explosions.

**5005.2.2.3 Spill control for hazardous material liquids.** Buildings, rooms or areas where hazardous material liquids are used in individual vessels exceeding a 55-gallon (208 L) capacity shall be provided with spill control in accordance with Section 5004.2.1.

- ❖ In addition to the other requirements that have been covered, if an individual vessel exceeds 55 gallons (208 L), spill control is required.

**5005.2.2.4 Secondary containment for hazardous material liquids.** Where required by Table 5005.2.1.4, buildings, rooms or areas where hazardous material liquids are used in vessels or systems shall be provided with secondary containment in accordance with Section 5004.2.2 where the capacity of an individual vessel or system or the capacity of multiple vessels or systems exceeds the following:

1. Individual vessel or system: greater than 55 gallons (208 L).
2. Multiple vessels or systems: greater than 1,000 gallons (3785 L).

- ❖ Secondary containment must be installed where required by Table 5005.2.1.4, where the capacity of an individual vessel is over 55 gallons (208 L) or where multiple vessels have a combined capacity greater than 1,000 gallons (3785 L).

**5005.3 Outdoor dispensing and use.** Dispensing and use of hazardous materials outdoors shall be in accordance with Sections 5005.3.1 through 5005.3.9.

- ❖ The following sections refer to outdoor storage. It is important to note that a noncombustible shed without sides is also considered outdoor storage.

**5005.3.1 Quantities exceeding the maximum allowable quantity per control area.** Outdoor dispensing or use of hazardous materials, in either closed or open containers or systems, in amounts exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(3) and 5003.1.1(4) shall be in accordance with Sections 5001, 5003, 5005.1 and 5005.3.

- ❖ Once the quantities in storage exceed the MAQs of Table 5003.1.1(3) and Section 5003.11(4), the storage must meet the requirements of Sections 5001, 5003, 5005.1 and 5005.3.

**5005.3.2 Quantities not exceeding the maximum allowable quantity per control area.** Outdoor dispensing or use of hazardous materials, in either closed or open containers or systems, in amounts not exceeding the *maximum allowable*

*quantity per control area* indicated in Tables 5003.1.1(3) and 5003.1.1(4) shall be in accordance with Sections 5001 and 5003.

- ❖ Where quantities in storage do not exceed the MAQs of Tables 5003.1.1(3) and 5003.1.1(4), the storage must meet the requirements of Sections 5001 and 5003.

**5005.3.3 Location.** Outdoor dispensing and use areas for hazardous materials shall be located as required for outdoor storage in accordance with Section 5004.

- ❖ See the commentary to Section 5004 for the location of storage.

**5005.3.4 Spill control for hazardous material liquids in open systems.** Outdoor areas where hazardous material liquids are dispensed in vessels exceeding a 1.3-gallon (5 L) capacity or used in *open systems* exceeding a 5.3-gallon (20 L) capacity shall be provided with spill control in accordance with Section 5004.2.1.

- ❖ The dispensing and use areas of open systems located outdoors also require spill controls when the individual containers being filled exceed 1.3 gallons (5 L) or the combined vessels or systems exceed 5.3 gallons (20 L).

**5005.3.5 Secondary containment for hazardous material liquids in open systems.** Where required by Table 5005.2.1.4, outdoor areas where hazardous material liquids are dispensed or used in *open systems* shall be provided with secondary containment in accordance with Section 5004.2.2 where the capacity of an individual vessel or system or the capacity of multiple vessels or systems exceeds the following:

1. Individual vessel or system: greater than 1.3 gallons (5 L).
2. Multiple vessels or systems: greater than 5.3 gallons (20 L).

- ❖ Dispensing and use areas of open systems located outdoors also require secondary spill controls when the requirements of Table 5005.2.1.4 are met and the individual containers being filled exceed 1.3 gallons (5 L) or the combined vessels or systems exceed 5.3 gallons (20 L).

**5005.3.6 Spill control for hazardous material liquids in closed systems.** Outdoor areas where hazardous material liquids are used in *closed systems* exceeding 55 gallons (208 L) shall be provided with spill control in accordance with Section 5004.2.1.

- ❖ Outdoor closed systems with a liquid capacity of over 55 gallons (208 L) must have spill control.

**5005.3.7 Secondary containment for hazardous material liquids in closed systems.** Where required by Table 5005.2.1.4, outdoor areas where hazardous material liquids are dispensed or used in *closed systems* shall be provided

with secondary containment in accordance with Section 5004.2.2 where the capacity of an individual vessel or system or the capacity of multiple vessels or systems exceeds the following:

1. Individual vessel or system: greater than 55 gallons (208 L).
  2. Multiple vessels or systems: greater than 1,000 gallons (3785 L).
- ❖ Dispensing and use areas of closed systems located outdoors also require secondary spill controls when the individual containers being filled exceed 55 gallons (208 L) or the combined vessels or systems exceed 1,000 gallons (3785 L).

**5005.3.8 Clearance from combustibles.** The area surrounding an outdoor dispensing or use area shall be kept clear of combustible materials and vegetation for a minimum distance of 30 feet (9144 mm).

- ❖ Vegetation and other combustible materials must be cut back for a distance of at least 30 feet (9144 mm) from outdoor storage to minimize the exposure to the dispensing or use area in the event of a fire in the combustible materials. Note that this section requires an additional 5 feet (1524 mm) of clearance beyond that required by Section 5004.11 due to the fact that in use, dispensing and handling scenarios, vapors may be present, whereas in storage, containers are closed and vapors are contained.

**5005.3.9 Weather protection.** Where overhead noncombustible construction is provided for sheltering outdoor hazardous material use areas, such use shall not be considered indoor use where the area is constructed in accordance with the requirements for weather protection as required in the *International Building Code*.

**Exception:** Use of *explosive* materials shall be considered as indoor use.

- ❖ This section allows for the construction of noncombustible covers over outdoor dispensing and use areas for weather protection. This area is not considered inside dispensing or use, except when explosive materials are dispensed or used under the noncombustible roof. IBC Section 414.6.1 contains the specific requirements for weather-protection construction.

**5005.4 Handling.** Handling of hazardous materials shall be in accordance with Sections 5005.4.1 through 5005.4.4.

- ❖ The handling of hazardous materials must meet the requirements of the following sections.

**5005.4.1 Quantities exceeding the maximum allowable quantity per control area.** Handling of hazardous materials in indoor and outdoor locations in amounts exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(1) through 5003.1.1(4) shall be in accordance with Sections 5001, 5003, 5005.1 and 5005.4.

- ❖ When the indoor and outdoor storage amounts of chemicals are below the MAQs per control area, the

area must meet the requirements of Sections 5001, 5003, 5005.1 and 5005.4.

**5005.4.2 Quantities not exceeding the maximum allowable quantity per control area.** Handling of hazardous materials in indoor locations in amounts not exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(1) and 5003.1.1(2) shall be in accordance with Sections 5001, 5003 and 5005.1. Handling of hazardous materials in outdoor locations in amounts not exceeding the *maximum allowable quantity per control area* indicated in Tables 5003.1.1(3) and 5003.1.1(4) shall be in accordance with Sections 5001 and 5003.

- ❖ When the indoor storage amounts of chemicals exceed the MAQ, the area must meet the requirements of Sections 5001, 5003 and 5005.1. When outdoor storage exceeds the MAQs listed in Tables 5003.1.1(3) and 5003.1.1(4), the area must meet the requirements of Sections 5001 and 5003.

**5005.4.3 Location.** Outdoor handling areas for hazardous materials shall be located as required for outdoor storage in accordance with Section 5004.

- ❖ Outdoor handling areas must meet the requirements of Section 5004.

**5005.4.4 Dispensing, use and handling.** Where hazardous materials having a hazard ranking of 3 or 4 in accordance with NFPA 704 are transported through *corridors*, interior *exit stairways* or *ramps* or *exit passageways*, there shall be an emergency telephone system, a local manual alarm station or an approved alarm-initiating device at not more than 150-foot (45 720 mm) intervals and at each *exit* and *exit access* doorway throughout the transport route. The signal shall be relayed to an approved central, proprietary or remote station service or constantly attended on-site location and shall also initiate a local audible alarm.

- ❖ When exit access corridors or exit enclosures are used to transport hazardous materials with a ranking of 3 or 4, a supervised emergency telephone system, local manual alarm or approved alarm-initiating device must be installed at intervals of no more than 150 feet (45 720 mm). In addition, these devices must be located at each exit and exit access doorway throughout the transport route.

## Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 51: Aerosols

## General Comments

The adequacy of aerosol storage protection became a major concern in the late 1970s and early 1980s because of a few major warehouse fires in which the involvement of aerosol products was a primary factor. These fire-loss incidents showed that, although these buildings were fully sprinklered, the level of sprinkler protection was inadequate and strict storage limitations for aerosol products were necessary.

The fire losses prompted extensive large-scale fire tests to develop protection requirements for aerosol product storage. The results of these tests led to the development, in 1990, of NFPA 30B, which is the basis for the provisions of this chapter. NFPA 30B recognizes that aerosol products represent a wide range of flammability and that classification criteria are necessary for all aerosol products to determine the desired level of protection. Prior to the development of NFPA 30B, flammable aerosols were classified as Class IA flammable liquids in accordance with NFPA 30; however, this classification was based primarily on a flame extension test designed to assess the in-use aerosol flammability hazard, but had little relevance to warehouse storage conditions.

Increased sprinkler water density and sprinkler head sensitivity, along with adequate separation and quantity control, are the most important factors in controlling aerosol product fires. Increased water density requirements improve the capability of the system to suppress the fire, as opposed to just controlling its spread, by applying more water to the base of the fire. Increased sprinkler activation speed also provides additional benefits. Early suppression fast-response (ESFR) sprinklers are specifically listed for high-challenge fire hazards. Increased sensitivity of ESFR sprinklers allows them to activate in response to a cardboard-carton packaging fire before aerosol cans rupture.

## Purpose

These requirements address the prevention, control and extinguishment of fires and explosions in facilities where retail aerosol products are displayed or stored. They impact both life safety and property protection from a fire; however, historically, aerosol product fires have caused property loss more frequently than loss of life.

---

## SECTION 5101 GENERAL

**5101.1 Scope.** The provisions of this chapter, the *International Building Code* and NFPA 30B shall apply to the manufacturing, storage and display of aerosol products. Manufacturing of aerosol products using hazardous materials shall also comply with Chapter 50.

- ❖ In addition to the provisions of this chapter, NFPA 30B is referenced for storing and displaying aerosol products because it was the original source document for this chapter. The requirements in Chapter 50 must also be complied with where applicable.

Although this chapter deals primarily with the storage and retail display of aerosol products, Chapter 50, the *International Building Code*® (IBC®) and NFPA 30B must be consulted for guidance on facilities involved in the manufacture of aerosol-containing products. For example, aerosol-charging operations that use flammable aerosols require special design considerations and operating procedures. An aerosol-charging room is where the aerosol containers are filled with the propellant. These rooms are either

located in a separate building or are separated within a building and in spaces that have explosion venting because of the deflagration potential of the products being handled. See the commentary to Section 5107.1 for further information.

**5101.2 Permit required.** Permits shall be required as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before a permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.1 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous properties.

## AEROSOLS

**5101.3 Material Safety Data Sheets.** Material Safety Data Sheet (MSDS) information for aerosol products displayed shall be kept on the premises at an *approved* location.

- ❖ This section gives the fire code official the authority to designate or approve the location where the Material Safety Data Sheets (MSDS) covering aerosol materials are kept for use by authorized personnel and first responders in case of an emergency.

**5101.4 Containers.** Metal aerosol containers shall be limited to a maximum size of 33.8 fluid ounces (1000 ml). Plastic aerosol containers shall be limited to a maximum 4 fluid ounces (118 ml) except as provided in Section 5104.1.1. Glass aerosol containers shall be limited to a maximum 4 fluid ounces (118 ml).

- ❖ Design criteria for aerosol containers, including the maximum size and minimum strength, are set by the U.S. Department of Transportation (DOTn 49 CFR). These container regulations are necessary for the safe transportation of aerosol products. These container design criteria were formerly contained in the definition of “aerosol container” in Chapter 2 but were moved since they are technical requirements that belong with the subject matter they regulate.

### SECTION 5102 DEFINITIONS

**5102.1 Definitions.** The following terms are defined in Chapter 2:

#### AEROSOL.

Level 1 aerosol products.

Level 2 aerosol products.

Level 3 aerosol products.

#### AEROSOL CONTAINER.

#### AEROSOL WAREHOUSE.

#### PROPELLANT.

#### RETAIL DISPLAY AREA.

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 5103 CLASSIFICATION OF AEROSOL PRODUCTS

**5103.1 Classification levels.** Aerosol products shall be classified as Level 1, 2 or 3 in accordance with Table 5103.1 and NFPA

30B. Aerosol products in cartons that are not identified in accordance with this section shall be classified as Level 3.

- ❖ Because of the wide range of flammability of aerosol products, a classification system was established to determine the required level of fire protection. Categories are defined according to the aerosol’s chemical heat of combustion expressed in British thermal units per pound (Btu/lb) [kilojoules/gram (kJ/g)] (see the commentary to Table 5103.1 for additional discussion of factors affecting classification).

Three categories determine the level of fire protection required (see Chapter 4 of NFPA 30B for fire protection requirements). Aerosol product classification Levels 1, 2 and 3 are used to avoid confusion with flammable and combustible liquid classifications (Classes I, II and III). Table 5103.1 shows the three aerosol classifications. Appendices A and C of NFPA 30B also contain additional background information on the development of the classification system.

This section also recognizes the importance of identifying the level of aerosols in storage cartons. Unless cartons are marked to identify their contents, it is difficult to determine the allowable quantity and fire protection requirements. Where cartons are not marked, there is no alternative but to consider the aerosol storage as Level 3 and apply the code requirements for that level (see commentary, Section 5106.1).

TABLE 5103.1  
CLASSIFICATION OF AEROSOL PRODUCTS

CHEMICAL HEAT OF COMBUSTION		AEROSOL CLASSIFICATION
Greater than (Btu/lb)	Less than or equal to (Btu/lb)	
0	8,600	1
8,600	13,000	2
13,000	—	3

For SI: 1 British thermal unit per pound = 0.002326 kJ/g.

- ❖ Table 5103.1 shows how to classify aerosol products based on their “chemical heat of combustion,” a term defined in Section 3.3.16.1 of NFPA 30B. NFPA 30B contains tables giving the heat of combustion (expressed in kJ/g) for representative materials and gives examples for calculating the chemical heat of combustion for aerosol products. Heat of combustion is determined using the method in ASTM D240. Factory Mutual Research Corporation (FMRC) correlated the chemical heat of combustion with the results of full-scale pallet tests to provide a classification method based on chemical heat of combustion that is more consistent than the original classification based on weight percentages. Examples are given in NFPA 30B for calculating the heat of combustion for aerosol products that contain a number of components so that they can be classified using Table 5103.1.

Examples of Level 1 aerosol products include air

fresheners, shaving gels and whipped cream. Fire tests involving Level 1 aerosols have demonstrated that they pose a fire hazard no greater than that of Class III commodities as defined in NFPA 13. Consequently, Level 1 aerosols are not regulated as a hazardous material and are essentially exempt from the requirements of this chapter.

Examples of Level 2 aerosol products include some hair sprays and insect repellents, based on the values in Table 5103.1.

Level 3 aerosol products, such as carburetor cleaner and other petroleum-based aerosols, require the highest level of fire protection.

**5103.2 Identification.** Cartons shall be identified on not less than one side with the classification level of the aerosol products contained within the carton as follows:

LEVEL \_\_\_\_\_ AEROSOLS

❖ Aerosol products are generally stored and transported in cardboard cartons that must be clearly marked with the level of aerosol products they contain so that the proper storage arrangements and fire protection are provided. The product label on the aerosol container may define whether the product is flammable or extremely flammable, but does not need to explain the actual classification level. If cartons are discarded or not marked, classification may be obtained from the submitted MSDS (see Section 5101.3). Fire protection requirements for the highest level of aerosols must be used where storage is mixed or unknown (see Section 5103.1).

## SECTION 5104

### INSIDE STORAGE OF AEROSOL PRODUCTS

**5104.1 General.** The inside storage of Level 2 and 3 aerosol products shall comply with Sections 5104.2 through 5104.7 and NFPA 30B. Level 1 aerosol products and those aerosol products covered by Section 5104.1.1 shall be considered equivalent to a Class III commodity and shall comply with the requirements for palletized or rack storage in NFPA 13.

❖ Sections 5104.1.1 through 5104.7, the applicable requirements in NFPA 30B and the applicable provisions of Chapter 32 regulate the inside storage of aerosol products. Permissible quantities, separation and fire protection depend on the occupancy type (see Sections 5104.2 and 5104.7) and storage condition, such as a general purpose warehouse (see Section 5104.3), aerosol warehouse (see Section 5104.4), inside flammable-liquid storage room (see Section 5104.5) or liquid warehouse (see Section 5104.6).

This section also specifies the level of protection required for Level 1 aerosols. The fire hazard associated with Level 1 aerosols has been demonstrated to be equivalent to Class III commodities as defined in Section 202 and NFPA 13. Therefore, Sections 5104.2 through 5104.7, and the applicable provisions of Chapter 32, apply only to Level 2 and 3 aerosol products. Level 2 aerosol products are classified as a

Group IV commodity in Section 3203.5; while aerosols, including Level 3 aerosols, are not regulated as hazardous materials, for the purpose of occupancy classification, Level 3 aerosols would still be considered a high-hazard commodity in accordance with Section 3203.6.

**5104.1.1 Plastic containers.** Aerosol products in plastic containers larger than 4 fluid ounces (118 ml), but not to exceed 33.8 fluid ounces (1000 ml), shall be allowed only where in accordance with this section. The commodity classification shall be Class III commodities, as defined in NFPA 13 where any of the following conditions are met:

1. Base product has no fire point where tested in accordance with ASTM D92, and nonflammable propellant.
  2. Base product has no sustained combustion as tested in accordance with Appendix H, "Method of Testing for Sustained Combustibility," in DOTn 49 CFR Part 173, and nonflammable propellant.
  3. Base product contains up to 20 percent by volume (15.8 percent by weight) of ethanol and/or isopropyl alcohol in an aqueous mix, and nonflammable propellant.
  4. Base product contains 4 percent by weight or less of an emulsified flammable liquefied gas propellant within an aqueous base. The propellant shall remain emulsified for the life of the product. Where such propellant is not permanently emulsified, the propellant shall be nonflammable.
- ❖ This section provides criteria for accepting certain aerosol product compositions in previously prohibited plastic containers. It also provides correlation with the referenced standard, NFPA 30B.

A significant amount of new research has been completed on aerosol products in plastic containers, clearly defining a "low hazard" version of the product that can be stored in general purpose warehouses without significantly increasing the fire hazard. The following discussions, excerpted from NFPA 308, provide an overview of the work done and the conclusions drawn that resulted in the criteria in this section:

**1. Aerosol Products in Plastic Containers – Propellant: Nonflammable; Base: Liquid Content that Does not Support Combustion:** The fire hazard created by aerosol products in metal containers is driven by their propellant and the liquid content. An aerosol product that contains a nonflammable propellant and a liquid content that does not support combustion would have a chemical heat of combustion of 0 kJ/g and be classified as a Level 1 aerosol product. Level 1 aerosols are protected using the same protection criteria needed for Class III commodities provided by NFPA 13.

The fire hazard of an aerosol product in plastic containers cannot be directly compared to aerosol products in metal containers. However, using commodity classification information for plastic containers filled with liquids that do not burn supports proposing a protection level for equivalent

aerosol products. In this case, the content of the aerosol would not contribute to a fire. Only the primary (plastic container) and secondary (carton) packaging would contribute. If the aerosol was not pressurized, it would directly compare to products listed in NFPA 13 Annex A, Table A.5.6.3 and FM Global Property Loss Prevention Data Sheet 8-1, Section 2.2.2.2. Both standards treat a plastic container filled with a liquid that does not burn as a Class I commodity. The addition of a nonflammable propellant to a plastic container will not change the burning properties of the commodity (it may result in a violent rupture with no change in burning rates or severity). The above discussion would point to classifying the aerosol products in plastic containers charged with a nonflammable propellant and liquid that does not burn as a Class I commodity. However, in an effort to provide consistency in the protection of aerosols, the protection proposal targets using the same protection currently recommended for Level 1 aerosols.

**2. Aerosol Products in Plastic Containers – Propellant: Nonflammable; Base: Liquid Content Consists of up to 20 percent Ethanol or Isopropyl Alcohol in Aqueous Solution:** An aerosol product in a plastic container that contains a liquid that burns will create a fire hazard at least as severe as the same liquid in an unpressurized plastic container. The fire hazard may increase because the container is pressurized and will definitely increase if it is pressurized with a flammable propellant. As the fire hazard of the aerosol's content increases, the fire hazard of the actual aerosol will increase as well. If, on the other hand, the aerosol product in a plastic container was charged with liquid components that can easily be protected in an unpressurized plastic container, similar to the discussion under Item 1, there is a good chance that the aerosol products in plastic containers can be similarly protected.

FM Global has developed protection criteria for several alcohol water mixtures in plastic bottles. The alcohols used in the testing were ethanol and isopropyl alcohol. The mixtures ranged from 100-percent alcohol (approximate) down to 20-percent alcohol/80-percent water by volume. Cartons of the 20-percent alcohol/80-percent water mixture in a plastic bottle were tested in a full-scale array. This alcohol/water mixture does have a definable fire point; however, it produces unstable burning.

Based on the results of this test, FM Global has recommended protecting 20-percent alcohol/80-percent water mixtures by volume in plastic bottles with the same protection recommended for liquids that do not burn in plastic containers, i.e., Class I commodities. A final question is whether pressurizing a plastic container filled with a 20-percent alcohol/80-percent water mixture by volume with nonflammable propellant will change the burning properties of the product.

Since the propellant will not burn, the only real opportunity to change the burning behavior would be to cause the alcohol/water mixture to burn more severely (e.g., possibly produce fireballs when the mixture is ejected from the container under pressure). To evaluate this potential, a small-scale test series was contracted with Underwriters Laboratories (UL) to investigate the impact of pressurizing aerosol products in plastic containers, filled with a 20-percent alcohol/80-percent water mixture by volume with nonflammable propellants. In the five tests that were run, two filling methods were investigated: direct fill (liquid and propellant in same space) and bag-on-valve (liquid in one compartment, propellant in outer compartment). UL reported the number of container failures. The overall fire behavior was provided through direct observation. The tests looked at two cases of six containers arranged with a 6-inch (15 cm) flue between them and a point igniter in the flue space. The cases were in a small pan.

None of the tests produced a pool fire or fireball. In all five tests, portions of the aerosol products in plastic containers and cardboard cases remained unburned. Based on these tests, it appears that the fire properties of the alcohol/water mixture remained unchanged when pressurized and that using Class III commodity protection will provide fully adequate protection for the aerosol products in plastic containers.

**3. Aerosol Products in Plastic Containers – Propellant: 4 percent by Weight Nonflammable Propellant or Flammable Propellant that is Emulsified in Liquid Base; Base: Aqueous Base with no Fire Point:** An emulsion, in an aerosol product, would be a mixture of two or more liquids in which one is present as droplets, of microscopic or ultramicroscopic size, distributed throughout the other. Emulsions are formed from the component liquids either spontaneously or, more often, by mechanical means, such as agitation, provided that the liquids that are mixed have no (or a very limited) mutual solubility. Emulsions are stabilized by agents that form films at the surface of the droplets (e.g., soap molecules) or that impart to them a mechanical stability (e.g., colloidal carbon or bentonite). Colloidal distributions or suspension of one or more liquid(s) with another will have a shelf life that varies with the efficiency of the recipe used.

A Level 1 aerosol (metal can) was defined by the fire performance of shave cream. This product had limited amounts of flammable liquefied gas propellant to eject the mixture and to cause foaming of the mixture. In a fire, the hydrocarbon propellant would be ejected and burn, but the large quantities of foam mix and water tended to produce a very limited fire severity. A similar product was evaluated when placed in a plastic aerosol container.

The product consisted of several liquid components that do not support combustion mixed with water and a maximum of 4 percent by weight flammable liquefied gas propellant. The liquefied gas was held within the liquid mixture as an emulsion. The gas would eject the liquid product and cause the liquid mixture to foam. Since the liquid components do not burn, the main concern centers around the flammable liquefied gas propellant. The evaluation used small, intermediate, and full-scale fire testing to evaluate the fire hazard created by this product. All of the testing was completed at UL.

The large-scale test used the 12-pallet aerosol classification test protocol. This methodology only applies to metal aerosol products but, lacking any test data, it was considered a good starting point. The 12 pallet load palletized array operated four sprinklers in 10 seconds at around a minute and a half after ignition. The fire was quickly knocked down. The test was run for 32 minutes. The liquid product was released during the test and did not contribute to the fire. The flammable liquefied gas did create brief flare-ups of the fire when released and continued to create small fireballs throughout the test. The high sprinkler discharge density [0.79 gpm/ft<sup>2</sup> (32 mm/min)] easily extinguished the majority of the array and limited the fire spread to the ignition flue located in the center of the array. The fire test seemed to demonstrate that the limited amount of flammable liquefied gas in the product would not produce a severe fire; however, the high water density does not permit easy comparison to a Class III commodity fire.

An intermediate-scale test was run under the calorimeter at UL to evaluate the effect of a significantly lower water density [0.25 gpm/ft<sup>2</sup> (10 mm/min)] on this product. The product was placed in a double-row rack with a storage height of 15 feet (4.6 m). Four open sprinklers were located 10 feet (3 m) above the top of the array and arranged to deliver a water density of 0.25 gallon per minute per square foot (10 mm/min). The sprinklers were activated at approximately 1 minute after ignition. The test was terminated at 4 minutes since the fire was extinguished. The percent damage was not provided in the UL report; however the pictures indicate that the fire was again confined to the ignition flue.

NFPA 13 requires a water density of 0.25 gallon per minute per square foot (10 mm/min) to protect a 15-foot-high (4.6 m) double-row rack storage of Class III commodity in a 25-foot (7.6 m) high building using low temperature ceiling sprinklers [NFPA 13, Table 16.2.1.3.2, Figure 16.2.1.3.2(c) curves E & F, Figure 16.2.1.3.4.1]. The intermediate-scale test indicates that this same protection level easily controlled/extinguished a fire involving the foam shave cream in a plastic aerosol container.

In addition to the intermediate and large-scale

fire test, a number of small-scale tests were also done to provide a visual documentation on how a plastic aerosol container with a shave foam-type product behaves when exposed to fire without sprinkler protection. These tests consisted of placing two cases of six containers on each side of a standard igniter. The containers were packed in a cardboard box. A shave cream and a hair mousse were tested.

Test 9 used a product that was very similar to what was tested in the intermediate and large-scale testing. It was a shave cream product that had a small percentage of a flammable liquefied gas that was in a stable emulsion with a multi-component liquid mixture. The liquid mixture did not support combustion. The product in Test 10 had a higher weight percent flammable liquefied gas that did not form a stable emulsion in the bottle. A liquefied gas layer formed in the container. It was not clear what the liquid mixture was made up of. In both products, the flammable liquefied gas was used to eject the liquid mixture out of the container and cause the liquid product to create foam.

In Test 9, all but two of the containers failed. The shave foam covered the cases, containers and pan after the test. The product burned weakly and extinguished the igniter used in the test. The product used in Test 10 did appear to burn more vigorously. Container failure produced momentary fireballs. While this limited-scale test cannot predict the behavior of a product in a full-scale arrangement, it did demonstrate that there were differences between the shave cream and the hair mousse, and that the hair mousse produced a more vigorous fire.

The results of the intermediate-scale testing, the full-scale testing and the small-scale testing indicate that an aerosol product in a plastic container filled with a liquid mixture that does not support combustion and no more than 4 percent by weight flammable liquefied gas in a stable emulsion with the liquid mixture can be protected using criteria recommended for a Class III commodity.

**5104.2 Storage in Groups A, B, E, F, I and R.** Storage of Level 2 and 3 aerosol products in occupancies in Groups A, B, E, F, I and R shall be limited to the following maximum quantities:

1. A net weight of 1,000 pounds (454 kg) of Level 2 aerosol products.
2. A net weight of 500 pounds (227 kg) of Level 3 aerosol products.
3. A combined net weight of 1,000 pounds (454 kg) of Level 2 and 3 aerosol products.

The maximum quantity shall be increased 100 percent where the excess quantity is stored in storage cabinets in accordance with Section 5704.3.2.

❖ This section strictly limits quantities of aerosols in buildings of Groups A, B, E, F, I and R because these

occupancy types will have higher occupant loads and host many activities not related to the storage of aerosol products. Storage exceeding the maximum permitted quantities would result in the building being classified as a high-hazard, Group H occupancy in accordance with the IBC. The indicated maximum quantities are applicable per building area and not per control area (see commentary, Section 5003).

This section would also allow the maximum quantities to be increased by 100 percent, if the quantities exceeding those indicated for Level 2 and 3 aerosol products are stored in approved storage cabinets in accordance with Section 5704.3.2, which contains specific requirements for the design, construction and capacity of storage cabinets.

**5104.2.1 Excess storage.** Storage of quantities exceeding the maximum quantities indicated in Section 5104.2 shall be stored in separate inside flammable liquid storage rooms in accordance with Section 5104.5.

❖ This section recognizes that in certain occupancies, the maximum quantities listed in Section 5104.2 may be exceeded. Any Level 2 or 3 aerosol product exceeding the maximum quantities specified in Section 5104.2, including the exception for approved storage cabinets, must be stored in a separate, inside, flammable liquid storage room to maintain a Group A, B, E, F, I or R occupancy classification for the building.

For example, 1,000 pounds (454 kg) of Level 2 aerosols are allowed in a building classified in occupancy Group B. An additional 1,000 pounds (454 kg) of Level 2 aerosols are also allowed, if the product is stored in approved storage cabinets (see Section 5104.2). If additional storage is desired, 1,000 pounds (454 kg) of Level 2 aerosols would be allowed in an inside, flammable liquid storage room having a floor area of 500 square feet (46 m<sup>2</sup>) or less, in accordance with Section 5104.5.1. Therefore, as much as 3,000 pounds (1362 kg) of Level 2 aerosols could be stored in a building of Group B occupancy, if all excess storage is in approved storage cabinets and in an inside, flammable liquid storage room having a floor area of no more than 500 square feet (46 m<sup>2</sup>). If an inside, flammable liquid storage room exceeding 500 square feet (46 m<sup>2</sup>) were used for the excess storage, the allowable quantity of Level 2 aerosols in the room could be increased to 2,500 pounds (1135 kg). The increased allowed quantities in the larger storage room results from the presence of an automatic sprinkler system. Compliance with these requirements would maintain the Group B occupancy classification for the building (see commentary, Section 5104.5).

**5104.3 Storage in general purpose warehouses.** Aerosol storage in general purpose warehouses utilized only for warehousing-type operations involving mixed commodities shall comply with Section 5104.3.1 or 5104.3.2.

❖ General purpose warehouses are used for storing general commodities and aerosol products (i.e.,

“mixed commodities”). Aerosol product storage located in general purpose warehouses is classified as either nonsegregated storage (see Section 5104.3.1) or segregated storage (see Section 5104.3.2).

Distribution warehouses for major department store chains containing large amounts of aerosols and various common mercantile commodities are typical of buildings classified as general purpose warehouses. Proper protection and separation of aerosol product storage areas are essential to protect ordinary storage commodities from the hazards of aerosol products in these types of buildings.

**5104.3.1 Nonsegregated storage.** Storage consisting of solid pile, palletized or rack storage of Level 2 and 3 aerosol products not segregated into areas utilized exclusively for the storage of aerosols shall comply with Table 5104.3.1.

❖ Nonsegregated storage is located in a general purpose warehouse in which Level 2 and 3 aerosol products are not physically or spatially separated from other commodities. The maximum quantity of Level 2 and 3 aerosol products that can be located in nonsegregated storage areas is specified in Table 5104.3.1.

**TABLE 5104.3.1  
NONSEGREGATED STORAGE OF LEVEL 2 AND 3 AEROSOL  
PRODUCTS IN GENERAL PURPOSE WAREHOUSES<sup>b</sup>**

AEROSOL LEVEL	MAXIMUM NET WEIGHT PER FLOOR (pounds) <sup>b</sup>			
	Palletized or solid-pile storage		Rack storage	
	Unprotected	Protected <sup>a</sup>	Unprotected	Protected <sup>a</sup>
2	2,500	12,000	2,500	24,000
3	1,000	12,000	1,000	24,000
Combination 2 and 3	2,500	12,000	2,500	24,000

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg, 1 square foot = 0.0929 m<sup>2</sup>.

a. Approved automatic sprinkler system protection and storage arrangements shall comply with NFPA 30B. Sprinkler system protection shall extend 20 feet beyond the storage area containing the aerosol products.

b. Storage quantities indicated are the maximum permitted in any 50,000-square-foot area.

❖ Table 5104.3.1 lists the maximum quantities of Level 2 and 3 aerosols permitted in general purpose warehouses with nonsegregated storage. Maximum quantities of aerosol products depend on the type of storage condition and the level of sprinkler protection.

Unprotected storage refers to areas that have no sprinkler protection or in which the sprinkler system does not meet specific NFPA 30B design requirements; therefore, protected storage refers only to areas in which sprinkler protection meets NFPA 30B design parameters for solid pile, palletized and rack structure storage conditions.

The “Maximum Net Weight” referred to in the table consists of the base aerosol product plus the propellant, as defined in NFPA 30B.

**5104.3.2 Segregated storage.** Storage of Level 2 and 3 aerosol products segregated into areas utilized exclusively for the

storage of aerosols shall comply with Table 5104.3.2 and Sections 5104.3.2.1 and 5104.3.2.2.

- ❖ Special requirements for storing aerosol products to prevent mixing with other commodities recognize that, without proper sprinkler protection and separation, fires involving Level 2 and 3 aerosols are difficult to control. Storage areas can be segregated by fire-resistance-rated interior walls, a chain-link fence enclosure or the establishment of a separation area. All aerosol product storage areas in segregated storage must have sprinkler protection in accordance with NFPA 30B. The maximum quantity of Level 2 and 3 aerosol products that can be placed in segregated storage is specified in Table 5104.3.2.

**TABLE 5104.3.2  
SEGREGATED STORAGE OF LEVEL 2 AND 3 AEROSOL  
PRODUCTS IN GENERAL PURPOSE WAREHOUSES**

STORAGE SEPARATION	MAXIMUM SEGREGATED STORAGE AREA <sup>a</sup>		SPRINKLER REQUIREMENTS
	Percentage of building area (percent)	Area limitation (square feet)	
Separation area <sup>e, f</sup>	15	20,000	Notes b, c
Chain-link fence enclosure <sup>d</sup>	20	20,000	Notes b, c
1-hour fire-resistance-rated interior walls	20	30,000	Note b
2-hour fire-resistance-rated interior walls	25	40,000	Note b
3-hour fire-resistance-rated interior walls	30	50,000	Note b

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>.

- a. The maximum segregated storage area shall be limited to the smaller of the two areas resulting from the percentage of building area limitation and the area limitation.
- b. Automatic sprinkler system protection in aerosol product storage areas shall comply with NFPA 30B and be approved. Building areas not containing aerosol product storage shall be equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.
- c. Automatic sprinkler system protection in aerosol product storage areas shall comply with NFPA 30B and be approved. Sprinkler system protection shall extend a minimum 20 feet beyond the aerosol storage area.
- d. Chain-link fence enclosures shall comply with Section 5104.3.2.1.
- e. A separation area shall be defined as an area extending outward from the periphery of the segregated aerosol product storage area as follows.
  1. The limits of the aerosol product storage shall be clearly marked on the floor.
  2. The separation distance shall be not less than 25 feet and maintained clear of all materials with a commodity classification greater than Class III in accordance with Section 903.3.1.1.
- f. Separation areas shall only be permitted where approved.

- ❖ Table 5104.3.2 lists maximum quantities of Level 2 and 3 aerosols allowed in general purpose warehouses with segregated storage. Storage areas can be segregated using either fire-resistance-rated interior walls, a chain-link fence enclosure (see Section 5104.3.2.1) or a separation area.

As indicated in Note e, a minimum separation dis-

tance of 25 feet (7620 mm) from commodity classifications greater than Class III must be maintained when using the separation area option (for additional guidance on commodity classifications, see NFPA 13).

Depending on the separation type provided, the segregated storage area is limited by both a percentage of the building area and a maximum area limitation, as indicated in Note a. The allowable area of segregated storage increases with the increased degree of separation. Segregated storage areas of Level 2 and 3 aerosols must have sprinkler protection in accordance with NFPA 30B.

**5104.3.2.1 Chain-link fence enclosures.** Chain-link fence enclosures required by Table 5104.3.2 shall comply with the following:

1. The fence shall not be less than No. 9 gage steel wire, woven into a maximum 2-inch (51 mm) diamond mesh.
2. The fence shall be installed from the floor to the underside of the roof or ceiling above.
3. Class IV and high-hazard commodities shall be stored outside of the aerosol storage area and not less than 8 feet (2438 mm) from the fence.
4. Access openings in the fence shall be provided with either self- or automatic-closing devices or a labyrinth opening arrangement preventing aerosol containers from rocketing through the access openings.
5. Not less than two *means of egress* shall be provided from the fenced enclosure.

- ❖ Table 5104.3.2 establishes limits on the use of a chain-link fence as a means of segregated storage of Level 2 and 3 aerosol products. A chain-link fence enclosure is intended to reduce the potential hazard of "rocketing" aerosol cans in a fire. Both fire tests and loss history have shown that ruptured aerosol cans in fires will "rocket" through the warehouse storage area, resulting in multiple ignition locations and overtaxing of the fire protection systems. Chain-link fence construction details as indicated in this section, in combination with proper sprinkler protection as specified in Notes b and c of Table 5104.3.2, provide a measure of additional safety, allowing increased storage quantities over that permitted where no physical barrier exists.

The No. 9 gage steel requirement for the chain-link fence is similar to a standard, industrial-grade chain-link gage that is commonly used for fencing property. This chain-link gage is considered the lightest acceptable fencing and is capable of restraining flying aerosol containers. A labyrinth opening arrangement in the fencing essentially works as an entryway maze. In place of a door, the access area to the chain-link fence enclosure would be constructed of other fencing, which is usually located at right angles, and through its arrangement, would obstruct the opening to prevent the aerosol containers from rocketing through the access opening.

**5104.3.2.2 Aisles.** The minimum aisle requirements for segregated storage in general purpose warehouses shall comply with Table 5104.3.2.2.

- ❖ Fires involving aerosol products can spread across aisles located between two rows of racks or palletized and solid pile storage. If the fire is severe enough, the radiant energy may ignite combustible cartons across an aisle, or a fireball from a rupturing container may be large enough to engulf adjacent storage. Table 5104.3.2.2 gives aisle requirements for segregated storage of Level 2 and 3 aerosol products located in general purpose warehouses.

**TABLE 5104.3.2.2  
SEGREGATED STORAGE AISLE WIDTHS AND DISTANCE TO  
AISLES IN GENERAL PURPOSE WAREHOUSES**

STORAGE CONDITION	MINIMUM AISLE WIDTH (feet)	MAXIMUM DISTANCE FROM STORAGE TO AISLE (feet)
Solid pile or palletized <sup>a</sup>	4 feet between piles	25
Racks with ESFR sprinklers <sup>a</sup>	4 feet between racks and adjacent Level 2 and 3 aerosol product storage	25
Racks without ESFR sprinklers <sup>a</sup>	8 feet between racks and adjacent Level 2 and 3 aerosol product storage	25

For SI: 1 foot = 304.8 mm.

a. Sprinklers shall comply with NFPA 30B.

- ❖ Table 5104.3.2.2 shows a minimum aisle width and a 25-foot-maximum (7620 mm) separation distance from aerosol storage to aisles where aerosols cannot be stored for segregated storage of Level 2 and 3 aerosol products located in general purpose warehouses. The minimum aisle width depends on the storage condition and the level of sprinkler protection. The 25-foot (7620 mm) distance between the storage and aisle not only isolates aerosols but also limits travel distances within the storage area.

Note a is intended to require the design of the automatic sprinkler system to meet the requirements of NFPA 30B. If the automatic sprinkler system is not designed in accordance with the conditions for ESFR sprinklers in NFPA 30B, then aisles must be 8 feet (2438 mm) wide when storing Level 2 or 3 aerosol products in rack structures. The storage area must be configured so that storage is no more than 25 feet (7620 mm) from the aisle, thus providing a storage footprint of 50 feet (15 240 mm) on a side.

**5104.4 Storage in aerosol warehouses.** The total quantity of Level 2 and 3 aerosol products in a warehouse utilized for the storage, shipping and receiving of aerosol products shall not be restricted in structures complying with Sections 5104.4.1 through 5104.4.4.

- ❖ Buildings classified as aerosol warehouses are detached buildings or a separate portion of a building used exclusively for storing and handling aerosol products. This section does not limit the quantity of Level 2 and 3 aerosol products in a building classified

as an aerosol warehouse complying with the provisions of Sections 5104.4.1 through 5104.4.4.

**5104.4.1 Automatic sprinkler system.** Aerosol warehouses shall be protected by an *approved wet-pipe automatic sprinkler system* in accordance with NFPA 30B. Sprinkler protection shall be designed based on the highest classification level of aerosol product present.

- ❖ The automatic sprinkler system for aerosol warehouses must be designed in accordance with NFPA 30B. The sprinkler protection must be designed for Level 3 aerosol products if both Level 2 and 3 aerosols are stored in the aerosol warehouse. With the approval of the fire code official, sprinkler protection can be omitted from an aerosol warehouse where a minimum separation distance of 100 feet (30 480 mm) from a lot line or structure is maintained and exposure protection is provided. Exposure protection would include either a public fire department or plant fire brigade that could apply cooling water streams on adjacent properties or structures. Exposure protection is not required where the distance is 200 feet (60 960 mm) or more to other buildings or lot lines.

**5104.4.2 Pile and palletized storage aisles.** Solid pile and palletized storage shall be arranged so the maximum travel distance to an aisle is 25 feet (7620 mm). Aisles shall have a minimum width of 4 feet (1219 mm).

- ❖ The maximum travel distance of 25 feet (7620 mm) to an aisle provides an adequate means of egress if an emergency occurs. This results in an allowable storage area of 50 feet by 50 feet (15 240 mm by 15 240 mm) surrounded by 4-foot (1219 mm) aisles for palletized and pile storage. The 4-foot (1219 mm) aisle width, in conjunction with a sprinkler system and in accordance with NFPA 30B, reduces the chance of fire spread across aisles involving pile and palletized storage.

**5104.4.3 Rack storage aisles.** Rack storage shall be arranged with a minimum aisle width of 8 feet (2438 mm) between rows of racks and 8 feet (2438 mm) between racks and adjacent solid pile or palletized storage. Where early suppression fast-response (ESFR) sprinklers provide automatic sprinkler protection, the minimum aisle width shall be 4 feet (1219 mm).

- ❖ The requirements in this section are similar to those in Table 5104.3.2.2 for segregated storage in general purpose warehouses. This section requires 8-foot (2438 mm) aisles between rows of racks or between racks and adjacent piles or palletized storage when the area is protected with sprinkler systems designed in accordance with NFPA 30B.

The 8-foot (2438 mm) minimum aisle width allows two unimpeded parallel columns of egressing occupants to travel in opposite directions, in addition to anticipating other obstructions occurring during an emergency situation. These obstructions could be in the form of a lift truck, or idle pallets or even the result of unstable commodities falling into the aisle. In addi-

tion, the 96-inch (2438 mm) width further reduces the hazard of aisle jumps (radiant heat from a burning rack or pile causing the rack or pile across the aisle to ignite) in case of a fire and provides the fire department with greater maneuvering capabilities during a fire, essentially providing an additional safety factor where aerosols are stored.

The second sentence of this section is an exception that recognizes the increased safety of the higher level of sprinkler protection provided by an ESFR system designed in accordance with NFPA 30B by allowing for a 50-percent reduction in aisle width. The maximum travel distance to an aisle is intended to be 25 feet (7620 mm), as indicated in Table 5104.3.2.2.

**5104.4.4 Combustible commodities.** Combustible commodities other than flammable and *combustible liquids* shall be permitted to be stored in an aerosol warehouse.

**Exception:** Flammable and *combustible liquids* in 1-quart (946 mL) metal containers and smaller shall be permitted to be stored in an aerosol warehouse.

❖ Based on the full-scale aerosol product fire tests discussed in earlier sections of the commentary, this section allows ordinary combustible commodities to be stored in aerosol warehouses, provided that the fire protection system for the entire facility is based on the appropriate fire protection design table from NFPA 30B and Section 5104.4.1. This is consistent with and correlates with Section 6.3.6.7 of NFPA 30B. See the commentary to Section 3203 for information on the classification of combustible commodities.

The exception allows small, 1 quart [32 ounce (0.95 L)] metal containers of flammable and combustible liquids to be stored in aerosol warehouses, along with the ordinary combustible commodities discussed in the previous paragraph, provided that the fire protection system for the entire facility is based on the appropriate fire protection design table from NFPA 30B. This is consistent with and correlates with Section 6.3.6.8 of NFPA 30B.

**5104.5 Storage in inside flammable liquid storage rooms.** Inside flammable liquid storage rooms shall comply with Section 5704.3.7. The maximum quantities of aerosol products shall comply with Section 5104.5.1 or 5104.5.2.

❖ This section recognizes another option for storing Level 2 and 3 aerosols. Depending on the anticipated quantities, storage in a Group H-3 inside flammable liquid storage room meeting the requirements of Section 5704.3.7 may be more economical.

Sections 5104.5.1 and 5104.5.2 limit maximum quantities of Level 2 and 3 aerosols that can be stored in an inside flammable liquid storage room depending on the size of the room and the degree of fire-resistance-rated separation and automatic sprinkler protection installed. Indicated maximum quantities of aerosol products are the same quantities listed in Section 5104.2. See the commentary to Section 202 for the definition of "Liquid storage room."

Storage of aerosols exceeding the quantities indi-

cated in Sections 5104.5.1 and 5104.5.2, and the storage of flammable and combustible liquids exceeding maximum allowable quantities (MAQs), must be classified as high-hazard Group H occupancies.

**5104.5.1 Storage rooms of 500 square feet or less.** The storage of aerosol products in flammable liquid storage rooms less than or equal to 500 square feet (46 m<sup>2</sup>) in area shall not exceed the following quantities:

1. A net weight of 1,000 pounds (454 kg) of Level 2 aerosol products.
2. A net weight of 500 pounds (227 kg) of Level 3 aerosol products.
3. A combined net weight of 1,000 pounds (454 kg) of Level 2 and 3 aerosol products.

❖ This section limits the amount of Level 2 and 3 aerosols that can be stored in an inside flammable liquid storage room 500 square feet (46 m<sup>2</sup>) or less in area that complies with NFPA 30. The degree of fire-resistance-rated construction depends on room size. Sprinkler protection may or may not be required depending on the quantity of other flammable and combustible liquids in the inside storage room (see commentary, Section 5104.2.1).

**5104.5.2 Storage rooms greater than 500 square feet.** The storage of aerosol products in flammable liquid storage rooms greater than 500 square feet (46 m<sup>2</sup>) in area shall not exceed the following quantities:

1. A net weight of 2,500 pounds (1135 kg) of Level 2 aerosol products.
2. A net weight of 1,000 pounds (454 kg) of Level 3 aerosol products.
3. A combined net weight of 2,500 pounds (1135 kg) of Level 2 and 3 aerosol products.

The maximum aggregate storage quantity of Level 2 and 3 aerosol products permitted in separate inside storage rooms protected by an *approved automatic sprinkler system* in accordance with NFPA 30B shall be 5,000 pounds (2270 kg).

❖ This section allows an increase in the quantity of Level 2 and 3 aerosols for inside, flammable, liquid storage rooms exceeding 500 square feet (46 m<sup>2</sup>) in area. These provisions assume that the storage room complies with fire-resistance-rated construction and the fire protection requirements of NFPA 30. Increased quantities compared to Section 5104.5.1 for rooms less than 500 square feet (46 m<sup>2</sup>) in area are based on having an automatic sprinkler system throughout the building in accordance with NFPA 13. The additional quantities allowed by the last paragraph of this section require the sprinkler system to comply with NFPA 30B (see commentary, Section 5104.2.1).

**5104.6 Storage in liquid warehouses.** The storage of Level 2 and 3 aerosol products in liquid warehouses shall comply with NFPA 30B. The storage shall be located within segre-

## AEROSOLS

gated storage areas in accordance with Section 5104.3.2 and Sections 5104.6.1 through 5104.6.3.

❖ This section contains requirements for storing Level 2 and 3 aerosol products in warehouses used primarily for storing flammable and combustible liquids. The aerosol product storage area is required to meet the segregated storage requirements of Section 5104.3.2, Sections 5104.6.1 through 5104.6.3 and NFPA 30B. This section is intended to address only protection for the segregated aerosol product storage area. NFPA 30 addresses protection for the flammable and combustible liquids in the liquid warehouse.

**5104.6.1 Containment.** Spill control or drainage shall be provided to prevent the flow of liquid to within 8 feet (2438 mm) of the segregated storage area.

❖ To reduce the potential for the segregated aerosol storage area to become involved in an emergency created by the flammable and combustible liquids stored elsewhere in the building, an approved means of spill control and drainage must be provided. The spill-control and drainage system is intended to keep the liquids away from the aerosols. Section 5004.2 contains additional guidance on the means of spill control and drainage for flammable and combustible liquids.

**5104.6.2 Sprinkler design.** Sprinkler protection shall be designed based on the highest level of aerosol product present.

❖ Design requirements for the sprinkler system are based on the highest level of aerosol products stored and the anticipated storage condition. The sprinkler system must be designed for Level 3 aerosol products where both Level 2 and 3 aerosol products are stored.

**5104.6.3 Opening protection into segregated storage areas.** Fire doors or gates opening into the segregated storage area shall either be self-closing or provided with automatic-closing devices activated by sprinkler water flow or an *approved* fire detection system.

❖ Openings for access to and from segregated storage areas must provide the intended degree of protection. Chain-link fence enclosures can have either self-closing or automatic-closing gates. If the segregated storage opening is protected with automatic-closing fire doors or gates, the closing device must be activated by water flow from the sprinkler system or by an approved fire detection system.

**5104.7 Storage in Group M occupancies.** Storage of Level 2 and 3 aerosol products in occupancies in Group M shall comply with Table 5104.7. Retail display shall comply with Section 5106.

❖ Both this section and Table 5104.7 contain storage limitations for Level 2 and 3 aerosol products in the storage area of a mercantile occupancy that is physically separated from the sales area and not accessible to the public. These areas are generally referred

to as “back-stock” storage areas. The storage limitation for aerosol products located in the retail sales area of mercantile occupancies is specified in Section 5106.

**TABLE 5104.7  
MAXIMUM QUANTITIES OF LEVEL 2 AND 3 AEROSOL  
PRODUCTS IN RETAIL STORAGE AREAS**

MAXIMUM NET WEIGHT PER FLOOR (pounds)			
Floor	Nonsegregated storage <sup>a, b</sup>	Segregated storage	
		Storage cabinets <sup>b</sup>	Separated from retail area <sup>c</sup>
Basement	Not Permitted	Not Permitted	Not Permitted
Ground floor	2,500	5,000	Note d
Upper floors	500	1,000	Note d

For SI: 1 pound = 0.454 kg, 1 square foot = 0.0929 m<sup>2</sup>.

a. The total aggregate quantity on display and in storage shall not exceed the maximum retail display quantity indicated in Section 5106.3.

b. Storage quantities indicated are the maximum permitted in any 50,000-square-foot area.

c. The storage area shall be separated from the retail area with a 1-hour fire-resistance-rated assembly.

d. See Table 5104.3.2.

❖ Table 5104.7 shows the maximum quantity limitations for Level 2 and 3 aerosol products in the back-stock storage areas of mercantile occupancies in both nonsegregated and segregated conditions. In nonsegregated storage, the aerosol product storage is neither separated from the retail display by a fire-resistance-rated barrier nor stored in approved flammable liquid storage cabinets. When the storage is nonsegregated, the quantity of Level 2 and 3 aerosols is the total quantity in the back-stock storage and display areas combined. Level 2 and 3 aerosol products would be limited to 2,500 pounds (1135 kg) and 500 pounds (227 kg) on the ground and upper floors, respectively, in any 50,000-square-foot (4645 m<sup>2</sup>) area. In the case of segregated back-stock storage using approved, flammable-liquid storage cabinets, the total aerosol product storage is independent of the displayed quantities. The back-stock storage area quantities can be increased to those specified in Table 5104.3.2.2 for segregated storage in general purpose warehouses where the storage has been separated from the retail sales area by no less than 1-hour fire-resistance-rated construction.

## SECTION 5105 OUTSIDE STORAGE

**5105.1 General.** The outside storage of Level 2 and 3 aerosol products, including storage in temporary storage trailers, shall be separated from exposures in accordance with Table 5105.1.

❖ Outside storage of Level 2 and 3 aerosol products must be separated from buildings, lot lines, public ways and other outside combustible storage as shown in Table 5105.1 to minimize potential exposure hazards to the aerosols. Temporary storage trailers must also be located a minimum of 50 feet (15 240 mm)

from buildings and other outside storage. Minimum separation distances are consistent with NFPA 30B and NFPA 80A. Areas surrounding outdoor aerosol storage areas also should be maintained free of miscellaneous combustible materials and vegetation for a distance of at least 20 feet (6096 mm) to avoid exposing the aerosols being stored to ignition or damage from unwanted fire involving rubbish, wind-borne debris and dry vegetation.

**TABLE 5105.1**  
**DISTANCE TO EXPOSURES FOR OUTSIDE STORAGE**  
**OF LEVEL 2 AND 3 AEROSOL PRODUCTS**

EXPOSURE	MINIMUM DISTANCE FROM AEROSOL STORAGE (feet) <sup>a</sup>
Public alleys, public ways, public streets	20
Buildings	50
Exit discharge to a public way	50
Lot lines	20
Other outside storage	50

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. The minimum separation distance indicated is not required where exterior walls having a 2-hour fire-resistance rating without penetrations separate the storage from the exposure. The walls shall extend not less than 30 inches above and to the sides of Level 2 and 3 aerosol products.

❖ Table 5105.1 specifies minimum separation requirements for the outside storage of Level 2 and 3 aerosol products for various exposure conditions.

In place of the minimum separation distance requirement, Note a allows the use of a minimum 2-hour fire-resistance-rated wall without openings or penetrations as the means of exposure protection. The wall with the required extensions beyond the aerosol product storage area is intended to act as an effective shield to protect the exposed area from the Level 2 and 3 aerosol products, equivalent to the spatial separations shown in the table.

## SECTION 5106

### RETAIL DISPLAY

**5106.1 General.** This section shall apply to the retail display of 500 pounds (227 kg) or more of Level 2 and 3 aerosol products.

❖ This section establishes the applicability of Section 5106 to the retail display of Level 2 and 3 aerosol products with a net weight exceeding 500 pounds (227 kg) in retail and wholesale stores classified in Group M in accordance with IBC Section 309.1.

Quantities of Level 1 aerosol products are not limited in Group M mercantile display areas because of their low content of flammable product or propellant.

**5106.2 Aerosol display and normal merchandising not exceeding 8 feet (2438 mm) high.** Aerosol display and nor-

mal merchandising not exceeding 8 feet (2438 mm) in height shall be in accordance with Sections 5106.2.1 through 5106.2.4.

❖ Prior to about 1990, the typical mercantile store displayed merchandise to heights of about 8 feet (2438 mm). In the years since, merchandising techniques have changed substantially so that item displays now exceed 8 feet (2438 mm) in what are called “big box” stores. Section 5106.2 and its subsections regulate the more traditional type of stores where display and merchandising of Level 2 and 3 aerosol products do not exceed 8 feet (2438 mm) in height. See the commentary to Section 5106.3 for information on displays greater than 8 feet (2438 mm) in height.

**5106.2.1 Maximum quantities in retail display areas.** Aerosol products in retail display areas shall not exceed quantities needed for display and normal merchandising and shall not exceed the quantities in Table 5106.2.1.

❖ This section is intended to restrict the quantities of aerosol products in display areas where the public would be exposed to them and where they might not be protected by fire barriers or sprinkler systems, as they would be in approved storage areas.

**TABLE 5106.2.1**  
**MAXIMUM QUANTITIES OF LEVEL 2 AND 3 AEROSOL**  
**PRODUCTS IN RETAIL DISPLAY AREAS**

MAXIMUM NET WEIGHT PER FLOOR (pounds) <sup>b</sup>			
Floor	Unprotected <sup>a</sup>	Protected in accordance with Section 5106.2 <sup>a,c</sup>	Protected in accordance with Section 5106.3 <sup>c</sup>
Basement	Not allowed	500	500
Ground	2,500	10,000	10,000
Upper	500	2,000	Not allowed

For SI: 1 pound = 0.454 kg, 1 square foot = 0.0929 m<sup>2</sup>.

a. The total quantity shall not exceed 1,000 pounds net weight in any one 100-square-foot retail display area.

b. Per 25,000-square-foot retail display area.

c. Minimum Ordinary Hazard Group 2 wet-pipe automatic sprinkler system throughout the retail sales occupancy.

❖ This table establishes quantity limits for display areas that are protected by sprinklers as well as those that are not. Note a deals only with product display in accordance with Section 5106.2. Note b deals with the entire table and does allow these quantities for each 25,000 square feet (2323 m<sup>2</sup>) of retail display area. This provides adequate separation of the quantities while allowing the display of various product types, such as paint, insect control and personal care products. Note c deals with Sections 5106.2 and 5106.3, and does require, at a minimum, an Ordinary Hazard Group 2 wet pipe sprinkler system throughout the retail sales occupancy, except where higher levels of protection are required, such as in Level 2 and 3 aerosol display areas.

**5106.2.2 Display of containers.** Level 2 and 3 aerosol containers shall not be stacked more than 6 feet (1829 mm) high from the base of the aerosol array to the top of the aerosol array unless the containers are placed on fixed shelving or otherwise secured in an *approved* manner. Where storage or retail display is on shelves, the height of such storage or retail display to the top of aerosol containers shall not exceed 8 feet (2438 mm).

❖ Restricting display heights of Level 2 and 3 aerosol containers where NFPA 30B protection tables are not followed serves three purposes. The first is, obviously, to limit the quantity of aerosols that can be housed in a given area; the second is to make certain the displays are stable and not likely to topple; and the third is to make certain the piles are not so high that they would be likely to interfere with the efficient operation of area sprinklers.

**5106.2.3 Combustible cartons.** Aerosol products located in retail display areas shall be removed from combustible cartons.

**Exceptions:**

1. Display areas that use a portion of combustible cartons that consist of only the bottom panel and not more than 2 inches (51 mm) of the side panel are allowed.
  2. When the display area is protected in accordance with Tables 6.3.2.7(a) through 6.3.2.7(l) of NFPA 30B, storage of aerosol products in combustible cartons is allowed.
- ❖ Removing combustible cartons from display areas reduces the potential fuel supply in case of a fire and also removes the combustible material that would surround the aerosol containers and heat them to the point that they could ignite, “rocket” or explode. It also keeps the display more open so that sprinklers can reach the individual containers more easily to help keep them below dangerous temperatures, as well as control or extinguish fire in other surrounding combustibles.

Exception 1 allows cut-down cartons in displays because they represent a somewhat reduced fuel load for a fire and also leave the sides of the aerosol containers exposed so that sprinkler water can reach them. The carton bottoms also help stabilize stacks in displays to keep them from toppling.

Exception 2 allows use of cartons in aerosol display and merchandising areas, which are protected in accordance with Tables 6.3.2.7(a) through 6.3.2.7(l) of NFPA 30B in accordance with Section 5106.3.

**5106.2.4 Retail display automatic sprinkler system.** Where an *automatic sprinkler system* is required for the protected retail display of aerosol products, the wet-pipe *automatic sprinkler system* shall be in accordance with Section 903.3.1.1. The minimum system design shall be for an Ordinary Hazard Group 2 occupancy. The system shall be provided throughout the retail display area.

❖ The reference to Section 903.3.1.1 indicates that the sprinkler system must meet the requirements of NFPA 13, which classifies mercantile groups used for retail display as an Ordinary Hazard Group 2 occupancy. This would require a minimum sprinkler design density of 0.20 gallon per minute (gpm) per square foot (8.14 L/min/m<sup>2</sup>) applied over the hydraulically most remote 1,500 square feet (139 m<sup>2</sup>) of system coverage, which is common for most mercantile occupancies. In areas that are equipped with a sprinkler system conforming to NFPA 13, this section limits the quantity of aerosols on display to 2 pounds per square foot (psf) (10 kg/m<sup>2</sup>) of the gross sales floor area with a maximum weight of 1,000 pounds (454 kg) of aerosols in any 10-foot by 10-foot (3048 mm by 3048 mm) area of the sales floor.

If more aerosol product storage is desired or anticipated, Section 5106.3 must be followed.

**5106.3 Aerosol display and normal merchandising exceeding 8 feet (2438 mm) high.** Aerosol display and merchandising exceeding 8 feet in height shall be in accordance with Sections 5106.3.1 through 5106.3.3.

❖ Many modern stores classified in Group M are included in the family of stores commonly known as “big box” or “warehouse”-type stores (Section 309.1 of the IBC calls them “wholesale stores”), so called because of their high-density, high-piled display and storage of products at heights greater than 8 feet (2438 mm) in areas accessible to the public. This section describes the requirements for displaying and merchandising Level 2 and 3 aerosol products where they exceed 8 feet (2438 mm) in height.

**5106.3.1 Maximum quantities in retail display areas.** Aerosol products in retail display areas shall not exceed quantities needed for display and normal merchandising and shall not exceed the quantities in Table 5106.2.1, with fire protection in accordance with Section 5106.3.2.

❖ This section is intended, as is Section 5106.2.1, to restrict the quantities of hazardous materials in display areas where the public would be exposed to them.

**5106.3.2 Automatic sprinkler protection.** Aerosol display and merchandising areas shall be protected by an *automatic sprinkler system* based on the requirements set forth in Tables 6.3.2.7(a) through 6.3.2.7(l) of NFPA 30B and the following:

1. Protection shall be based on the highest level of aerosol product in the array and the packaging method of the storage located more than 6 feet (1829 mm) above the finished floor.
2. Where using the cartoned aerosol tables of NFPA 30B, uncartoned or display-cut Level 2 and 3 aerosols shall be permitted not more than 6 feet (1829 mm) above the finished floor.

- 3. The design area for Level 2 and 3 aerosols shall extend not less than 20 feet (6096 mm) beyond the Level 2 and 3 aerosol display and merchandising areas.
- 4. Where ordinary and high-temperature ceiling sprinkler systems are adjacent to each other, noncombustible draft curtains shall be installed at the interface.

❖ This section describes the automatic sprinkler protection requirements for Level 2 and 3 aerosol products where pile heights exceed 8 feet (2438 mm) in height. The sprinkler protection is the same as that required in a warehouse and must follow the appropriate requirements in Tables 6.3.2.7(a) through 6.3.2.7(l) of NFPA 30B. See Commentary Figure 5106.3.2. The protection table to be used is based on:

- The highest level of aerosol product found in the array.
- The packaging method of product located more than 6 feet (1829 mm) above the floor; that is, whether the product is in cartons or is uncartoned.
- The display/storage method: bulk, palletized or rack.

When using the tables for cartoned product, all product above the 6-foot (1829 mm) level must be cartoned. This is to increase the likelihood that the sprinkler protection will properly protect the storage array.

The design area for the ceiling sprinklers for the Level 2 or 3 aerosols must extend at least 20 feet (6096 mm) beyond the display and merchandising area. This is to provide the outer part of the aerosol area with adequate ceiling sprinkler water distribution regardless of whether the fire is internal or external to the aerosols.

Noncombustible draft curtains are to be installed at interfaces between ordinary- and high-temperature ceiling sprinkler systems in order to prevent a fire

beneath high-temperature sprinklers from activating ordinary-temperature sprinklers located away from the fire. This could put a strain on water availability in the fire area.

**5106.3.3 Separation of Level 2 and 3 aerosol areas.** Separation of Level 2 and 3 aerosol areas shall comply with the following:

- 1. Level 2 and 3 aerosol display and merchandising areas shall be separated from each other by not less than 25 feet (7620 mm). See Table 5106.2.1.
- 2. Level 2 and 3 aerosol display and merchandising areas shall be separated from flammable and *combustible liquids* storage and display areas by one or a combination of the following:
  - 2.1. Segregating areas from each other by horizontal distance of not less than 25 feet (7620 mm).
  - 2.2. Isolating areas from each other by a noncombustible partition extending not less than 18 inches (457 mm) above the merchandise.
  - 2.3. In accordance with Section 5106.5.
- 3. Where Item 2.2 is used to separate Level 2 or 3 aerosols from flammable or *combustible liquids*, and the aerosol products are located within 25 feet (7620 mm) of flammable or *combustible liquids*, the area below the noncombustible partition shall be liquid tight at the floor to prevent spilled liquids from flowing beneath the aerosol products.

❖ As indicated in Table 5106.2.1, Note b, the maximum net weight shown is for each 25,000 square feet (2323 m<sup>2</sup>) of sales display area. This section provides for the separation of aerosols in any one of these areas from those in any other area. This 25-foot (7620 mm) separation prevents back-to-back, 10,000-pound (4540 kg) arrays of product, which would defeat the purpose of the MAQs.

Separation of Level 2 and 3 aerosol products from

TABLE 6.3.2.7 SUFFIX	STORAGE METHOD		PACKAGING TYPE		AEROSOL LEVEL	
	Pallet or Solid Pile	Rack Storage	Cartoned	Uncartoned	Level 2	Level 3
(a) Metric (b) English	X		X		X	X
(c) Metric (d) English	X			X	X	
(e) Metric (f) English		X	X		X	
(g) Metric (h) English		X	X			X
(i) Metric (j) English		X		X	X	
(k) Metric (l) English		X		X		X

a. There Are Two Versions Of Each Table, One That Uses Si Units (Metric) And One That Uses English Units.

**Figure 5106.3.2**  
**GUIDE TO CONTENTS OF NFPA 30B TABLES 6.3.2.7(a) through (l)**

flammable and combustible liquids is required in order to prevent a liquid spill fire from immediately involving the aerosol products. The burning liquid could easily overwhelm the automatic sprinkler protection provided for the aerosol products, thus increasing the size of the loss.

The separation can be accomplished in any one or a combination of three ways:

1. Separation by a horizontal distance of at least 25 feet (7620 mm). This will prevent immediate involvement of the aerosols; and, if the burning liquid does eventually flow toward the aerosols, the in-rack sprinklers or fast-response sprinklers should activate so as to provide prewetting of the area.
2. A noncombustible partition between the products to prevent liquid flow into the aerosol area. When the partition is used and the aerosols and liquids are within 25 feet (7620 mm) of one another, this partition is to be liquid tight at the floor to prevent spilled liquids from flowing under the aerosol products.
3. A special protection design in accordance with Section 5106.5.

**5106.4 Maximum quantities in storage areas.** Aerosol products in storage areas adjacent to retail display areas shall not exceed the quantities in Table 5106.4.

❖ This section establishes quantity limits on aerosol products held in storage areas adjacent to retail sales floors. The limits are given in Table 5106.4, except for those in the right-hand column. Table 5104.7 designates this column as applying to areas that are separated from the retail sales area. The requirement for a barrier having a 1-hour fire-resistance rating is given in the notes to Table 5104.7. Applicable quantities for that storage condition are given in Table 5104.3.2. In the case of Table 5106.4, the separation is called a “1-hour occupancy separation,” which, within the IBC, would be considered a fire barrier constructed in accordance with Section 707. The quantity limits are as found in NFPA 30B.

**TABLE 5106.4.** See below.

❖ The quantities stated in this table are the same as those in Table 5104.7 (see commentary, Table 5104.7).

**5106.5 Special protection design for Level 2 and 3 aerosols adjacent to flammable and combustible liquids in double-row racks.** The display and merchandising of Level 2 and 3 aerosols adjacent to flammable and *combustible liquids* in double-row racks shall be in accordance with Sections 5106.5.1 through 5106.5.8 or Section 5106.3.3.

❖ This is the third method referred to in Section 5106.3.3, Item 2.3, for the separation of Level 2 and 3 aerosol display and merchandising areas from flammable and combustible liquid storage and display areas.

This special protection design is based on large-scale fire testing, with the storage arrays and sprinkler protection based on that testing. Rather than requiring the separation of aerosols and liquids in retail display and merchandising, it is a specific method to allow some of these products to be adjacent to one another.

**5106.5.1 Fire protection.** Fire protection for the display and merchandising of Level 2 and 3 aerosols in double-row racks shall be in accordance with Table 7.4.1 and Figure 7.4.1 of NFPA 30B.

❖ This specific method requires that the aerosols be in double-row racks, and that the fire protection be in accordance with Table 7.4.1 and Figure 7.4.1 of NFPA 30B. This fire protection scheme is based on a successful large-scale fire test.

**5106.5.2 Cartoned products.** Level 2 and 3 aerosols displayed or merchandised more than 8 feet (2438 mm) above the finished floor shall be in cartons.

❖ The Level 2 and 3 aerosols displayed or merchandised up to 8 feet (2438 mm) in height are allowed to be uncartoned or in display-cut cartons. All aerosols stored or displayed higher than 8 feet (2438 mm) must be in cartons to satisfy this special method.

**5106.5.3 Shelving.** Shelving in racks shall be limited to wire mesh shelving having uniform openings not more than 6 inches (152 mm) apart, with the openings comprising not less than 50 percent of the overall shelf area.

❖ All shelving in the racks for this special protection design must be wire mesh, with openings as prescribed in this section. This open wire mesh will allow sprinkler water flow between shelves and will not allow early collapse of the shelves.

**TABLE 5106.4**  
**MAXIMUM STORAGE QUANTITIES FOR STORAGE AREAS ADJACENT TO RETAIL DISPLAY OF LEVEL 2 AND 3 AEROSOLS**

MAXIMUM NET WEIGHT PER FLOOR (pounds)			
Floor	Unseparated <sup>a,b</sup>	Separated	
		Storage Cabinets <sup>b</sup>	1-hour Occupancy Separation
Basement	Not Allowed	Not Allowed	Not Allowed
Ground	2,500	5,000	In accordance with Sections 6.3.4.3 and 6.3.4.4 of NFPA 30B
Upper	500	1,000	In accordance with Sections 6.3.4.3 and 6.3.4.4 of NFPA 30B

For SI: 1 pound = 0.454 kg, 1 square foot = 0.0929 m<sup>2</sup>.

a. The aggregate quantity in storage and retail display shall not exceed the quantity limits for retail display.

b. In any 50,000-square-foot area.

**5106.5.4 Aisles.** Racks shall be arranged so that aisles not less than 7½ feet (2286 mm) wide are maintained between rows of racks and adjacent solid-piled or palletized merchandise.

❖ Aisles of at least 7½ feet (2286 mm) in width must be maintained. This is based on the successful large-scale fire test and is to help prevent fire spread.

**5106.5.5 Flue spaces.** Flue spaces in racks shall comply with the following:

1. Transverse flue spaces—Nominal 3-inch (76 mm) transverse flue spaces shall be maintained between merchandise and rack uprights.
2. Longitudinal flue spaces—Nominal 6-inch (152 mm) longitudinal flue spaces shall be maintained.

❖ This section requires nominal 3-inch (76 mm) transverse flue spaces and nominal 6-inch (152 mm) longitudinal flue spaces. These flue spaces are provided to allow sprinkler discharge water to freely flow between rack levels. As in Section 5106.5.3, the flue spaces are necessary so that lower levels of the array have adequate protection.

**5106.5.6 Horizontal barriers.** Horizontal barriers constructed of minimum ¾-inch-thick (10 mm) plywood or minimum 0.034-inch (0.086 mm) (No. 22 gage) sheet metal shall be provided and located in accordance with Table 7.4.1 and Figure 7.4.1 of NFPA 30B where in-rack sprinklers are installed.

❖ Whenever in-rack sprinklers are used, horizontal barriers of the thickness and materials indicated in this section are to be provided directly above the in-rack sprinklers. Their location shall be in accordance with Table 7.4.1 and Figure 7.4.1 of NFPA 30B. Their presence above the in-rack sprinkler will trap heat and ensure that these sprinklers, closest to any fire, will properly activate in a timely manner.

**5106.5.7 Class I, II, III, IV and plastic commodities.** Class I, II, III, IV and plastic commodities located adjacent to Level 2 and 3 aerosols shall be protected in accordance with NFPA 13.

❖ Class I through IV and plastic commodities located adjacent to the aerosols in this array must be protected in accordance with NFPA 13.

**5106.5.8 Flammable and combustible liquids.** Class I, II, III A and III B Liquids shall be allowed to be located adjacent to Level 2 and 3 aerosol products where both of the following conditions are met:

1. Class I, II, IIIA and IIIB liquid containers: Containers for Class I, II, IIIA and IIIB liquids shall be limited to 1.06-gallon (4 L) metal-relieving and nonrelieving style containers and 5.3-gallon (20 L) metal-relieving style containers.

2. Fire protection for Class I, II, IIIA and IIIB Liquids: Automatic sprinkler protection for Class I, II, IIIA and IIIB liquids shall be in accordance with Chapter 57.

❖ This section identifies the maximum size and style of metal containers that must be used for flammable and combustible liquids stored adjacent to the aerosols. Section 6.8.1.3 and Appendix A-6.8.1.3 of NFPA 30 provide information on relieving- and nonrelieving-type metal containers.

No plastic containers of flammable or combustible liquids are allowed for this special protection design. Fire protection for the flammable and combustible liquids must be in accordance with Chapter 57.

## SECTION 5107 MANUFACTURING FACILITIES

**5107.1 General.** Manufacturing facilities shall be in accordance with NFPA 30B.

❖ The hazards of aerosol manufacturing are significantly different from those of a storage facility where aerosols are stored in cartons in their individual steel or aluminum containers. The manufacturing process involves the hazards of handling flammable and combustible liquids under pressure and potentially in aerosol form, which is an even greater fire hazard. Since the manufacturing of aerosol products is not included in the list of exceptions to a Group H occupancy classification found in IBC Section 307.1, Exception 11, such facilities could warrant a Group H classification. See the commentary to Section 5101.1 for further information.

The code relies upon the referenced standard, NFPA 30B, for the regulation of aerosol manufacturing facilities. Chapter 5 of that standard includes basic requirements for manufacturing facilities, including, among others, requirements for the protection and separation of propellant-charging areas and pump rooms, explosion and deflagration venting, special ventilation requirements, electrical requirements, control of static electricity and fire protection systems.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

**CHAPTER 52**  
**RESERVED**

# Chapter 53: Compressed Gases

## General Comments

This chapter regulates the storage, use and handling of all flammable and nonflammable compressed gases, such as those that are used in medical facilities, air separation plants, industrial plants, agricultural equipment and similar occupancies. Standards for the design, construction and marking of compressed gas cylinders and pressure vessels are referenced. Compressed gases used in welding and cutting, cryogenic liquids and liquefied petroleum gases (LP-gases) are also regulated under Chapters 35, 55 and 61, respectively. Compressed gases that are classified as hazardous materials are also regulated in Chapter 50, which includes general requirements.

## Purpose

Chapter 53 sets requirements for the storage, handling and use of all compressed gases, whether flammable or nonflammable.

## Flammable compressed gases

The principal hazard posed by flammable compressed gas is its ready ignitability, or even explosivity, when mixed with air in the proper proportions. The question in a flammable gas release usually is not if the mixture will ignite, but rather when or how it will ignite if not controlled. Consequently, occupancies storing or handling more than 1,000 cubic feet (28 m<sup>3</sup>) of flammable compressed gases or 30 gallons (114 L) of liquefied flammable gases per control area are classified as Group H-2 (high hazard) by the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>).

## Nonflammable compressed gases

The principal danger in the case of nonflammable compressed gas is its toxicity, reactivity or the ability to support combustion. Many gases do not fall into any of these categories; however, oxygen, perhaps the most abundant compressed gas, obviously does. Gaseous commodities containing oxygen, such as oxygen-helium and oxygen-nitrogen mixtures, oxides (e.g., nitrous oxide) and peroxides, all support the combustion. Fluorine (F<sub>2</sub>) and chlorine (Cl<sub>2</sub>) may also support the combustion of certain materials. Saacke and Associates (1990) discussed some of the properties of these two gases. Since these commodities are stored under pressure, their release from a cylinder causes them to expand to many times their initial volume. In confined and poorly ventilated spaces, this will cause certain gases to create an oxygen-enriched atmosphere that will accelerate burning. The release of other gases dis-

places atmospheric oxygen, thereby creating a dangerous, oxygen-deficient atmosphere. Many materials that do not burn in atmospheric concentrations of oxygen (19 to 21 percent) will support combustion at elevated levels. Chapter 60 contains specific provisions for highly toxic and toxic compressed gases.

## Container supports

The one common danger presented by all compressed gases is the enormous amount of energy released by container or fitting failures. For this reason, Sections 5303.5 and 5303.5.2 require all compressed gas cylinders to be properly secured as a means of protection against physical or mechanical damage. Containers should always be checked for obvious physical damage. Dented, bulging, gouged or corroded cylinders should be returned to the gas supplier for inspection and, if necessary, retesting.

## Overpressure protection

All compressed gas storage vessels, except those containing highly toxic materials, are equipped with pressure relief devices as a measure of protection against catastrophic container failure. These devices operate when compressed gas pressure, temperature or both exceed safe limits. Fusible discs and plugs, bimetallic "snap" discs, spring-operated valves or a combination of these methods are used to vent excess gas to the atmosphere. Some of these devices self-restore and stop the release of container contents; others do not. The fire code official should check pressure relief devices to see that they have not been painted, removed, damaged, contaminated, obstructed or otherwise impaired. Additionally, temperature extremes in the operating area [greater than 120°F (49°C) and less than 20°F (-7°C)] should be avoided.

## Housekeeping

Check valves, filters, flash arrestors and other gas system apparatus must be maintained in good operating condition. Dirt is the primary enemy of any gas system: debris can clog filters and block valves; damaged valves may permit the gradual release of tank contents and accumulations of grease and other organic materials become a fire hazard in the presence of oxidizing gases. Combustibles should be kept clear of all compressed gas installations, especially oxidizing gases. External fires involving accumulated combustibles can cause containers to fail.

## Separation

Separating gas system installations and incompatible gases (flammables and oxidizers) to minimize exposures is one of the simplest safeguards to implement. If possible, a suitable fire barrier should be constructed around container installations. The best location for compressed gas container installations is outside of buildings. In such cases, adequate access and weather protection should be provided to facilitate maintenance and emergency response.

## Ignition sources

Controlling ignition sources around both flammable compressed gas and oxidizing gas installations is the most important and most difficult safeguard to implement. Sparks, frictional heat, electrical arcs, static electricity, smoking materials and hot surfaces are only a few of the potential ignition sources. Every reasonable effort must be made to eliminate these sources or limit the adverse impact of an unintentional ignition. Smoking, welding, cutting and other obvious sources of ignition must be prohibited in the vicinity of compressed gases, and steps must be taken to prevent the accumulation of static electricity. Compressed gas cylinders should never be permitted to come into contact with energized electrical equipment.

## SECTION 5301 GENERAL

**5301.1 Scope.** Storage, use and handling of *compressed gases* in *compressed gas* containers, cylinders, tanks and systems shall comply with this chapter and NFPA 55, including those gases regulated elsewhere in this code. Partially full *compressed gas* containers, cylinders or tanks containing residual gases shall be considered as full for the purposes of the controls required.

Liquefied natural gas for use as a vehicular fuel shall also comply with NFPA 52 and NFPA 59A.

*Compressed gases* classified as hazardous materials shall also comply with Chapter 50 for general requirements and chapters addressing specific hazards, including Chapters 58 (Flammable Gases), 60 (Highly Toxic and Toxic Materials), 63 (Oxidizers, Oxidizing Gases and Oxidizing Cryogenic Fluids) and 64 (Pyrophoric Materials).

Compressed hydrogen (CH<sub>2</sub>) for use as a vehicular fuel shall also comply with Chapters 23 and 58 of this code, the *International Fuel Gas Code* and NFPA 2.

Cutting and welding gases shall also comply with Chapter 35.

LP-gas shall also comply with Chapter 61 and the *International Fuel Gas Code*.

### Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
  2. Compressed natural gas (CNG) for use as a vehicular fuel shall comply with Chapter 23, NFPA 52 and the *International Fuel Gas Code*.
  3. *Cryogenic fluids* shall comply with Chapter 55.
- ❖ This section establishes the scope of Chapter 53 with respect to the storage, use and handling of compressed gases, containers, cylinders, tanks and sys-

tems. The requirements of this chapter and the referenced standards are applicable, in addition to the general storage requirements of Chapter 50 for hazardous materials.

**5301.2 Permits.** Permits shall be required as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit; Section 105.6.9 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter; and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous properties.

## SECTION 5302 DEFINITIONS

**5302.1 Definitions.** The following terms are defined in Chapter 2:

**COMPRESSED GAS.**

**COMPRESSED GAS CONTAINER.**

**COMPRESSED GAS SYSTEM.**

**NESTING.**

**TUBE TRAILER.**

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chap-

ter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 5303 GENERAL REQUIREMENTS

**5303.1 Containers, cylinders and tanks.** *Compressed gas* containers, cylinders and tanks shall comply with this section. *Compressed gas* containers, cylinders or tanks that are not designed for refillable use shall not be refilled after use of the original contents.

❖ This section addresses protection from physical damage and prevents the gas containers, cylinders and tanks from being tampered with and otherwise damaged. It also requires marking for identification of the contents and the hazard degree. Only compressed gas containers, cylinders and tanks designed to be refillable may be done so after the original contents have been used.

**5303.2 Design and construction.** *Compressed gas* containers, cylinders and tanks shall be designed, fabricated, tested, marked with the specifications of manufacture and maintained in accordance with the regulations of DOTn 49 CFR Parts 100-185 or the ASME *Boiler and Pressure Vessel Code*, Section VIII.

❖ This section establishes basic requirements for the construction of pressure vessels. These requirements are in harmony with standards used by the suppliers of compressed gases and also correlate the code with standards promulgated by the Compressed Gas Association (CGA) as adopted by the Occupational Safety and Health Administration (OSHA). Manufacturing pressure vessels to standards is an essential element of safety that is warranted for materials of the type to be contained. Department of Transportation (DOTn) specification containers are used for pressure vessels in transport; while American Society of Mechanical Engineers (ASME) design specifications are typically used for stationary installations or where the pressure vessel is not designed as a transport vessel. By providing these requirements in the code, users who otherwise might devise a noncompliant system will be guided to appropriate standards of design.

**5303.3 Pressure relief devices.** Pressure relief devices shall be in accordance with Sections 5303.3.1 through 5303.3.5.

❖ Pressure relief devices are essential for compressed gases because of the high pressures at which they are maintained. Pressure relief devices provide a method of relieving overpressures and avoiding a hazardous situation. Sections 5303.3.1 through 5303.3.5 contain requirements related to accessibility for maintenance, general sizing, installation require-

ments and freeze protection for pressure relief devices.

**5303.3.1 Where required.** Pressure relief devices shall be provided to protect containers, cylinders and tanks containing *compressed gases* from rupture in the event of overpressure.

**Exception:** Cylinders, containers and tanks where exempt from the requirements for pressure relief devices specified by the standards of design *listed* in Section 5303.3.2.

❖ All compressed gas containers, cylinders and tanks must be equipped with pressure relief protection to reduce the likelihood of catastrophic vessel failure because of an overpressure condition. The exception recognizes that under certain conditions, the referenced design standards may not require pressure relief devices for certain vessels.

**5303.3.2 Design.** Pressure relief devices to protect containers shall be designed and provided in accordance with CGA S-1.1, CGA S-1.2, CGA S-1.3 or the ASME *Boiler and Pressure Vessel Code*, Section VIII, as applicable.

❖ There are two forms of pressure relief devices (PRDs): reusable devices or sacrificial devices. The type of PRD selected is based on the size of the gas container and the characteristics and hazards of the stored gas. The reusable form of a PRD is a spring-loaded safety relief valve that has the ability to open and close as excess pressures are relieved. Sacrificial PRDs are either a rupture disk or a fusible plug. When a sacrificial PRD operates, it cannot reclose; thus, its operation expels the entire contents of the gas container. Sacrificial PRDs operate when the device's pressure or temperature limits are exceeded.

Heat-activated PRDs are manufactured using fusible relief valves, known as fusible plugs. Frangible plugs operate when they are subjected to direct heating or heat from an exposure fire. Fusible plugs are normally set to operate at 212-350°F and are manufactured with metals with extremely reliable and predictable melting temperatures. Heat-activated PRDs operate when they are heated by direct fire contact or radiant and convective energies of an exposure fire.

Pressure-activated PRDs are known as burst discs or rupture discs. A burst disc is an engineered device that uses a metal or graphite disc weakened by scoring. Scoring is a mechanical process where the metal is partially cut to cause a predictable failure at the opening pressure of the burst disc. The disc's size, geometry and material of construction governs its opening or "burst" pressure. When a burst disc operates, it opens like a flower, and the gas is released into the atmosphere.

Pressure relief devices are to be designed in accordance with established engineering principles. Three CGA standards that cover the full range of container types, from portable to stationary, are referenced in this section, along with the ASME code, which is also referenced in Section 5303.2 for compressed gas container, cylinder and tank design.

**5303.3.3 Sizing.** Pressure relief devices shall be sized in accordance with the specifications to which the container was fabricated and to material-specific requirements as applicable.

❖ This section contains only general language requiring that the pressure relief device be properly designed to fit the needs of the particular container, cylinder or tank. In most cases, the manufacturer will already have the devices installed on the vessel at the factory. There are cases, however, when a compressed gas system or vessel may be constructed for a specific purpose and user. In those cases, the relief valves must be sized and installed by the user.

**5303.3.4 Arrangement.** Pressure relief devices shall be arranged to discharge upward and unobstructed to the open air in such a manner as to prevent any impingement of escaping gas upon the container, adjacent structures or personnel.

**Exception:** DOTn specification containers having an internal volume of 30 cubic feet (0.855 m<sup>3</sup>) or less.

❖ Pressure relief devices must be located so as to direct vented vapors away from personnel, containers and structures, as well as enclosed spaces to prevent personal injury and property damage. The arrangement will vary from one installation to another based on the use and location of the container and the system. The exception for DOTn containers with an internal volume less than or equal to 30 cubic feet (0.855 m<sup>3</sup>) recognizes that the amount of gas released from these containers is small enough to make this section unnecessary.

**5303.3.5 Freeze protection.** Pressure relief devices or vent piping shall be designed or located so that moisture cannot collect and freeze in a manner that would interfere with the operation of the device.

❖ A concern related to the integrity of pressure relief valves is their exposure to below-freezing temperatures that, in addition to having the tendency to make materials brittle and more susceptible to failure, cause accumulated moisture to freeze and possibly obstruct the relief valve opening, increasing the potential for a catastrophic container overpressure failure. This section requires that pressure relief devices be either not subject to extreme temperatures at all or provided with an approved freeze-protection technology as an integral part of the design.

**5303.4 Marking.** Stationary and portable *compressed gas* containers, cylinders, tanks and systems shall be marked in accordance with Sections 5303.4.1 through 5303.4.3.

❖ This section introduces the marking requirements for specific systems or gas containers, cylinders and tanks, including color and labeling of the name of the gas it contains.

**5303.4.1 Stationary compressed gas containers, cylinders and tanks.** Stationary *compressed gas* containers, cylinders and tanks shall be marked with the name of the gas and in

accordance with Sections 5003.5 and 5003.6. Markings shall be visible from any direction of approach.

❖ In order to provide emergency personnel with critical information regarding potential hazard exposure, gas storage vessels are to be marked in accordance with Sections 5003.5 (that references NFPA 704) and 5003.6 (see commentary, Sections 5003.5 and 5003.6). The markings need to be readily visible from any direction of approach (see Commentary Figure 5303.4.1).

**5303.4.2 Portable containers, cylinders and tanks.** Portable *compressed gas* containers, cylinders and tanks shall be marked in accordance with CGA C-7.

❖ Portable units are to be marked in accordance with Compressed Gas Association (CGA) standard C-7. The scope of that standard is to provide guidance on the appropriate labeling of containers of compressed gases for the purpose of identifying their contents; warning personnel of the physical and health hazards of the container contents, such as flammability, corrosivity, pyrophoricity and poison, among others; and providing information regarding precautions to be taken relative to the container contents. Such labels and markings must be prominently displayed and durable, identifying the standard that governed its construction, the material of construction, its design pressure, and an indication that it is qualified for the compressed gas it contains. These requirements are based on the hazardous material regulations promulgated by the U.S. Department of Transportation (DOTn) in 49 CFR Parts 100 through 185. DOTn markings indicate the specification to which the cylinder was constructed, its type and material of construction, its service pressure measured in pounds per square inch gage (PSIG), the manufacturer's mark and the cylinder's serial number. Additional markings are required to indicate the month and year the cylinder was manufactured and the cylinder testing requirements.

A common misconception is that the color of a cylinder indicates its contents. The only means of identifying the contents of a cylinder is by labeling or marking the cylinder. Cylinders require markings in accordance with CGA C-7. These labels are located on the shoulder or wall of the cylinder. CGA C-7 requires that markings contain the name of the hazardous material and its DOTn and UN hazardous-material identification label and hazard-division identification number, which is used in the DOTn *Hazardous Materials Emergency Response Guidebook*. If the compressed gas is an inhalation hazard, warning statements about this hazard are required, as is a statement about its reportable quantity (RQ), if such a value is assigned by the DOTn.

**5303.4.3 Piping systems.** Piping systems shall be marked in accordance with ASME A13.1. Markings used for piping systems shall consist of the content's name and include a direc-

tion-of-flow arrow. Markings shall be provided at each valve; at wall, floor or ceiling penetrations; at each change of direction; and at not less than every 20 feet (6096 mm) or fraction thereof throughout the piping run.

**Exceptions:**

1. Piping that is designed or intended to carry more than one gas at various times shall have appropriate signs or markings posted at the manifold, along the piping and at each point of use to provide clear identification and warning.
  2. Piping within gas manufacturing plants, gas processing plants, refineries and similar occupancies shall be marked in an *approved* manner.
- ❖ Piping systems are to be marked in accordance with ASME A13.1 to provide information to personnel, including emergency responders, as to the piping content and flow. The marking locations indicated are intended to provide continuity of identification of the piping at valves, certain fittings and structure penetrations. Exception 1 addresses piping systems that carry more than one gas. In these cases, signs are posted at the manifold and at each point of use. This will provide a clear identification and warning. Exception 2 recognizes that gas manufacturing plants need to be evaluated individually to provide clear and adequate piping identification.

**5303.5 Security.** *Compressed gas* containers, cylinders, tanks and systems shall be secured against accidental dislodgement and against access by unauthorized personnel in accordance with Sections 5303.5.1 through 5303.5.3.

❖ Compressed gas containers, cylinders and tanks must be adequately safeguarded. A fence or other approved protection should be provided around the storage area to minimize the likelihood of someone unknowingly entering the area, as well as to deter vandalism or theft.

**5303.5.1 Security of areas.** Areas used for the storage, use and handling of *compressed gas* containers, cylinders, tanks and systems shall be secured against unauthorized entry and safeguarded in an *approved* manner.

❖ Areas such as yards, loading platforms and any area where gas containers, cylinders and tanks are used, handled or stored are to be secured and safeguarded against unauthorized access.

**5303.5.2 Physical protection.** *Compressed gas* containers, cylinders, tanks and systems that could be exposed to physical damage shall be protected. Guard posts or other *approved* means shall be provided to protect *compressed gas* containers, cylinders, tanks and systems indoors and outdoors from vehicular damage and shall comply with Section 312.

❖ Compressed gas containers, cylinders and tanks must be adequately protected against physical or mechanical damage to the container and any valves or fittings. Where damage from vehicles may occur, guard posts or other kinds of guards are required to afford protection that complies with Section 312.

**5303.5.3 Securing compressed gas containers, cylinders and tanks.** *Compressed gas* containers, cylinders and tanks shall be secured to prevent falling caused by contact, vibration or seismic activity. Securing of *compressed gas* containers, cylinders and tanks shall be by one of the following methods:

1. Securing containers, cylinders and tanks to a fixed object with one or more restraints.
2. Securing containers, cylinders and tanks on a cart or other mobile device designed for the movement of *compressed gas* containers, cylinders or tanks.
3. Nesting of *compressed gas* containers, cylinders and tanks at container filling or servicing facilities or in sellers' warehouses not accessible to the public. Nesting shall be allowed provided the nested containers, cylinders or tanks, if dislodged, do not obstruct the required *means of egress*.
4. Securing of *compressed gas* containers, cylinders and tanks to or within a rack, framework, cabinet or similar assembly designed for such use.

**Exception:** *Compressed gas* containers, cylinders and tanks in the process of examination, filling, transport or servicing.

❖ A primary safety objective in the storage of compressed gas cylinders is the prevention of accidents from cylinders being knocked over. The best method to reliably achieve this objective is somewhat dependent on the frequency of cylinders being moved in and out of storage. For operations involving the infrequent movement of cylinders, the safest operation, obviously, would include chains or other means to completely secure all cylinders in place.

Securing all cylinders in place is not necessarily efficient for high-volume operations that are not open to the public, denoted in Method 3 of this section, such as container filling or servicing facilities, or seller's warehouses. When containers, cylinders and tanks are frequently moved, a chain or other restraining device can become a safety impediment to the efficiency of the operation. The tendency in a high-volume operation might be to drop a chain to the floor and roll cylinders over it, which would increase the likelihood of tripping a cylinder. Ideally, a chain should be moved out of the way, but in high-volume operations this can become impractical. Hence, the permissibility of nesting for these cases. See the commentary to the Section 202 definition of "Nesting."

In summary, the fire code official must determine whether the frequency of cylinder movement would qualify an operation as a "seller's warehouse" and allow the nesting exception as a safe alternative to securing cylinders with chains or similar devices. This decision should be based on criteria that is uniformly applied throughout the jurisdiction but that considers the unique characteristics of each operation. For an example of restrained cylinders in a compressed gas

system, see Commentary Figure 5303.4.1.

The exception recognizes that the container will not be secure when it is being filled, examined, transported or serviced. The container should be attended and monitored by adequately trained personnel during these operations.

**5303.6 Valve protection.** *Compressed gas* container, cylinder and tank valves shall be protected from physical damage by means of protective caps, collars or similar devices in accordance with Sections 5303.6.1 and 5303.6.2.

❖ This section states that all compressed gas container, cylinder and tank valves must be protected from physical damage in accordance with Sections 5303.6.1 and 5303.6.2. Avoiding damage to the cylinder valves is extremely important because such damage could result in the cylinder being propelled by the sudden release of its contents, which are under high pressure.

**5303.6.1 Compressed gas container, cylinder or tank protective caps or collars.** *Compressed gas* containers, cylinders and tanks designed for protective caps, collars or other protective devices shall have the caps or devices in place except when the containers, cylinders or tanks are in use or are being serviced or filled.

❖ Valve protection designed into the container, cylinder or tank by the manufacturer is the best means to prevent damage that could result in a “rocketing cylinder” scenario. When the design of gas containers, cylinders or tanks includes protective caps, collars or other protective devices, it only makes sense that these devices must be in place, except when servicing or filling the container, cylinder or tank makes it impractical.

**5303.6.2 Caps and plugs.** Compressed gas containers, cylinders and tanks designed for valve protection caps or other

protective devices shall have the caps or devices in place. When outlet caps or plugs are installed, they shall be in place.

**Exception:** *Compressed gas* containers, cylinders or tanks in use, being serviced or being filled.

❖ As stated in the commentary to Section 5303.6.1, in gas containers, cylinders and tanks that are designed to include valve protection caps or other protective devices, these devices must be tightly in place except when the container, cylinder or tank is in use or connected for use.

**5303.7 Separation from hazardous conditions.** *Compressed gas* containers, cylinders and tanks and systems in storage or use shall be separated from materials and conditions that pose exposure hazards to or from each other. *Compressed gas* containers, cylinders, tanks and systems in storage or use shall be separated in accordance with Sections 5303.7.1 through 5303.7.11.2.

❖ This section recognizes the danger of improperly storing materials, which can pose an exposure hazard to surrounding materials. Compressed gas containers, cylinders and tanks must, therefore, be separated in accordance with Sections 5303.7.1 through 5303.7.11.2.

**5303.7.1 Incompatible materials.** *Compressed gas* containers, cylinders and tanks shall be separated from each other based on the hazard class of their contents. *Compressed gas* containers, cylinders and tanks shall be separated from *incompatible materials* in accordance with Section 5003.9.8.

❖ Separating gas systems to minimize exposures is one of the simplest safeguards to implement. Section 5003.9.8 provides the minimum separation requirements for incompatible materials (see commentary, Section 5003.9.8).

**5303.7.2 Combustible waste, vegetation and similar materials.** Combustible waste, vegetation and similar materials

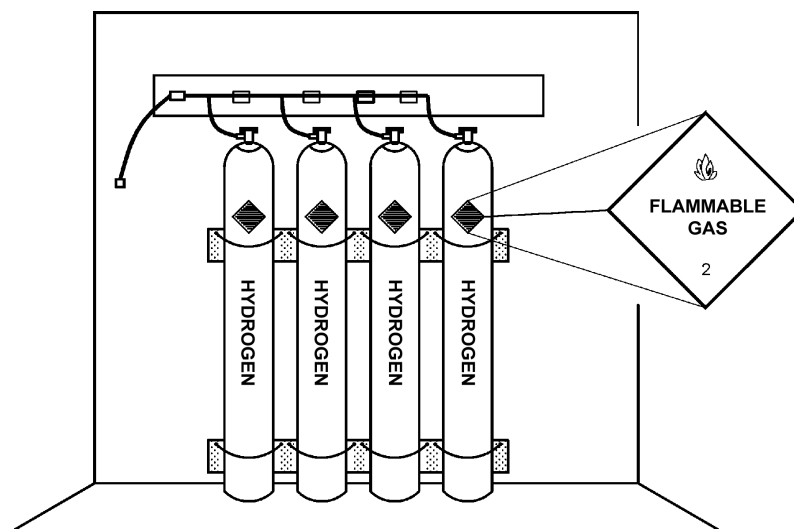

Figure 5303.4.1  
STORAGE AND LABELING OF CYLINDERS

shall be kept not less than 10 feet (3048 mm) from *compressed gas* containers, cylinders, tanks and systems. A non-combustible partition, without openings or penetrations and extending not less than 18 inches (457 mm) above and to the sides of the storage area is allowed in lieu of such distance. The wall shall either be an independent structure, or the exterior wall of the building adjacent to the storage area.

❖ This section indicates that combustible waste, vegetation and similar materials must be kept at least 10 feet (3048 mm) from compressed gas containers, cylinders and tanks because external fires involving accumulated combustibles can cause such vessels to fail. This section does permit a noncombustible partition instead of the 10-foot (3048 mm) requirement, provided the partition has no openings or penetrations and extends at least 18 inches (457 mm) above and 18 inches (457 mm) beyond the sides of the storage area. The partition must be an independent structure or may be an exterior wall of a building adjacent to the storage area. Note that no fire-resistance rating for this partition is required, only a stipulation that it be constructed of noncombustible materials.

**5303.7.3 Ledges, platforms and elevators.** *Compressed gas* containers, cylinders and tanks shall not be placed near elevators, unprotected platform ledges or other areas where falling would result in *compressed gas* containers, cylinders or tanks being allowed to drop distances exceeding one-half the height of the container, cylinder or tank.

❖ This section addresses concerns about gas containers, cylinders and tanks being damaged by a fall. Gas containers, cylinders and tanks cannot be placed on platform ledges, elevators and other areas where the container, if dropped, would fall more than one-half the height of the container.

**5303.7.4 Temperature extremes.** *Compressed gas* containers, cylinders and tanks, whether full or partially full, shall not be exposed to artificially created high temperatures exceeding 125°F (52°C) or subambient (low) temperatures unless designed for use under the exposed conditions.

❖ This section identifies the limits of the temperature extremes to which gas containers, cylinders and tanks can be exposed without creating a danger of the possibility of catastrophic failure. The section also recognizes the added safety of gas containers, cylinders and tanks that are designed to be used beyond the indicated limitations.

**5303.7.5 Falling objects.** *Compressed gas* containers, cylinders, tanks and systems shall not be placed in areas where they are capable of being damaged by falling objects.

❖ This section is similar in intent to Section 5303.5.2 for the physical protection of gas containers, cylinders and tanks, except this section addresses falling objects, which could cause physical damage.

**5303.7.6 Heating.** *Compressed gas* containers, cylinders and tanks, whether full or partially full, shall not be heated by devices that could raise the surface temperature of the con-

tainer, cylinder or tank to above 125°F (52°C). Heating devices shall comply with the *International Mechanical Code* and NFPA 70. *Approved* heating methods involving temperatures of less than 125°F (52°C) are allowed to be used by trained personnel. Devices designed to maintain individual *compressed gas* containers, cylinders or tanks at constant temperature shall be *approved* and shall be designed to be fail-safe.

❖ This section requires that any heating devices comply with the *International Mechanical Code*® (IMC®) and NFPA 70. It also requires that heating devices be used only by trained personnel and be designed to be fail-safe.

**5303.7.7 Sources of ignition.** Open flames and high-temperature devices shall not be used in a manner that creates a hazardous condition.

❖ Controlling ignition sources around compressed gas is both very important and somewhat difficult. This section addresses open flames and high-temperature devices. These ignition sources should be used only when necessary and by trained personnel, provided adequate safeguards are in place.

**5303.7.8 Exposure to chemicals.** *Compressed gas* containers, cylinders, tanks and systems shall not be exposed to *corrosive* chemicals or fumes that could damage containers, cylinders, tanks, valves or valve-protective caps.

❖ This section requires protection against corrosive chemicals or fumes that could cause damage to the container or valves and valve caps.

**5303.7.9 Exhausted enclosures.** Where exhausted enclosures are provided as a means to segregate *compressed gas* containers, cylinders and tanks from exposure hazards, such enclosures shall comply with the requirements of Section 5003.8.5.

❖ Exhausted enclosures, as defined in Section 5002.1, are one means of isolating compressed gas containers from hazardous conditions. When such equipment is utilized, performance requirements are needed and may be found in Section 5003.8.5.

**5303.7.10 Gas cabinets.** Where gas cabinets are provided as a means to separate *compressed gas* containers, cylinders and tanks from exposure hazards, such gas cabinets shall comply with the requirements of Section 5003.8.6.

❖ Gas cabinets, as defined in Section 202, are one means of isolating compressed gas containers from hazardous conditions. When such equipment is utilized, performance requirements are needed and may be found in Section 5003.8.6.

**5303.7.11 Tube trailers.** Tube trailers, including those containing compatible *compressed gases*, shall be surrounded by a clear space of not less than 3 feet (914 mm) to allow for maintenance, access and inspection.

❖ This section presents minimum requirements for siting one or more tube trailers (see Commentary Figure 5303.7.11) in an industrial plant or another setting

for the supply of compressed gases. It also provides requirements for installations at a single location delivering several compressed gases using multiple tube trailers.

A minimum clear space must be provided between tube trailers, and between tube trailers and other objects, including buildings, to allow for the access and passage of personnel involved in activities associated with the servicing and use of the trailer. At filling plants, operators must access the vehicles for maintenance and service-related work, and at user locations, access is needed to allow users unimpeded movement, including access and egress. A clear space of 36 inches (914 mm) has been selected to accommodate a “person width” of 22 inches (559 mm) while addressing the fact that there could be service-related connections or fittings that require the trailer to be attended. This is similar to Section 2306.2.6, which requires a 3-foot (914 mm) clearance around flammable liquid tanks when installed in a special enclosure inside of buildings to allow for access and maintenance.

It should also be noted that these minimum clearance requirements do not supercede or replace distances from storage to exposures contained in other chapters of the code. Siting of tube trailers will be based on the hazard classification of the compressed gas. For example, consider a six-pack tube trailer of compressed methane, a flammable gas regulated by Chapter 58, with each tube having a rated volume of 10,000 standard cubic feet (scf) (283 m<sup>3</sup>) at a design pressure of 3,000 pounds per square inch gauge (psig) (20 613 kPa) for a total volume of 60,000 scf (1699 m<sup>3</sup>). In this example, the application of Table 5804.2.1 would result in the following minimum distances from the tube trailer to exposures:

**MINIMUM DISTANCE:**

- Between storage areas: 10 feet (3048 mm).
- To lot lines of property that can be built upon: 20 feet (6096 mm).
- To public streets, public alleys or public ways: 20 feet (6096 mm).

**Figure 5303.7.11  
TUBE TRAILER**

**MINIMUM DISTANCE TO BUILDINGS ON THE SAME PROPERTY:**

- To nonrated construction or opening within 25 feet (7620 mm):  
20 feet (6096 mm).
- To 2-hour construction and no openings within 25 feet (7620 mm):  
5 feet (1524 mm).
- To 4-hour construction and no openings within 25 feet (7620 mm):  
0 feet (0 mm).

**5303.7.11.1 Individual tube trailers containing incompatible materials.** Increased separation distances between individual tube trailers containing incompatible gases shall be provided where required by Section 5303.7.1.

❖ See the commentary to the Section 202 definition of “Tube trailer,” and the commentary to Sections 5003.9.8 and 5303.7.1.

**5303.7.11.2 Connections.** Piping systems used to connect tube trailers to a user piping system shall not be viewed as an encroachment into the 3-foot (914 mm) clear space.

❖ This section clarifies that the 3-foot (914 mm) clearance in Section 5303.7.11 is to be measured from a building or object to the tube trailer itself. The extension of any piping system to the tube trailer is not viewed as an encroachment on the clearance otherwise required.

**5303.8 Wiring and equipment.** Electrical wiring and equipment shall comply with NFPA 70. *Compressed gas* containers, cylinders, tanks and systems shall not be located where they could become part of an electrical circuit. *Compressed gas* containers, cylinders, tanks and systems shall not be used for electrical grounding.

❖ This section requires that any electrical wiring and equipment comply with NFPA 70. It further requires that no compressed gas containers, cylinders or tanks be placed where they could become part of an electrical circuit. Cylinders and systems cannot be part of any electrical grounding system.

**5303.9 Service and repair.** Service, repair, modification or removal of valves, pressure-relief devices or other *compressed gas* container, cylinder or tank appurtenances shall be performed by trained personnel.

❖ This section requires individuals who service, repair or modify gas containers, cylinders and tanks, or tank appurtenances to be fully trained in the particular function they are performing.

**5303.10 Unauthorized use.** *Compressed gas* containers, cylinders, tanks and systems shall not be used for any purpose other than to serve as a vessel for containing the product that it is designed to contain.

❖ This section requires that gas containers, cylinders and tanks hold only the product they were designed to contain. These containers, cylinders and tanks may not be used for any other purpose. This section

prohibits the filling of a gas container, cylinder or tank with a gas for which it was not designed.

**5303.11 Exposure to fire.** *Compressed gas* containers, cylinders and tanks that have been exposed to fire shall be removed from service. Containers, cylinders and tanks so removed shall be handled by *approved*, qualified persons.

❖ This section requires any gas containers, cylinders and tanks that have been exposed to fire to be removed from service and be handled only by qualified persons. This is especially important because the container may still be under pressure.

**5303.12 Leaks, damage or corrosion.** Leaking, damaged or corroded *compressed gas* containers, cylinders and tanks shall be removed from service. Leaking, damaged or corroded *compressed gas* systems shall be replaced or repaired in accordance with the following:

1. *Compressed gas* containers, cylinders and tanks that have been removed from service shall be handled in an *approved* manner.
2. *Compressed gas* systems that are determined to be leaking, damaged or corroded shall be repaired to a serviceable condition or removed from service.

❖ Leaking, damaged or corroded gas containers, cylinders and tanks must be removed from service and be replaced or repaired in accordance with Items 1 and 2 of this section. Damaged gas containers, cylinders and tanks pose a potential content-release hazard. Care must be taken to determine that disposal does not present a greater hazard than the damaged container. Small gas containers, cylinders and tanks usually cannot be repaired easily. Large gas containers, cylinders and tanks, and fixed tank installations, often cannot be easily replaced and must be repaired. Temporary storage of materials during the repair of these gas containers, cylinders and tanks must comply with code requirements.

**5303.13 Surface of unprotected storage or use areas.** Unless otherwise specified in Section 5303.14, *compressed gas* containers, cylinders and tanks are allowed to be stored or used without being placed under overhead cover. To prevent bottom corrosion, containers, cylinders and tanks shall be protected from direct contact with soil or unimproved surfaces. The surface of the area on which the containers are placed shall be graded to prevent accumulation of water.

❖ This section requires that adequate protection be provided to prevent bottom corrosion of the container from direct contact with soil or unimproved surfaces. Grading is also required to eliminate the accumulation of water in the container storage area to prevent the container bottoms from being immersed. Overhead cover is not required unless extreme temperatures are present. Section 5303.14 addresses overhead protection.

**5303.14 Overhead cover.** *Compressed gas* containers, cylinders and tanks are allowed to be stored or used in the sun except in locations where extreme temperatures prevail.

Where extreme temperatures prevail, overhead covers shall be provided.

❖ This section requires that overhead cover be provided when extreme temperatures exist. Many of these structures are constructed as an attached canopy to provide ready access to materials. IBC Section 414.6 prescribes construction requirements applicable to weather protection for hazardous materials.

**5303.15 Lighting.** *Approved* lighting by natural or artificial means shall be provided.

❖ Lighting sufficient for good visibility must be maintained at all times in both inside and outside areas. Natural light for outdoor areas may be sufficient where operations are limited to daylight hours.

**5303.16 Vaults.** Generation, compression, storage and dispensing equipment for *compressed gases* shall be allowed to be located in either above- or below-grade vaults complying with Sections 5303.16.1 through 5303.16.14.

❖ This section extends the permissible use of vaults to include gaseous materials. The code previously allowed vaults to be used for the protection of all hazardous material liquids, but the protection features have been modified for inclusion in Chapter 53 to accommodate the protection of compressed gases. The provisions of the section are derived from Section 5704.2.8, which regulates vaults used for flammable and combustible liquids. The code has previously allowed gases to be stored and handled inside of buildings, and it is also appropriate to allow gas storage and handling equipment to be in vaults, given that a vault environment is unoccupied and offers fewer possible accident scenarios.

**5303.16.1 Listing required.** Vaults shall be *listed* by a nationally recognized testing laboratory.

**Exception:** Where *approved* by the *fire code official*, below-grade vaults are allowed to be constructed on site, provided that the design is in accordance with the *International Building Code* and that special inspections are conducted to verify structural strength and compliance of the installation with the *approved* design in accordance with Section 1707 of the *International Building Code*. Installation plans for below-grade vaults that are constructed on site shall be prepared by, and the design shall bear the stamp of, a professional engineer. Consideration shall be given to soil and hydrostatic loading on the floors, walls and lid; anticipated seismic forces; uplifting by ground water or flooding; and to loads imposed from above, such as traffic and equipment loading on the vault lid.

❖ Where prefabricated vaults are used, they must be listed by a testing laboratory experienced in evaluating such design and construction. While this section does not reference any particular standard to which a vault is to be listed, UL 2245 is the referenced standard in Section 5704.2.8.1 for vaults containing flammable or combustible liquid tanks and could be used to provide guidance to the fire code official.

The exception recognizes that vaults may also be site-built, provided that they are approved by the fire code official. Site-built vaults must be designed by a qualified design professional to comply with IBC Chapter 16, and the construction is to be overseen with special inspections conducted in accordance with IBC Chapter 17. Flood hazard areas are defined in IBC Section 202.

**5303.16.2 Design and construction.** The vault shall completely enclose generation, compression, storage or dispensing equipment located in the vault. There shall not be openings in the vault enclosure except those necessary for vault ventilation and access, inspection, filling, emptying or venting of equipment in the vault. The walls and floor of the vault shall be constructed of reinforced concrete not less than 6 inches (152 mm) thick. The top of an above-grade vault shall be constructed of noncombustible material and shall be designed to be weaker than the walls of the vault to ensure that the thrust of any explosion occurring inside the vault is directed upward.

The top of an at- or below-grade vault shall be designed to relieve safely or contain the force of an explosion occurring inside the vault. The top and floor of the vault and the tank foundation shall be designed to withstand the anticipated loading, including loading from vehicular traffic, where applicable. The walls and floor of a vault installed below grade shall be designed to withstand anticipated soil and hydrostatic loading. Vaults shall be designed to be wind and earthquake resistant, in accordance with the *International Building Code*.

❖ The vault is to be of noncombustible materials with openings required only for the operation and maintenance of the equipment it contains. In order to provide structural integrity, thermal exposure protection and equipment physical protection, reinforced concrete is to be used for the walls and floor. The vault top for above-grade vaults is required only to be constructed of noncombustible materials and must be designed to vent the forces of an explosion. If the vault is constructed such that the top is located below grade, or is subject to vehicular traffic, then the top must be designed to withstand vehicle loads and also contain the forces of an explosion. The structural design of the vault must also comply with IBC Chapter 16 for wind and earthquake loads, as applicable.

**5303.16.3 Secondary containment.** Vaults shall be substantially liquid-tight and there shall not be backfill within the vault. The vault floor shall drain to a sump. For premanufactured vaults, liquid tightness shall be certified as part of the listing provided by a nationally recognized testing laboratory. For field-erected vaults, liquid tightness shall be certified in an *approved* manner.

❖ The vault is to function as secondary containment for the tank in the event of a leak or spillage. Any leakage or spillage must be removed by draining to a sump in the vault floor. Premanufactured vaults are required to be listed; during this listing process, an analysis program is performed that includes an evalu-

ation of the effectiveness of secondary containment provided by a vault. It is much more difficult to accomplish a liquid-tight installation on a field-erected vault, as evidenced by the proliferation of leaky basements found throughout the country; therefore, to enhance the quality of field-erected vaults, such units must be certified for liquid tightness to the satisfaction of the fire code official. Methods that might be used include third-party inspection/evaluation and full-scale liquid retention testing.

**5303.16.4 Internal clearance.** There shall be sufficient clearance within the vault to allow for visual inspection and maintenance of equipment in the vault.

❖ Maintenance and inspection of the tank requires that the clearance between the tank and the vault be sufficient for personnel to perform these functions.

**5303.16.5 Anchoring.** Vaults and equipment contained therein shall be suitably anchored to withstand uplifting by groundwater or flooding. The design shall verify that uplifting is prevented even where equipment within the vault is empty.

❖ The tank and the vault may float if the water table is high or flooding occurs. The tank is to be anchored to the vault to prevent the tank from floating while the vault is also to be anchored to prevent it, in turn, from floating. Flood hazard areas are defined in IBC Section 202.

**5303.16.6 Vehicle impact protection.** Vaults shall be resistant to damage from the impact of a motor vehicle, or vehicle impact protection shall be provided in accordance with Section 312.

❖ Protection from the impact of vehicles is provided by guard posts or other approved barriers. Section 312 contains the specifications for guard posts or the design forces required for an approved barrier to comply with the code. Protection from vehicle impact is also required under Section 5303.5.2.

**5303.16.7 Arrangement.** Equipment in vaults shall be *listed* or *approved* for above-ground use. Where multiple vaults are provided, adjacent vaults shall be allowed to share a common wall. The common wall shall be liquid and vapor tight and shall be designed to withstand the load imposed when the vault on either side of the wall is filled with water.

❖ Tanks and equipment designed for underground use typically rely upon proper backfilling and burial in soil for their structural support and stability; therefore, tanks and equipment installed in the vault must be appropriate for above-ground use since there will be no backfill to provide support. Equipment and tanks installed in vaults are to be independent of each other and a separate vault is to be constructed for each. The individual vaults are allowed to use a common separation wall if it does not allow the gases from one vault to enter an adjacent vault. This common wall must be able to structurally resist the hydrostatic loads if the adjacent vault is flooded.

**5303.16.8 Connections.** Connections shall be provided to permit the venting of each vault to dilute, disperse and remove vapors prior to personnel entering the vault.

❖ In order to provide a safe environment for inspection or repair personnel to operate inside the vault, openings must be provided to facilitate the purging of harmful or oxygen-depleting inert gases from the vault prior to entry.

**5303.16.9 Ventilation.** Vaults shall be provided with an exhaust ventilation system installed in accordance with Section 5004.3. The ventilation system shall operate continuously or be designed to operate upon activation of the vapor or liquid detection system. The system shall provide ventilation at a rate of not less than 1 cubic foot per minute (cfm) per square foot [ $0.00508 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of floor area, but not less than 150 cfm (4  $\text{m}^3/\text{min}$ ). The exhaust system shall be designed to provide air movement across all parts of the vault floor for gases having a density greater than air and across all parts of the vault ceiling for gases having a density less than air. Supply ducts shall extend to within 3 inches (76 mm), but not more than 12 inches (305 mm), of the floor. Exhaust ducts shall extend to within 3 inches (76 mm), but not more than 12 inches (305 mm) of the floor or ceiling, for heavier-than-air or lighter-than-air gases, respectively. The exhaust system shall be installed in accordance with the *International Mechanical Code*.

❖ The removal of hazardous gases from a vault requires that a ventilation system be installed in accordance with Section 5004.3 and the IMC. The ventilation system must have supply and exhaust ducts 3 to 12 inches (76 to 305 mm) from the vault floor. These ducts are to provide ventilation across the entire vault floor to allow air movement across the lowest part of the vault where heavier-than-air gases could settle, remove them and provide breathable air.

**5303.16.10 Monitoring and detection.** Vaults shall be provided with *approved* vapor and liquid detection systems and equipped with on-site audible and visual warning devices with battery backup. Vapor detection systems shall sound an alarm when the system detects vapors that reach or exceed 25 percent of the lower explosive limit (LEL) or one-half the immediately dangerous to life and health (IDLH) concentration for the gas in the vault. Vapor detectors shall be located not higher than 12 inches (305 mm) above the lowest point in the vault for heavier-than-air gases and not lower than 12 inches (305 mm) below the highest point in the vault for lighter-than-air gases. Liquid detection systems shall sound an alarm upon detection of any liquid, including water. Liquid detectors shall be located in accordance with the manufacturers' instructions. Activation of either vapor or liquid detection systems shall cause a signal to be sounded at an *approved*, constantly attended location within the facility served by the tanks or at an *approved* location. Activation of vapor detection systems shall also shut off gas-handling equipment in the vault and dispensers.

❖ The vault is to have liquid and vapor detection systems that sound an alarm when either is present in

the quantities specified. The systems should have battery backup in the event of a power failure, and are to sound an alarm on the premises at a constantly attended location that is approved by the fire code official (see commentary to the Section 202 definition of "Constantly attended location").

**5303.16.11 Liquid removal.** Means shall be provided to recover liquid from the vault. Where a pump is used to meet this requirement, it shall not be permanently installed in the vault. Electric-powered portable pumps shall be suitable for use in Class I, Division I locations, as defined in NFPA 70.

❖ A method for removing liquid from the vault must be provided. This can be a gravity drain, if the site is appropriate, or manual or portable electric pumps suitable for use in hazardous locations.

**5303.16.12 Relief vents.** Vent pipes for equipment in the vault shall terminate not less than 12 feet (3658 mm) above ground level.

❖ Vent pipes must be terminated so as to direct gases and vapors into the airstream and away from the vault and any nearby buildings. Some compressed gases are normally heavier than air so they will settle to lower levels. The termination of a vent pipe, a minimum of 12 feet (3658 mm) above grade, will provide space for the gases to disperse to below the lower flammable limit (LFL). This high termination elevation also reduces the potential for the termination being close to grade-level ignition sources. The design features of nearby buildings that may allow hazardous gases to reenter the building or to collect on the building are to be avoided.

**5303.16.13 Accessway.** Vaults shall be provided with an *approved* personnel accessway with a minimum dimension of 30 inches (762 mm) and with a permanently affixed, nonferrous ladder. Accessways shall be designed to be nonsparking. Travel distance from any point inside a vault to an accessway shall not exceed 20 feet (6096 mm). At each entry point, a warning sign indicating the need for procedures for safe entry into confined spaces shall be posted. Entry points shall be secured against unauthorized entry and vandalism.

❖ Access to the vault must have a minimum dimension of 30 inches (762 mm) for ease of personnel passage. Because there is the possibility of hazardous and potentially flammable gases in the vault, the accessway and ladder are to be constructed of *approved*, nonsparking material. Since gases can replace the air in a vault, for personnel safety, the travel distance is limited and warning signs must be posted to remind personnel of the potential hazards.

**5303.16.14 Classified area.** The interior of a vault containing a flammable gas shall be designated a Class I, Division I location, as defined in NFPA 70.

❖ The interior of a vault storing flammable gas is classified as a Class 1, Division I hazardous electrical location, in accordance with NFPA 70 for determining the type of electrical system to be installed.

### SECTION 5304 STORAGE OF COMPRESSED GASES

**5304.1 Upright storage.** *Compressed gas* containers, cylinders and tanks, except those designed for use in a horizontal position, and all *compressed gas* containers, cylinders and tanks containing nonliquefied gases, shall be stored in an upright position with the valve end up. An upright position shall include conditions where the container, cylinder or tank axis is inclined as much as 45 degrees (0.80 rad) from the vertical.

#### Exceptions:

1. *Compressed gas* containers with a water volume less than 1.3 gallons (5 L) are allowed to be stored in a horizontal position.
  2. Cylinders, containers and tanks containing nonflammable gases, or cylinders, containers and tanks containing nonliquefied flammable gases that have been secured to a pallet for transportation purposes.
- ❖ Containers, cylinders or tanks designed to be used in the horizontal position with the valve end up and accessible are to be stored in an upright position, unless the conditions of one of the two listed exceptions are met. Exception 1 allows gas containers, cylinders and tanks with a water volume of less than 1.3 gallons (5 L) to be stored in the horizontal position. Exception 2 permits gas containers, cylinders and tanks containing nonflammable gases to be in the horizontal position when secured to a pallet for transportation.

**5304.2 Material-specific regulations.** In addition to the requirements of this section, indoor and outdoor storage of *compressed gases* shall comply with the material-specific provisions of Chapters 54, 58 and 60 through 67.

- ❖ In addition to meeting the requirements of this section, storage of compressed gases needs to comply with the material-specific provisions of Chapters 54, 58 and 60 through 67. For example, the storage and use of flammable gases must be in accordance with Chapter 58 in addition to the requirements of this section.

### SECTION 5305 USE AND HANDLING OF COMPRESSED GASES

**5305.1 Compressed gas systems.** *Compressed gas* systems shall be suitable for the use intended and shall be designed by persons competent in such design. *Compressed gas* equipment, machinery and processes shall be *listed* or *approved*.

- ❖ This section contains requirements for gas systems. A system includes stationary or movable gas containers, cylinders and tanks; pressure regulators; safety relief devices; manifolds; interconnecting piping; and controls. It is important that persons designing these systems be competent in this area. All equipment, machinery and processes need to be listed or approved for that particular use.

**5305.2 Controls.** *Compressed gas* system controls shall be designed to prevent materials from entering or leaving process or reaction systems at other than the intended time, rate or path. Automatic controls shall be designed to be fail safe.

- ❖ In designing the system controls, provisions must be made to prevent materials from escaping the system other than at the intended time. Automatic controls must be designed so that they are fail safe to provide safe conditions when personnel are not present.

**5305.3 Piping systems.** Piping, including tubing, valves, fittings and pressure regulators, shall comply with this section and Chapter 50. Piping, tubing, pressure regulators, valves and other apparatus shall be kept gas tight to prevent leakage.

- ❖ All apparatus, connected and part of the system, shall comply with this section and Chapter 50. Proper maintenance of all the components ensures that gas leaks are prevented.

**5305.4 Valves.** Valves utilized on *compressed gas* systems shall be suitable for the use intended and shall be accessible. Valve handles or operators for required shutoff valves shall not be removed or otherwise altered to prevent access.

- ❖ This section is intended to provide adequate safeguards for valves. Valves are to be employed solely for the use for which they were designed. They must be accessible and must not be removed or altered to prevent access.

**5305.5 Venting.** Venting of gases shall be directed to an *approved* location. Venting shall comply with the *International Mechanical Code*.

- ❖ This section indicates that gases must be vented to an approved location. It refers the user to the IMC to ensure compliance with venting requirements.

**5305.6 Upright use.** *Compressed gas* containers, cylinders and tanks, except those designed for use in a horizontal position, and all *compressed gas* containers, cylinders and tanks containing nonliquefied gases, shall be used in an upright position with the valve end up. An upright position shall include conditions where the container, cylinder or tank axis is inclined as much as 45 degrees (0.80 rad) from the vertical. Use of nonflammable liquefied gases in the inverted position where the liquid phase is used shall not be prohibited provided that the container, cylinder or tank is properly secured and the dispensing apparatus is designed for liquefied gas use.

**Exception:** *Compressed gas* containers, cylinders and tanks with a water volume less than 1.3 gallons (5 L) are allowed to be used in a horizontal position.

- ❖ This section has some of the general requirements found in Section 5304.1. Unless the container is designed to be used in the horizontal position, it must be in the upright position with the valve end up and accessible. In a gas system, the container may be in the inverted position when using nonflammable liquefied gases, provided that the container is secured and the dispensing apparatus is designed for liquefied gas use. Exception 1 to Section 5304.1 also applies

here: if the container has a water volume less than 1.3 gallons (5 L), it may be used in the horizontal position.

**5305.7 Transfer.** Transfer of gases between containers, cylinders and tanks shall be performed by qualified personnel using equipment and operating procedures in accordance with CGA P-1.

**Exception:** The fueling of vehicles with CNG or CH<sub>2</sub>, conducted in accordance with Chapter 23.

❖ In order to increase the likelihood that the inherent hazards involved in the transfer of compressed gases between gas containers, cylinders and tanks are mitigated, this section requires that only qualified personnel, using equipment and procedures in accordance with CGA P-1, execute the transfer. The exception to this occurs when fueling vehicles with compressed natural gas (CNG) or compressed hydrogen gas, provided that the fueling is conducted in accordance with the applicable provisions of Chapter 23 of the code.

**5305.8 Use of compressed gas for inflation.** Inflatable equipment, devices or balloons shall only be pressurized or filled with compressed air or inert gases.

❖ This section permits inflatable items, such as balloons, to be pressurized with compressed air or an inert gas only.

**5305.9 Material-specific regulations.** In addition to the requirements of this section, indoor and outdoor use of *compressed gases* shall comply with the material-specific provisions of Chapters 54, 58 and 60 through 67.

❖ In addition to the requirements of this section, storage of compressed gases must comply with the material-specific provisions of Chapters 54, 58 and 60 through 67. For example, the storage and use of a flammable gas system must comply with Chapter 58 in addition to the requirements of this section.

**5305.10 Handling.** The handling of *compressed gas* containers, cylinders and tanks shall comply with Sections 5305.10.1 and 5305.10.2.

❖ The requirements of Sections 5303.10.1 and 5305.10.2 are specific for handling gas containers, cylinders and tanks.

**5305.10.1 Carts and trucks.** Containers, cylinders and tanks shall be moved using an *approved* method. Where containers, cylinders or tanks are moved by hand cart, hand truck or other mobile device, such carts, trucks or devices shall be designed for the secure movement of containers, cylinders or tanks. Carts and trucks utilized for transport of *compressed gas* containers, cylinders and tanks within buildings shall comply with Section 5003.10. Carts and trucks utilized for transport of *compressed gas* containers, cylinders and tanks exterior to buildings shall be designed so that the containers, cylinders and tanks will be secured against dropping or otherwise striking against each other or other surfaces.

❖ This section contains regulations for moving gas containers, cylinders and tanks with carts and trucks.

When carts or trucks are used inside buildings, they must also comply with Section 5003.10. The potential release of gas is greatly increased during the handling process. A leak caused by improper handling, such as dropping a container, striking containers against each other or striking a container on another surface, poses a potential hazard to persons and property. Proper handling of the containers greatly reduces this risk.

**5305.10.2 Lifting devices.** Ropes, chains or slings shall not be used to suspend *compressed gas* containers, cylinders and tanks unless provisions at time of manufacture have been made on the container, cylinder or tank for appropriate lifting attachments, such as lugs.

❖ This section states that, in order to be suspended by ropes, chains or slings, compressed gas containers, cylinders and tanks must be fitted with lifting attachments at the time of manufacture.

## SECTION 5306 MEDICAL GASES

**5306.1 General.** Medical gases at health care-related facilities intended for patient care, inhalation or sedation including, but not limited to, analgesia systems for dentistry, podiatry, veterinary and similar uses shall comply with Sections 5306.2 through 5306.4 in addition to other requirements of this chapter.

❖ Compressed gases used in healthcare-related facilities include oxygen, nitrogen and nitrogen oxides, carbon dioxide and other gases that pose a variety of hazards if not handled and stored properly. Oxygen, for example, represents both a fire and an explosion hazard. Nitrogen oxides are useful for sedation, but in uncontrolled amounts in a confined space can asphyxiate an unknowing occupant. The remainder of these sections are intended to minimize hazards by setting the requirements for storage and supply locations. Note that the use of the phrase “healthcare-related facilities” indicates the intent that these provisions apply to not only hospitals but also to nursing homes and ambulatory care facilities.

**5306.2 Interior supply location.** Medical gases shall be stored in areas dedicated to the storage of such gases without other storage or uses. Where containers of medical gases in quantities greater than the permit amount are located inside buildings, they shall be in a 1-hour exterior room, a 1-hour interior room or a gas cabinet in accordance with Section 5306.2.1, 5306.2.2 or 5306.2.3, respectively. Rooms or areas where medical gases are stored or used in quantities exceeding the *maximum allowable quantity per control area* as set forth in Section 5003.1 shall be in accordance with the *International Building Code* for high-hazard Group H occupancies.

❖ This section states that medical gases must be stored in dedicated areas not used for other storage or any other purpose. Where medical gases are stored

inside buildings in quantities greater than the permit amount indicated in Table 105.6.9, they are required to be in a 1-hour exterior room, in a 1-hour interior room or a gas cabinet in accordance with Section 5306.2.1, 5306.2.2 or 5306.2.3.

The section also makes it clear that where hazardous gases are stored or used in quantities in excess of the maximum allowable quantity per control area (MAQ), the storage room must be constructed as an appropriate Group H area in accordance with the IBC.

**5306.2.1 One-hour exterior rooms.** A 1-hour exterior room shall be a room or enclosure separated from the remainder of the building by *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or horizontal assemblies constructed in accordance with Section 711 of the *International Building Code*, or both, with a *fire-resistance rating* of not less than 1 hour. Openings between the room or enclosure and interior spaces shall be self-closing smoke- and draft-control assemblies having a *fire protection rating* of not less than 1 hour. Rooms shall have not less than one exterior wall that is provided with not less than two nonclosable louvered vents. Each vent shall have a minimum free opening area of 24 square inches (155 cm<sup>2</sup>) for each 1,000 cubic feet (28 m<sup>3</sup>) at normal temperature and pressure (NTP) of gas stored in the room and shall be not less than 72 square inches (465 cm<sup>2</sup>) in aggregate free opening area. One vent shall be within 6 inches (152 mm) of the floor and one shall be within 6 inches (152 mm) of the ceiling. Rooms shall be provided with not less than one automatic sprinkler to provide container cooling in case of fire.

❖ This section contains specific construction, ventilation and suppression requirements for exterior rooms that contain medical gases in quantities greater than the permit amount indicated in Table 105.6.9. All openings between medical gas storage rooms and building interior spaces are required to be protected by self-closing smoke- and fire-rated assemblies to maintain separate airspaces. Even automatic-closing assemblies, which close on detection of fire or smoke, are not allowed since they cause the airspaces to be normally connected. The purpose of keeping airspaces separate is to prevent gas that may escape from a leak in the medical gas room from migrating into other areas of the building. These requirements are consistent with those of NFPA 99 and NFPA 101 used by the federal Centers for Medicare Services (CMS) for healthcare facility licensure.

**5306.2.2 One-hour interior room.** Where an exterior wall cannot be provided for the room, automatic sprinklers shall be installed within the room. The room shall be exhausted through a duct to the exterior. Supply and exhaust ducts shall be enclosed in a 1-hour-rated shaft enclosure from the room to the exterior. *Approved* mechanical ventilation shall comply with the *International Mechanical Code* and be provided at a

minimum rate of 1 cubic foot per minute per square foot [0.00508 m<sup>3</sup>/(s · m<sup>2</sup>)] of the area of the room.

❖ This section contains specific construction, ventilation and suppression requirements for interior rooms that contain medical gases in quantities greater than the permit amount indicated in Table 105.6.9.

**5306.2.3 Gas cabinets.** Gas cabinets shall be constructed in accordance with Section 5003.8.6 and the following:

1. The average velocity of ventilation at the face of access ports or windows shall be not less than 200 feet per minute (1.02 m/s) with not less than 150 feet per minute (0.76 m/s) at any point of the access port or window.
2. They shall be connected to an exhaust system.
3. They shall be internally sprinklered.

❖ This section contains specific requirements for the construction of gas cabinets that contain medical gases in quantities greater than the permit amount indicated in Table 105.6.8. These requirements are in addition to those contained in Section 5003.8.6. The cabinet ventilation system must be designed to operate at a negative pressure and be connected to an exhaust system to maintain a safe atmosphere inside the room in the event of a leak, especially during the normal opening and closing of the cabinet. Additionally, the section requires that gas cabinets be protected with an internal automatic sprinkler system to provide cooling of the gas cylinders housed in the cabinet in the event of a fire that is outside of the cabinet. Other types of extinguishing systems are prohibited.

**5306.3 Exterior supply locations.** Oxidizer medical gas systems located on the exterior of a building with quantities greater than the permit amount shall be located in accordance with Section 6304.2.1.

❖ This section requires compliance with Section 6304.2.1 for oxidizer medical gas systems located on the exterior of the building in amounts greater than permitted in Table 105.6.9 (see commentary, Section 6304.2.1).

**5306.4 Transfilling.** Transfilling areas and operations including, but not limited to, ventilation and separation, shall comply with NFPA 99.

❖ Transfilling is the transfer of oxygen to smaller portable containers from larger storage containers. This can occur in the liquid or gaseous state. The reference to NFPA 99 will provide restrictions on the construction of floors used in transfilling areas, limiting them to concrete or ceramic tile due to their noncombustible nature.

**5306.5 Medical gas systems.** Medical gas systems including, but not limited to, distribution piping, supply manifolds, connections, pressure regulators and relief devices and valves,

shall be installed in accordance with NFPA 99 and the general provisions of this chapter. Existing medical gas systems shall be maintained in accordance with the maintenance, inspection and testing provisions of NFPA 99 for medical gas systems.

- ❖ Compressed medical gas piping systems in hospitals and similar institutions may not be used to distribute flammable gases. Nonflammable compressed gas piping systems installed and used as detailed in NFPA 99 are permitted. Systems are to comply with the general, maintenance, inspection and testing provisions of this chapter and NFPA 99.

### SECTION 5307 CARBON DIOXIDE (CO<sub>2</sub>) SYSTEMS USED IN BEVERAGE DISPENSING APPLICATIONS

**5307.1 General.** Carbon dioxide systems with more than 100 pounds (45.4 kg) of carbon dioxide used in beverage dispensing applications shall comply with Sections 5307.2 through 5307.5.2.

- ❖ Several fatal carbon dioxide (CO<sub>2</sub>) poisoning (asphyxiation) incidents have occurred in restaurants where CO<sub>2</sub> leaked from large storage tanks and displaced oxygen in the area. CO<sub>2</sub> is an odorless and colorless gas with a vapor density of 1.53, making it 50 percent heavier than air. As such, the CO<sub>2</sub> will fill a room from the floor up and displace the oxygen in the room. Just a short exposure to a 10-percent concentration of CO<sub>2</sub> can be fatal. A 2-percent CO<sub>2</sub> concentration in air can increase the breathing rate by 50 percent and a 3-percent concentration can increase it by 100 percent. As the breathing rate increases, so does the amount of CO<sub>2</sub> being drawn into the person's system with the eventual results being headache, nausea, dizziness, disorientation, unconsciousness and death. The displacement of oxygen is more severe in smaller rooms or enclosures.

The intent of Section 5307 is to address locations, typically restaurants or other food service facilities, where liquefied CO<sub>2</sub> is used in conjunction with carbonators to produce carbonated beverages. CO<sub>2</sub> is stored as a compressed gas or a liquefied compressed gas but many larger restaurants are converting from gaseous CO<sub>2</sub> and taking advantage of liquefied CO<sub>2</sub> because the reduced container size and the reduced number of cylinders frees up valuable floor space. Note that CO<sub>2</sub> is not classified as a cryogenic fluid because its boiling point is -109°F.

A minimum trigger of more than 100 pounds was selected for these requirements because it was felt that systems with lesser amounts of CO<sub>2</sub> do not pose as great a risk of asphyxiation as large quantities of the gas.

**5307.2 Permits.** Permits shall be required as set forth in Section 105.6.

- ❖ Operational permits in accordance with Section 105.6.4 are required for CO<sub>2</sub> systems used in the beverage dispensing applications. See the commentary to Section 5301.2.

**5307.3 Equipment.** The storage, use, and handling of liquid carbon dioxide shall be in accordance with Chapter 53 and the applicable requirements of NFPA 55, Chapter 13. Insulated liquid carbon dioxide systems shall have pressure relief devices vented in accordance with NFPA 55.

- ❖ Components in compressed gas systems, including CO<sub>2</sub> systems, are required to comply with Chapter 53, which covers items such as pressure vessel and piping requirements, among others. An additional reference to NFPA 55, Chapter 13 addresses insulated liquid CO<sub>2</sub> systems in indoor and outdoor locations consisting of containers with a capacity of 1,000 pounds or less. The requirements address:

- Pressure relief devices.
- Pressure and level indicators.
- Piping systems including materials of construction.
- Operating instructions.

Some typical equipment are pictured in Commentary Figures 5307.3(1) and (2).

**Figure 5307.3(1)  
EXTERIOR FITTING TO FILL THE  
BULK CO<sub>2</sub> CYLINDER INSIDE THE BUILDING**

**Figure 5307.3(2)**  
**BULK CO<sub>2</sub> CYLINDER IN A**  
**CARBONATED BEVERAGE DISPENSING SYSTEM**

**5307.4 Protection from damage.** Carbon dioxide systems shall be installed so the storage tanks, cylinders, piping and fittings are protected from damage by occupants or equipment during normal facility operations.

❖ A CO<sub>2</sub> release can accumulate and displace oxygen, creating an asphyxiation hazard. To prevent a potential mishap, the CO<sub>2</sub> storage tanks, cylinders, piping, and fittings must be protected from physical damage. This section includes basic requirements intended to protect CO<sub>2</sub> storage tanks, cylinders, piping and fittings from damage by occupants or equipment during normal facility operations. This will decrease the chance of damage that may cause leaks, especially important in facilities where gas detection systems are not provided in accordance with Section 5307.5.2.

**5307.5 Required protection.** Where carbon dioxide storage tanks, cylinders, piping and equipment are located indoors, rooms or areas containing carbon dioxide storage tanks, cylinders, piping and fittings and other areas where a leak of carbon dioxide can collect shall be provided with either

ventilation in accordance with Section 5307.5.1 or an emergency alarm system in accordance with Section 5307.5.2.

❖ This section requires buildings in which the CO<sub>2</sub> systems are installed to be provided with either ventilation that complies with Section 5307.5.1 or an emergency alarm system that complies with Section 5307.5.2. It does not require that both ventilation and gas detection be provided. The hazard associated with these systems is that the heavier-than-air CO<sub>2</sub> may accumulate and displace oxygen, creating an asphyxiation hazard. Leaks are most likely to occur from fittings and connections, but could also be from plastic or other runs of piping.

**5307.5.1 Ventilation.** Mechanical ventilation shall be in accordance with the *International Mechanical Code* and shall comply with all of the following:

1. Mechanical ventilation in the room or area shall be at a rate of not less than 1 cubic foot per minute per square foot [0.00508 m<sup>3</sup>/(s • m<sup>2</sup>)].
2. Exhaust shall be taken from a point within 12 inches (305 mm) of the floor.
3. The ventilation system shall be designed to operate at a negative pressure in relation to the surrounding area.

❖ This section provides the requirements for mechanical ventilation when such is the chosen means of protection for CO<sub>2</sub> storage areas. The minimum ventilation rate of not less than 1 cubic foot per minute per square foot [0.00508 m<sup>3</sup>/(s • m<sup>2</sup>)] is a “standard” rate used for many applications throughout the code and the IMC. Since the room or area must be at a negative pressure to the surrounding areas to prevent any fugitive CO<sub>2</sub> from escaping the room, that “standard” rate may need to be adjusted upward to gain compliance. Though the exhaust system is not specifically required to be constantly in operation, such a precaution would be advisable due to the asphyxiation hazard that could arise in the event of an undetected CO<sub>2</sub> leak. The exhaust ventilation intakes must be located within 12 inches of the floor to allow the airflow to “sweep” the entire lowest part of the room, since CO<sub>2</sub> is heavier than air.

**5307.5.2 Emergency alarm system.** An emergency alarm system shall comply with all of the following:

1. Continuous gas detection shall be provided to monitor areas where carbon dioxide can accumulate.
2. The threshold for activation of an alarm shall not exceed 5,000 parts per million (9,000 mg/m<sup>3</sup>).
3. Activation of the emergency alarm system shall initiate a local alarm within the room or area in which the system is installed.

❖ As the second alternative provided by Section 5307.5, this section contains the requirements for an emergency alarm system consisting of continuous gas detection with CO<sub>2</sub> detectors of adequate number

and spacing to cover the protected area and a local alarm within the room where the CO<sub>2</sub> is stored. The emergency alarm trigger level of 5,000 parts per million (ppm) is the 8-hour time-weighted average (TWA) exposure limit for CO<sub>2</sub> established by the United States Department of Labor, Occupational Safety and Health Administration (OSHA) for CO<sub>2</sub>. This section also provides correlation with CGA-6.5 which, although not referenced in the code, is a national standard on the subject.

### SECTION 5308 COMPRESSED GASES NOT OTHERWISE REGULATED

**5308.1 General.** *Compressed gases* in storage or use not regulated by the material-specific provisions of Chapters 6, 54, 55 and 60 through 67, including asphyxiant, irritant and radioactive gases, shall comply with this section in addition to other requirements of this chapter.

❖ Statistics show that there are more deaths every year from the use of inert and asphyxiant gases than from toxic gases. The indoor storage or use of compressed gases falling into categories such as inert, asphyxiants, irritants and radioactive can be hazardous regardless of the type of gas involved simply due to the hazards related to asphyxiation. Sections 5301 through 5305 have been designed as generic provisions that apply to all compressed gases. Sections 5306 and 5307 are unique in that they establish additional requirements for specific uses. This section is intended to fill a void in the regulations of compressed gases by addressing compressed gases posing material hazards not otherwise regulated while not creating unnecessary additional material-specific chapters in the code. Note that this section requires that the storage and handling of cylinders containing the gases must comply with the remaining requirements of Chapter 53 because their contents are under positive pressure.

The question is often asked as to why the code does not include more comprehensive regulation of these “compressed gases not otherwise regulated.” Historically, the U.S. did not develop comprehensive hazardous materials regulations in the model building and fire codes until the mid-1980s. Prior to that time there were various regulations but they were not correlated, and more importantly, were not tied to a building’s occupancy classification, a material’s hazard classification or how the building was used. As a result, a task group was formed that worked on completely revising the legacy building and fire codes by creating comprehensive hazardous materials regulations.

Part of these early requirements included requirements for radioactive, asphyxiant and irritant gases. In recognition that some of these gases presented minimal risks, the codes reduced the requirements for irritant and asphyxiant gases. Later changes essentially

exempted radioactive gases since they are highly regulated in the U.S. at the state and federal level, and their requirements are driven by the isotope and its respective hazards.

At the time that the hazardous material regulations were being formulated, a number of fire code officials were concerned about a release of simple asphyxiant gases within a room in which they were being stored. Because simple asphyxiant gases are colorless and odorless, some fire code officials were concerned about the potential for a person walking into a room where a simple asphyxiant gas leak had occurred and becoming incapacitated due to an oxygen deficient atmosphere. To minimize this risk, Section 5308 was developed. And more recently, Section 5307 was created in response to several life-loss incidents involving asphyxiation by CO<sub>2</sub> in public assembly occupancies.

**5308.2 Ventilation.** Indoor storage and use areas and storage buildings shall be provided with mechanical exhaust ventilation or natural ventilation in accordance with the requirements of Section 5004.3 or 5005.1.9. Where mechanical ventilation is provided, the systems shall be operational during such time as the building or space is occupied

❖ The provisions of this section are limited to basic ventilation requirements when these materials are stored or used indoors. Section 5004.3 of the code provides the fundamental requirements for ventilation systems. The basic provisions allow natural ventilation to be used as a means to address the concern, and mechanical ventilation is not required when it can be shown that natural ventilation is adequate. By including basic provisions for ventilation for the specified material hazards, a reasonable level of safety for building occupants is maintained.

### Bibliography

The following resource was used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code.* Washington, DC: International Code Council, 2014.

# Chapter 54: Corrosive Materials

## General Comments

This chapter regulates the storage of corrosive materials, which pose unusual risks to fire fighters, emergency personnel and the general public when they are involved in a spill, fire or explosion.

Section 5401 establishes the scope of Chapter 54 and the quantities requiring a permit. This section also lists the exempt amounts per control area for corrosive materials to aid in establishing the appropriate occupancy group classification for the building.

Section 5402 provides the definition of “Corrosive,” which is derived from DOT 49 CFR, Part 173.

Section 5403 provides the requirements for structures used for the storage of corrosive materials. These requirements are applicable to storage in excess of the exempt amounts per control area.

Section 5404 provides the maintenance provisions for both indoor and outdoor storage conditions, regardless of quantities.

Section 5405 provides the requirements for both the indoor and outdoor use of corrosives, regardless of the quantities.

Corrosive materials may be found in solid, liquid or gaseous states, although the most frequently encountered corrosive materials are liquids and solids. They may be found in all types of occupancies, including research laboratories, hospitals, industrial facilities, warehouses and retail stores.

Corrosive materials may pose multiple hazards, such as radioactivity, toxicity, flammability or detonability. The focus of this chapter is on materials whose primary hazard is corrosivity; that is, the ability to destroy or irreparably damage living tissue on contact.

These regulations are intended to minimize the exposure of the public, fire fighters and other emergency responders to the harmful vapors, liquid matter or splashes resulting from fire or accidental releases. Advance knowledge of the materials in structures through the permit process and the submittal of Material Safety Data Sheets (MSDS) are essential for effective prefire planning by the fire department. NFPA 471 provides useful guidance for managing hazardous material incidents.

## Purpose

Chapter 54 addresses the hazards of corrosive materials that have a destructive effect on living tissues. Though corrosive gases exist, most corrosive materials are solid and classified as either acids or bases (alkalis). These materials may pose a wide range of hazards other than corrosivity, such as combustibility, reactivity or oxidizing hazards. This chapter, however, addresses the hazards associated with the storage of materials based on their corrosivity only. Materials posing multiple hazards must conform to the requirements of the code with respect to all their known hazards.

---

## SECTION 5401 GENERAL

**5401.1 Scope.** The storage and use of *corrosive* materials shall be in accordance with this chapter. *Compressed gases* shall also comply with Chapter 53.

### Exceptions:

1. Display and storage in Group M and storage in Group S occupancies complying with Section 5003.11.
2. Stationary storage battery systems in accordance with Section 608.
3. This chapter shall not apply to R-717 (ammonia) where used as a refrigerant in a refrigeration system (see Section 606).

❖ Chapter 54 details specific requirements for the storage and use of corrosive materials. The requirements of this chapter are intended to complement the haz-

ardous materials general storage requirements of Chapter 50.

Exception 1 addresses mercantile displays to which this chapter is not applicable. Section 5003.11 addresses requirements for the storage of hazardous material in mercantile occupancies. Exceptions 2 and 3 state that stationary lead-acid battery systems and R-717 refrigerants are not addressed in this chapter.

**5401.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.21 for discussion of specific operational permits for hazardous materials,

## CORROSIVE MATERIALS

Section 105.7 for a general discussion of activities requiring a construction permit and Section 105.7.10 for discussion of specific construction permits for hazardous materials. The permit process also notifies the fire department of the need for prefire planning for hazardous properties.

### SECTION 5402 DEFINITION

**5402.1 Definition.** The following term is defined in Chapter 2:

#### **CORROSIVE.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated term used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

### SECTION 5403 GENERAL REQUIREMENTS

**5403.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of *corrosive* materials in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5401.

❖ The stored quantities per control area are addressed in Section 5001 if the quantities do not exceed the amounts in Table 5003.1.1(2) or 5003.1.1(4). The tables address quantities posing a health hazard for control areas located indoors and outdoors.

**5403.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of *corrosive* materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with this chapter and Chapter 50.

❖ Tables 5003.1.1(2) and 5003.1.1(4) give the maximum allowable quantity per control area (MAQ). If the amounts exceed the allowable quantities, the occupancy classifications in Chapter 2 and this chapter must be used for requirements. Section 5003.1.4 states that compliance with Chapter 50 is also required.

### SECTION 5404 STORAGE

**5404.1 Indoor storage.** Indoor storage of *corrosive* materials in amounts exceeding the *maximum allowable quantity per*

*control area* indicated in Table 5003.1.1(2), shall be in accordance with Sections 5001, 5003 and 5004 and this chapter.

❖ Table 5003.1.1(2) gives the maximum quantities for an indoor storage control area. Section 5004 addresses the storage requirements of hazardous materials in the amounts that exceed the MAQ.

**5404.1.1 Liquid-tight floor.** In addition to the provisions of Section 5004.12, floors in storage areas for *corrosive* liquids shall be of liquid-tight construction.

❖ Section 5004.12 requires that floors of storage areas must be of noncombustible construction, except for surfacing. This section requires them to be liquid tight, as well.

**5404.2 Outdoor storage.** Outdoor storage of *corrosive* materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(4) shall be in accordance with Sections 5001, 5003 and 5004 and this chapter.

❖ Table 5003.1.1(4) gives the maximum quantities for an outdoor storage control area. Section 5004 addresses storage of hazardous materials in amounts that exceed the MAQ.

**5404.2.1 Above-ground outside storage tanks.** Above-ground outside storage tanks exceeding an aggregate quantity of 1,000 gallons (3785 L) of *corrosive* liquids shall be provided with secondary containment in accordance with Section 5004.2.2.

❖ In order to help confine a leak or spill from an outside above-ground storage tank containing corrosive liquids, secondary containment in accordance with Section 5004.2 must be provided. This section applies to all outside storage areas with an aggregate tank capacity in excess of 1,000 gallons (3785 L).

**5404.2.2 Distance from storage to exposures.** Outdoor storage of *corrosive* materials shall not be within 20 feet (6096 mm) of buildings not associated with the manufacturing or distribution of such materials, *lot lines*, public streets, public alleys, *public ways* or *means of egress*. A 2-hour *fire barrier* without openings or penetrations, and extending not less than 30 inches (762 mm) above and to the sides of the storage area, is allowed in lieu of such distance. The wall shall either be an independent structure, or the *exterior wall* of the building adjacent to the storage area.

❖ The required separation distances for corrosive materials are intended to reduce the hazard of radiant heat transfer from nearby exposures on or off the property. This section also recognizes that a 2-hour fire barrier constructed in accordance with Section 706 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>) will provide physical barrier protection as an alternative to the required separation distance. Note that the wall must be positioned to restrict the spread of fire around or over it.

## SECTION 5405 USE

**5405.1 Indoor use.** The indoor use of *corrosive* materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(2) shall be in accordance with Sections 5001, 5003 and 5005 and this chapter.

❖ Table 5003.1.1(2) gives the MAQ for use in either a closed system or an open system. Section 5005 addresses the use, dispensing and handling of hazardous materials in amounts that exceed the MAQ.

**5405.1.1 Liquid transfer.** *Corrosive* liquids shall be transferred in accordance with Section 5005.1.10.

❖ Section 5005.1.10 lists five methods that can be used for the transfer of corrosive liquids. These methods are for liquids having a hazard ranking of 3 or 4 in accordance with NFPA 704.

**5405.1.2 Ventilation.** Where *corrosive* materials are dispensed or used, mechanical exhaust ventilation in accordance with Section 5005.2.1.1 shall be provided.

❖ This section requires mechanical exhaust ventilation for all storage areas containing corrosive liquids with positive vapor pressures, which, if exposed under standard room temperature and atmospheric pressure, give off hazardous fumes and vapors. Adequate mechanical ventilation will reduce the chance for the accumulation of hazardous concentration levels of toxic fumes and vapors. Corrosive liquids without a positive vapor pressure do not readily give off vapors at hazardous concentration levels under normal conditions and, therefore, do not require mechanical exhaust ventilation.

**5405.2 Outdoor use.** The outdoor use of *corrosive* materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(4) shall be in accordance with Sections 5001, 5003 and 5005 and this chapter.

❖ Table 5003.1.1(4) gives the MAQ for an outdoor control area. Section 5005 addresses the use, dispensing and handling of hazardous materials in the amounts that exceed the MAQ.

**5405.2.1 Distance from use to exposures.** Outdoor use of *corrosive* materials shall be located in accordance with Section 5404.2.2.

❖ The required separation distances for corrosive materials are intended to reduce the hazard of radiant heat transfer to nearby structures or public areas. The distances also help protect the property in question from heat exposure from incidents on or off the property. The exception recognizes that a 2-hour fire separation wall will provide physical barrier protection as an alternative to the required separation distance.

# Chapter 55: Cryogenic Fluids

## General Comments

The code regulates the hazards associated with materials that are considered to be cryogenic fluids. These requirements are in addition to the other code requirements that address hazards such as flammability and toxicity. Cryogenics are hazardous because they are held at extremely low temperatures and high pressures. Many cryogenic fluids, however, are actually inert gases and would not be regulated elsewhere in the code.

Cryogenics pose several hazards to humans who come in close contact with them. The first is the potential for severe freeze burns and tissue damage that can result from direct contact with cryogenic liquids, uninsulated cryogenic pipes or uninsulated cryogenic equipment. Also, a jet of cryogen can freeze the skin or the eyes faster than liquid contact. Eyes are especially susceptible to cryogen exposure.

In addition to freeze hazards, cryogens pose an asphyxiation hazard because they rapidly boil and convert from a liquid to a gas. As will be discussed in the definitions, cryogens have extremely low boiling points. When converting from a liquid to a gas, there is a great deal of expansion that displaces breathable air. This hazard is compounded when the gases are also toxic or flammable.

There is also the potential for air surrounding a cryogen containment system to condense. This is especially the case when transferring liquid nitrogen through uninsulated metal pipes. Because nitrogen has a lower boiling point than oxygen, it will evaporate first and leave an

oxygen-enriched atmosphere, which has the potential of improving the conditions for combustion.

Finally, a release of cryogens at extremely low temperatures has the effect of making some materials such as rubber, carbon steel and plastic so brittle that failure of those materials can occur very easily. Materials like stainless steel, copper, brass and most alloys of aluminum must be used when handling cryogenic fluids.

The extreme low temperatures also have the tendency to create thermal stresses in badly designed cryogen containment systems. Uneven temperature distributions can create stress in some piping or related equipment.

The more common cryogens include helium, hydrogen, nitrogen, argon, oxygen and methane. Note that some of these gases are inert but, based on the specific concerns related to cryogens, are still a potential hazard. Cryogens are used for many applications but specifically have had widespread use in the biomedical field and in space programs.

## Purpose

Hazards created by cryogenic materials are sometimes compounded by additional hazard characteristics, such as flammability or toxicity. These other characteristics are dealt with in Chapter 50 and other chapters, such as Chapter 58 dealing with flammable gases. This chapter covers the storage, use and handling of cryogenic fluids through regulation of such things as pressure relief mechanisms and proper container storage.

---

## SECTION 5501 GENERAL

**5501.1 Scope.** Storage, use and handling of *cryogenic fluids* shall comply with this chapter and NFPA 55. *Cryogenic fluids* classified as hazardous materials shall also comply with the general requirements of Chapter 50. Partially full containers containing residual *cryogenic fluids* shall be considered as full for the purposes of the controls required.

### Exceptions:

1. Fluids used as refrigerants in refrigeration systems (see Section 606).
2. Liquefied natural gas (LNG), which shall comply with NFPA 59A.

Oxidizing *cryogenic fluids*, including oxygen, shall comply with Chapter 63, as applicable.

Flammable *cryogenic fluids*, including hydrogen, methane and carbon monoxide, shall comply with Chapters 23 and 58, as applicable.

Inert *cryogenic fluids*, including argon, helium and nitrogen, shall comply with ANSI/CGA P-18.

❖ This section states that the chapter focuses on the hazards related to cryogenic fluids. If the materials are also classified as a hazardous material, additional requirements, as found in Chapter 50, must be reviewed as well.

Exception 1 is for cryogens used in refrigeration systems, which are specifically regulated in Section 606 of the code.

Exception 2 is for liquefied natural gas (LNG) since there are more specific and appropriate sections or standards that address those hazards, most notably NFPA 59A.

Following the exceptions are three requirements that reference three additional chapters of the code and an associated standard dealing with inert cryogenic fluids that must be adhered to in addition to complying with Chapter 55.

See also Appendix G for weight and volume equivalents of cryogenic fluids. It is important to note that the appendices are not considered part of the code unless specifically adopted (see Section 1 of the sample adopting ordinance on page xxi of the code book).

**5501.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.11 for discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7.4 for a discussion of activities involving cryogenic fluids requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

## SECTION 5502 DEFINITIONS

**5502.1 Definitions.** The following terms are defined in Chapter 2.

**CRYOGENIC CONTAINER.**

**CRYOGENIC FLUID.**

**CRYOGENIC VESSEL.**

**FLAMMABLE CRYOGENIC FLUID.**

**LOW-PRESSURE TANK.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 5503 GENERAL REQUIREMENTS

**5503.1 Containers.** Containers employed for storage or use of *cryogenic fluids* shall comply with Sections 5503.1.1 through 5503.1.3.2 and Chapter 50.

❖ The focus of this section is the proper use of containers when storing, using or handling cryogenic fluids so that they can handle concerns such as pressures, thermal stresses and embrittlement. Chapter 50 would also apply in cases where issues are not specifically dealt with in Chapter 55.

**5503.1.1 Nonstandard containers.** Containers, equipment and devices that are not in compliance with recognized standards for design and construction shall be *approved* upon presentation of satisfactory evidence that they are designed and constructed for safe operation.

❖ Various standards are available for the construction of containers for use with cryogenic materials. In some cases, applications using cryogenics can facilitate the use of a uniquely designed container that does not meet the specifics of the available standards. This section allows such containers with proper technical justification; criteria are listed. Material properties of cryogenic fluids vary based on differences in the boiling point and critical point. For instance, a material with a lower boiling point would require colder temperatures and perhaps higher pressures; therefore, design calculations or test results must show that container designs can meet the specific pressure and temperature criteria for the cryogenic fluid to be stored.

**5503.1.1.1 Data submitted for approval.** The following data shall be submitted to the *fire code official* with reference to the deviation from the recognized standard with the application for approval.

1. Type and use of container, equipment or device.
2. Material to be stored, used or transported.
3. Description showing dimensions and materials used in construction.
4. Design pressure, maximum operating pressure and test pressure.
5. Type, size and setting of pressure relief devices.
6. Other data requested by the *fire code official*.

❖ This section lists approval criteria for nonstandard containers that are to be used with cryogenic fluids. Material properties of cryogenic fluids vary based on differences in the boiling point and critical point. For

instance, a material with a lower boiling point would require colder temperatures and perhaps higher pressures; therefore, design calculations or test results must show that container designs can meet the specific pressure and temperature criteria for the cryogenic fluid to be stored. Approval applications must include specific references to the portions of recognized standards from which they deviate.

**5503.1.2 Concrete containers.** Concrete containers shall be built in accordance with the *International Building Code*. Barrier materials and membranes used in connection with concrete, but not functioning structurally, shall be compatible with the materials contained.

❖ Because concrete containers are often built on site, this section requires that they be built in accordance with the *International Building Code*® (IBC®) and its requirements in Chapter 16 for structural strength and other related issues. Additionally, this section acknowledges the fact that any material in contact with cryogenics must be compatible. This will vary based on what cryogenic fluids are stored and the type of barrier materials chosen.

**5503.1.3 Foundations and supports.** Containers shall be provided with substantial concrete or masonry foundations, or structural steel supports on firm concrete or masonry foundations. Containers shall be supported to prevent the concentration of excessive loads on the supporting portion of the shell. Foundations for horizontal containers shall be constructed to accommodate expansion and contraction of the container. Foundations shall be provided to support the weight of vaporizers or heat exchangers.

❖ Critical to avoiding catastrophic failure of a container is the proper construction of the elements that support the container. The design must anticipate the equipment loads that may be used in conjunction with the container, such as vaporizers or heat exchangers. The foundations and supports need to be strong and firmly set in place by either placing the containers directly on a concrete or masonry foundation or on steel supports that are set into a concrete or masonry foundation.

**5503.1.3.1 Temperature effects.** Where container foundations or supports are subject to exposure to temperatures below -130°F (-90°C), the foundations or supports shall be constructed of materials to withstand the low-temperature effects of *cryogenic fluid* spillage.

❖ As was mentioned in the general comments at the beginning of this chapter, exposure to extremely low temperatures will cause some materials, such as carbon steel, to become brittle and lose structural strength. For this reason, any portion of a foundation or structural support for cryogenic fluid tanks that might be exposed to the fluid in case of a spill must be constructed of materials that will not be affected by the exposure. A cryogenic fluid is defined in Chapter 2 as having a boiling point lower than -130°F. The requirements of this section should apply at that temperature, otherwise the foundations or supports of those cryo-

genic fluid containers within the range not covered are at risk. This section also correlates with the provisions of NFPA 55.

**5503.1.3.2 Corrosion protection.** Portions of containers in contact with foundations or saddles shall be painted to protect against corrosion.

❖ Corrosion can occur for a number of reasons. Because tanks and their supports will probably be constructed of dissimilar materials, this can cause galvanic corrosion. Exposure to moisture can cause oxidation of metals, otherwise known as rust.

If the corrosion occurs in the metal skin of the tank, leakage of the cryogenic fluid could occur. If the corrosion is extensive, tank failure and spillage of pressurized tank contents could occur.

If the corrosion occurs in the saddle or other part of the supporting foundation structure, collapse of the structure could cause the tank to fall and rupture, resulting in spillage of the cryogenic fluid. If the cryogenic fluid is flammable, tank failure could lead to a fire or explosion.

Prevention of corrosion, therefore, is important. The most common way of protecting metal structures from corrosion is to paint them. This painting becomes even more important where dissimilar metals contact each other. This section specifies that the containers must be painted where they are in contact with foundation structures. Good maintenance practice suggests that both tanks and their supporting structures might benefit from painting.

**5503.2 Pressure relief devices.** Pressure relief devices shall be provided in accordance with Sections 5503.2.1 through 5503.2.7 to protect containers and systems containing *cryogenic fluids* from rupture in the event of overpressure. Pressure relief devices shall be designed in accordance with CGA S-1.1, CGA S-1.2 and CGA S-1.3.

❖ Pressure relief devices are essential for cryogenics because of the high pressures and low temperatures at which cryogenics are maintained. Although storage tanks, other containers and transfer piping are normally well insulated, some heating of the contents will occur over time, causing internal pressures to increase. Pressure relief mechanisms provide a method of relieving these overpressures and avoiding a hazardous situation. Three Compressed Gas Association (CGA) standards that cover the full range of container types, from portable to stationary, are referenced at the end of this section.

Sections 5503.2.1 through 5503.2.7 contain requirements related to accessibility for maintenance, general sizing, installation requirements and device integrity.

**5503.2.1 Containers.** Containers shall be provided with pressure relief devices.

❖ This section states very clearly that pressure relief devices are required for cryogenic containers. Section 5503.2.2 addresses associated equipment. Generally, the container is the main area of concern

because it is the primary storage vessel for cryogenics and has the largest potential for overpressurization.

**5503.2.2 Vessels or equipment other than containers.** Heat exchangers, vaporizers, insulation casings surrounding containers, vessels and coaxial piping systems in which liquefied *cryogenic fluids* could be trapped because of leakage from the primary container shall be provided with a pressure relief device.

❖ Just as Section 5503.2.1 requires pressure relief devices on the container itself, this section mentions other areas where overpressures occur if there is a leak in the primary container. This is a smaller hazard potential, but requirements make it more likely that all potential overpressures are addressed.

**5503.2.3 Sizing.** Pressure relief devices shall be sized in accordance with the specifications to which the container was fabricated. The relief device shall have sufficient capacity to prevent the maximum design pressure of the container or system from being exceeded.

❖ This section contains only general language that makes it likely that the pressure relief device is properly designed to fit the needs of the particular container. In most cases, the manufacturer will already have the devices installed on the container. There are cases, however, when a cryogenic system or container may be constructed for a specific purpose and user. In those cases, the relief valves must be sized and installed by the user.

**5503.2.4 Accessibility.** Pressure relief devices shall be located such that they are provided with ready access for inspection and repair.

❖ This section addresses the long-term reliability of pressure relief devices by making maintenance and repair more convenient through accessibility.

**5503.2.5 Arrangement.** Pressure relief devices shall be arranged to discharge unobstructed to the open air in such a manner as to prevent impingement of escaping gas on personnel, containers, equipment and adjacent structures or to enter enclosed spaces.

**Exception:** DOTn-specified containers with an internal volume of 2 cubic feet (0.057 m<sup>3</sup>) or less.

❖ Pressure relief devices must be located to direct vented vapors away from personnel, containers and structures as well as enclosed spaces to prevent personal injury and property damage. The arrangement will vary from one installation to another based on the use and location of the container and the system.

The exception for Department of Transportation (DOT) containers with an internal volume less than or equal to 2 cubic feet (0.057 m<sup>3</sup>) recognizes that the amount of vapor released from these containers is small enough to make this section impractical and unnecessary.

**5503.2.6 Shutoffs between pressure relief devices and containers.** Shutoff valves shall not be installed between pressure relief devices and containers.

**Exceptions:**

1. A shutoff valve is allowed on containers equipped with multiple pressure relief device installations where the arrangement of the valves provides the full required flow through the minimum number of required relief devices at all times.
2. A locking-type shutoff valve is allowed to be used upstream of the pressure relief device for service-related work performed by the supplier when in accordance with the requirements of the ASME *Boiler and Pressure Vessel Code*.

❖ This section prohibits shutoff valves from being installed between the pressure relief device and the container because the closing of a valve in that position would allow pressure in the tank to build without relief. Exception 1 covers containers designed with multiple pressure relief devices that can still handle the pressure relief even when a valve is shut off. Exception 2 is consistent with NFPA 55. The ASME *Boiler and Pressure Vessel Code* (BPVC) allows the use of a locking valve on the upstream side of a pressure relief device in instances where it is impractical to install multiple pressure relief devices and valves, or where having the multiple valves creates more potential safety hazards during maintenance work on the devices. The BPVC has detailed requirements for working on relief devices with the use of upstream valves, including the requirement to lock the valve open when not working on the valve and the requirement to lower pressure in the pressure vessel before maintenance. The BPVC also requires that personnel monitor vessel pressure during maintenance and have access to an alternate valve other than a pressure relief valve to relieve unexpected pressure rises during maintenance activities. Petrochemical plants and industrial gas plant personnel have used the procedures successfully for many years, as evidenced by the continued endorsement of the procedure in the BPVC.

**5503.2.7 Temperature limits.** Pressure relief devices shall not be subjected to *cryogenic fluid* temperatures except when operating.

❖ One concern related to the integrity of the relief valves is deterioration of the valves as a result of extended exposure to extremely low temperatures, which often have the tendency to make materials brittle and more susceptible to failure. This requirement ensures that pressure relief devices are not subject to these extreme temperatures. Instead, the materials can directly interact with the pressure relief valve only when the valve is operating.

**5503.3 Pressure relief vent piping.** Pressure relief vent-piping systems shall be constructed and arranged so as to remain

functional and direct the flow of gas to a safe location in accordance with Sections 5503.3.1 and 5503.3.2.

❖ Because of tank locations, piping must sometimes be used to extend the discharge location of the pressure relief vent. This section generally states that piping can be used along with the pressure relief device when needed for safety. The requirements that follow are similar to those found in the section on pressure relief devices.

**5503.3.1 Sizing.** Pressure relief device vent piping shall have a cross-sectional area not less than that of the pressure relief device vent opening and shall be arranged so as not to restrict the flow of escaping gas.

❖ Though somewhat obvious, this section points out in the most generic way the need for piping to have at least the same diameter as the pressure relief device itself, if not larger. This section also states that piping must be free of any bends or other features that could potentially restrict the flow of gases.

**5503.3.2 Arrangement.** Pressure relief device vent piping and drains in vent lines shall be arranged so that escaping gas will discharge unobstructed to the open air and not impinge on personnel, containers, equipment and adjacent structures or enter enclosed spaces. Pressure relief device vent lines shall be installed in such a manner to exclude or remove moisture and condensation and prevent malfunction of the pressure relief device because of freezing or ice accumulation.

❖ This section is similar to Section 5503.2.5 in that it requires the vent piping to be arranged so that the discharge itself does not cause additional damage simply because of its location. As discussed in Section 5503.2.5, cryogenic liquids can damage materials and pose asphyxiation and burn hazards to people in the surrounding areas.

This section also addresses the fact that moisture accumulated in piping has the potential to freeze and cause an obstruction that could interfere with the proper operation of the pressure relief device.

**5503.4 Marking.** Cryogenic containers and systems shall be marked in accordance with Sections 5503.4.1 through 5503.4.6.

❖ This section is important for the safe and effective use of cryogenics and is also a necessary tool for emergency response teams. The marking requirements apply to a variety of locations, from the area in which these materials are stored, to the marking of the piping and emergency shutoff valves.

**5503.4.1 Identification signs.** Visible hazard identification signs in accordance with NFPA 704 shall be provided at entrances to buildings or areas in which *cryogenic fluids* are stored, handled or used.

❖ This section refers to the placarding requirements in NFPA 704, which are an important tool for emergency response teams when entering a building or

room containing hazardous materials. This section requires all rooms and buildings containing cryogenic fluids, regardless of the amount, to be properly marked.

**5503.4.2 Identification of contents.** Stationary and portable containers shall be marked with the name of the gas contained. Stationary above-ground containers shall be placarded in accordance with Sections 5003.5 and 5003.6. Portable containers shall be identified in accordance with CGA C-7.

❖ Because different cryogens present different hazards, the contents of the container must be specifically identified. This section refers to other sections or standards that contain more detailed identification requirements.

**5503.4.3 Identification of containers.** Stationary containers shall be identified with the manufacturing specification and maximum allowable working pressure with a permanent nameplate. The nameplate shall be installed on the container in an accessible location. The nameplate shall be marked in accordance with the ASME *Boiler and Pressure Vessel Code* or DOTn 49 CFR Parts 100-185.

❖ This section establishes a requirement for the manufacturer of permanently installed tanks to label the tanks with a nameplate meeting the requirements of the ASME *Boiler and Pressure Vessel Code* (BPVC) or DOTn 49 CFR, Parts 100-185. The nameplate must be clearly visible to anyone entering the tank location. The manufacturer's specifications and maximum allowable tank working pressure must be included on the nameplate.

**5503.4.4 Identification of container connections.** Container inlet and outlet connections, liquid-level limit controls, valves and pressure gauges shall be identified in accordance with one of the following:

1. Marked with a permanent tag or label identifying the function.
2. Identified by a schematic drawing that portrays the function and designates whether connected to the vapor or liquid space of the container.

Where a schematic drawing is provided, it shall be attached to the container and maintained in a legible condition.

❖ Cryogens are often used as part of a system or process. Failure of parts of the system or process can be as hazardous as failure of the main container. Also, the better the components of a process or system are understood, the less likely a hazardous situation will be. This section requires that all components, including shutoff valves, gauges, inlet and outlet connections and others, be labeled or that a schematic drawing of the process or system be attached to the container. The labeling and drawings will help personnel responding to an emergency understand both what has gone wrong and how to most effectively handle the situation.

**5503.4.5 Identification of piping systems.** Piping systems shall be identified in accordance with ASME A13.1.

❖ Piping systems are to be labeled using the industry standard requirements found in ASME A13.1. This standard is specific to the identification of piping systems for all types of materials. Use of this standard results in consistency from one type of industrial process to another and again decreases the likelihood of large-scale failures.

**5503.4.6 Identification of emergency shutoff valves.** Emergency shutoff valves shall be identified and the location shall be clearly visible and indicated by means of a sign.

❖ Emergency valves can play the most important role during an emergency. For this reason, they must be clearly visible and identified using signs. This is particularly important because the emergency responders may not be as familiar with the facility as are the daily occupants.

**5503.5 Security.** Cryogenic containers and systems shall be secured against accidental dislodgement and against access by unauthorized personnel in accordance with Sections 5503.5.1 through 5503.5.4.

❖ The security measures stated in the four subsections that follow this general statement are intended to safeguard cryogenic containers and systems from both accidental and intentional damage. Entry of unauthorized personnel into a cryogenic storage or use area can result in personal injury as well as physical damage.

**5503.5.1 Security of areas.** Containers and systems shall be secured against unauthorized entry and safeguarded in an *approved* manner.

❖ This section addresses the restriction of access to the cryogenic containers and associated equipment. The requirements are generic because each facility has unique characteristics. The fire code official is responsible for reviewing and approving security plans.

**5503.5.2 Securing of containers.** Stationary containers shall be secured to foundations in accordance with the *International Building Code*. Portable containers subject to shifting or upset shall be secured. Nesting shall be an acceptable means of securing containers.

❖ This section focuses on the protection of containers from unintentional physical damage by increasing the integrity of the storage arrangement. Stationary containers are addressed through a reference to the IBC or requirements on foundations and similar support systems because they are permanent structures.

Portable containers are addressed only generally because container sizes and locations vary so widely; however, they must be secured to prevent falling due to contact, vibration or seismic activity. See the commentary to the definition of "Nesting" in Section 5502.1 and the commentary to Section 5503.5.3.

Those discussions can be just as useful for guidance in the safeguarding of cryogen containers as they are for compressed gases since the containers and hazards are similar. Fire code official approval is required for proposed security plans.

**5503.5.3 Securing of vaporizers.** Vaporizers, heat exchangers and similar equipment shall be anchored to a suitable foundation and its connecting piping shall be sufficiently flexible to provide for the effects of expansion and contraction due to temperature changes.

❖ The stability of vaporizers and other equipment can be as important as the containers themselves because they regulate the conditions of the fluids. Equipment must be anchored securely and protected from damage. Piping must be able to expand and contract with temperature changes either from the process itself or climatic conditions.

**5503.5.4 Physical protection.** Containers, piping, valves, pressure relief devices, regulating equipment and other appurtenances shall be protected against physical damage and tampering.

❖ The wording of this section is broad and general because the equipment involved can vary so widely. The intent of the section is to ensure that all associated equipment, components and piping are protected from impacts that are fairly likely to occur within a facility and also to reduce the chances for someone to tamper with the components. This could mean restricting access to certain critical areas of the system.

**5503.6 Electrical wiring and equipment.** Electrical wiring and equipment shall comply with NFPA 70 and Sections 5503.6.1 and 5503.6.2.

❖ This section addresses compliance with NFPA 70 requirements.

**5503.6.1 Location.** Containers and systems shall not be located where they could become part of an electrical circuit.

❖ Containers and systems accidentally becoming part of an electrical circuit simply because of where they are placed could overheat, which could lead to expansion of the fluids and overpressure situations.

**5503.6.2 Electrical grounding and bonding.** Containers and systems shall not be used for electrical grounding. Where electrical grounding and bonding is required, the system shall comply with NFPA 70. The grounding system shall be protected against corrosion, including corrosion caused by stray electric currents.

❖ Containers and systems should not be used to ground or bond because this may cause a rise in temperature, which, similar to being part of a circuit, may cause heating (see also Section 5503.6.1).

**5503.7 Service and repair.** Service, repair, modification or removal of valves, pressure relief devices or other container appurtenances shall comply with Sections 5503.7.1 and

5503.7.2 and the ASME *Boiler and Pressure Vessel Code*, Section VIII or DOTn 49 CFR Parts 100-185.

- ❖ To ensure that the initial reliability of the containers and systems is maintained, minimum requirements for the qualifications and procedures for repair are mandated. The general requirements in Sections 5503.7.1 and 5503.7.2 are supplemented by a reference to the ASME BPVC and DOT requirements.

**5503.7.1 Containers.** Containers that have been removed from service shall be handled in an *approved* manner.

- ❖ This section requires that containers out of service must be handled according to procedures previously approved by the authority having jurisdiction. These procedures have to be written to accommodate all types and uses of containers, including stationary and portable containers.

**5503.7.2 Systems.** Service and repair of systems shall be performed by trained personnel.

- ❖ This section gives the jurisdiction having authority the right to enforce training requirements that are consistent with the fluids being handled and the physical plant being operated.

**5503.8 Unauthorized use.** Containers shall not be used for any purpose other than to serve as a vessel for containing the product that it is designed to contain.

- ❖ To ensure that the container can actually handle the pressures and temperatures for which it was designed, containers are limited to the materials they were specifically designed to contain. This can be a material compatibility concern as well. A container designed to be compatible with one cryogenic fluid may not be compatible with other fluids.

**5503.9 Leaks, damage and corrosion.** Leaking, damaged or corroded containers shall be removed from service. Leaking, damaged or corroded systems shall be replaced, repaired or removed in accordance with Section 5503.7.

- ❖ This requirement states that faulty containers must be removed from service before a failure can occur. The section allows repair of the faulty container either before or after it is removed from service as well as the option for replacement.

**5503.10 Lighting.** Where required, lighting, including emergency lighting, shall be provided for fire appliances and operating facilities such as walkways, control valves and gates ancillary to stationary containers.

- ❖ This section gives the fire code official the authority to require lighting around essential features of the facility both for routine use and during emergency operations. This might include paths to such features. This requirement also allows the fire code official to ask for additional lighting that can be used as emergency lighting when it is appropriate. Typically, the phrase “where required” in other places within the code means that another section would enact the requirement. In this case, however, it appears that the intent is to provide authority to the fire code official to ask

for specific lighting to address emergency response in individual situations.

## SECTION 5504 STORAGE

**5504.1 General.** Storage of containers shall comply with this section.

- ❖ As with all the chapters associated with hazardous materials, there is a section specific to storage and one specific to use. This section covers storage aspects, which tend to be less hazardous than use. The requirements are split into indoor and outdoor storage locations. Whether cryogenics are indoors or outdoors will affect the number and type of safeguards required.

**5504.2 Indoor storage.** Indoor storage of containers shall be in accordance with Sections 5504.2.1 through 5504.2.2.3.

- ❖ The indoor storage requirements are divided into stationary and portable containers.

**5504.2.1 Stationary containers.** Stationary containers shall be installed in accordance with the provisions applicable to the type of fluid stored and this section.

- ❖ This section acknowledges that requirements will vary depending on the type of fluid being stored.

**5504.2.1.1 Containers.** Stationary containers shall comply with Section 5503.1.

- ❖ See the commentary to Section 5503.1.

**5504.2.1.2 Construction of indoor areas.** *Cryogenic fluids* in stationary containers stored indoors shall be located in buildings, rooms or areas constructed in accordance with the *International Building Code*.

- ❖ This section requires that indoor storage areas be constructed in accordance with the IBC. This addresses occupancy requirements in terms of maximum allowable quantities (MAQs) and other relevant issues. Again, note that all cryogenics do not necessarily have a characteristic that would classify them as hazardous in the context of MAQs.

**5504.2.1.3 Ventilation.** Storage areas for stationary containers shall be ventilated in accordance with the *International Mechanical Code*.

- ❖ Ventilation is more critical for indoor areas than for outdoor areas because the fluids cannot disperse and be removed as easily. This section refers to the *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>) for the ventilation requirements. The IMC ventilation requirements in Section 502 are based on the use of the space. Chapter 50 also addresses ventilation requirements in Sections 5003.8 and 5005.2. These particular requirements apply only when the maximum allowable quantities have been exceeded. Further requirements for ventilation and treatment systems, in some cases, are found in the hazard-specific chapters of the code, such as Chapter 60, which addresses highly toxic and toxic materials.

**5504.2.2 Portable containers.** Indoor storage of portable containers shall comply with the provisions applicable to the type of fluid stored and Sections 5504.2.2.1 through 5504.2.2.3.

❖ This section is a reminder that storage requirements will vary with the fluid being stored.

**5504.2.2.1 Containers.** Portable containers shall comply with Section 5503.1.

❖ See the commentary to Section 5503.1.

**5504.2.2.2 Construction of indoor areas.** *Cryogenic fluids* in portable containers stored indoors shall be stored in buildings, rooms or areas constructed in accordance with the *International Building Code*.

❖ This section is the same as Section 5504.2.1.2 for stationary containers and requires compliance with the IBC for the construction of the building, which means the occupancy classification and related construction requirements must be considered. The use of cryogenics alone may not drive the need for a Group H occupancy. The additional hazard characteristics and amounts of fluids will drive those requirements.

**5504.2.2.3 Ventilation.** Storage areas shall be ventilated in accordance with the *International Mechanical Code*.

❖ These requirements are the same as those for stationary containers (see commentary, Section 5504.2.1.3).

**5504.3 Outdoor storage.** Outdoor storage of containers shall be in accordance with Sections 5504.3.1 through 5504.3.1.2.3.

❖ This section is specific to outdoor areas, which are generally less hazardous because the fluids can more easily disperse if released, thereby reducing the potential for harm to both people in the surrounding area and property. Outdoor storage areas are, however, more susceptible to damage from both weather and people. As with the indoor area section, the requirements are divided into portable and stationary containers.

**5504.3.1 Separation from hazardous conditions.** Cryogenic containers and systems in outdoor storage shall be separated from materials and conditions that pose exposure hazards to or from each other in accordance with Sections 5504.3.1.1 through 5504.3.1.1.5.

❖ This introductory statement emphasizes that cryogenic containers and systems, whether for storage or for use, must be separated from other materials and conditions that could pose a hazard to them or when they could be hazardous to other materials. The two subsections that follow address stationary containers and portable containers.

**5504.3.1.1 Stationary containers.** Stationary containers shall be separated from exposure hazards in accordance with

the provisions applicable to the type of fluid contained and the minimum separation distances indicated in Table 5504.3.1.1.

❖ This section refers to Table 5504.3.1.1 and also notes that there may be other separation requirements associated with the fluids that may increase this distance. For example, Table 5804.2.1 for flammable gases has more restrictive distance requirements in certain cases. This table states that the minimum distance to buildings for 0 to 4,225 cubic feet (0 to 120 m<sup>3</sup>) of flammable gases is 5 feet (1524 mm), whereas Table 5504.3.1.1 requires only a 1-foot (305 mm) separation.

**TABLE 5504.3.1.1  
SEPARATION OF STATIONARY CONTAINERS FROM  
EXPOSURE HAZARDS**

EXPOSURE	MINIMUM DISTANCE (feet)
Buildings, regardless of construction type	1
Building exits	10
Wall openings	1
Air intakes	10
Lot lines	5
Places of public assembly	50
Nonambulatory patient areas	50
Combustible materials such as paper, leaves, weeds, dry grass or debris	15
Other hazardous materials	In accordance with Chapter 50

For SI: 1 foot = 304.8 mm.

❖ This table has several different separation distance criteria for stationary containers. Generally, the distances are larger when exposure to people is involved, such as places of public assembly and areas where nonambulatory patients are housed. These restrictions are related more to the hazards associated with their low temperatures, high pressures and asphyxiation hazards than they are to flammability or toxicity, which are dealt with in other chapters. Depending on these additional characteristics, larger distances to buildings and lot lines are sometimes required. Also, the restrictions in Table 5504.3.1.1 of the code are for any amounts of cryogens where the requirements for other hazards typically vary based on the volume of gas.

**5504.3.1.1.1 Point-of-fill connections.** Remote transfer points and fill connection points shall not be positioned closer to exposures than the minimum distances required for stationary containers.

❖ Because there is a potential for a large release of cryogens from faulty connections, the same separation requirements found in Table 5504.3.1.1 would apply to the point-of-fill connection.

**5504.3.1.1.2 Surfaces beneath containers.** Containers shall be placed on surfaces that are compatible with the fluid in the container.

❖ To ensure that a reaction does not occur with the surface below the container in the event of a cryogen spill, the surface beneath the container and its point of fill must be compatible with the fluid stored. The surface below the container must never be made of materials that may become brittle when exposed to extremely low temperatures or be corroded by the stored fluid. Either embrittlement or corrosion could weaken the supporting structure and affect the stability of the container.

**5504.3.1.1.3 Location.** Containers of *cryogenic fluids* shall not be located within diked areas containing other hazardous materials.

❖ Cryogenic fluids cannot share diked areas with other hazardous materials because of the risk that one type of hazardous material could create an exposure hazard for the other. Cryogenics, if released, will be at very low temperatures and high pressures that could potentially compromise the integrity of the other containers and tanks.

**5504.3.1.1.4 Areas subject to flooding.** Stationary containers located in areas subject to flooding shall be securely anchored or elevated to prevent the containers from separating from foundations or supports.

❖ Because stationary containers are considered permanent, issues such as flooding and the effect that flooding will have on the stability of the container are important. Flooding has the tendency to cause containers to pull away from their foundations because of their potential buoyancy. This section requires that the container either be anchored or elevated; if elevated, containers must be elevated to or above the elevation requirements of the IBC. Flood hazard areas are defined in IBC Section 202.

**5504.3.1.1.5 Drainage.** The area surrounding stationary containers shall be provided with a means to prevent accidental discharge of fluids from endangering personnel, containers, equipment and adjacent structures or to enter enclosed spaces. The stationary container shall not be placed where spilled or discharged fluids will be retained around the container.

**Exception:** These provisions shall not apply where it is determined by the *fire code official* that the container does not constitute a hazard, after consideration of special features such as crushed rock utilized as a heat sink, topographical conditions, nature of occupancy, proximity to structures on the same or adjacent property, and the capacity and construction of containers and character of fluids to be stored.

❖ This section deals with both exposure hazards and the need to avoid a buildup of spilled fluids. People and property must be protected from the exposure hazards of the initial spill. How this is to be done is

not specified because the needs for installation vary considerably.

In terms of the drainage, if the fluids are released, they cannot be held in the immediate vicinity of the container; therefore, diking may be a practical method of containment, but the impounded spill would have to be diverted away from the container once it has been released.

There is an exception for areas where the exposure hazards are very low, such as a container in a very remote location. Several factors need to be addressed before such allowances can be given. In some cases, a smaller container may be able to take advantage of this exception whereas a larger container may not, based on the potential size of the discharge.

**5504.3.1.2 Outdoor storage of portable containers.** Outdoor storage of portable containers shall comply with Section 5503 and Sections 5504.3.1.2.1 through 5504.3.1.2.3.

❖ Portable containers are typically smaller than stationary containers; therefore, the requirements are less detailed and are generally less substantial.

**5504.3.1.2.1 Exposure hazard separation.** Portable containers in outdoor storage shall be separated from exposure hazards in accordance with Table 5504.3.1.2.1.

❖ Concerns with portable containers are similar to those with stationary containers because of low temperatures and high pressures. This section refers to Table 5504.3.1.2.1 for the required separation distances.

**TABLE 5504.3.1.2.1  
SEPARATION OF PORTABLE  
CONTAINERS FROM EXPOSURE HAZARDS**

EXPOSURE	MINIMUM DISTANCE (feet)
Building exits	10
Wall openings	1
Air intakes	10
Lot lines	5
Combustible materials such as paper, leaves, weeds, dry grass or debris	15
Other hazardous materials	In accordance with Chapter 50

For SI: 1 foot = 304.8 mm.

❖ Because portable tanks are generally much smaller than stationary containers and are more easily moved, the separation distances do not address areas of assembly or buildings housing nonambulatory patients. Instead, the focus is on exits and areas where portable tanks are more likely to cause an immediate threat. For those locations that correlate with Table 5504.3.1.1 of the code, the distances are the same. For instance, the distance to wall openings must be at least 1 foot (305 mm) for both stationary and portable containers. Again, these separation

requirements are for all amounts of cryogenics stored in portable containers. Concerns over flammability or toxicity are covered in other chapters.

**5504.3.1.2.2 Surfaces beneath containers.** The surface of the area on which stationary containers are placed, including the surface of the area located below the point where connections are made for the purpose of filling such containers, shall be compatible with the fluid in the container.

❖ This section is identical in intent to Section 5504.3.1.1.2; however, because portable containers are not permanently attached to foundations or similar supports, they can be moved to various locations with different surfaces. Personnel responsible for handling and placing the portable containers must be educated and trained on the interaction of cryogenics with certain materials.

**5504.3.1.2.3 Drainage.** The area surrounding portable containers shall be provided with a means to prevent accidental discharge of fluids from endangering adjacent containers, buildings, equipment or adjoining property.

**Exception:** These provisions shall not apply where it is determined by the *fire code official* that the container does not constitute a hazard.

❖ This section requires placement of the containers where they will not further endanger buildings and other exposures if a spill occurs. If impounding is used to contain a spill, the spilled fluid must be diverted to a location where it would not cause personal injury or property damage. This requirement is in addition to the distances specified in Section 5504.3.1. As in Section 5504.3.1.1.5, there is an exception that allows the fire code official to review container locations and evaluate the potential hazard of a spill. If the arrangement of the container does not create a hazard, compliance with this section is not necessary. A good example is a well-isolated storage area.

## SECTION 5505 USE AND HANDLING

**5505.1 General.** Use and handling of *cryogenic fluid* containers and systems shall comply with Sections 5505.1.1 through 5505.5.2.

❖ These provisions are not quantity-specific but apply generally any time cryogenics are being used or handled. This section addresses system components and the integrity of the components. The container itself is addressed primarily in Section 5504.

**5505.1.1 Cryogenic fluid systems.** *Cryogenic fluid* systems shall be suitable for the use intended and designed by persons competent in such design. Equipment, machinery and processes shall be *listed* or *approved*.

❖ This section contains general requirements for the design of systems, including the requirement for the competency of the designer. Because the use of

cryogenics is varied, a single listed system is not available. There is, however, a requirement that all components of the system either be listed or specifically approved.

The nature of the listing should be understood because it may be unrelated to the performance of the system. Use of listed parts and components alone does not guarantee that a system as a whole operates as intended.

**5505.1.2 Piping systems.** Piping, tubing, valves and joints and fittings conveying *cryogenic fluids* shall be installed in accordance with the material-specific provisions of Section 5501.1 and Sections 5505.1.2.1 through 5505.1.2.6.

❖ See the commentary to Section 5501.1 and for the subsections that follow.

**5505.1.2.1 Design and construction.** Piping systems shall be suitable for the use intended through the full range of pressure and temperature to which they will be subjected. Piping systems shall be designed and constructed to provide adequate allowance for expansion, contraction, vibration, settlement and fire exposure.

❖ This section sets out the basic elements that need to be addressed in an acceptable design, including temperature and pressures and the type of events or climatic exposures that the system must withstand. A competent designer must show that all of these elements have been satisfied.

**5505.1.2.2 Joints.** Joints on container piping and tubing shall be threaded, welded, silver brazed or flanged.

❖ This section lists the acceptable types of joints allowed with cryogenic fluids. Joints represent potential weak points in a system if they are not properly designed and constructed. Friction joints would not be allowed. A high level of reliability is needed from joints to decrease the likelihood of joint failure.

**5505.1.2.3 Valves and accessory equipment.** Valves and accessory equipment shall be suitable for the intended use at the temperatures of the application and shall be designed and constructed to withstand the maximum pressure at the minimum temperature to which they will be subjected.

❖ This section sets the basic criterion for approval, which requires valves and any accessory equipment to be able to withstand the minimum temperature at the highest operating pressure. This will ensure that the valves can withstand the most critical forces to which they may be subject during normal operation.

**5505.1.2.3.1 Shutoff valves on containers.** Shutoff valves shall be provided on all container connections except for pressure relief devices. Shutoff valves shall be provided with access thereto and located as close as practical to the container.

❖ This section requires shutoff valves on all container connections. This allows isolation of the container to prevent a large release. It is critical that shutoff valves not be placed on pressure relief devices.

**5505.1.2.3.2 Shutoff valves on piping.** Shutoff valves shall be installed in piping containing *cryogenic fluids* where needed to limit the volume of liquid discharged in the event of piping or equipment failure. Pressure relief valves shall be installed where liquid is capable of being trapped between shutoff-valves in the piping system (see Section 5503.2).

❖ Further shutoff valves are required at strategic locations within the piping systems where a large release may be possible. The containers themselves must have shutoff valves in accordance with Section 5505.1.2.3.1. This section is quite general. Because piping systems vary so much, there is no single solution based on either use or process layouts. There is an additional requirement for pressure relief devices to be installed where shutoff of the flow could potentially cause a buildup of pressure between the source and the shutoff valve.

**5505.1.2.4 Physical protection and support.** Piping systems shall be supported and protected from physical damage. Piping passing through walls shall be protected from mechanical damage.

❖ This is a general section that requires a level of protection from physical and other damage when piping is either exposed or passes through elements, such as walls and floors, that are subject to movement. These requirements, along with the others, are intended to increase the reliability of the piping and associated processes.

**5505.1.2.5 Corrosion protection.** Above-ground piping that is subject to corrosion because of exposure to corrosive atmospheres, shall be constructed of materials to resist the corrosive environment or otherwise protected against corrosion. Below-ground piping shall be protected against corrosion.

❖ Another possible mode of failure is the weakening of the piping system caused by corrosion. The extent of corrosion protection required will depend on the piping material used, the particular climate or, in the case of the underground installations, the soil condition and content of the soil. In some areas, this may be a significant problem whereas in others it may not. Corrosion-resistant construction materials are the preferred means of compliance with this section.

**5505.1.2.6 Testing.** Piping systems shall be tested and proven free of leaks after installation as required by the standards to which they were designed and constructed. Test pressures shall be not less than 150 percent of the maximum allowable working pressure where hydraulic testing is conducted or 110 percent where testing is conducted pneumatically.

❖ To increase the reliability of the system to work as designed without the occurrence of leaks or other more substantial failures, proof testing of the piping is required. This section sets the testing criteria for either a hydraulic test or a pneumatic test.

**5505.2 Indoor use.** Indoor use of *cryogenic fluids* shall comply with the material-specific provisions of Section 5501.1.

❖ The code does not provide detail on the specifics of indoor use. That is contained in the standards listed in Section 5501.1, principally NFPA 55.

**5505.3 Outdoor use.** Outdoor use of *cryogenic fluids* shall comply with the material specific provisions of Sections 5501.1, 5505.3.1 and 5505.3.2.

❖ This section refers back to the standards, principally NFPA 55, in Section 5501.1 for specific details on the use of cryogenes, and emphasizes the separation requirements and placement of necessary shutoff valves.

**5505.3.1 Separation.** Distances from lot lines, buildings and exposure hazards shall comply with Section 5504.3 and the material-specific provisions of Section 5501.1.

❖ Because use is more hazardous than storage, the basic separation requirements found in Tables 5504.3.1.1 and 5504.3.1.2.1 would apply in addition to any of the restrictions found in the referenced standards in Section 5501.1.

**5505.3.2 Emergency shutoff valves.** Manual or automatic emergency shutoff valves shall be provided to shut off the *cryogenic fluid* supply in case of emergency. An emergency shutoff valve shall be located at the source of supply and at the point where the system enters the building.

❖ This section establishes the requirement for emergency shutoff valves to be provided and be readily available during an emergency to either on-site personnel or the local emergency response personnel. Essentially, the ability must exist to both shut down the supply of cryogenes and also to shut off the supply at the location where it enters the building. Pressure relief devices may be necessary where liquid could be trapped between the source and the emergency shutoff valve at the entrance to the building (see also the commentary to the definitions of “Emergency shutoff valve,” “Emergency shutoff valve, manual” and “Emergency shutoff valve, automatic” in Section 202 and to Section 5505.1.2.3.2 for further information).

**5505.4 Filling and dispensing.** Filling and dispensing of *cryogenic fluids* shall comply with Sections 5505.4.1 through 5505.4.3.

❖ Filling and dispensing is an activity that could result in fluid release because of the connections and disconnections involved with such processes. This section addresses the location and construction of dispensing areas, the approval of loading and unloading activities and controls on the amount of fluids dispensed into stationary tanks. All of these requirements focus on preventing an unwanted fluid release and possible physical damage or personal injury.

**5505.4.1 Dispensing areas.** Dispensing of *cryogenic fluids* with physical or *health hazards* shall be conducted in *approved* locations. Dispensing indoors shall be conducted in areas constructed in accordance with the *International Building Code*.

❖ This section focuses on dispensing of fluids with a physical or health hazard rating, such as flammability or toxicity. This section also refers back to the IBC for construction requirements, primarily for the determination of whether a Group H occupancy would be required. This specifically relates to whether the MAQs of hazardous materials have been exceeded.

**5505.4.1.1 Ventilation.** Indoor areas where *cryogenic fluids* are dispensed shall be ventilated in accordance with the requirements of the *International Mechanical Code* in a manner that captures any vapor at the point of generation.

**Exception:** *Cryogenic fluids* that can be demonstrated not to create harmful vapors.

❖ In addition to the basic ventilation requirements for the indoor storage of cryogens, this section requires that vapors be captured at the source; therefore, special ventilation would be required at the point of fill for the dispensing operation. These ventilation requirements appear to be for normal operation rather than emergency operation.

There is an exception if the amount and type of gas would not be sufficient enough to create a hazardous situation.

**5505.4.1.2 Piping systems.** Piping systems utilized for filling or dispensing of *cryogenic fluids* shall be designed and constructed in accordance with Section 5505.1.2.

❖ This is simply a reference back to Section 5505.1.2 for the general piping requirements to ensure correct design and construction (see commentary, Section 5505.1.2).

**5505.4.2 Vehicle loading and unloading areas.** Loading or unloading areas shall be conducted in an *approved* manner in accordance with the standards referenced in Section 5501.1.

❖ Generally, loading, unloading, dispensing and filling operations have a high potential for creating a hazardous situation if not properly conducted. This section ensures that the areas are constructed and operated as required by approved standards.

**5505.4.3 Limit controls.** Limit controls shall be provided to prevent overfilling of stationary containers during filling operations.

❖ This is a mechanism to prevent a release of fluids caused by an overflow.

**5505.5 Handling.** Handling of cryogenic containers shall comply with Sections 5505.5.1 and 5505.5.2.

❖ This section is focused on portable containers and the prevention of a fluid release.

**5505.5.1 Carts and trucks.** Cryogenic containers shall be moved using an *approved* method. Where cryogenic containers are moved by hand cart, hand truck or other mobile

device, such carts, trucks or devices shall be designed for the secure movement of the container.

Carts and trucks used to transport cryogenic containers shall be designed to provide a stable base for the commodities to be transported and shall have a means of restraining containers to prevent accidental dislodgement.

❖ This section does not specify a particular handling method, but gives the fire code official the authority to determine whether the method chosen by the facility is acceptable. If carts, hand trucks or other similar methods are chosen, they must be able to transport the containers safely and securely. This includes restraining containers while they are being moved.

**5505.5.2 Closed containers.** Pressurized containers shall be transported in a closed condition. Containers designed for use at atmospheric conditions shall be transported with appropriate loose-fitting covers in place to prevent spillage.

❖ This section recognizes that containers designed to hold pressure can be moved safely if they are properly closed. Containers designed for use at normal atmospheric pressure need only have an appropriate cover to ensure that fluid does not escape.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code.* Washington, DC: International Code Council, 2014.

*Fire Protection Handbook,* 20th ed. Quincy, MA: National Fire Protection Association, 2008.

# Chapter 56: Explosives and Fireworks

## General Comments

The safe handling of explosives in transportation, storage and use requires preventing ignitions and reducing the hazard to exposures. These exposures include people who may be harmed and property that may be damaged by an accidental detonation and other circumstances involving accidental or malicious detonation of the explosive materials. All requirements applicable to explosives are based on these principles. To apply the requirements of this chapter, the fire code official must recognize conditions that are liable to cause ignition or create exposures.

To varying degrees, all explosives, ammunition and blasting agents are susceptible to ignition from heat, sparks and, in certain cases, shock or pressure. Explosives are considered the most susceptible to ignition from these stimuli and may detonate when exposed to any of them, even under controlled conditions. Blasting agents are generally more stable and less susceptible to detonation, but such agents may become sensitized or unstable when exposed to heat or contaminated by certain organic materials. Sources of ignition include: sparks from tools, friction, static electricity, electrical devices, hot surfaces, open flames and open-flame devices, smoking materials, chemical reactions, electric currents, pressure and shock from explosions or impact.

Exposure protection involves protecting people, buildings and public rights-of-way from detonations, and protecting explosives, ammunition and blasting agents from fires or explosions occurring outside the magazine or blasting area. Such protection also includes security—protecting the magazine or blasting area from entry by unauthorized personnel. Two techniques—separation distance requirements and security precautions—are used to reduce exposure hazards.

An excellent discussion of the origin and rationale behind the separation distances specified in Table 5604.5.2(1) is presented in Appendix C of NFPA 495. Required magazine construction features include: weather resistance, bullet resistance, spark resistance, fire resistance, theft resistance and ventilation to prevent excessive heating or dampening of explosives.

Regulation of explosives is a complex enforcement issue. Local fire code officials must understand that many state and federal agencies have concurrent jurisdiction over the manufacture, transportation, storage, sale, handling and use of explosive materials. The U.S. Department of Justice, which oversees the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) division, is the federal agency responsible (see 18 USC, Chapter 40) for regulating the manufacture, sale, distribution and storage of explosives. In addition to enforc-

ing explosives laws and regulations, ATF investigates incidents of theft or misuse of explosives and has extensive resources for investigating bombings and incendiary acts. Recently, ATF's inspection of explosives manufacturing plants has been credited with improving industry safety.

Many states, especially where mining is an important industry, also regulate explosives. States often pick up where federal authority ends, especially in the areas of blasting and siting of explosive material facilities.

Fireworks regulation is one of the most controversial and hotly debated topics in American fire protection. The National Fire Protection Association (NFPA) and U.S. Consumer Product Safety Commission (CPSC) have called for stricter rules to govern the sale and use of common fireworks and trick and novelty items. To understand the tenor of the debate, it is helpful to appreciate the scope of the problem and look back at the origins of this chapter and other standards that were drafted in response to fireworks misuse and injuries.

According to statistics quoted by NFPA and gathered by the CPSC, more than 10,000 citizens are injured each year by the misuse of common and illegally manufactured fireworks. These injuries result in millions of dollars in medical and legal expenses, and untold suffering. The injuries include burns and the loss of fingers, limbs, vision or hearing; most injuries leave permanent scarring. The overwhelming majority of persons injured are younger than 20 years old. Public displays of fireworks have also resulted in several serious accidents. Many of these accidents have involved local fire departments and untrained operators performing public fireworks displays.

Parts of Chapter 56 had their origin in former NFPA 1121L, Model Fireworks Law, which was first published in 1938. According to NFPA, this is the most widely adopted fireworks regulation in the United States. Many states have enacted this model as part of state law and prohibit all fireworks except toy paper or plastic caps and authorized public displays. Other states have adopted modified versions that prohibit all but trick and novelty items, toy paper or plastic caps and permitted public displays. The NFPA Standards Council withdrew NFPA 1121L as an NFPA standard and in 1988 transferred control of the document to the Fire Marshal's Association of North America (FMANA) [now the International Fire Marshals Association (IFMA)], a membership section of NFPA. Copies of the document may be obtained from IFMA or from various internet sources.

This chapter requires the display of fireworks to comply with NFPA 1123. The standard includes criteria for the firing and on-site storage of fireworks, display site location, fallout area and operator qualifications. This

chapter also references NFPA 1124 for the regulation of fireworks manufacture and storage of fireworks at manufacturing plants. Federal regulations also provide useful guidance.

### Purpose

Chapter 56 prescribes minimum requirements for the safe manufacture, storage, handling and use of explosives, ammunition and blasting agents for commercial and industrial occupancies. These provisions are

intended to protect the general public, emergency responders and individuals who handle explosives.

This chapter regulates the manufacturing, retail sale, display and wholesale distribution of fireworks, establishing the requirements for obtaining approval to manufacture, store, sell, discharge or conduct a public display, and references national standards for regulations governing manufacture, storage and public displays.

## SECTION 5601 GENERAL

**5601.1 Scope.** The provisions of this chapter shall govern the possession, manufacture, storage, handling, sale and use of *explosives, explosive materials*, fireworks and small arms ammunition.

### Exceptions:

1. The Armed Forces of the United States, Coast Guard or National Guard.
  2. *Explosives* in forms prescribed by the official United States Pharmacopoeia.
  3. The possession, storage and use of small arms ammunition where packaged in accordance with DOTn packaging requirements.
  4. The possession, storage and use of not more than 1 pound (0.454 kg) of commercially manufactured sporting black powder, 20 pounds (9 kg) of smokeless powder and 10,000 small arms primers for hand loading of small arms ammunition for personal consumption.
  5. The use of *explosive materials* by federal, state and local regulatory, law enforcement and fire agencies acting in their official capacities.
  6. Special industrial *explosive* devices that in the aggregate contain less than 50 pounds (23 kg) of *explosive materials*.
  7. The possession, storage and use of blank industrial-power load cartridges where packaged in accordance with DOTn packaging regulations.
  8. Transportation in accordance with DOTn 49 CFR Parts 100–185.
  9. Items preempted by federal regulations.
- ❖ This chapter contains specific requirements for the manufacture, transportation, handling, storage and use of explosives, ammunition and blasting agents by nonmilitary and nongovernmental agencies and individuals.
- Exceptions in this section detail situations in which compliance with the requirements of this chapter is not required. Generally, these situations are governed by more stringent federal requirements or

another chapter of the code or they may represent a low hazard.

Exception 1 recognizes that the U.S. military promulgates its own regulations governing the manufacture and storage of explosives, ammunition and blasting agents. These regulations are similar to those that apply to civilian explosives with a few exceptions for identifying and marking them in transportation and storage.

An example of Exception 2 is nitroglycerin in tablet and transdermal patch form used for the treatment of angina pectoris and other pharmaceuticals containing explosive materials which are not dangerous in the form dispensed and thus are exempt from these requirements.

Exception 4 exempts small amounts of materials for making small arms ammunition for personal use based on the limited potential hazard due to the quantity.

Exception 5 is a limited exception that exempts certain federal, state and local agencies from the application of Article 56 when using explosive materials while acting in the course of their official capacities. All other applicable provisions contained in the chapter would apply, i.e., possession, storage and handling regulations.

Exception 6 exempts from the provisions of this chapter special industrial explosive devices in an aggregate quantity of 50 pounds of explosive materials. See the commentary to Chapter 2 definitions of “Special industrial explosive device” and “Explosive material.”

Exception 7 exempts from the provisions of this chapter the possession, storage, and use of blank industrial power load cartridges. Sometimes called propellant-actuated power devices, these articles include devices such as rivets, nail guns, bolt or stud drivers, punches and cutting tools which use explosive cartridges to perform their function. Devices employing explosive mixtures to produce a flame or jet for cutting, propelling or directing work would not be included.

Exceptions 8 and 9 recognize that adequate regulations may already exist at the federal level for certain materials.

**5601.1.1 Explosive material standard.** In addition to the requirements of this chapter, NFPA 495 shall govern the manufacture, transportation, storage, sale, handling and use of *explosive* materials.

❖ The requirements in NFPA 495 apply to situations not specifically addressed by this chapter.

**5601.1.2 Explosive material terminals.** In addition to the requirements of this chapter, the operation of *explosive material* terminals shall conform to the provisions of NFPA 498.

❖ The requirements of NFPA 498 apply to situations not specifically addressed by this chapter.

**5601.1.3 Fireworks.** The possession, manufacture, storage, sale, handling and use of fireworks are prohibited.

**Exceptions:**

1. Storage and handling of fireworks as allowed in Section 5604.
2. Manufacture, assembly and testing of fireworks as allowed in Section 5605.
3. The use of fireworks for fireworks displays as allowed in Section 5608.
4. The possession, storage, sale, handling and use of specific types of Division 1.4G fireworks where allowed by applicable laws, ordinances and regulations, provided such fireworks and facilities comply with NFPA 1124, CPSC 16 CFR Parts 1500 and 1507, and DOTn 49 CFR Parts 100–185, for consumer fireworks.

❖ The possession, manufacture, storage, sale and unauthorized use of fireworks are prohibited by this section. The prohibition of retail sales allows communities to have direct control over the hazards associated with small amounts of storage typical of retail sales. Exception 1 allows storage and handling of fireworks within the limitations of Section 5604. Exception 2 allows the manufacture, assembly and testing of fireworks within the limitations of Section 5605. Exception 3 allows those displays to be specifically approved by the fire code official in accordance with Section 5608.

Exception 4 recognizes that, in some instances, the possession, storage, sale, handling and use of certain types of fireworks may be allowed by provisions of the preemptive laws of superior jurisdictions, most typically the state. Even if such laws preempt the local jurisdiction, the exception stipulates that the fireworks and the facilities allowed by such laws must still meet the minimum requirements of the referenced standards. The scope of NFPA 1124 includes important criteria related to construction, allowable area, egress and protection which is not identified in CPSC 16 CFR, Parts 1500 and 1507, or DOTn 49 CFR, Parts 100–185 for facilities for the storage, handling and sale of consumer fireworks. See also Section 5609.1.

**5601.1.4 Rocketry.** The storage, handling and use of model and high-power rockets shall comply with the requirements of NFPA 1122, NFPA 1125 and NFPA 1127.

❖ NFPA 1122 contains instructional guidelines and specific standards for the design, construction, limitation of charge and power, and reliability of rocket motors manufactured for sale to the general public; for the design and construction of rockets propelled by these motors; and for tests, launchings and other operations involving such rockets in order to minimize hazards. NFPA 1125 applies to the manufacture of model rocket motors designed, sold and used for the purpose of propelling recoverable aero models. NFPA 1127 contains instructional guidelines and specific standards for the design, construction, limitation of charge and power and reliability of high-power rocket motors manufactured for sale to users; for the qualification and certification of users; for the design and construction of high-power rockets propelled by these motors; and for tests, launchings and other operations involving rockets so that hazards are minimized.

**5601.1.5 Ammonium nitrate.** The storage and handling of ammonium nitrate shall comply with the requirements of NFPA 400 and Chapter 63.

**Exception:** Storage of ammonium nitrate in magazines with blasting agents shall comply with the requirements of NFPA 495.

❖ NFPA 400 addresses storage and Chapter 63 addresses oxidizers and separation distances for ammonium nitrate. Ammonium nitrate can be sensitized by both heat and contaminants, causing it to become a greater explosive danger (commercial blasting agents are made from a mixture of diesel oil and ammonium nitrate).

It cannot be determined when or if contamination will occur. No matter how many times it has failed to explode in fires, the important point is that ammonium nitrate might explode and has the potential to explode in any fire.

**5601.2 Permit required.** Permits shall be required as set forth in Section 105.6 and regulated in accordance with this section.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.6.14 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter. The permit process also notifies the fire department of the need for prefire planning for the hazardous property.

**5601.2.1 Residential uses.** Persons shall not keep or store, nor shall any permit be issued to keep or store, any *explosives* at any place of habitation, or within 100 feet (30 480 mm) thereof.

**Exception:** Storage of smokeless propellant, black powder and small arms primers for personal use and not for resale in accordance with Section 5606.

❖ Small amounts of materials for making small arms ammunition for personal use are exempt based on the limited potential hazard of the small quantities.

**5601.2.2 Sale and retail display.** Persons shall not construct a retail display nor offer for sale *explosives*, *explosive materials* or fireworks upon highways, sidewalks, public property or in Group A or E occupancies.

❖ Where retail sales are allowed by Section 5601.1.3, Exception 4, the intent of this section is to prohibit the retail display and sale of explosives, including fireworks 1.3G and 1.4G, in public rights-of-way, on public property and in assembly (Group A) and educational (Group E) buildings. This reduces the likelihood of theft and personal injury if a fire or explosion occurs. See also the commentary to Section 5601.1.3 for further discussion of retail sales of fireworks.

**5601.2.3 Permit restrictions.** The *fire code official* is authorized to limit the quantity of *explosives*, *explosive materials* or fireworks permitted at a given location. Persons possessing a permit for storage of *explosives* at any place, shall not keep or store an amount greater than authorized in such permit. Only the kind of *explosive* specified in such a permit shall be kept or stored.

❖ The fire code official may set limits on the quantity of explosive materials or blasting agents stored at any site as a means of maintaining control over the degree of hazard posed by explosive storage. Limits should be based on the severity of the exposure if an explosion or fire occurs in the magazine. This section is not intended to give the fire code official authority to prohibit the storage of explosives or blasting agents on any site.

**5601.2.4 Financial responsibility.** Before a permit is issued, as required by Section 5601.2, the applicant shall file with the jurisdiction a corporate surety bond in the principal sum of \$100,000 or a public liability insurance policy for the same amount, for the purpose of the payment of all damages to persons or property that arise from, or are caused by, the conduct of any act authorized by the permit upon which any judicial judgment results. The *fire code official* is authorized to specify a greater or lesser amount when, in his or her opinion, conditions at the location of use indicate a greater or lesser amount is required. Government entities shall be exempt from this bond requirement.

❖ The fire code official should understand that some insurance coverages are invalidated by violations of federal, state and local regulations. Insurance coverages obtained by an owner or operator provide no protection from liability for the fire code official who is

responsible for issuing approvals or conducting inspections. Moreover, third-party insurance may conflict with other coverages obtained by the jurisdiction, as well as governmental immunity or tort claims protections under state or local statutes.

**5601.2.4.1 Blasting.** Before approval to do blasting is issued, the applicant for approval shall file a bond or submit a certificate of insurance in such form, amount and coverage as determined by the legal department of the jurisdiction to be adequate in each case to indemnify the jurisdiction against any and all damages arising from permitted blasting.

❖ Insurance coverage is required in an amount specified by a jurisdiction's legal department. This coverage is intended to indemnify the operator or responsible individual from damages arising from accidents involving blasting operations.

**5601.2.4.2 Fireworks display.** The permit holder shall furnish a bond or certificate of insurance in an amount deemed adequate by the *fire code official* for the payment of all potential damages to a person or persons or to property by reason of the permitted display, and arising from any acts of the permit holder, the agent, employees or subcontractors.

❖ The bonding requirement is intended to indemnify the display operator and, if required by the fire code official, the jurisdiction in the event of an accident. Jurisdictions desiring coverage under the display operator's policy should require that the jurisdiction be named on the policy as an additional insured or a named insured. (Before making this requirement, check with legal counsel to determine the fire code official's and the jurisdiction's liability. Many tort claims acts exempt the government from certain claims, while others limit the amount of liability. The standard of care that must be exercised by the fire code official when reviewing conditions for a permit varies widely.)

The fire code official must exercise great care when establishing bonding requirements. Insurance companies underwriting fireworks displays often issue a large number of policies at the same time of year. Often the face value of these policies far exceeds the total of the companies' assets and reserves. Insurance evaluation services should be consulted to evaluate the companies' ratings. (Like credit bureaus, these evaluation services rate the companies' financial health on a letter scale—AAA being the highest rating, B and C the lowest.) Most policies include some coverage restrictions. Losses within 150 feet (45 720 mm) of the discharge site are often excluded from coverage, and claims within 600 feet (182 m) of the discharge site are frequently severely limited. When included in the policy, these separation distances usually conform to the separation requirements of NFPA 1123. This is done purposely to encourage display operators to follow nationally recognized standards.

The fire code official may require the approval holder to submit an original copy of the certificate of insurance verifying indemnification of the display.

When an original copy cannot be obtained, a facsimile of the original from the issuing broker is a good alternative. Most insurance companies authorize only highly trusted, specially trained, bonded employees to issue these certificates. The fire code official should examine the certificate carefully and never accept a photocopy of this document unless it can be thoroughly authenticated. Unscrupulous operators have been known to alter old certificates or produce and submit counterfeit certificates. The fire code official may contact the broker, underwriter or other insurance company representative to verify coverage, although these agents may be reluctant to confirm coverage if the jurisdiction is not named as an additional insured on the policy.

**5601.3 Prohibited explosives.** Permits shall not be issued or renewed for possession, manufacture, storage, handling, sale or use of the following materials and such materials currently in storage or use shall be disposed of in an *approved* manner.

1. Liquid nitroglycerin.
2. Dynamite containing more than 60-percent liquid *explosive* ingredient.
3. Dynamite having an unsatisfactory absorbent or one that permits leakage of a liquid *explosive* ingredient under any conditions liable to exist during storage.
4. Nitrocellulose in a dry and uncompressed condition in a quantity greater than 10 pounds (4.54 kg) of net weight in one package.
5. Fulminate of mercury in a dry condition and fulminate of all other metals in any condition except as a component of manufactured articles not hereinafter forbidden.
6. *Explosive* compositions that ignite spontaneously or undergo marked decomposition, rendering the products of their use more hazardous, when subjected for 48 consecutive hours or less to a temperature of 167°F (75°C).
7. New *explosive materials* until *approved* by DOTn, except that permits are allowed to be issued to educational, governmental or industrial laboratories for instructional or research purposes.
8. *Explosive materials* forbidden for transport by DOTn.
9. *Explosive materials* containing an ammonium salt and a chlorate.
10. *Explosives* not packed or marked as required by DOTn 49 CFR Parts 100–185.

**Exception:** Gelatin dynamite.

- ❖ The fire code official is not authorized to issue approval for manufacture, transportation, storage, sale or use because of extreme or unusual hazards presented by the listed materials.

**5601.4 Qualifications.** Persons in charge of magazines, blasting, fireworks display or pyrotechnic special effect operations shall not be under the influence of alcohol or drugs that impair sensory or motor skills, shall be not less than 21 years

of age and shall demonstrate knowledge of all safety precautions related to the storage, handling or use of *explosives*, *explosive materials* or fireworks.

- ❖ The only discharge of fireworks permissible under the code is a public display conducted by competent pyrotechnicians in accordance with the requirements of NFPA 1123 and authorized by the fire code official.

The competence of the display operator is first among the important safeguards that must be observed for a safe and enjoyable public display. Chapter 6 of NFPA 1123 details the qualifications of competent fireworks display operators. Many jurisdictions also require display operators to possess a license or certificate of fitness. To obtain such a certificate, the operator must be bonded or indemnified, pass a written examination and serve an apprenticeship under another licensed or certified pyrotechnician.

The best sites are free of overhead obstructions and are well isolated, with clear viewing paths and landing areas. Fallout areas should be large, open areas, clear of spectators, vehicles and combustible materials. Generally, the discharge site must have a minimum radius of 70 feet (21 336 mm) for each inch of aerial shell diameter. Table 31.3 of NFPA 1123 specifies the separation distances.

Fireworks discharge sites must be separated from institutional and high-hazard occupancies by at least twice the distance specified in the table [140 feet (42 672 mm) per inch of shell diameter]. When mortars are positioned vertically (zero degrees), they must be located at the center of the display area. When mortars or shells stored at the discharge site are angled, they must be aimed away from principal spectator viewing and shell storage areas. When angled, mortars may be placed up to one-third the distance from the center of the display area to the principal spectator viewing area. Aerial shell trajectories must not come within 25 feet (7620 mm) of overhead obstructions, such as power lines and trees. Tents and canvas structures must be at least 100 feet (30 480 mm) from the discharge site.

High winds, precipitation or extremely hot, dry conditions should be avoided. Moisture-damaged shells must not be fired. If, in the opinion of the fire code official or the display operator, weather conditions present a danger, the display must be postponed or canceled.

**5601.5 Supervision.** The *fire code official* is authorized to require operations permitted under the provisions of Section 5601.2 to be supervised at any time by the *fire code official* in order to determine compliance with all safety and fire regulations.

- ❖ Only supervised public displays of fireworks, approved in advance by the fire code official, and wholesale sales in accordance with Section 5601.1.3, Exception 4, are permitted under the requirements of this chapter. Written application for approval of public displays must be made at least 15 days prior to the

display. Before approval can be issued, the fire code official must review the qualifications and determine the competence of the display operator, verify the operator's proof of insurance or indemnification, inspect the proposed discharge site and viewing area and review the operator's fire protection and crowd control plans.

**5601.6 Notification.** Whenever a new *explosive material* storage or manufacturing site is established, including a temporary job site, the local law enforcement agency, fire department and local emergency planning committee shall be notified 48 hours in advance, not including Saturdays, Sundays and holidays, of the type, quantity and location of *explosive materials* at the site.

❖ Local law enforcement, fire department and emergency planning officials must be notified of all new explosive materials storage and handling sites at least 48 hours, excluding weekends and holidays, prior to operations beginning. This period is intended to give officials time to prepare response plans for the new site, communicate the operation's potential hazards to first responders and train site personnel and emergency responders on the management of emergencies at the new site.

In practice, this notice should be submitted well in advance of the required 48 hours. Approval should not be granted or should be suspended if local law enforcement, fire department or emergency planning officials believe that adequate and proper preparations cannot be made to safeguard the public and emergency responders prior to the planned start of such operations.

**5601.7 Seizure.** The *fire code official* is authorized to remove or cause to be removed or disposed of in an *approved* manner, at the expense of the *owner, explosives, explosive materials* or fireworks offered or exposed for sale, stored, possessed or used in violation of this chapter.

❖ The seizure and disposal of controlled articles, in this case fireworks, at the owner's expense is usually considered a lawful taking of private property under the U.S. Constitution. However, before taking such measures, fire code officials should consult with legal counsel regarding due process requirements.

Seizure requires probable cause that the article or device being seized is unlawful itself, is being used in an unlawful manner, has been used in conjunction with an unlawful activity or poses an imminent danger to life and property. Recovery of expenses may require the filing of civil or criminal charges against the owner or his or her agents.

Before taking possession of fireworks, it is also prudent for the jurisdiction to verify that it has adequate facilities for safely handling, transporting, storing and disposing of the articles. The jurisdiction may require assistance to dispose of large quantities of special fireworks. Transportation of special fireworks is governed by DOTn 49 CFR. A commercial driver's

license with a hazardous materials endorsement is required, as well as a vehicle with special equipment and inspections.

**5601.8 Establishment of quantity of explosives and distances.** The quantity of *explosives* and distances shall be in accordance with Sections 5601.8.1 and 5601.8.1.1.

❖ This section provides a methodology for establishing the explosive quantities and distances based on the class of explosives.

**5601.8.1 Quantity of explosives.** The quantity-distance (Q-D) tables in Sections 5604.5 and 5605.3 shall be used to provide the minimum separation distances from potential explosion sites as set forth in Tables 5601.8.1(1) through 5601.8.1(3). The classification and the weight of the *explosives* are primary characteristics governing the use of these tables. The net *explosive* weight shall be determined in accordance with Sections 5601.8.1.1 through 5601.8.1.4.

❖ The hazards presented by explosive materials range across a spectrum identified by hazard Divisions 1.1 through 1.6. When all of the explosive materials are in a single hazard division, the quantity is easily determined; however, when the materials are mixed among multiple hazard divisions, a method is needed to determine the level of hazard in order to apply the quantity-distance (Q-D) tables contained in Sections 5604 and 5605. The concepts in this and the following sections have been drawn from applicable federal regulations governing the use of these materials [i.e., the Department of Defense (DOD) *Contractor's Safety Manual for Ammunition and Explosives*].

This section requires the quantity of explosives and the distances used to be in accordance with the limits expressed in the Q-D Tables 5604.5.2(2), 5604.5.2(3) and 5605.3, as appropriate, based on application of Tables 5601.8.1(1) through 5601.8.1(3).

The intent of the tables is not unlike the intent behind Table 5604.5.2(1). They serve as guides to assist the user in answering the question as to what is the appropriate table to use when Q-D is to be determined. The relationship between intraplant distance (IPD), intraline distance (ILD), intermagazine distance (IMD), public traffic route (PTR), etc., is cross referenced in each of the tables.

Guidance is provided as to the interpolation of distances when using the tables. In general, linear interpolation is not appropriate for high explosives as the effects of an explosion vary with the cube root of the distance [Table 5601.8.1(1)]. Nonlinear interpolation may be performed with the provision that the interpolation be documented in an approved technical opinion and report as required by Section 104.7.2. For materials with mass fire hazards shown in Table 5601.8.1(2), linear interpolation is allowed as noted in Note b to the table.

**5601.8.1.1 Mass-detonating explosives (Division 1.1, 1.2 or 1.5).** The total net *explosive* weight of mass-detonating explo-

sives (Division 1.1, 1.2 or 1.5) shall be used. See Table 5604.5.2(1) or Table 5605.3 as appropriate.

**Exception:** Where the TNT equivalence of the *explosive material* has been determined, the equivalence is allowed to be used to establish the net *explosive* weight.

❖ Mass-detonating explosives are typically classified as Group H-1 by the *International Building Code*® (IBC®), and present a detonation hazard and a greater threat to adjacent objects and structures. The code, therefore, contains provisions in Table 5605.3 to deal with the separation distances for mass explosion hazards. This section establishes the weights to be used when applying that table as the total net weight of all mass-detonating explosive hazard divisions.

**TABLE 5601.8.1(1).** See below.

❖ See the commentary to Section 5601.8.1.

**TABLE 5601.8.1(2).** See below.

❖ See the commentary to Section 5601.8.1.

**TABLE 5601.8.1(3).** See page 56-8.

❖ See the commentary to Section 5601.8.1.

**5601.8.1.2 Nonmass-detonating explosives (excluding Division 1.4).** Nonmass-detonating *explosives* (excluding Division 1.4) shall be as follows:

1. Division 1.3 propellants. The total weight of the propellants alone shall be the net *explosive* weight. The net weight of propellant shall be used. See Table 5604.5.2(2).
2. Combinations of bulk metal powder and pyrotechnic compositions. The sum of the net weights of metal powders and pyrotechnic compositions in the containers shall be the net *explosive* weight. See Table 5604.5.2(2).

❖ This section establishes the explosive material weight for entering in Table 5604.5.2(3) for explosives classified as nonmass detonating.

**5601.8.1.3 Combinations of mass-detonating and non-mass-detonating explosives (excluding Division 1.4).** Combination of mass-detonating and nonmass-detonating *explosives* (excluding Division 1.4) shall be as follows:

1. Where Division 1.1 and 1.2 *explosives* are located in the same site, determine the distance for the total quan-

**TABLE 5601.8.1(1)**

For SI: 1 foot = 304.8 mm.

- a. The minimum separation distance (D<sub>s</sub>) shall be 60 feet. Where a building or magazine containing explosives is barricaded, the minimum distance shall be 30 feet.
- b. Linear interpolation between tabular values in the referenced Q-D tables shall not be allowed. Nonlinear interpolation of the values shall be allowed subject to an approved technical opinion and report prepared in accordance with Section 104.7.2.
- c. For definitions of Quantity-Distance abbreviations IBD, ILD, IMD, IPD and PTR, see Chapter 2.

**TABLE 5601.8.1(2)**  
**APPLICATION OF SEPARATION DISTANCE (Q-D) TABLES—DIVISION 1.3 EXPLOSIVES<sup>a, b, c</sup>**

ITEM	MAGAZINE	Q-D	OPERATING BUILDING	Q-D	INHABITED BUILDING	Q-D	PUBLIC TRAFFIC ROUTE	Q-D
Magazine	Table 5604.5.2(2)	IMD	Table 5604.5.2(2)	ILD or IPD	Table 5604.5.2(2)	IBD	Table 5604.5.2(2)	PTR
Operating building	Table 5604.5.2(2)	ILD or IPD	Table 5604.5.2(2)	ILD or IPD	Table 5604.5.2(2)	IBD	Table 5604.5.2(2)	PTR
Inhabited building	Table 5604.5.2(2)	IBD	Table 5604.5.2(2)	IBD	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Public traffic route	Table 5604.5.2(2)	PTR	Table 5604.5.2(2)	PTR	Not Applicable	Not Applicable	Not Applicable	Not Applicable

For SI: 1 foot = 304.8 mm.

- a. The minimum separation distance (D<sub>s</sub>) shall be not less than 50 feet.
- b. Linear interpolation between tabular values in the referenced Q-D table shall be allowed.
- c. For definitions of Quantity-Distance abbreviations IBD, ILD, IMD, IPD and PTR, see Chapter 2.

tity considered first as 1.1 and then as 1.2. The required distance is the greater of the two. Where the Division 1.1 requirements are controlling and the TNT equivalence of the 1.2 is known, the TNT equivalent weight of the 1.2 items shall be allowed to be added to the total *explosive* weight of Division 1.1 items to determine the net *explosive* weight for Division 1.1 distance determination. See Table 5604.5.2(2) or Table 5605.3 as appropriate.

2. Where Division 1.1 and 1.3 *explosives* are located in the same site, determine the distances for the total quantity considered first as 1.1 and then as 1.3. The required distance is the greater of the two. Where the Division 1.1 requirements are controlling and the TNT equivalence of the 1.3 is known, the TNT equivalent weight of the 1.3 items shall be allowed to be added to the total *explosive* weight of Division 1.1 items to determine the net *explosive* weight for Division 1.1 distance determination. See Table 5604.5.2(1), 5604.5.2(2) or 5605.3, as appropriate.
3. Where Division 1.1, 1.2 and 1.3 *explosives* are located in the same site, determine the distances for the total quantity considered first as 1.1, next as 1.2 and finally as 1.3. The required distance is the greatest of the three. As allowed by paragraphs 1 and 2 above, TNT equivalent weights for 1.2 and 1.3 items are allowed to be used to determine the net weight of *explosives* for Division 1.1 distance determination. Table 5604.5.2(1) or 5605.3 shall be used where TNT equivalency is used to establish the net *explosive* weight.
4. For composite pyrotechnic items Division 1.1 and Division 1.3, the sum of the net weights of the pyrotechnic composition and the *explosives* involved shall be used. See Tables 5604.5.2(1) and 5604.5.2(2).

❖ This section establishes the explosive material weights to be used when applying the various distance tables in Sections 5604 and 5605 for mixed storage combinations of explosives classified as both mass detonating and nonmass detonating. The most hazardous explosives will likely drive the distance requirements.

**5601.8.1.4 Moderate fire—no blast hazards (Division 1.4).** For Division 1.4 explosives, the total weight of the explosive material alone is the net weight. The net weight of the explosive material shall be used.

❖ This section establishes the explosive material weight to be used when applying Table 5604.5.2(3) for explosives classified as a moderate fire hazard without a blast hazard.

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or

the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 5603

### RECORD KEEPING AND REPORTING

**5603.1 General.** Records of the receipt, handling, use or disposal of *explosive materials*, and reports of any accidents, thefts or unauthorized activities involving *explosive materials* shall conform to the requirements of this section.

- ❖ An accumulation of invoices, sales slips, delivery tickets, receipts or similar records representing individual transactions will satisfy the requirements for record keeping if they include the signature of the receiver of the explosive materials.

**5603.2 Transaction record.** The permittee shall maintain a record of all transactions involving receipt, removal, use or disposal of *explosive materials*. Such records shall be maintained for a period of 5 years.

**Exception:** Where only Division 1.4G (consumer fireworks) are handled, records need only be maintained for a period of 3 years.

- ❖ A permit holder must keep a record of all transactions or operations involving explosive materials for 5 years and that record should be made available to the issuing authority upon request.

**5603.3 Loss, theft or unauthorized removal.** The loss, theft or unauthorized removal of *explosive materials* from a magazine or permitted facility shall be reported to the *fire code official*, local law enforcement authorities and the U.S. Department of Treasury, Bureau of Alcohol, Tobacco, Firearms and Explosives within 24 hours.

**Exception:** Loss of Division 1.4G (consumer fireworks) need not be reported to the Bureau of Alcohol, Tobacco, Firearms and Explosives.

- ❖ The loss, theft or unlawful removal of explosive materials must be reported within 24 hours to the ATF, to the permit-issuing authority and to the local law enforcement agency.

**5603.4 Accidents.** Accidents involving the use of *explosives*, *explosive materials* and fireworks that result in injuries or property damage shall be reported to the *fire code official* immediately.

- ❖ Accidents involving explosive material that cause a lost-time injury or property damage must be reported immediately to the authority having jurisdiction for its records.

**5603.5 Misfires.** The pyrotechnic display operator or blaster in charge shall keep a record of all aerial shells that fail to fire or charges that fail to detonate.

- ❖ A record of all misfires must be kept, eliminating the possibility of using the misfires in other displays and shows.

**5603.6 Hazard communication.** Manufacturers of *explosive materials* and fireworks shall maintain records of chemicals,

## EXPLOSIVES AND FIREWORKS

chemical compounds and mixtures required by DOL 29 CFR Part 1910.1200, and Section 407.

- ❖ Manufacturers of explosive materials and fireworks are required to assess the hazards of chemicals that they produce or import. Employers must inform their employees of the hazardous chemicals to which they are exposed, using a hazard communication program, labels and other forms of warning, Material Safety Data Sheets (MSDS) and information and training. In addition, this section requires distributors to transmit the required information to employers.

**5603.7 Safety rules.** Current safety rules covering the operation of magazines, as described in Section 5604.7, shall be posted on the interior of the magazine in a visible location.

- ❖ Magazine safety rules must be posted conspicuously on the interior of the magazine as a reminder to employees of the requirements for the safe operation of the magazine. These safety rules must cover security; open flames and lights; area around the magazine; separation distance of combustibles; instructions for packing and unpacking; acceptable tools and equipment.

### SECTION 5604 EXPLOSIVE MATERIALS STORAGE AND HANDLING

**5604.1 General.** Storage of *explosives* and *explosive materials*, small arms ammunition, small arms primers, propellant-actuated cartridges and smokeless propellants in magazines shall comply with the provisions of this section.

- ❖ This section establishes requirements for various magazines associated with explosive materials storage.

**5604.2 Magazine required.** *Explosives* and *explosive materials*, and Division 1.3G fireworks shall be stored in magazines constructed, located, operated and maintained in accordance with the provisions of Section 5604 and NFPA 495 or NFPA 1124.

#### Exceptions:

1. Storage of fireworks at display sites in accordance with Section 5608.5 and NFPA 1123 or NFPA 1126.
2. Portable or mobile magazines not exceeding 120 square feet (11 m<sup>2</sup>) in area shall not be required to comply with the requirements of the *International Building Code*.

- ❖ Explosives and blasting agents must be kept in magazines when not in use to reduce the exposure hazard.

**5604.3 Magazines.** The storage of *explosives* and *explosive materials* in magazines shall comply with Table 5604.3.

- ❖ This section gives the requirements for magazine storage of explosives and explosive materials. The section covers high explosives, low explosives and detonating cord.

**TABLE 5604.3.** See below.

- ❖ This table gives both the new and the old classification of explosives. It also states whether the explosive is a low or high type of explosive. The table specifies the maximum amounts allowed in the control areas, whether indoors or outdoors. The last columns specify the type of magazine required for storage of various explosives. Then Table 5604.5.2(1) refers to the proper table for separation distances.

**5604.3.1 High explosives.** *Explosive materials* classified as Division 1.1 or 1.2 or formerly classified as Class A by the

1.6	Not Applicable	Not Applicable	0	0	1	2	1	X	X	X	X	X

For SI: 1 pound = 0.454 kg, 1 pound per gallon = 0.12 kg per liter, 1 ounce = 28.35 g.

a. A factor of 10 pounds per gallon shall be used for converting pounds (solid) to gallons (liquid) in accordance with Section 5003.1.2.

b. Black powder shall be stored in a Type 1, 2, 3 or 4 magazine as provided for in Section 5604.3.1.

c. This table shall not apply to consumer fireworks, 1.4G.

U.S. Department of Transportation shall be stored in Type 1, 2 or 3 magazines.

**Exceptions:**

1. Black powder shall be stored in a Type 1, 2, 3 or 4 magazine.
2. Cap-sensitive *explosive material* that is demonstrated not to be bullet sensitive shall be stored in a Type 1, 2, 3, 4 or 5 magazine.

❖ Type 1, 2 and 3 magazines are constructed with stricter requirements for the prevention of possible fire, water damage or bullet hazards.

**5604.3.2 Low explosives.** *Explosive materials* that are not cap sensitive shall be stored in a Type 1, 2, 3, 4 or 5 magazine.

❖ There are fewer restrictions on the storage of low explosives that are not cap sensitive. Protection against theft is a primary concern.

**5604.3.3 Detonating cord.** For quantity and distance purposes, detonating cord of 50 grains per foot shall be calculated as equivalent to 8 pounds (4 kg) of high *explosives* per 1,000 feet (305 m). Heavier or lighter core loads shall be rated proportionally.

❖ Standard detonating cord averaging about 50 grains per foot, which is considered the equivalent of 8 pounds (4 kg) of high explosives per 1,000 feet (305 m), is a benchmark for detonating cord. Heavier cord would be 60 grains per foot equaling 9 pounds (4 kg) of high explosive per 1,000 feet (305 m).

**5604.4 Prohibited storage.** Detonators shall be stored in a separate magazine for blasting supplies and shall not be stored in a magazine with other *explosive materials*.

❖ Storage of detonators with explosives may result in an accidental mass detonation. Detonators may be stored with other explosives only if that storage is approved by the fire code official and is under the following conditions [see DOTy 27 CFR, Part 55.213(b)]:

1. Nonmass-detonating detonators may be stored with electric squibs, safety fuses, ignitors and ignitor cord in a Type 4 magazine.
2. Detonators may be stored with delay devices, electric squibs, safety fuses, ignitors and ignitor cord in Type 1 and 2 magazines.

**5604.5 Location.** The use of magazines for storage of *explosives* and *explosive materials* shall comply with Sections 5604.5.1 through 5604.5.3.3.

❖ Explosives and blasting agents must be kept in magazines when not in use to reduce the exposure hazard.

**5604.5.1 Indoor magazines.** The use of indoor magazines for storage of *explosives* and *explosive materials* shall com-

ply with the requirements of Sections 5604.5.1.1 through 5604.5.1.7.

❖ The following sections address the requirements for indoor magazines. These sections cover the use, construction, quantity limit, prohibited use, number and separation distance of indoor magazines.

**5604.5.1.1 Use.** The use of indoor magazines for storage of *explosives* and *explosive materials* shall be limited to occupancies of Group F, H, M or S, and research and development laboratories.

❖ Section 5604.2 requires all explosives in storage to be located in magazines. This section, however, recognizes that certain operations engaged in manufacturing or research processes require the use of magazines (commonly referred to as “day boxes”) inside the building for the purposes of storing small quantities of material awaiting use.

**5604.5.1.2 Construction.** Indoor magazines shall comply with the following construction requirements:

1. Construction shall be fire resistant and theft resistant.
2. Exterior shall be painted red.
3. Base shall be fitted with wheels, casters or rollers to facilitate removal from the building in an emergency.
4. Lid or door shall be marked with conspicuous white lettering not less than 3 inches (76 mm) high and minimum  $\frac{1}{2}$  inch (12.7 mm) stroke, reading EXPLOSIVES—KEEP FIRE AWAY.
5. The least horizontal dimension shall not exceed the clear width of the entrance door.

❖ Indoor magazines need not be bullet resistant if the building in which they are located gives protection from bullet penetration. Not more than 50 pounds (23 kg) of high explosives may be stored in an indoor magazine, and not more than one indoor magazine may be stored inside a single building if the 50-pound (23 kg) limit has not been exceeded. The following comments clarify the intent of special requirements applying to magazines used indoors:

1. Construction specifications in this section state the minimum acceptable degree of protection from physical hazards and an exterior fire exposure when wood is used as a construction material for the magazine. Interior nails and screws must be countersunk to prevent damage to explosives and friction or sparks when the magazine is in transit or explosives are moved within the magazine.
2. The required color serves as a reminder of flammable, explosive and detonation hazards.
3. If a fire or an emergency occurs in the building, wheels or casters will permit the magazine to

be removed from the building or relocated to a safer area.

4. The required sign serves as a reminder to keep open flames and ignition sources away from the magazine.
5. In case of emergency, the magazine should clear the opening of the door for transfer of the magazine to the outdoors.

**5604.5.1.3 Quantity limit.** Not more than 50 pounds (23 kg) of *explosives* or *explosive materials* shall be stored within an indoor magazine.

**Exception:** Day boxes used for the storage of in-process material in accordance with Section 5605.6.4.1.

❖ Section 5605.6.4.1 establishes the requirements for magazines used for in-process materials that are consumed over the course of the workday. Magazines used in daily operations are generally referred to as “day boxes” by the industry. The ATF uses the term “day box” in its description of a Type 3 magazine. Magazines may either be used as storage magazines or as designated holding containers or structures within an operating building. The primary differences between a storage magazine and the magazines that are used as day boxes are limited to operational controls and the duration that the materials are allowed to be present in the work area.

A storage magazine is regulated by ATF, which requires materials present in the magazine to be identified on written logs and the inventory closely maintained during the time when it is present in the magazine. On the other hand, ATF does not regulate in-process materials that may be located in holding containers or structures, including day boxes located within an operating building.

Magazines (day boxes) that are used for the interim storage or staging of in-process materials are required to be emptied at the end of the work day. As containers for in-process material, they are not “storage” magazines, and as such are not further regulated by ATF. They are, however, regulated by Sections 5605.6.4 and 5605.6.4.1. The magazines (day boxes) used for in-process materials are protective enclosures that serve to isolate the materials from the work area and to minimize the exposure risk to personnel when materials are located outside of areas that may otherwise be provided with workstation protection. They serve to protect the material contained from potential fire exposure as well as to serve as a means to separate various in-process materials in order to avoid propagation hazards.

On the other hand, explosives stored in manufacturing buildings where the materials are not staged for in-process use are limited to quantities not exceeding 50 pounds (23 kg) net explosive weight. This storage can remain in the building without regard to a time limit, and all such storage may be further regulated by the operational controls required by ATF.

Day boxes or magazines used for process operations are used as a means to isolate in-process material from a workstation and to minimize the potential for involvement should an event occur within the immediate area of the workstation. This same material could be located in the same work space without the benefit of a day box.

Quantity control for these in-process magazines is limited to aggregating the quantity contained within the Q-D relationships of the building as specified by Section 5605.4. The 50-pound (23 kg) limit specified by this section applies to the storage of material where the storage can remain in an unattended mode and left in place during times when the building is unoccupied.

**5604.5.1.4 Prohibited use.** Indoor magazines shall not be used within buildings containing Group R occupancies.

❖ Indoor magazines are not permitted inside residences or dwellings because of the life hazard present and the difficulty of maintaining control over their use through routine inspections.

**5604.5.1.5 Location.** Indoor magazines shall be located within 10 feet (3048 mm) of an entrance and only on floors at or having ramp access to the exterior grade level.

❖ The location of these magazines must be chosen to minimize exposure of means of egress but maintain ready access from the exterior to facilitate fire fighting.

**5604.5.1.6 Number.** Not more than two indoor magazines shall be located in the same building. Where two such magazines are located in the same building, one magazine shall be used solely for the storage of not more than 5,000 detonators.

❖ The location of magazines in wholesale and retail establishments should be coordinated with and approved by the fire department’s prefire plans. Any changes in magazine locations require prior approval of the fire code official and should be noted on the permit.

**5604.5.1.7 Separation distance.** Where two magazines are located in the same building, they shall be separated by a distance of not less than 10 feet (3048 mm).

❖ Explosives and blasting agents that are offered for sale must be stored in separate magazines to prevent an explosion in one magazine from triggering an explosion in another magazine or mass detonation.

**5604.5.2 Outdoor magazines.** Outdoor magazines other than Type 3 shall be located so as to comply with Table 5604.5.2(2) or 5604.5.2(3) as set forth in Tables 5601.8.1(1) through 5601.8.1(3). Where a magazine or group of magazines, as described in Section 5604.5.2.2, contains different classes of *explosive materials*, and Division 1.1 materials are present, the required separations for the magazine or magazine group as a whole shall comply with Table 5604.5.2(2).

❖ Specified separation distances in the tables are intended to minimize the potential damage to life and property that may result from a blast inside a maga-

zine. Additionally, the separation distances help control the hazard to a given magazine from exposure fires involving ground cover or a fire occurring in another magazine and thus provide clear access for emergency response personnel. Separation and the rules governing blasting for those magazines are addressed by Section 5607.

Tables 5601.8.1(1) through (3) enhance the code and provide guidance in application for operating buildings as well as magazines.

Sections 5604.5.2.1 and 5604.5.2.2 recognize the circumstance surrounding the use of multiple magazines and magazines that are arranged in groups where the separation between magazines is less than the tabular distance established by the intermagazine (inter = between or among) distances. The basis for these provisions is Note d to the American Table of Distances [Table 5604.5.2(1)], except that the permissive language has been removed and the note divided into two distinct provisions. The provisions of Sections 5604.5.2.1 and 5604.5.2.2 are consistent with the footnote, and applicable to Division 1.3 and 1.4 materials as well as to the materials addressed by Table 5604.5.2(1). It is common to group a number of magazines, each containing different materials, on manufacturing sites for the purposes of operational control and dedication to specific manufacturing lines.

**5604.5.2.1 Separation.** Where two or more storage magazines are located on the same property, each magazine shall comply with the minimum distances specified from inhabited buildings, public transportation routes and operating buildings. Magazines shall be separated from each other by not less than the intermagazine distances (IMD) shown for the separation of magazines.

❖ See the commentary to Section 5604.5.2.

**TABLE 5604.5.2(1).** See page 56-14.

❖ Table 5604.5.2(1) establishes minimum separation distances for the permanent storage of explosives from selected property classes. The intent of the table is to place explosive storage far enough away from occupied buildings, highways, railways and other magazines to reduce exposure of those properties to damage if a detonation of a magazine occurs. Storage exceeding tabular amounts in a single magazine is rare and thus requires special approval by the fire code official.

**5604.5.2.2 Grouped magazines.** Where two or more magazines are separated from each other by less than the intermagazine distances (IMD), such magazines as a group shall be considered as one magazine and the total quantity of *explosive materials* stored in the group shall be treated as if stored in a single magazine. The location of the group of magazines shall comply with the intermagazine distances (IMD) speci-

fied from other magazines or magazine groups, inhabited buildings (IBD), public transportation routes (PTR) and operating buildings (ILD or IPD) as required.

❖ See the commentary to Section 5604.5.2.

**TABLE 5604.5.2(2).** See page 56-16.

❖ Magazines containing special fireworks, other than special salutes, and black powder or other low explosives must be separated from each other and from inhabited buildings, public highways and passenger railways. Amounts of low explosives are located in the left two columns. The separation distances are located on the row of the amount of low explosives in reference to inhabited buildings, railways or other magazines.

**TABLE 5604.5.2(3).** See page 56-16.

❖ Items in Division 1.4 present a fire hazard with no blast hazard and virtually no fragmentation hazard beyond the fire-hazard clearance ordinarily specified for high-risk materials. Separate facilities for storage and handling of this division should not be less than 100 feet (30 480 mm) from other facilities, except those of noncombustible construction, which can be 50 feet (15 240 mm) from each other, provided both are noncombustible.

Division 1.4 materials are finished goods or devices that contain energetic materials. A fire or explosive event with Division 1.4 materials is limited to the individual devices involved and, unlike the materials in the other divisions, there is no mass reaction. The table of distances has been based on federal regulations as published by the DOD.

**5604.5.3 Special requirements for Type 3 magazines.** Type 3 magazines shall comply with Sections 5604.5.3.1 through 5604.5.3.3.

❖ These requirements are intended to provide a reasonable degree of safety for Type 3 magazines at blasting sites.

**5604.5.3.1 Location.** Wherever practicable, Type 3 magazines shall be located away from neighboring inhabited buildings, railways, highways and other magazines in accordance with Table 5604.5.2(2) or 5604.5.2(3) as applicable.

❖ Type 3 magazines must be located as remotely as practical from public rights-of-way, buildings and other magazines to reduce exposures between them.

**5604.5.3.2 Supervision.** Type 3 magazines shall be attended when *explosive materials* are stored within. *Explosive materials* shall be removed to appropriate storage magazines for unattended storage at the end of the work day.

❖ The magazine must be constantly supervised by a trained attendant when explosives are being stored to prevent unauthorized removal of the contents and to enforce safety rules.

**EXPLOSIVES AND FIREWORKS**

250,000	275,000	2,215	2,215	670	1,340	1,950	2,000	360	720
275,000	300,000 <sup>b</sup>	2,275	2,275	690	1,380	2,000	2,000	385	770

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg.

- This table applies only to the manufacture and permanent storage of commercial explosive materials. It is not applicable to transportation of explosives or any handling or temporary storage necessary or incident thereto. It is not intended to apply to bombs, projectiles or other heavily encased explosives.
- Storage in excess of 300,000 pounds of explosive materials in one magazine is not allowed.
- Where a manufacturing building on an explosive materials plant site is designed to contain explosive materials, such building shall be located with respect to its proximity to inhabited buildings, public highways and passenger railways based on the maximum quantity of explosive materials permitted to be in the building at one time.
- Where two or more storage magazines are located on the same property, each magazine shall comply with the minimum distances specified from inhabited buildings, railways and highways, and, in addition, they should be separated from each other by not less than the distances shown for separation of magazines, except that the quantity of explosives in detonator magazines shall govern in regard to the spacing of said detonator magazines from magazines containing other explosive materials. Where any two or more magazines are separated from each other by less than the specified separation of magazines distances, then two or more such magazines, as a group, shall be considered as one magazine, and the total quantity of explosive materials stored in such group shall be treated as if stored in a single magazine located on the site of any magazine in the group and shall comply with the minimum distances specified from other magazines, inhabited buildings, railways and highways.

**EXPLOSIVES AND FIREWORKS**

**TABLE 5604.5.2(2)**

**TABLE OF DISTANCES (Q-D) FOR BUILDINGS AND MAGAZINES CONTAINING EXPLOSIVES—DIVISION 1.3 MASS-FIRE HAZARD<sup>a, b, c</sup>**

QUANTITY OF DIVISION 1.3 EXPLOSIVES (NET EXPLOSIVES WEIGHT)		DISTANCES IN FEET			
Pounds over	Pounds not over	Inhabited Building Distance (IBD)	Distance to Public Traffic Route (PTR)	Intermagazine Distance (IMD)	Intraline Distance (ILD) or Intraplant Distance (IPD)
0	1,000	75	75	50	50
1,000	5,000	115	115	75	75
5,000	10,000	150	150	100	100
10,000	20,000	190	190	125	125
20,000	30,000	215	215	145	145
30,000	40,000	235	235	155	155
40,000	50,000	250	250	165	165
50,000	60,000	260	260	175	175
60,000	70,000	270	270	185	185
70,000	80,000	280	280	190	190
80,000	90,000	295	295	195	195
90,000	100,000	300	300	200	200
100,000	200,000	375	375	250	250
200,000	300,000	450	450	300	300

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg

- a. Black powder, when stored in magazines, is defined as low explosive by the Bureau of Alcohol, Tobacco, Firearms and Explosives (BATF).
- b. For quantities less than 1,000 pounds, the required distances are those specified for 1,000 pounds. The use of lesser distances is allowed where supported by approved test data and/or analysis.
- c. Linear interpolation of explosive quantities between table entries is allowed.

**TABLE 5604.5.2(3)**

**TABLE OF DISTANCES (Q-D) FOR BUILDINGS AND MAGAZINES CONTAINING EXPLOSIVES—DIVISION 1.4<sup>c</sup>**

QUANTITY OF DIVISION 1.4 EXPLOSIVES (NET EXPLOSIVES WEIGHT)		DISTANCES IN FEET			
Pounds over	Pounds not over	Inhabited Building Distance (IBD)	Distance to Public Traffic Route (PTR)	Intermagazine Distance <sup>a, b</sup> (IMD)	Intraline Distance (ILD) or Intraplant Distance <sup>a</sup> (IPD)
50	Not Limited	100	100	50	50

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg.

- a. A separation distance of 100 feet is required for buildings of other than Type I or Type II construction as defined in the *International Building Code*.
- b. For earth-covered magazines, specific separation is not required.
  - 1. Earth cover material used for magazines shall be relatively cohesive. Solid or wet clay and similar types of soil are too cohesive and shall not be used. Soil shall be free from unsanitary organic matter, trash, debris and stones heavier than 10 pounds or larger than 6 inches in diameter. Compaction and surface preparation shall be provided, as necessary, to maintain structural integrity and avoid erosion. Where cohesive material cannot be used, as in sandy soil, the earth cover over magazines shall be finished with a suitable material to ensure structural integrity.
  - 2. The earth fill or earth cover between earth-covered magazines shall be either solid or sloped, in accordance with the requirements of other construction features, but not less than 2 feet of earth cover shall be maintained over the top of each magazines. To reduce erosion and facilitate maintenance operations, the cover shall have a slope of 2 horizontal to 1 vertical.
- c. Restricted to articles, including articles packaged for shipment, that are not regulated as an explosive under Bureau of Alcohol, Tobacco, Firearms and Explosives regulations, or unpacked articles used in process operations that do not propagate a detonation or deflagration between articles. This table shall not apply to consumer fireworks, 1.4G.

**5604.5.3.3 Use.** Not more than two Type 3 magazines shall be located at the same blasting site. Where two Type 3 magazines are located at the same blasting site, one magazine shall be used solely for the storage of detonators.

❖ Detonators must be stored in separate magazines from explosives to prevent an accidental mass detonation.

**5604.6 Construction.** Magazines shall be constructed in accordance with Sections 5604.6.1 through 5604.6.5.2.

❖ Magazine construction requirements are based on requirements in DOTy 27 CFR, Part 55 and NFPA 495. Magazines are identified by designation as one of five types: Types 1 through 5.

**5604.6.1 Drainage.** The ground around a magazine shall be graded so that water drains away from the magazine.

❖ Grading land away from the magazine allows storm water to run off and not accumulate in, under or around a magazine. Water may damage explosives. Contaminated water may conduct an electric current, possibly resulting in the detonation of explosives.

**5604.6.2 Heating.** Magazines requiring heat shall be heated as prescribed in NFPA 495 by either hot water radiant heating within the magazine or by indirect warm air heating.

❖ Indirect heating systems can prevent freezing and avoid excessive heating of magazine contents. These systems also do not constitute an ignition hazard.

**5604.6.3 Lighting.** Where lighting is necessary within a magazine, electric safety flashlights or electric safety lanterns shall be used, except as provided in NFPA 495.

❖ Safety flashlights and safety lanterns used inside magazines must be designed for use in hazardous locations. Fixed electric lighting installed as specified in Section 65.5.1 of NFPA 495 is acceptable. All electrical work must conform to NFPA 70 requirements. DOTy 27 CFR, Part 55.217(c), requires that copies of documents indicating that the electrical installation conforms to NFPA 70 to be maintained on site and always available for inspections. Requirements of NFPA 70 and NFPA 495 are intended to minimize the possibility that sparks generated by electrical arcing during normal operations or through equipment failures will ignite explosives within the magazine.

**5604.6.4 Nonsparking materials.** In other than Type 5 magazines, there shall not be exposed ferrous metal on the interior of a magazine containing packages of *explosives*.

❖ Ferrous metal must not be exposed in the interior of a Type 1, 2, 3 or 4 magazine where the metal could come in contact with packages of explosives.

**5604.6.5 Signs and placards.** Property upon which Type 1 magazines and outdoor magazines of Types 2, 4 and 5 are located shall be posted with signs stating: EXPLOSIVES—KEEP OFF. These signs shall be of contrasting colors with a minimum letter height of 3 inches (76 mm) with a minimum brush stroke of 1/2 inch (12.7 mm). The signs shall be located

to minimize the possibility of a bullet shot at the sign hitting the magazine.

❖ Signs are intended to identify the public hazard and provide warning to fire fighters. Signs should also be prominently displayed at the entrance to the property and at regular intervals around the perimeter of the property. Contrasting letters and backgrounds on the signs (red on white preferred) should be used with letters that are legible from a distance. A minimum 3-inch (76 mm) height is recommended for the letters. The Institute of Makers of Explosives (IME) recommends the following wording in addition to that required by this section:

**DANGER!**  
**NEVER FIGHT EXPLOSIVE FIRES.**  
**EXPLOSIVES ARE STORED AT THIS SITE.**  
CALL: \_\_\_\_\_.

Military and DOT explosives warning signs use black letters, numerals and symbols on orange backgrounds. Nonreflective sign materials make these types of signs difficult to identify and read. Signs must always be conspicuously posted and maintained in a clear, clean and legible condition.

Signs are attractive targets for irresponsible fire-arms bearers. Therefore, signs must be located, in anticipation of an individual shooting a rifle or handgun at the sign, so the bullet will not hit the magazine.

The absence of clear warning signs was cited as a contributing factor in the November 1988 deaths of six Kansas City, Missouri, fire fighters who were approaching a Type 4 magazine at a remote highway construction site when it exploded. A similar incident in March 1989 in Peterborough, England, killed one fire fighter and injured 76 other persons, including six fire fighters. The Peterborough, England, incident occurred while fire fighters were trying to control a fire in a motor carrier hauling explosives.

**5604.6.5.1 Access road signs.** At the entrance to *explosive* material manufacturing and storage sites, all access roads shall be posted with the following warning sign or other *approved* sign:

**DANGER!**  
**NEVER FIGHT EXPLOSIVE FIRES.**  
**EXPLOSIVES ARE STORED ON THIS SITE**  
CALL \_\_\_\_\_.

The sign shall be weather-resistant with a reflective surface and have lettering not less than 2 inches (51 mm) high.

❖ Signs are intended to identify the public hazard and warn fire fighters. Signs should also be prominently displayed at the entrance to the property and at regular intervals around the perimeter of the property. Contrasting letters and backgrounds on the signs (red on white preferred) should be used with letters that are legible from a distance. A minimum 2-inch (51 mm) height is recommended for the letters.

**5604.6.5.2 Placards.** Type 5 magazines containing Division 1.5 blasting agents shall be prominently placarded as required during transportation by DOTn 49 CFR Part 172 and DOTy 27 CFR Part 55.

- ❖ Requirements for placarding explosives shipments are found in DOTn 49 CFR; Part 172, Subpart F. Commentary Figure 5604.6.5.2 depicts the format of a typical explosives placard (black graphics on an orange background). Placards allow emergency response personnel to readily identify the explosive materials being transported if a fire or accident involving the transport vehicle occurs.

**5604.7 Operation.** Magazines shall be operated in accordance with Sections 5604.7.1 through 5604.7.9.

- ❖ The following sections address the operations of magazines. Items covered include security; open flames; brush; combustible storage; unpacking and packing; tools and equipment.

**5604.7.1 Security.** Magazines shall be kept locked in the manner prescribed in NFPA 495 at all times except during placement or removal of *explosives* or inspection.

- ❖ Security precautions must be taken to minimize the possibility of theft, tampering or misuse of explosives.

**5604.7.2 Open flames and lights.** Smoking, matches, flame-producing devices, open flames, firearms and firearms cartridges shall not be allowed inside of or within 50 feet (15 240 mm) of magazines.

- ❖ The carrying or use of open flames, spark-producing devices, matches and firearms is prohibited to prevent accidental ignition of explosives within the magazine.

**5604.7.3 Brush.** The area located around a magazine shall be kept clear of brush, dried grass, leaves, trash, debris and similar combustible materials for a distance of 25 feet (7620 mm).

- ❖ Brush and dry grass, leaves, trash and other easily ignitable debris must be kept clear for a distance of 25 feet (7620 mm) around magazines containing explosives to minimize the threat to magazine contents from fire exposure.

**5604.7.4 Combustible storage.** Combustible materials shall not be stored within 50 feet (15 240 mm) of magazines.

- ❖ Elimination of combustible materials within 50 feet (15 240 mm) of magazines eliminates both a fuel source and a possible source of ignition for stored explosives.

**5604.7.5 Unpacking and repacking explosive materials.** Containers of *explosive materials*, except fiberboard containers, and packages of damaged or deteriorated *explosive materials* or fireworks shall not be unpacked or repacked inside or within 50 feet (15 240 mm) of a magazine or in close proximity to other *explosive materials*.

- ❖ The packing or unpacking of boxes, crates, drums or other containers with metal staples, bands, nails or other ferrous parts may generate sparks, which could possibly ignite explosives stored within a magazine. The separation distance is intended to reduce the possibility of secondary explosions if an accident involving the explosives being handled occurs.

**5604.7.5.1 Storage of opened packages.** Packages of *explosive materials* that have been opened shall be closed before being placed in a magazine.

- ❖ The closing of the opened packages eliminates the hazard of mixing with other explosives, being available in case of an ignition source and causing an explosion or fire.

**5604.7.5.2 Nonsparking tools.** Tools used for the opening and closing of packages of *explosive materials*, other than metal slitters for opening paper, plastic or fiberboard containers, shall be made of nonsparking materials.

- ❖ Nonsparking tools are used to avoid producing sparks and igniting explosives. These tools must either be made from nonsparking materials or be painted to prevent them from producing sparks.

**5604.7.5.3 Disposal of packaging.** Empty containers and paper and fiber packaging materials that previously contained *explosive materials* shall be disposed of or reused in a *approved* manner.

- ❖ Debris from explosives shipments or use, including discarded packages, bags and cartons, must be disposed in accordance with the explosive manufacturer's instructions.

**5604.7.6 Tools and equipment.** Metal tools, other than non-ferrous transfer conveyors and ferrous metal conveyor stands

protected by a coat of paint, shall not be stored in a magazine containing *explosive materials* or detonators.

- ❖ Tools that can be stored in a magazine are limited to those needed to maintain the magazine and facilitate the transfer of explosives. These tools must be non-sparking or painted to prevent them from producing sparks. Ferrous tools with chipped or worn protective coatings must be removed from service and repainted before being placed back in use.

**5604.7.7 Contents.** Magazines shall be used exclusively for the storage of *explosive materials*, blasting materials and blasting accessories.

- ❖ Additional materials likely to pose a fire hazard or produce sparks when used cannot be stored inside magazines.

**5604.7.8 Compatibility.** Corresponding grades and brands of *explosive materials* shall be stored together and in such a manner that the grade and brand marks are visible. Stocks shall be stored so as to be easily counted and checked. Packages of *explosive materials* shall be stacked in a stable manner not exceeding 8 feet (2438 mm) in height.

- ❖ Identical grades and brands of explosives must be stored together, with the brands and grade marks showing. Explosive materials must be stored so they can be easily checked and counted.

**5604.7.9 Stock rotation.** When *explosive material* is removed from a magazine for use, the oldest usable stocks shall be removed first.

- ❖ Use of the oldest usable stock first assists in elimination of explosive material before it can deteriorate and become hazardous.

**5604.8 Maintenance.** Maintenance of magazines shall comply with Sections 5604.8.1 through 5604.8.3.

- ❖ This section addresses housekeeping, repairs and the floors on which the magazines are maintained.

**5604.8.1 Housekeeping.** Magazine floors shall be regularly swept and be kept clean, dry and free of grit, paper, empty packages and rubbish. Brooms and other cleaning utensils shall not have any spark-producing metal parts. Sweepings from magazine floors shall be disposed of in accordance with the manufacturers' *approved* instructions.

- ❖ Dirt and debris may contain materials that produce sparks or friction when explosives are moved within the magazine. Some blasting agents become sensitized or unstable when contaminated; therefore, regular cleaning and a maintenance schedule should be established and followed.

Cleaning implements with ferrous parts may produce sparks when used improperly. Only nonsparking tools may be used inside the magazine.

Finely divided residue on packages may pose an extreme fire hazard when improperly discarded. Most manufacturers recommend burning packages and debris from explosives at an approved remote location. The IME Safety Library Publication No. 21 con-

tains general guidance on the subject of disposing packages of explosives. Poor housekeeping often indicates other safety hazards.

**5604.8.2 Repairs.** *Explosive materials* shall be removed from the magazine before making repairs to the interior of a magazine. *Explosive materials* shall be removed from the magazine before making repairs to the exterior of the magazine where there is a possibility of causing a fire. *Explosive materials* removed from a magazine under repair shall either be placed in another magazine or placed a safe distance from the magazine, where they shall be properly guarded and protected until repairs have been completed. Upon completion of repairs, the *explosive materials* shall be promptly returned to the magazine. Floors shall be cleaned before and after repairs.

- ❖ Explosives must be removed from the magazine under repair and placed in another magazine or a safe distance away before beginning repair activities that could cause sparks or fire, and the floor must be cleaned before beginning repairs inside a magazine. Explosives must be properly guarded until they are returned to the magazine.

**5604.8.3 Floors.** Magazine floors stained with liquid shall be dealt with in accordance with instructions obtained from the manufacturer of the *explosive material* stored in the magazine.

- ❖ Floors stained with nitroglycerin must be cleaned according to the manufacturer's instructions. If the manufacturer cannot be identified or reached, another manufacturer, the nearest U.S. military installation, the ATF regional office or a local law enforcement agency must be contacted to request an explosive ordnance disposal (EOD) team.

**5604.9 Inspection.** Magazines containing *explosive materials* shall be opened and inspected at maximum seven-day intervals. The inspection shall determine whether there has been an unauthorized or attempted entry into a magazine or an unauthorized removal of a magazine or its contents.

- ❖ The importance of magazine security and explosives accountability cannot be overestimated, especially in light of the upsurge in incidents of international terrorists using bombs. In most cases of illicit use of explosives, the source of the explosive materials has been legitimate operating explosive material users. Magazines must be inspected at least weekly to determine that no theft or attempted theft has occurred. Thefts or tampering should be reported immediately to the fire code official and local and federal law enforcement officials.

**5604.10 Disposal of explosive materials.** *Explosive materials* shall be disposed of in accordance with Sections 5604.10.1 through 5604.10.7.

- ❖ Sections 5604.10.1 through 5604.10.7 cover the procedures for proper disposal of explosive materials. Areas covered are notification, deteriorated materials, qualified persons, storage of misfires, disposal sites, reuse of sites and personnel safeguards.

## EXPLOSIVES AND FIREWORKS

**5604.10.1 Notification.** The *fire code official* shall be notified immediately where deteriorated or leaking *explosive materials* are determined to be dangerous or unstable and in need of disposal.

- ❖ The notification must include the following for each site where explosive material is stored: type of explosives, magazine capacity and location.

**5604.10.2 Deteriorated materials.** Where an *explosive material* has deteriorated to an extent that it is in an unstable or dangerous condition, or when a liquid has leaked from an *explosive material*, the person in possession of such material shall immediately contact the material's manufacturer to obtain disposal and handling instructions.

- ❖ Damaged or deteriorated explosives may become sensitized and unpredictable. Extreme caution must be used in handling such materials. Some explosives, such as nitroglycerin, become shock sensitive when contaminated or deteriorated because of age, exposure to ultraviolet light or excessive heating. Emergency forces should be summoned for standby while cleanup procedures are underway in situations involving sensitized or unstable explosives. If an accident occurs, fire fighters should attempt to protect exposures only from a distance and rescue individuals who are in immediate danger and safely reachable. Explosives manufacturers do not recommend fighting fires involving explosives because of the extreme danger associated with such operations. Manufacturers can provide advice and assistance in identifying a safe means of disposing of damaged explosives.

**5604.10.3 Qualified person.** The work of destroying *explosive materials* shall be directed by persons experienced in the destruction of *explosive materials*.

- ❖ Only an approved and experienced explosives technician is permitted to dispose of damaged, dangerous or unstable explosives. IME Safety Library Publication No. 21 contains general guidance on the safe destruction of damaged explosives and explosive waste. However, the manufacturer's specific guidance should always be followed first.

A military or law enforcement EOD team should be contacted if the licensee or permittee cannot provide a suitable explosives technician. Member companies of the IME have entered into a cooperative agreement to give advice and consultation to law enforcement agencies, fire departments and regulatory officials regarding the destruction or disposal of dangerous, damaged or unstable commercial explosives. Another manufacturer can lend assistance if the manufacturer of the damaged or dangerous goods cannot be identified or located.

**5604.10.4 Storage of misfires.** *Explosive materials* and fireworks recovered from blasting or display misfires shall be placed in a magazine until an experienced person has determined the proper method for disposal.

- ❖ Explosives recovered from misfires must be placed in a separate licensed magazine until they can be dis-

posed of according to the manufacturer's recommendations.

**5604.10.5 Disposal sites.** Sites for the destruction of *explosive materials* and fireworks shall be *approved* and located at the maximum practicable safe distance from inhabited buildings, public highways, operating buildings and all other exposures to ensure keeping air blast and ground vibration to a minimum. The location of disposal sites shall not be closer to magazines, inhabited buildings, railways, highways and other rights-of-way than is allowed by Tables 5604.5.2(1), 5604.5.2(2) and 5604.5.2(3). Where possible, *barricades* shall be utilized between the destruction site and inhabited buildings. Areas where *explosives* are detonated or burned shall be posted with adequate warning signs.

- ❖ A blasting shelter should be located near the burn area for protection from the blast and for emergency use of personnel.

**5604.10.6 Reuse of site.** Unless an *approved* burning site has been thoroughly saturated with water and has passed a safety inspection, 48 hours shall elapse between the completion of a burn and the placement of scrap explosive materials for a subsequent burn.

- ❖ Procedures and safeguards must be in place to prevent scrap explosive material from being placed in any burn location until at least 48 hours has passed since the last fires have gone out.

**5604.10.7 Personnel safeguards.** Once an *explosive* burn operation has been started, personnel shall relocate to a safe location where adequate protection from air blast and flying debris is provided. Personnel shall not return to the burn area until the person in charge has inspected the burn site and determined that it is safe for personnel to return.

- ❖ A warning device must be used when explosives and fireworks materials are being destroyed. This warning device may also be used to advise personnel when the area is safe for reentry.

### SECTION 5605 MANUFACTURE, ASSEMBLY AND TESTING OF EXPLOSIVES, EXPLOSIVE MATERIALS AND FIREWORKS

**5605.1 General.** The manufacture, assembly and testing of *explosives*, ammunition, blasting agents and fireworks shall comply with the requirements of this section and NFPA 495 or NFPA 1124.

#### Exceptions:

1. The hand loading of small arms ammunition prepared for personal use and not offered for resale.
  2. The mixing and loading of blasting agents at blasting sites in accordance with NFPA 495.
  3. The use of binary *explosives* or phosphoric materials in blasting or pyrotechnic special effects applications in accordance with NFPA 495 or NFPA 1126.
- ❖ This section covers emergency planning; separation of operating and manufacturing buildings; control

areas; operations and maintenance for the manufacturing, assembling and testing of explosives, blasting agents and fireworks. Section 5606 covers small arms ammunition. Exceptions 2 and 3 are addressed in NFPA standards.

Fireworks manufacturing is a relatively localized or concentrated industry. Most fireworks plants have settled and remain in predominantly rural locations for several reasons. Substantial sites are required to allow for isolation of manufacturing and storage buildings from one another to limit hazard exposures. These sites permit insulation from regulatory supervision. Skilled workers are required to assemble the fireworks; as a result, a loyal workforce usually develops in the regions where plants are located. Consequently, the local economy usually becomes heavily dependent on the industry's presence. Further, public concern and outcry is minimized by these factors, since occasional accidents are more or less expected. Increased regulatory attention and the prohibition of common fireworks in many states has, however, led to increased foreign competition that has further impacted the industry. Today, fewer than 100 American firms are engaged in this activity and they employ less than 3,000 persons. The U.S. Department of Treasury (DOTy) enforces regulations (DOTy 27 CFR; 55 and 181) restricting the import, manufacture, storage and use of fireworks and explosives.

**5605.2 Emergency planning and preparedness.** Emergency plans, emergency drills, employee training and hazard communication shall conform to the provisions of this section and Sections 404, 405, 406 and 407.

❖ Reference to Sections 404, 405 and 407 are also included for assistance with this section. See the commentary to those sections.

**5605.2.1 Hazardous Materials Management Plans and Inventory Statements required.** Detailed Hazardous Materials Management Plans (HMMP) and Hazardous Materials Inventory Statements (HMIS) complying with the requirements of Section 407 shall be prepared and submitted to the local emergency planning committee, the *fire code official* and the local fire department.

❖ Section 407.6 requires that Hazardous Materials Management Plans (HMMP) be in accordance with Section 2701.4.1, which gives the requirements for a facility site plan. Section 407.5 requires that the Hazardous Materials Inventory Statements (HMIS) be in accordance with Section 2701.4.2, which gives the items required in an HMIS.

**5605.2.2 Maintenance of plans.** A copy of the required HMMP and HMIS shall be maintained on site and furnished to the *fire code official* on request.

❖ A copy of the plant's plans must be kept in the office on the premises of each explosives, ammunition, blasting agent or fireworks manufacturing plant and must be made available to the *fire code official* or an authorized representative upon request.

**5605.2.3 Employee training.** Workers who handle *explosives* or *explosive* charges or dispose of *explosives* shall be trained in the hazards of the materials and processes in which they are to be engaged and with the safety rules governing such materials and processes.

❖ Employees who are required to handle the explosive materials need instructions concerning the hazards of the products. MSDS are a great source for the hazards of the materials. The employees must go through an orientation on the rules and regulations concerning the processes.

**5605.2.4 Emergency procedures.** *Approved* emergency procedures shall be formulated for each plant and shall include personal instruction in any anticipated emergency. Personnel shall be made aware of an emergency warning signal.

❖ Emergency procedures must be developed for each plant and building. Fire and disaster drills must be conducted and records of those drills must be kept at the plant office.

**5605.3 Intraplant separation of operating buildings.** *Explosives* manufacturing buildings and fireworks manufacturing buildings, including those where *explosive* charges are assembled, manufactured, prepared or loaded utilizing Division 1.1, 1.2, 1.3, 1.4 or 1.5 *explosives*, shall be separated from all other buildings, including magazines, within the confines of the manufacturing plant, at a distance not less than those shown in Table 5605.3 or 5604.5.2(3), as appropriate.

**Exception:** Fireworks manufacturing buildings separated in accordance with NFPA 1124.

The quantity of *explosives* in an operating building shall be the net weight of all *explosives* contained therein. Distances shall be based on the hazard division requiring the greatest separation, unless the aggregate *explosive* weight is divided by *approved* walls or shields designed for that purpose. Where dividing a quantity of *explosives* into smaller stacks, a suitable barrier or adequate separation distance shall be provided to prevent propagation from one stack to another.

Where distance is used as the sole means of separation within a building, such distance shall be established by testing. Testing shall demonstrate that propagation between stacks will not result. Barriers provided to protect against *explosive* effects shall be designed and installed in accordance with *approved* standards.

❖ Manufacturing operations frequently contain explosive materials that may fall into more than one division. When such is the case, Q-D relationships are established on the most severe case. The separation of explosives into piles by distance or the construction of substantial dividing walls (barrier wall) is a recognized means of mitigating the effects of conflagration by propagation. Propagation distances are established by testing. The construction of barriers can be accomplished by various means; however, the design of such structures must be specific to address the nature (impulse pressures) and time factors involved with the energy produced by explosive materials. The primary reference is U.S. Army

**EXPLOSIVES AND FIREWORKS**

Technical Manual TM 51300, Air Force Manual (AFM) 8822 and Navy NAVFAC P397, *Structures to Resist the Effects of Accidental Explosions*.

The exception recognizes that NFPA 1124 requirements cover site security; separation distances for manufacturing facilities; storage of salute and black powder; building construction and transportation of fireworks.

**TABLE 5605.3.** See below.

❖ Table 5605.3 has been designed to recognize explosives that either detonate or present a mass-explosion hazard (Divisions 1.1, 1.2 and 1.5). Under the classification system used by the code there is a need to recognize the various hazards of explosive materials when classified in other divisions, specifically Division 1.3 and 1.4 materials. The hazards of Division 1.3 materials are mass fire hazards where fire can involve the aggregate amount of undivided material. As finished goods, the hazards of Division

1.4 materials are limited to events with the individual articles. Division 1.5 materials are capable of detonation, and including them in Table 5605.3 represents the most conservative case. This table applies to the separation distances of buildings within an explosive manufacturing plant. Of course, the distance is related to the amount of explosives in storage. Distance and barricades are means of reducing damage to property and injury to personnel. With a barricade, the distance is sufficient, but without a barricade, the distance must be doubled to be the equivalent of a barricade. The quantity is calculated in pounds in each structure or building.

**5605.4 Separation of manufacturing operating buildings from inhabited buildings, public traffic routes and magazines.** Where an operating building on an *explosive* materials plant site is designed to contain *explosive* materials, such a building shall be located away from inhabited buildings, public traffic routes and magazines in accordance with Table 5604.5.2(2) or 5604.5.2(3) as appropriate, based on the maxi-

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg.

a. Where a building or magazine containing explosives is not barricaded, the intraline distances shown in this table shall be doubled.

mum quantity of *explosive* materials permitted to be in the building at one time (see Section 5601.8).

**Exception:** Fireworks manufacturing buildings constructed and operated in accordance with NFPA 1124.

- ❖ Buildings and other facilities used for mixing of blasting agents at a fixed location must comply with the separation requirements of Table 5604.5.2(1). The buildings must be isolated for the protection of life and nearby property. Suitable exterior barricades, natural or artificial, are to be provided on pressure-relief sides of buildings. The exception recognizes that NFPA 1124 requirements cover site security; separation distances for manufacturing facilities; storage of salute and black powder; building construction and transportation of fireworks.

**5605.4.1 Determination of net explosive weight for operating buildings.** In addition to the requirements of Section 5601.8 to determine the net *explosive* weight for materials stored or used in operating buildings, quantities of *explosive materials* stored in magazines located at distances less than intraline distances from the operating building shall be added to the contents of the operating building to determine the net *explosive* weight for the operating building.

- ❖ Manufacturing buildings are operating buildings within the context of the code. Explosive materials located in manufacturing buildings or process areas are classified as in-process materials and considered to be in use within the context of the code. The in-process materials are either located at workstations or are being staged as they enter or exit the manufacturing process.

It is common practice to utilize day boxes constructed to meet the requirements of a Type 3 magazine as a means to store explosives that are consumed over the course of a single workday or work shift so the magazine may be located either inside or immediately outside of the building in which the explosive materials are used. The use of pass-through type magazines that allow for delivery of explosive materials from the outside, and extraction of the explosive material from inside the building is commonplace. When pass-throughs are used, the magazine is located to abut the exterior building wall, with access to the inside limited to one or more access doors. In the most conservative sense, such magazines are considered to be outdoors and the exception granted by Section 5606.6.4.1 applicable to in-process material does not apply.

When the storage is located outside the building, there is a literal encroachment on the distances imposed by the code that require the magazines to be separated from the building in which the material is used. The net explosive weight (or contents) of the operating building or magazine is used to determine the separation distances required. Section 5604.5.1.3 allows the storage of up to 50 pounds (23 kg) of explosive material to be located in an indoor magazine when such magazines are not regulated by Section 5605.6.4.1. Quantities in excess of 50 pounds

(23 kg) in a storage magazine are required to be stored in outdoor magazines. For the storage of finished goods or raw materials there is seldom a problem because the outdoor magazines are normally located well away from the manufacturing area.

The problem arises with storage of explosives, other than those designated for in-process use, when small quantities of up to 50 pounds (23 kg) are to be located outdoors in a magazine that could otherwise be located indoors. Literally interpreted, the code requires a separation between any magazine and an operating building regardless of the contents of the magazine. Whether an indoor magazine limited to 50 pounds (23 kg) net explosive weight is located either immediately inside an access door to the work area or immediately outside the same door does not change the hazard of its contents. It is reasonable to restrict the quantities of explosive materials located outside the door to an amount not to exceed that which would otherwise be allowed to be located inside the door, i.e., 50 pounds (23 kg). Quantities that exceed the amount allowed indoors must be in magazines located at not less than the tabular distances specified by the IPD tables.

Explosives stored or used within the ILD assigned to an operating building must be accounted for in determining the location of the building with its proximity to others. This section requires that the aggregate quantity of explosives stored or used in an operating building be derived by adding the totals of all material stored in magazines inside or outside the building to the total of material in process.

Sections 5605.4.1.1 through 5605.4.1.4 limit the quantity of explosives allowed to be stored in magazines within the ILD whether located inside or outside of the building, or both, to not more than 50 pounds (23 kg), thereby maintaining the intent of the code, which is to move larger quantities of material away from the building to storage arrangements of a more permanent nature.

By establishing clear rules that recognize the need for operating buildings to have limited quantities of explosive materials other than in-process materials in storage proximate to the point of use, operational safety is enhanced and the concept of quantity control remains intact.

**5605.4.1.1 Indoor magazines.** The storage of *explosive* materials located in indoor magazines in operating buildings shall be limited to a net *explosive* weight not to exceed 50 pounds (23 kg).

- ❖ See the commentary to Section 5605.4.1.

**5605.4.1.2 Outdoor magazines with a net explosive weight less than 50 pounds.** The storage of *explosive materials* in outdoor magazines located at less than intraline distances from operating buildings shall be limited to a net *explosive* weight not to exceed 50 pounds (23 kg).

- ❖ See the commentary to Section 5605.4.1.

**5605.4.1.3 Outdoor magazines with a net explosive weight greater than 50 pounds.** The storage of *explosive materials*

## EXPLOSIVES AND FIREWORKS

in outdoor magazines in quantities exceeding 50 pounds (23 kg) net *explosive* weight shall be limited to storage in outdoor magazines located not less than intraline distances from the operating building in accordance with Section 5604.5.2.

❖ See the commentary to Section 5605.4.1.

**5605.4.1.4 Net explosive weight of materials stored in combination indoor and outdoor magazines.** The aggregate quantity of *explosive materials* stored in any combination of indoor magazines or outdoor magazines located at less than the intraline distances from an operating building shall not exceed 50 pounds (23 kg).

❖ See the commentary to Section 5605.4.1.

**5605.5 Buildings and equipment.** Buildings or rooms that exceed the *maximum allowable quantity per control area* of *explosive materials* shall be operated in accordance with this section and constructed in accordance with the requirements of the *International Building Code* for Group H occupancies.

**Exception:** Fireworks manufacturing buildings constructed and operated in accordance with NFPA 1124.

❖ The IBC addresses the issue of buildings that exceed the maximum allowable quantities per control area (MAQ) found in Table 307.7(1) of the IBC as well as in Chapter 50 of the code. The exception recognizes that NFPA 1124 requirements cover site security, separation distances for manufacturing facilities, storage of salute and black powder, building construction and transportation of fireworks.

**5605.5.1 Explosives dust.** *Explosives* dust shall not be exhausted to the atmosphere.

❖ Exhausting explosive dust into the atmosphere creates an explosive hazard. When the concentration of air and dust reaches the ignition stage, explosions can occur and cause both physical and structural damage.

**5605.5.1.1 Wet collector.** When collecting *explosives* dust, a wet collector system shall be used. Wetting agents shall be compatible with the *explosives*. Collector systems shall be interlocked with process power supplies so that the process cannot continue without the collector systems also operating.

❖ Wet processes will be used wherever practicable in mixing explosive materials. Wet processing eliminates the probability of dust being an explosive hazard.

**5605.5.1.2 Waste disposal and maintenance.** *Explosives* dust shall be removed from the collection chamber as often as necessary to prevent overloading. The entire system shall be cleaned at a frequency that will eliminate hazardous concentrations of *explosives* dust in pipes, tubing and ducts.

❖ Ducts are to be grounded and be as short and straight as possible with no caps, outlets, pockets or other dead-end spaces where explosives might accumulate.

**5605.5.2 Exhaust fans.** Squirrel cage blowers shall not be used for exhausting hazardous fumes, vapors or gases. Only nonferrous fan blades shall be used for fans located within the

ductwork and through which hazardous materials are exhausted. Motors shall be located outside the duct.

❖ Ventilation and dust control equipment must be of such a type and installed and operated to not endanger employees by possible ignition of explosives.

**5605.5.3 Work stations.** Work stations shall be separated by distance, barrier or other *approved* alternatives so that fire in one station will not ignite material in another work station. Where necessary, the operator shall be protected by a personnel shield located between the operator and the *explosive* device or *explosive material* being processed. This shield and its support shall be capable of withstanding a blast from the maximum amount of *explosives* allowed behind it.

❖ Using safety precautions should eliminate most problems in a work station; however, sometimes accidents happen beyond our control. The separation requirements in this section are intended to protect workstations from accidents in another station and their operators from all accidental blasts. Protection of the worker must always be of high priority.

**5605.6 Operations.** Operations involving *explosives* shall comply with Sections 5605.6.1 through 5605.6.10.

❖ The following sections address the operations that involve explosives. These sections apply to isolating the operations; controlling static electricity; using approved containers for bulk materials; having quantity limits; properly disposing of waste; abiding by safety rules, posting limits and not storing explosive materials near a heat source.

**5605.6.1 Isolation of operations.** Where the type of material and processing warrants, mechanical operations involving *explosives* in excess of 1 pound (0.454 kg) shall be carried on at isolated stations or at intraplant distances, and machinery shall be controlled from remote locations behind *barricades* or at separations so that workers will be at a safe distance while machinery is operating.

❖ The machinery used in processing operations on explosive items weighing more than 1 pound (0.454 kg) must be controlled from remote locations and behind barricades for the safety of personnel. These extra safety controls are not required when no unit or separate article of any manufactured or assembled explosive device contains more than 1 pound (0.454 kg) of explosive material.

**5605.6.2 Static controls.** The work area where the screening, grinding, blending and other processing of static-sensitive *explosives* or pyrotechnic materials is done shall be provided with *approved* static controls.

❖ The working area must be maintained above 20-percent relative humidity. If the relative humidity drops below 20 percent, the above operations must be stopped and secured until the relative humidity can be raised above 20 percent. It is desirable to keep the relative humidity above 20 to 30 percent, except where metal powders are involved. In that case, the relative humidity should be between 50 and 60 per-

cent. Means must be provided and used to discharge static electricity from hand trucks, buggies and similar equipment before they enter buildings containing static-sensitive explosives. Conductive wheels, including metal wheels that could not cause sparks, are recommended for this equipment.

**5605.6.3 Approved containers.** Bulk *explosives* shall be kept in *approved*, nonsparking containers when not being used or processed. *Explosives* shall not be stored or transported in open containers.

- ❖ Explosive materials must be kept in covered containers except when being used or processed. The closed containers eliminate the possibility of an ignition source falling into the containers and causing an explosion.

**5605.6.4 Quantity limits.** The quantity of *explosives* at any particular work station shall be limited to that posted on the load limit signs for the individual work station. The total quantity of *explosives* for multiple workstations shall not exceed that established by the intraplant distances in Table 5605.3 or 5604.5.2(3), as appropriate.

- ❖ The maximum permissible quantities of explosive materials allowed by Table 5605.3 must be clearly indicated with suitable signs, usually with letters not less than 3 inches (76 mm) high.

**5605.6.4.1 Magazines.** Magazines used for storage in processing areas shall be in accordance with the requirements of Section 5604.5.1. *Explosive materials* shall be removed to appropriate storage magazines for unattended storage at the end of the work day. The contents of indoor magazines shall be added to the quantity of *explosives* contained at individual workstations and the total quantity of material stored, processed or used shall be utilized to establish the intraplant separation distances indicated by Table 5605.3 or 5604.5.2(3), as appropriate.

- ❖ This section makes it clear that indoor magazines can be used in manufacturing areas when in accordance with the requirements of the code, including quantity limits, separation distances and limitations on the number of magazines. Materials contained in magazines add to the net explosive weight (NEW) for the building, and intraplant separations are based on NEW.

This section also recognizes that there may be more than one workstation in a process area with the control on the location of process areas established by IPD. Removal of any residual stored contents at the end of the day is consistent with requirements of NFPA 495 and military standards governing process operations.

**5605.6.5 Waste disposal.** *Approved* receptacles with covers shall be provided for each location for disposing of waste material and debris. These waste receptacles shall be emptied and cleaned as often as necessary but not less than once each day or at the end of each shift.

- ❖ Waste receptacles with tight-fitting covers must be supplied at or just outside of each working area for

the disposal of waste material, cleaning rags and other combustible waste and debris. The containers must be emptied daily or at the end of each shift.

**5605.6.6 Safety rules.** General safety rules and operating instructions governing the particular operation or process conducted at that location shall be available at each location.

- ❖ Operating instructions must be posted at or near each working area. These instructions must include the technical steps for the process and the safety precautions the operators must follow for their personal safety.

**5605.6.7 Personnel limits.** The number of occupants in each process building and in each magazine shall not exceed the number necessary for proper conduct of production operations.

- ❖ The number of persons involved in performing the process must be held to a minimum to make sure there is enough room for those performing the operation. Too many occupants reduces operating space, increasing the potential for an accident that could result in injury or building damage.

**5605.6.8 Pyrotechnic and explosive composition quantity limits.** Not more than 500 pounds (227 kg) of pyrotechnic or *explosive* composition, including not more than 10 pounds (5 kg) of salute powder shall be allowed at one time in any process building or area. Compositions not in current use shall be kept in covered nonferrous containers.

**Exception:** Composition that has been loaded or pressed into tubes or other containers as consumer fireworks.

- ❖ The maximum amount of pyrotechnic or explosive materials contained at any one time in any building used for the manufacture or assembly of products using or containing explosive materials must not exceed the amounts listed above. This action will assist in eliminating the possibility of a catastrophic explosion.

**5605.6.9 Posting limits.** The maximum number of occupants and maximum weight of pyrotechnic and *explosive* composition permitted in each process building shall be posted in a conspicuous location in each process building or magazine.

- ❖ Only persons essential to the operation can be allowed in the mixing and packaging area. Usually, no more than one day's production of explosive material should be allowed in the mixing and packaging area. These limitations must be posted in an obvious location.

**5605.6.10 Heat sources.** Fireworks, *explosives* or *explosive* charges in *explosive materials* manufacturing, assembly or testing shall not be stored near any source of heat.

**Exception:** *Approved* drying or curing operations.

- ❖ Storing the explosive materials near heat sources obviously will be an explosion hazard. Stored explosive products must be separated an adequate distance from any heat source. The building heat source should be located outside the building.

## EXPLOSIVES AND FIREWORKS

**5605.7 Maintenance.** Maintenance and repair of *explosives*-manufacturing facilities and areas shall comply with Section 5604.8.

- ❖ Section 5604.8 covers the subjects of housekeeping, repairs and floors of buildings and facilities. Having a periodic maintenance program in place will keep hazards to a minimum.

**5605.8 Explosive materials testing sites.** *Detonation* of *explosive* materials or ignition of fireworks for testing purposes shall be done only in isolated areas at sites where distance, protection from missiles, shrapnel or flyrock, and other safeguards provides protection against injury to personnel or damage to property.

- ❖ Operations or activities on a site where explosive materials are used, stored or handled could be subject to additional or more restrictive requirements or conditions at the discretion of the local fire code official.

**5605.8.1 Protective clothing and equipment.** Protective clothing and equipment shall be provided to protect persons engaged in the testing, ignition or *detonation* of *explosive materials*.

- ❖ Personnel must be dressed in proper personal protective equipment to eliminate the hazard of physical injury.

**5605.8.2 Site security.** Where tests are being conducted or *explosives* are being detonated, only authorized persons shall be present. Areas where *explosives* are regularly or frequently detonated or burned shall be *approved* and posted with adequate warning signs. Warning devices shall be activated before burning or detonating *explosives* to alert persons approaching from any direction that they are approaching a danger zone.

- ❖ Only authorized personnel can be allowed in test area enclosures. Audible and visible warning devices must be used to warn nearby personnel before detonating or burning any explosive material.

**5605.9 Waste disposal.** Disposal of *explosive materials* waste from manufacturing, assembly or testing operations shall be in accordance with Section 5604.10.

- ❖ Section 5604.10 addresses the issues of notification, deteriorated materials, qualified people, storage of misfires, sites for disposal and reuse and safety for personnel.

### SECTION 5606

#### SMALL ARMS AMMUNITION AND SMALL ARMS AMMUNITION COMPONENTS

**5606.1 General.** Indoor storage and display of black powder, smokeless propellants, small arms primers and small arms ammunition shall comply with this section and NFPA 495.

- ❖ This section addresses the storage of small arms ammunition and its components, including proper packaging, in residential and commercial occupan-

cies. NFPA 495 also contains requirements for these materials.

**5606.2 Prohibited storage.** Small arms ammunition shall not be stored together with Division 1.1, Division 1.2 or Division 1.3 *explosives* unless the storage facility is suitable for the storage of *explosive materials*.

- ❖ Small arms ammunition must not be stored with explosives that have mass explosion, projection or fire hazards. If the storage facility meets the requirements of the local fire code official, however, this storage is allowed. Separation and explosive wave prevention are two requirements that should be met.

**5606.3 Packages.** Smokeless propellants shall be stored in *approved* shipping containers conforming to DOTn 49 CFR Part 173.

- ❖ Smokeless propellants must not be stored in their original factory containers. DOTn 49 CFR, Part 173 addresses precautions such as not allowing metal (nails, staples, etc.) to penetrate the interior of a container, interior packaging not allowing contents to shift and become loose and packaging being made compatible with the explosives kept in the container.

**5606.3.1 Repackaging.** The bulk repackaging of smokeless propellants, black powder and small arms primers shall not be performed in retail establishments.

- ❖ Bulk repackaging must be performed by qualified personnel. The product should be handled by trained explosives personnel and in the proper location for human and property safety.

**5606.3.2 Damaged packages.** Damaged containers shall not be repackaged.

**Exception:** *Approved* repackaging of damaged containers of smokeless propellant into containers of the same type and size as the original container.

- ❖ Damaged containers must not be repackaged. Smokeless propellants must not be transferred from the approved container into one that is not approved.

**5606.4 Storage in Group R occupancies.** The storage of small arms ammunition components in Group R occupancies shall comply with Sections 5606.4.1 through 5606.4.3.

- ❖ The following sections cover storage requirements for black powder, smokeless propellants and small arms primers in Group R occupancies [which do not include detached one- and two-family dwellings or townhouses constructed under the *International Residential Code*<sup>®</sup> (IRC<sup>®</sup>)].

**5606.4.1 Black powder.** Black powder for personal use in quantities not exceeding 20 pounds (9 kg) shall be stored in original containers in occupancies limited to Group R-3. Quantities exceeding 20 pounds (9 kg) shall not be stored in any Group R occupancy.

- ❖ Black powder used in muzzle-loading firearms intended for personal use in quantities not exceeding 20 pounds (9 kg) in original containers may be stored without restriction in Group R-3 occupancies. Quanti-

ties exceeding 20 pounds (9 kg) are not allowed, regardless of the type of container.

**5606.4.2 Smokeless propellants.** Smokeless propellants for personal use in quantities not exceeding 20 pounds (9 kg) shall be stored in original containers in occupancies limited to Group R-3. Smokeless propellants in quantities exceeding 20 pounds (9 kg) but not exceeding 50 pounds (23 kg) and kept in a wooden box or cabinet having walls of not less than 1 inch (25 mm) nominal thickness shall be allowed to be stored in occupancies limited to Group R-3. Quantities exceeding these amounts shall not be stored in any Group R occupancy.

- ❖ Small arms smokeless propellant intended for personal use in quantities not exceeding 20 pounds (9 kg) in original containers may be stored without restriction in Group R-3 occupancies; quantities exceeding 20 pounds (9 kg) but not exceeding 50 pounds (23 kg) must be stored in a strong box or cabinet constructed with 1-inch (25 mm) wood (minimum) or equivalent on all sides, top and bottom.

**5606.4.3 Small arms primers.** Not more than 10,000 small arms primers shall be stored in occupancies limited to Group R-3.

- ❖ This section mirrors the provisions of NFPA 495, which allows storage of no more than 10,000 primers in a private residence. Even the most avid small arms ammunition reloader should have no reason to store in excess of 1,000 each of large rifle, large rifle magnum, small rifle, large pistol, large pistol magnum, small pistol, small pistol magnum and shotgun primers, (a total of 8,000 primers). See the description of Group R-3 occupancies in Chapter 2.

**5606.5 Display and storage in Group M occupancies.** The display and storage of small arms ammunition components in Group M occupancies shall comply with Sections 5606.5.1 through 5606.5.2.3.

- ❖ Ignited stored powder can raise pressure within the storage area; therefore, there are specific requirements for keeping powder on hand. The first of these is never to transfer any propellant from its original container, which is designed to burst or partially open at very low pressures. Some container caps will simply just push off if the contents are ignited.

**5606.5.1 Display.** Display of small arms ammunition components in Group M occupancies shall comply with Sections 5606.5.1.1 through 5606.5.1.3.

- ❖ The display quantities of smokeless propellants, black powder and small arms primers are given in the following sections.

**5606.5.1.1 Smokeless propellant.** Not more than 20 pounds (9 kg) of smokeless propellants, in containers of 1 pound (0.454 kg) or less capacity each, shall be displayed in Group M occupancies.

- ❖ Displayed containers of smokeless propellant must be limited to 1 pound (0.454 kg) each. The total quantity of smokeless propellant not in an approved magazine is limited to 20 pounds (9 kg).

The 20-pound (9 kg) limit can be traced back to the

original edition of the legacy *Uniform Fire Code* in 1971. This quantity was considered by the International Conference of Building Officials (ICBO) membership to be the maximum allowable quantity in retail sales occupancies based on the potential risk posed to the public. There was no “magic reason” for establishing the 20-pound (9 kg) limit other than agreement by the various ICBO code development committees that it would be unreasonable to expose the public to potential accidents involving greater quantities. According to records, the 20-pound (9 kg) limitation originated from the Explosives Committee of the California Fire Chiefs Association/Southern Division, Fire Prevention Officers Section. Quoting from this committee, its reason for the limit was as follows:

“The quantities were arrived at over a protracted period of time by a mutual exchange of information between representatives of public and private sectors of the economy, who possessed experience in dealing with these materials. Specific regulations represented a compromise between the various points of view expressed during several meetings. In general, the public safety was the key issue in the final proposed regulations. The committee would like to point out that at some point the line must be drawn. A recent series of tests conducted by this committee on both smokeless and black powder indicated that there is an appreciable hazard involved when even small amounts of these materials are exposed to fire. Black powder is much more sensitive than smokeless and should be kept in a magazine at all times to reduce the chance of ignition and propagation. Smokeless powder, which is less sensitive than black powder, can be openly displayed, but the amount should be limited due to its capacity for increasing a fire hazard. It is our feeling that the current 20 pound limit on display should be the maximum.”

**5606.5.1.2 Black powder.** Not more than 1 pound (0.454 kg) of black powder shall be displayed in Group M occupancies.

- ❖ Safety must be the first priority when black powder is accessible to the public. The 1-pound (0.454 kg) limitation holds to the objective of keeping the public from having access to enough black powder to cause serious damage if mishandled.

**5606.5.1.3 Small arms primers.** Not more than 10,000 small arms primers shall be displayed in Group M occupancies.

- ❖ Because of their explosive nature, only the absolute minimum should be kept on display. With care in replacing exhausted supplies, it is not difficult to adhere to the 10,000-primer limit.

**5606.5.2 Storage.** Storage of small arms ammunition components shall comply with Sections 5606.5.2.1 through 5606.5.2.3.

- ❖ Generally, propellants used in sporting arms cartridges will not explode or detonate when ignited. Burning smokeless propellants do not generate the

shock wave produced by an explosive. Unlike smokeless propellants, shock waves produced by ignition of an explosive cannot be adequately vented, even when ignition occurs in the open.

**5606.5.2.1 Smokeless propellant.** Commercial stocks of smokeless propellants shall be stored as follows:

1. Quantities exceeding 20 pounds (9 kg), but not exceeding 100 pounds (45 kg) shall be stored in portable wooden boxes having walls of not less than 1 inch (25 mm) nominal thickness.
2. Quantities exceeding 100 pounds (45 kg), but not exceeding 800 pounds (363 kg), shall be stored in non-portable storage cabinets having walls not less than 1 inch (25 mm) nominal thickness. Not more than 400 pounds (182 kg) shall be stored in any one cabinet, and cabinets shall be separated by a distance of not less than 25 feet (7620 mm) or by a *fire partition* having a *fire-resistance rating* of not less than 1 hour.
3. Storage of quantities exceeding 800 pounds (363 kg), but not exceeding 5,000 pounds (2270 kg) in a building shall comply with all of the following:
  - 3.1. The warehouse or storage room is unaccessible to unauthorized personnel.
  - 3.2. Smokeless propellant shall be stored in nonportable storage cabinets having wood walls not less than 1 inch (25 mm) nominal thickness and having shelves with not more than 3 feet (914 mm) of separation between shelves.
  - 3.3. Not more than 400 pounds (182 kg) is stored in any one cabinet.
  - 3.4. Cabinets shall be located against walls of the storage room or warehouse with not less than 40 feet (12 192 mm) between cabinets.
  - 3.5. The minimum required separation between cabinets shall be 20 feet (6096 mm) provided that *barricades* twice the height of the cabinets are attached to the wall, midway between each cabinet. The *barricades* must extend not less than 10 feet (3048 mm) outward, be firmly attached to the wall and be constructed of steel not less than  $\frac{1}{4}$  inch thick (6.4 mm), 2-inch (51 mm) nominal thickness wood, brick or concrete block.
  - 3.6. Smokeless propellant shall be separated from materials classified as *combustible liquids*, flammable liquids, flammable solids or oxidizing materials by a distance of 25 feet (7620 mm) or by a *fire partition* having a *fire-resistance rating* of 1 hour.
  - 3.7. The building shall be equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
4. Smokeless propellants not stored in accordance with Item 1, 2, or 3 above shall be stored in a Type 2 or 4

magazine in accordance with Section 5604 and NFPA 495.

- ❖ Storage cabinets are often made of 1-inch-thick (25 mm) wood with one or more walls designed to open outward or blow free at very low pressures. They should be many times larger than necessary to store the minimum quantities of powder. Propellants must not be stored in the same area with solvents, flammable gases, primers or highly combustible materials. Smoking should never be allowed in the storage areas or while handling or using powder.

**5606.5.2.2 Black powder.** Commercial stocks of black powder in quantities less than 50 pounds (23 kg) shall be allowed to be stored in Type 2 or 4 indoor or outdoor magazines. Quantities greater than 50 pounds (23 kg) shall be stored in outdoor Type 2 or 4 magazines. Where black powder and smokeless propellants are stored together in the same magazine, the total quantity shall not exceed that permitted for black powder.

- ❖ Black powder must be stored in a magazine no matter the quantity. The guideline quantity of 50 pounds (23 kg) is the dividing line between storage in an indoor or outdoor magazine. The code does allow storage of smokeless propellants along with black powder as long as the total quantity given in this section for black powder is not exceeded. The maximum quantity is given to limit the explosive potential in considering life safety and property damage.

**5606.5.2.3 Small arms primers.** Commercial stocks of small arms primers shall be stored as follows:

1. Quantities not to exceed 750,000 small arms primers stored in a building shall be arranged such that not more than 100,000 small arms primers are stored in any one pile and piles are not less than 15 feet (4572 mm) apart.
2. Quantities exceeding 750,000 small arms primers stored in a building shall comply with all of the following:
  - 2.1. The warehouse or storage building shall not be accessible to unauthorized personnel.
  - 2.2. Small arms primers shall be stored in cabinets. Not more than 200,000 small arms primers shall be stored in any one cabinet.
  - 2.3. Shelves in cabinets shall have vertical separation of not less than 2 feet (610 mm).
  - 2.4. Cabinets shall be located against walls of the warehouse or storage room with not less than 40 feet (12 192 mm) between cabinets. The minimum required separation between cabinets shall be allowed to be reduced to 20 feet (6096 mm) provided that *barricades* twice the height of the cabinets are attached to the wall, midway between each cabinet. The *barricades* shall be firmly attached to the wall and shall be constructed of steel not less than  $\frac{1}{4}$  inch thick (6.4

mm), 2-inch (51 mm) nominal thickness wood, brick or concrete block.

2.5. Small arms primers shall be separated from materials classified as *combustible liquids*, flammable liquids, flammable solids or oxidizing materials by a distance of 25 feet (7620 mm) by a *fire partition* having a *fire-resistance rating* of 1 hour.

2.6. The building shall be protected throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.

3. Small arms primers not stored in accordance with Item 1 or 2 of this section shall be stored in a magazine meeting the requirements of Section 5604 and NFPA 495.

- ❖ Primers must be stored in a remote area away from any possible source of ignition, including bullet impact. Primers are by nature explosive. As a result, they may explode if subjected to friction, percussion, crushing or excessive heat from any cause, whether open flame or not. Static electricity and many other abuses can cause primers to explode; therefore, public access to storage containers must not be allowed.

Primers must be stored away from oxidizing agents and flammable liquids and solids. Naturally, smoking should be prohibited around primers. The storage cabinet is strongly recommended. The cabinet should be constructed of 1-inch-thick (25 mm) lumber to delay the transfer of heat to contents in the event of a fire or other mishap.

## SECTION 5607 BLASTING

**5607.1 General.** Blasting operations shall be conducted only by *approved*, competent operators familiar with the required safety precautions and the hazards involved and in accordance with the provisions of NFPA 495.

- ❖ Personnel using explosives must be at least 21 years old and possess all required federal [see Title 18 U.S. Code (USC), Chapter 40], state and local approvals or permits. Employees under 21 years old but at least 18 years old may serve as apprentices or assistants under direct supervision of a permittee. In addition to these requirements, individuals who handle explosives must not:

1. Be under the influence of alcohol or drugs.
2. Smoke or carry matches or firearms.
3. Use or carry an open flame or open flame-producing device.

Many states require individuals who handle explosives to obtain a certificate of fitness, which is dubbed a “blaster’s permit,” before being authorized to handle or use explosives. The individual must be bonded or show acceptable proof of insurance, pass a written examination demonstrating an adequate understand-

ing of the applicable codes and ordinances and demonstrate adequate experience (usually a minimum of three years) in handling explosives safely in an approved apprenticeship program to obtain a fitness certificate.

**5607.2 Manufacturer’s instructions.** Blasting operations shall be performed in accordance with the instructions of the manufacturer of the *explosive materials* being used.

- ❖ No blasting operation will be performed in a manner contrary to the instructions of the manufacturer of the explosive materials being used. Each manufacturer has its own instructions for discharging its explosives.

**5607.3 Blasting in congested areas.** Where blasting is done in a congested area or in close proximity to a structure, railway or highway, or any other installation, precautions shall be taken to minimize earth vibrations and air blast effects. Blasting mats or other protective means shall be used to prevent fragments from being thrown.

- ❖ Precautions must be taken to minimize damage from blasting operations where those operations are likely to generate projectiles, scatter debris or produce significant blast-wave effects.

**5607.4 Restricted hours.** Surface-blasting operations shall only be conducted during daylight hours between sunrise and sunset. Other blasting shall be performed during daylight hours unless otherwise *approved* by the *fire code official*.

- ❖ Darkness impairs the effectiveness of the most important sense involved in setting surface explosive charges—sight. This section improves the safety of surface blasting by allowing it only between sunrise and sunset when ample natural light is available. Care must be taken throughout blasting operations to inspect all elements of the explosive setup.

Nighttime nonsurface blasting operations require approved artificial illumination. The lighting could pose a hazard if improper equipment or procedures are used. Only the fire code official may authorize nighttime blasting operations.

**5607.5 Utility notification.** Where blasting is being conducted in the vicinity of utility lines or rights-of-way, the blaster shall notify the appropriate representatives of the utilities not less than 24 hours in advance of blasting, specifying the location and intended time of such blasting. Verbal notices shall be confirmed with written notice.

**Exception:** In an emergency situation, the time limit shall not apply where *approved*.

- ❖ Steps must be taken to prevent disruption of public utility services. Location of underground utilities in many areas must be designated by a utility locator service before blasting or construction begins. Notification may not relieve the blaster of liability if operations disrupt utility service. Therefore, great care must be exercised when blasting in the vicinity of utilities. Blasting must not proceed without the approval of utility officials and the fire code official.

The exception recognizes that there may be emergency conditions under which it is not possible to

strictly comply with the full 24-hour advance notice requirement. Conditions represented as an emergency must be approved as such by the fire code official. (Note: Both verbal and written notification must still be made in as timely a manner as the emergency will permit prior to blasting operations.)

**5607.6 Electric detonator precautions.** Precautions shall be taken to prevent accidental discharge of electric detonators from currents induced by radar and radio transmitters, lightning, adjacent power lines, dust and snow storms, or other sources of extraneous electricity.

❖ Wires connecting elements of the explosive train may act as an antenna or conduct electricity from sources outside of those controlled by the blaster. Therefore, special precautions are required to prevent inadvertent detonation of explosive materials:

1. The 350-foot (106 m) separation distance provides a significant safety margin. Recommended minimum clearances for citizens band, VHF, UHF and cellular telephone transmitters with up to 50 watts vary from 5 to 180 feet (1524 to 54 864 mm). Nearly all mobile transmitters operate between 3 and 30 watts.
2. Power lines may also emit radio frequency energy (see IME Safety Library Publication No. 20 for guidance on separation from other radio frequency sources).
3. Lightning produces more than sufficient energy to detonate explosive materials. Charges should not be placed when there has been adequate warning of an approaching storm. If charges have been set before warning of an approaching storm is received, blast site workers should abandon their operations and take cover until the storm passes.

**5607.7 Nonelectric detonator precautions.** Precautions shall be taken to prevent accidental initiation of nonelectric detonators from stray currents induced by lightning or static electricity.

❖ All elements of pneumatic loading devices must be electrically bonded and a positive grounding device for the equipment must be used to prevent the accumulation of static electricity. Water lines, air lines, rails or permanent electric grounding systems for other equipment must not be used to ground pneumatic loading equipment.

**5607.8 Blasting area security.** During the time that holes are being loaded or are loaded with *explosive materials*, blasting agents or detonators, only authorized persons engaged in drilling and loading operations or otherwise authorized to enter the site shall be allowed at the blast site. The blast site shall be guarded or barricaded and posted. Blast site security shall be maintained until after the post-blast inspection has been completed.

❖ Loading and firing operations are the most hazardous steps in the blasting process. To prevent inadvertent detonation while electrically fired charges are being

set, only the individual making lead wire connections must fire the shot [see DOL 29 CFR, Parts 1910.109 (e)(4)(viii) and 1926.906(s)]. Similar precautions must be taken when firing explosives using other methods. Individuals performing or supervising loading and firing operations must hold all required federal (see 18 USC Chapter 40 and DOTy 27 CFR 55, Subpart D), state and local approvals or permits.

**5607.9 Drill holes.** Holes drilled for the loading of *explosive* charges shall be made and loaded in accordance with NFPA 495.

❖ Drill holes must be large enough to allow free insertion of cartridges of explosive materials and cannot be collared in bootlegs or in holes that previously contained explosive materials. Holes must not be drilled where there is a danger of intersecting another hole containing explosive material. Of utmost importance, all drill holes must be inspected and cleared of any obstruction before loading. NFPA 495 gives other requirements for drilling the holes.

**5607.10 Removal of excess explosive materials.** After loading for a blast is completed and before firing, excess *explosive materials* shall be removed from the area and returned to the proper storage facilities.

❖ After loading is completed, surplus explosive materials must be returned to an approved magazine before firing.

**5607.11 Initiation means.** The initiation of blasts shall be by means conforming to the provisions of NFPA 495.

❖ Cap and fuse cannot be used to initiate blasts on or adjacent to highways open to traffic or in congested areas. NFPA 495 gives the burning rate and safety fuse length in units of time.

**5607.12 Connections.** The blaster shall supervise the connecting of the blastholes and the connection of the loadline to the power source or initiation point. Connections shall be made progressively from the blasthole back to the initiation point.

Blasting lead lines shall remain shunted (shorted) and shall not be connected to the blasting machine or other source of current until the blast is to be fired.

❖ Connections must be made progressively from the blast holes to the source of firing current. The shorted lead wire must remain unconnected until the blast is ready for firing. Only insulated leading wire of adequate current-carrying capacity can be used.

**5607.13 Firing control.** A blast shall not be fired until the blaster has made certain that all surplus *explosive materials* are in a safe place in accordance with Section 5607.10, all persons and equipment are at a safe distance or under sufficient cover and that an adequate warning signal has been given.

❖ The blaster must conduct a complete survey of the blast site before blasting begins. Surplus charges must be placed in a magazine or day box and individuals and vehicles must be cleared from the blast site.

A loud warning signal (claxon horn or whistle) must be sounded before charges are fired to alert workers that blasting is about to begin (see also IME Safety Library Publication Nos. 3, 4 and 17).

**5607.14 Post-blast procedures.** After the blast, the following procedures shall be observed.

1. No person shall return to the blast area until allowed to do so by the blaster in charge.
2. The blaster shall allow sufficient time for smoke and fumes to dissipate and for dust to settle before returning to or approaching the blast area.
3. The blaster shall inspect the entire blast site for misfires before allowing other personnel to return to the blast area.

❖ Blast areas must not be reentered after firing until concentrations of smoke, dust and fumes have been reduced to safe limits as determined by the blaster in charge. The blaster must determine the length of time before any person is permitted in the blast area. When a misfire is known or suspected, no person should enter the area for at least 1 hour.

**5607.15 Misfires.** Where a misfire is suspected, all initiating circuits shall be traced and a search made for unexploded charges. Where a misfire is found, the blaster shall provide proper safeguards for excluding all personnel from the blast area. Misfires shall be reported to the blasting supervisor immediately. Misfires shall be handled under the direction of the person in charge of the blasting operation in accordance with NFPA 495.

❖ All misfires are potential accidents. A misfire may be caused by many different factors. Only qualified and experienced personnel should attempt to handle disposal of a misfire. DOL 29 CFR, Parts 1910.109(e)(4)(v) and 1926.911(c) prohibit the extraction of explosives from a blasthole unless it is impossible to detonate the unexploded charge by insertion of a fresh primer.

No one should enter the blasting area to handle a misfire or investigate the cause until it is safe to do so. Recommended waiting periods for investigating misfires are listed in Commentary Figure 5607.15. The IME waiting periods correspond with the recommendation in IME Safety Library Publication No. 17.

Description	IME	OSHA
Blasting cap and fuse	30 minutes	1 hour
Electric blasting cap, shock tube, gas tube or detonating cord	15 minutes	30 minutes
Refiring of a misfired charge	1 hour	1 hour

Source: DOL 29 CFR 1910 and IME Safety Library Publication No. 17.

**Figure 5607.15  
RECOMMENDED WAITING PERIODS  
FOR INVESTIGATING MISFIRES**

Occupational Safety and Health Administration (OSHA) waiting periods are those specified in DOL 29 CFR, Parts 1910.109 and 1926.911(d).

The safest way to dispose of most misfires is by detonation; however, even this method has distinct hazards. Misfired explosives may be unstable or sensitive, so any procedure to dispose of a misfire must be carried out with extreme caution. Removing a misfired explosive charge should be attempted only if all other alternatives are unsuccessful or unadvisable. After a misfired charge has been removed, it must be transported immediately to a storage magazine and disposed of as soon as possible.

**SECTION 5608  
FIREWORKS DISPLAY**

**5608.1 General.** Outdoor fireworks displays, use of pyrotechnics before a *proximate audience* and pyrotechnic special effects in motion picture, television, theatrical and group entertainment productions shall comply with Sections 5608.2 through 5608.10 and NFPA 1123 or NFPA 1126.

❖ The only discharge of fireworks permissible under the code is a public display conducted by competent pyrotechnicians in accordance with the requirements of NFPA 1123 and NFPA 1126 and authorized by the fire code official.

The use of pyrotechnic special effects in theatrical performances has become a topic of some concern. In December 1990, a pyrotechnic effect exploded during a band concert in a Florida hotel lounge, injuring seven people, one critically. NFPA 1126 was published in response to this event.

**5608.2 Permit application.** Prior to issuing permits for a fireworks display, plans for the fireworks display, inspections of the display site and demonstrations of the display operations shall be *approved*. A plan establishing procedures to follow and actions to be taken in the event that a shell fails to ignite in, or discharge from, a mortar or fails to function over the fallout area or other malfunctions shall be provided to the *fire code official*.

❖ This section addresses approval and permit issuance for fireworks displays. A 15-day time limitation is suggested to give the fire code official reasonable time to verify the completeness and accuracy of the information in the application and to allow a thorough inspection of the display site. Customarily, only the display operator or pyrotechnician may apply for approval and a permit. Issuing approvals and permits to corporations, associations, boards or other corporate entities may hamper accountability. Because only a single individual can be assigned overall control of the discharge of fireworks, only the individual responsible for operating the display should be issued an approval, and ultimately a permit. However, all other organizations, institutions or individuals acting together or alone to contract the display should also be named in the permit application and, if considered appropriate by the fire code official, named as addi-

tional insureds in the bond indemnifying the jurisdiction for the display. Strict prohibitions against transfers and extensions are needed for the continuing supervision of fireworks operations.

This section also requires the applicant for approval and permit to provide an action plan for those occasions during the conduct of a fireworks display when a shell fails in some manner (often referred to as a “misfire,” a term which is often misinterpreted since it is not defined in either the code or NFPA 1123). The terminology used in this section makes it clear that the concerns are specifically with malfunctions of shells that either fail to discharge from a mortar or fail to function properly within the fallout area of the display venue, which could jeopardize safety of the audience or display operators. The fireworks display industry has established procedures for responding to various types and degrees of incidents that may occur as a result of a malfunction. This section enables the fire code official to be aware of the proposed procedures in order to evaluate their appropriateness to the particular event. The terminology used is consistent with that found in NFPA 1123.

**5608.2.1 Outdoor fireworks displays.** In addition to the requirements of Section 403, permit applications for outdoor fireworks displays using Division 1.3G fireworks shall include a diagram of the location at which the fireworks display will be conducted, including the site from which fireworks will be discharged; the location of buildings, highways, overhead obstructions and utilities; and the lines behind which the audience will be restrained.

❖ The best sites are free of overhead obstructions and are well isolated, with clear viewing paths and landing areas. Fallout areas should be large, open areas, clear of spectators, vehicles and combustible materials. Generally, the discharge site must have a minimum radius of 70 feet (21 336 mm) for each inch of aerial shell diameter.

**5608.2.2 Use of pyrotechnics before a proximate audience.** Where the separation distances required in Section 5608.4 and NFPA 1123 are unavailable or cannot be secured, fireworks displays shall be conducted in accordance with NFPA 1126 for *proximate audiences*. Applications for use of pyrotechnics before a *proximate audience* shall include plans indicating the required clearances for spectators and combustibles, crowd control measures, smoke control measures and requirements for standby personnel and equipment where provision of such personnel or equipment is required by the *fire code official*.

❖ This section applies to any outdoor use of pyrotechnics at distances less than those required by NFPA 1123. The use of pyrotechnics before a proximate audience is not a display of fireworks as regulated by NFPA 1123 but is regulated by NFPA 1126.

The separation distance between the audience and where the pyrotechnic device is fired during a performance must be at least 15 feet (4572 mm) but not less than twice the fallout radius of the device. The

audience must be separated from concussion mortars by a minimum of 25 feet (7620 mm) and there must be no glowing or flaming particles within 10 feet (3048 mm) of the audience.

**5608.3 Approved fireworks displays.** *Approved* fireworks displays shall include only the *approved* fireworks 1.3G, fireworks 1.4G, fireworks 1.4S and pyrotechnic articles, 1.4G, which shall be handled by an *approved*, competent operator. The *approved* fireworks shall be arranged, located, discharged and fired in a manner that will not pose a hazard to property or endanger any person.

❖ The competence of the display operator is foremost among the important safeguards that must be observed for a safe and enjoyable public display. NFPA 1123 details the qualifications of competent fireworks display operators. Many jurisdictions require display operators to possess a license or certificate of fitness. To obtain such a certificate, the operator must be bonded or indemnified, pass a written examination and serve an apprenticeship under another licensed or certified pyrotechnician.

**5608.4 Clearance.** Spectators, spectator parking areas, and *dwellings*, buildings or structures shall not be located within the display site.

**Exceptions:**

1. This provision shall not apply to pyrotechnic special effects and fireworks displays using Division 1.4G materials before a *proximate audience* in accordance with NFPA 1126.
2. This provision shall not apply to unoccupied *dwellings*, buildings and structures with the approval of the building *owner* and the *fire code official*.

❖ Aerial displays must meet the requirements of NFPA 1123. The site for the outdoor display should have at least a 70-foot (21 336 mm) radius per inch of the internal mortar diameter of the largest aerial shell being fired, except as noted in NFPA 1123. Some jurisdictions require 100 feet (30 480 mm) of radius per inch of diameter of aerial shell. No spectators, dwellings or spectator parking areas can be located within the display site.

**5608.5 Storage of fireworks at display site.** The storage of fireworks at the display site shall comply with the requirements of this section and NFPA 1123 or NFPA 1126.

❖ NFPA 1123 addresses weather protection, inspection, sorting and ready boxes for fireworks. The standard also addresses construction of display fireworks aerial shells.

**5608.5.1 Supervision and weather protection.** Beginning as soon as fireworks have been delivered to the display site, they shall not be left unattended.

❖ Never leave fireworks unattended. Too many events can cause serious problems during the show. For example, someone could replace good fireworks with faulty ones. Constant supervision is necessary both after and before inspection of the fireworks.

**5608.5.2 Weather protection.** Fireworks shall be kept dry after delivery to the display site.

- ❖ Protecting the fireworks from inclement weather is the responsibility of everyone involved in the display. If the fireworks get wet from rain, they will not fire properly, thus possibly causing harm to personnel and spectators. A tarpaulin will serve nicely for protection from rain.

**5608.5.3 Inspection.** Shells shall be inspected by the operator or assistants after delivery to the display site. Shells having tears, leaks, broken fuses or signs of having been wet shall be set aside and shall not be fired. Aerial shells shall be checked for proper fit in mortars prior to discharge. Aerial shells that do not fit properly shall not be fired. After the fireworks display, damaged, deteriorated or dud shells shall either be returned to the supplier or destroyed in accordance with the supplier's instructions and Section 5604.10.

**Exception:** Minor repairs to fuses shall be allowed. For electrically ignited displays, attachment of electric matches and similar tasks shall be allowed.

- ❖ Prior to acceptance of display fireworks from a wholesaler, the permit holder or designated agent must confirm that the outside of all cartons, containers or cases is in good condition and all documentation is in order. Shells can be damaged during transport from the factory. It is good safety practice to examine all shells before placing them into the mortars for firing. If there is any sign of damage, the shells should be set aside and not fired, reducing the risk of injury to personnel. The exception does allow minor repairs that are safe in the judgement of the pyrotechnician.

**5608.5.4 Sorting and separation.** After delivery to the display site and prior to the fireworks display, all shells shall be separated according to their size and their designation as salutes.

**Exception:** For electrically fired displays, or displays where all shells are loaded into mortars prior to the show, there is no requirement for separation of shells according to their size or their designation as salutes.

- ❖ Where aerial shells are to be stored at the discharge site for subsequent loading into mortars during the display, the mortars must be placed usually at one-sixteenth, but not more than one-third, the distance from the center of the display site toward the main spectator area.

**5608.5.5 Ready boxes.** Display fireworks, 1.3G, that will be temporarily stored at the site during the fireworks display shall be stored in ready boxes located upwind and not less than 25 feet (7620 mm) from the mortar placement and separated according to their size and their designation as salutes.

**Exception:** For electrically fired fireworks displays, or fireworks displays where all shells are loaded into mortars prior to the show, there is no requirement for separation of

shells according to their size, their designation as salutes or for the use of ready boxes.

- ❖ A ready box should be a weather-resistant container that protects contents from burning debris with a self-closing cover or equivalent means of closure required. If the wind shifts during a display, the ready boxes must be relocated to again be upwind from the discharge site. Tarpaulins can be used as weather protection for ready boxes but not considered as ready boxes.

**5608.6 Installation of mortars.** Mortars for firing fireworks shells shall be installed in accordance with NFPA 1123 and shall be positioned so that shells are propelled away from spectators and over the fallout area. Under no circumstances shall mortars be angled toward the spectator viewing area. Prior to placement, mortars shall be inspected for defects, such as dents, bent ends, damaged interiors and damaged plugs. Defective mortars shall not be used.

- ❖ Mortars can be buried to a depth of at least two-thirds to three-quarters of their length in the ground, in above-ground troughs or drums or however the local fire code official considers necessary. Eliminating as much of a risk as possible from spectator injury is a good reason for angling away from the viewing area. See also the commentary to the definition of "Fallout area" for further information.

**5608.7 Handling.** Aerial shells shall be carried to mortars by the shell body. For the purpose of loading mortars, aerial shells shall be held by the thick portion of the fuse and carefully loaded into mortars.

- ❖ During the firing of the display, personnel in the discharge site should wear head, eye, hearing and foot protection, and cotton, wool or similarly flame-resistant, long-sleeved, long-legged clothing. Personal protective equipment, as necessary, should be worn by the operator and assistants during the setup and cleanup of the display. Shells must be carried from the storage area to the discharge site only by their bodies and shall never be carried by their fuses.

**5608.8 Fireworks display supervision.** Whenever in the opinion of the *fire code official* or the operator a hazardous condition exists, the fireworks display shall be discontinued immediately until such time as the dangerous situation is corrected.

- ❖ All displays must be set up using methods that allow an interruption in firing in case an unforeseen danger becomes evident. The judgement of the display operator and the fire code official will determine whether an ongoing display or one that has been set up and is ready to begin must be stopped or delayed because of hazardous conditions.

**5608.9 Post-fireworks display inspection.** After the fireworks display, the firing crew shall conduct an inspection of the fallout area for the purpose of locating unexploded aerial

## EXPLOSIVES AND FIREWORKS

shells or live components. This inspection shall be conducted before public access to the site shall be allowed. Where fireworks are displayed at night and it is not possible to inspect the site thoroughly, the operator or designated assistant shall inspect the entire site at first light.

A report identifying any shells that fail to ignite in, or discharge from, a mortar or fail to function over the fallout area or otherwise malfunction, shall be filed with the *fire code official*.

❖ This section is intended to identify those display fireworks shells that fail to discharge or function properly over the fallout area of the fireworks display site, and provide a means of notification to the fire code official of the disposition of malfunctioning or misfired fireworks within the jurisdiction.

The firing crew will consist of the operator and assistants. For the public's own safety, no one should be allowed entry into the fallout area of the display site until inspection is completed. Mortar inspection and removal should be conducted within 10 minutes after show completion. When fireworks are displayed at night and it is impossible to thoroughly inspect the site, the crew must reinspect the entire site early the following morning. Preparation of an inspection report will enhance the level of safety provided for displays and is consistent with the requirements of Section 5608.2. See the commentary to that section for a further discussion of fireworks malfunctions.

**5608.10 Disposal.** Any shells found during the inspection required in Section 5608.9 shall not be handled until not less than 15 minutes have elapsed from the time the shells were fired. The fireworks shall then be doused with water and allowed to remain for not less than 5 additional minutes before being placed in a plastic bucket or fiberboard box. The disposal instructions of the manufacturer as provided by the fireworks supplier shall then be followed in disposing of the fireworks in accordance with Section 5604.10.

❖ In addition to the above requirements, any aerial shell that misfires in a mortar should be left alone for a minimum of 30 minutes, carefully loaded into a bucket of water and left for a minimum of 15 minutes and then properly disposed of.

### SECTION 5609 TEMPORARY STORAGE OF CONSUMER FIREWORKS

**5609.1 General.** Where the temporary storage of consumer fireworks, 1.4G is allowed by Section 5601.1.3, Exception 4, such storage shall comply with the applicable requirements of NFPA 1124.

❖ Where approved by the fire code official, this section allows for the temporary storage of consumer fireworks in accordance with Chapter 6 of NFPA 1124. NFPA 1124 defines "permanent" as any building or structure constructed on a foundation that has fixed

utility connections for more than 180 consecutive calendar days—if the utilities remain in use for 90 consecutive days or less and the building is not permanent as defined by NFPA 1124, it is defined as temporary. See also Section 5601.1.3, Exception 4.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*1997 Uniform Fire Code Applications Manual.* Whittier, CA: International Fire Code Institute, 1998.

*Structures to Resist the Effects of Accidental Explosions.* U.S. Army Technical Manual TM 51300. Air Force Manual (AFM) 8822 and Navy NAVFAC P397. Washington, DC: U.S. Government Printing Office.

# Chapter 57: Flammable and Combustible Liquids

## General Comments

Flammable and combustible liquids are essential in our modern lifestyles. These liquids are used for fuel, lubricants, cleaners, solvents, medicine and even drinking. The danger associated with flammable and combustible liquids is that the vapors from these liquids, when combined with air in their flammable range, will burn or explode at temperatures near our normal living and working environment.

The use of these liquids is accepted in all occupancies if the liquids are in appropriate containers and the quantity is very limited. When the quantities exceed these limited amounts or the use of the flammable or combustible liquids increases the potential danger, the code requires that measures be taken to control the potential danger. These measures are to prevent the possibility of flammable and combustible liquids igniting.

Although the dangers of flammable liquids are well known, accidents involving flammable liquids remain one of the most common fire scenarios in the United States. Statistically, the more common flammable or combustible liquids (gasoline) rather than the most dangerous flammable or combustible liquids account for the most fires. There are five factors that account for the involvement of flammable liquids in these fires: 1. Personnel inadequately trained in safe operating procedures; 2. Hazardous operations not isolated from other operations; 3. Equipment and flammable or combustible liquids improperly used; 4. Poor property maintenance and supervision and 5. Inadequate control systems.

These five factors suggest that a holistic approach to flammable and combustible liquid fire safety is required. By beginning with people, a safety system has a better chance of working successfully and consistently. Trained personnel recognize the importance of safe practices to their personal safety, and are more likely to demand that necessary safeguards be installed in their homes and workplaces. Because all of us tend to become complacent as time passes, inspectors, owners, operators, managers and employees must work together to maintain vigilance over the system's continued operation.

## Hazardous characteristics

Although the classification boundaries are somewhat arbitrary, flammable and combustible liquids are distinguished by their flash points. The flash point is that temperature at which the liquid produces sufficient vapor to form an ignitable vapor-air mixture above its surface. Because Class I flammable liquids all have flash points below 100°F (38°C), it is prudent to assume that they may be capable of igniting when unconfined under nor-

mal environmental conditions. On the other hand, combustible liquids [those materials with flash points above 100°F (38°C)] must usually be heated above their flash points, or in the case of extremely high flash point liquids, above their boiling points, before they will ignite.

## Physical characteristics

Flammable liquids possess other characteristics besides their low flash points. Significant characteristics when evaluating relative fire hazards include ignition temperature, autoignition temperature, flammable (explosive) range, viscosity, vapor density, vapor pressure, boiling point, evaporation rate, specific gravity and water solubility. Once the liquid is ignited, these variables have little influence over the material's heat release rate; however, factors such as evaporation rate, viscosity and water solubility may profoundly affect how these fires are extinguished.

## Hazards

In general, flammable and combustible liquids have low specific gravities, high vapor densities and narrow flammable (explosive) ranges. These characteristics mean that the liquids will usually float on water, the vapors will usually hug the ground and ignitable vapor-air mixtures will be confined to a range between 6 and 15 percent in air. Thus, smothering is difficult and ignition sources near the ground are more likely to pose a hazard. Low and high concentrations within the flammable range are likely to produce deflagrations, while concentrations near the middle of the flammable (explosive) range are more likely to produce detonations.

## Protection

The protection provided by the code is to prevent the flammable and combustible liquids from becoming ignited. This is accomplished by one or more of the following procedures:

1. Preventing the flammable and combustible liquids from vaporizing. Equipment and devices are used to safely store, transport, dispense, mix or use the flammable and combustible liquids so that the liquid does not have the opportunity to evaporate except where intended.
2. Preventing the concentration of vapors of flammable and combustible liquids from reaching the vapor-air mixture between the lower flammable limit (LFL) and the upper flammable limit (UFL). Ventilation of the area is used to dilute and

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

- disperse the vapors before the vapor-air mixture reaches the LFL.
3. Preventing an accumulation of the vapor-air mixture of flammable and combustible liquids. The ventilation of the area as well as the design of the area is used to prevent the vapors from collecting.
  4. Removing ignition sources from the area. These ignition sources are from people, equipment or static electricity sources.
  5. Precautions against spontaneous ignition.
  6. Removing other combustibles from the area. Other combustibles may become involved in a fire, creating the ignition source for the flammable and combustible liquid.
  7. Designing the equipment (piping, vessels, containers, etc.) and facilities to prevent the loss of flammable and combustible liquids and to protect the flammable and combustible liquids from exterior fire exposure. This protection is also used to protect other property and flammable and combustible liquids from fire exposure.
  8. Controlling the volume of flammable and combustible liquids to reduce the size of a potential fire.
  9. Providing fire-fighting equipment to control fire from combustibles other than flammable and combustible liquids as well as fire from flammable and combustible liquids.
  10. Security to ensure that only trained personnel have access to flammable and combustible liquids.
  11. Training of personnel to ensure they are aware of the potential dangers and know the operating procedures and safety procedures.

### Purpose

The requirements of this chapter are intended to reduce the likelihood of fires involving the storage, handling, use or transportation of flammable and combustible liquids. Adherence to these practices may also limit damage in the event of an accidental fire involving these materials.

---

## SECTION 5701 GENERAL

**5701.1 Scope and application.** Prevention, control and mitigation of dangerous conditions related to storage, use, dispensing, mixing and handling of flammable and *combustible liquids* shall be in accordance with Chapter 50 and this chapter.

❖ This chapter regulates the storage, handling and use of flammable and combustible liquids. Although U.S. Department of Transportation (DOT) regulations govern the construction of tank vehicles and the interstate transportation of flammable and combustible liquids, this chapter regulates the parking, garaging, filling and discharging of tank vehicles. This chapter is used in conjunction with Chapter 50 to regulate flammable and combustible liquids. Related operations, materials and processes are regulated elsewhere in the code.

**5701.2 Nonapplicability.** This chapter shall not apply to liquids as otherwise provided in other laws or regulations or chapters of this code, including:

1. Specific provisions for flammable liquids in motor fuel-dispensing facilities, repair garages, airports and marinas in Chapter 23.
2. Medicines, foodstuffs, cosmetics and commercial or institutional products containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solution not being flammable,

provided that such materials are packaged in individual containers not exceeding 1.3 gallons (5 L).

3. Quantities of alcoholic beverages in retail or wholesale sales or storage occupancies, provided that the liquids are packaged in individual containers not exceeding 1.3 gallons (5 L).
4. Storage and use of fuel oil in tanks and containers connected to oil-burning equipment. Such storage and use shall be in accordance with Section 603. For abandonment of fuel oil tanks, this chapter applies.
5. Refrigerant liquids and oils in refrigeration systems (see Section 606).
6. Storage and display of aerosol products complying with Chapter 51.
7. Storage and use of liquids that do not have a fire point when tested in accordance with ASTM D92.
8. Liquids with a *flash point* greater than 95°F (35°C) in a water-miscible solution or dispersion with a water and inert (noncombustible) solids content of more than 80 percent by weight, which do not sustain combustion.
9. Liquids without *flash points* that can be flammable under some conditions, such as certain halogenated hydrocarbons and mixtures containing halogenated hydrocarbons.
10. The storage of distilled spirits and wines in wooden barrels and casks.

11. Commercial cooking oil storage tank systems located within a building and designed and installed in accordance with Section 610 and NFPA 30.

- ❖ This section is an acknowledgment that some flammable and combustible liquids are regulated by other laws or by other chapters of the code. The application of these other laws or code chapters takes precedence over the requirements in this chapter. Note that most of the items listed in this section correlate to Section 9.1.4 of NFPA 30 (see also commentary, Section 5001.1).

Item 1 covers the unique use of flammable liquids at motor fuel-dispensing facilities, airports and marinas, which require specific regulations that are addressed in Chapter 23.

Item 2 indicates that individually packaged consumer products consisting of medicines, foodstuffs, cosmetics and commercial and institutional products with a limited quantity of flammable liquid used in the product are exempt from the requirements of this chapter. Such products present a reduced hazard due to their limited ignitability and because the packaging limitation helps in keeping spills, due to a leaking package or broken container, to a manageable size. A similar exception appears in Section 5001.1.

Item 3 indicates that alcoholic beverages in retail or wholesale Group M occupancies or in storage occupancies are not regulated by this chapter where the individual containers do not exceed 1.3 gallons (4.92 L). The packaging limitation helps in keeping spills, due to a leaking package or broken container, to a manageable size. A similar exception appears in Section 5001.1.

Item 4 states that fuel oil tanks and containers connected to oil-burning equipment are regulated by Chapter 6. See the commentary to Sections 603.3 through 603.3.3. This chapter regulates abandoned fuel tanks.

Item 5 notes that refrigerant liquids and oils in refrigeration systems are also regulated by Chapter 6.

Item 6 refers the reader to Chapter 51 for requirements covering the storage and display of aerosol products. Where the storage or display of aerosols does not comply with Chapter 51, this chapter will regulate the storage and display of aerosols in those specific circumstances.

Item 7 notes that the storage and use of a liquid whose vapor cannot be ignited and sustain burning for a minimum of 5 seconds (fire point) is not regulated by this chapter. The test procedure for determining the fire point of a petroleum product is ASTM D92. The fire point is based on a specific barometric pressure established by ASTM International (ASTM). An example of such a liquid would be water-based paints.

Item 8 exempts certain liquids that, although they have a flash point, will not sustain combustion.

Item 9 notes that some liquids do not have a flash point except in specific circumstances; for example, halogenated hydrocarbons that may become explosive when exposed to aluminum. These liquids are

not regulated by the code.

Item 10 makes the storage of distilled spirits and wines in wooden barrels and casks exempt from this chapter. Although their contents are classified as flammable liquids, the containers do not pose the rupture hazard that other containers do. Barrels and casks will leak their contents and contribute to the fire as the metal bands that secure the staves expand and loosen. Even this hazard feature is generally mitigated by the operation of automatic sprinklers that prevent the fire from progressing to the point where the metal bands get hot enough to expand. A similar exception also appears in Section 5001.1.

Item 11 exempts high flash point cooking oil (Class IIIB liquid) storage in a restaurant back-of-house setting because it presents a different, and generally lower, hazard than commonly anticipated by Chapter 57, which is more relevant to industrial flammable and combustible liquid tank requirements. This exemption to Section 5701.2 unifies all pertinent fire safety requirements into Section 610 and the standards referenced therein and establishes the level of safety commensurate with this hazard. This approach is consistent with other exceptions in this section, in particular the exception for fuel oil tanks connected with oil burning equipment.

**5701.3 Referenced documents.** The applicable requirements of Chapter 50, other chapters of this code, the *International Building Code* and the *International Mechanical Code* pertaining to flammable liquids shall apply.

- ❖ The requirements to regulate the design, construction and maintenance of facilities using flammable and combustible liquids are contained in more than one document. The code contains several chapters that address requirements for the storage, handling, dispensing, processing, transportation and use of flammable and combustible liquids. The *International Building Code*® (IBC®) covers the construction requirements for the structure, while the *International Mechanical Code*® (IMC®) covers the construction requirements for mechanical systems.

**5701.4 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.17 for discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7.8 for a discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for the hazardous property.

**5701.5 Material classification.** Flammable and *combustible liquids* shall be classified in accordance with the definitions in Chapter 2.

When mixed with lower flash-point liquids, Class II or III liquids are capable of assuming the characteristics of the lower flash-point liquids. Under such conditions, the appropriate provisions of this chapter for the actual *flash point* of the mixed liquid shall apply.

When heated above their *flash points*, Class II and III liquids assume the characteristics of Class I liquids. Under such conditions, the appropriate provisions of this chapter for flammable liquids shall apply.

❖ Flammable and combustible liquids are defined in Chapter 2. Mixing or heating the liquid may modify flammable and combustible liquids. This process will change the flash point of the liquid. The mixed liquid is to be classified and handled based on the flash point determined by the appropriate test procedure and apparatus as specified in ASTM D56, ASTM D93 or ASTM D3278. A Class II or III liquid that is heated above its flash point during handling or processing must be treated as a Class I liquid.

## SECTION 5702 DEFINITIONS

**5702.1 Definitions.** The following terms are defined in Chapter 2:

**ALCOHOL-BASED HAND RUB.**

**BULK PLANT OR TERMINAL.**

**BULK TRANSFER.**

**COMBUSTIBLE LIQUID.**

Class II.

Class IIIA.

Class IIIB.

**FIRE POINT.**

**FLAMMABLE LIQUID.**

Class IA.

Class IB.

Class IC.

**FLASH POINT.**

**FUEL LIMIT SWITCH.**

**LIQUID STORAGE ROOM.**

**LIQUID STORAGE WAREHOUSE.**

**MOBILE FUELING.**

**PROCESS TRANSFER.**

**REFINERY.**

**REMOTE EMERGENCY SHUTOFF DEVICE.**

**REMOTE SOLVENT RESERVOIR.**

**SOLVENT DISTILLATION UNIT.**

**TANK, PRIMARY.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 5703 GENERAL REQUIREMENTS

**5703.1 Electrical.** Electrical wiring and equipment shall be installed and maintained in accordance with Section 605 and NFPA 70.

❖ The installation of electrical wiring and equipment is regulated by NFPA 70.

**5703.1.1 Classified locations for flammable liquids.** Areas where flammable liquids are stored, handled, dispensed or mixed shall be in accordance with Table 5703.1.1. A classified area shall not extend beyond an unpierced floor, roof or other solid partition.

The extent of the classified area is allowed to be reduced, or eliminated, where sufficient technical justification is provided to the *fire code official* that a concentration in the area in excess of 25 percent of the lower flammable limit (LFL) cannot be generated.

❖ Electrical systems can create sparks that can be a source of ignition. Areas of a building where flammable liquids are present are to have the electrical wiring and equipment installed to prevent the electrical system from becoming an ignition source. This type of electrical installation is not required in other areas of the building where the construction prevents the spread of flammable liquids and their vapors. This construction can be accomplished only by eliminating penetrations. Class I equipment locations, which require special installation of wiring and equipment, are listed in Table 5703.1.1.

**TABLE 5703.1.1.** See page 57-5.

❖ The table lists the Class I, Group D locations that require installation of the electrical system or its components to prevent them from becoming an ignition source. Class I is defined as a location where flammable liquids or gases may be present in sufficient quantities to produce an explosive or ignitable mixture. Group D is defined as an atmosphere containing flammable or combustible liquids or gases. Group D is divided into two divisions: Division 1 is for locations where flammable or combustible vapors are present; Division 2 is for locations where flammable or combustible vapors may be present.

TABLE 5703.1.1  
CLASS I ELECTRICAL EQUIPMENT LOCATIONS\*

LOCATION	GROUP D DIVISION	EXTENT OF CLASSIFIED AREA
<b>Underground tank fill opening</b>	1	Pits, boxes or spaces below grade level, any part of which is within the Division 1 or 2 classified area.
	2	Up to 18 inches above grade level within a horizontal radius of 10 feet from a loose-fill connection and within a horizontal radius of 5 feet from a tight-fill connection.
<b>Vent—Discharging upward</b>	1	Within 3 feet of open end of vent, extending in all directions.
	2	Area between 3 feet and 5 feet of open end of vent, extending in all directions.
<b>Drum and container filling</b> Outdoor or indoor with adequate ventilation	1	Within 3 feet of vent and fill opening, extending in all directions.
	2	Area between 3 feet and 5 feet from vent of fill opening, extending in all directions. Also up to 18 inches above floor or grade level within a horizontal radius of 10 feet from vent or fill opening.
<b>Pumps, bleeders, withdrawal fittings, meters and similar devices</b> Indoor	2	Within 5 feet of any edge of such devices, extending in all directions, and up to 3 feet above floor or grade level within 25 feet horizontally from any edge of such devices.
	2	Within 3 feet of any edge of such devices, extending in all directions, and up to 18 inches above floor or grade level within 10 feet horizontally from an edge of such devices.
<b>Pits</b> Without mechanical ventilation With mechanical ventilation Containing valves, fittings or piping, and not within a Division 1 or 2 classified area	1	Entire area within pit if any part is within a Division 1 or 2 classified area.
	2	Entire area within pit if any part is within a Division 1 or 2 classified area.
	2	Entire pit.
<b>Drainage ditches, separators, impounding basins</b> Indoor Outdoor	1 or 2	Same as pits.
	2	Area up to 18 inches above ditch, separator or basin, and up to 18 inches above grade within 15 feet horizontal from any edge.
<b>Tank vehicle and tank car<sup>b</sup></b> Loading through open dome Loading through bottom connections with atmospheric venting	1	Within 3 feet of edge of dome, extending in all directions.
	2	Area between 3 feet and 15 feet from edge of dome, extending in all directions.
	1	Within 3 feet of point of venting to atmosphere, extending in all directions.
	2	Area between 3 feet and 15 feet from point of venting to atmosphere, extending in all directions. Also up to 18 inches above grade within a horizontal radius of 10 feet from point of loading connection.

(continued)

TABLE 5703.1.1—continued  
CLASS I ELECTRICAL EQUIPMENT LOCATIONS<sup>a</sup>

LOCATION	GROUP D DIVISION	EXTENT OF CLASSIFIED AREA
<b>Tank vehicle and tank car<sup>b</sup>—continued</b> Loading through closed dome with atmospheric venting	1	Within 3 feet of open end of vent, extending in all directions.
	2	Area between 3 feet and 15 feet from open end of vent, extending in all directions, and within 3 feet of edge of dome, extending in all directions.
Loading through closed dome with vapor control	2	Within 3 feet of point of connection of both fill and vapor lines, extending in all directions.
Bottom loading with vapor control or any bottom unloading	2	Within 3 feet of point of connection, extending in all directions, and up to 18 inches above grade within a horizontal radius of 10 feet from point of connection.
<b>Storage and repair garage for tank vehicles</b>	1	Pits or spaces below floor level.
	2	Area up to 18 inches above floor or grade level for entire storage or repair garage.
<b>Garages for other than tank vehicles</b>	Ordinary	Where there is an opening to these rooms within the extent of an outdoor classified area, the entire room shall be classified the same as the area classification at the point of the opening.
<b>Outdoor drum storage</b>	Ordinary	—
<b>Indoor warehousing where there is no flammable liquid transfer</b>	Ordinary	Where there is an opening to these rooms within the extent of an indoor classified area, the room shall be classified the same as if the wall, curb or partition did not exist.
<b>Indoor equipment where flammable vapor/air mixtures could exist under normal operations</b>	1	Area within 5 feet of any edge of such equipment, extending in all directions.
	2	Area between 5 feet and 8 feet of any edge of such equipment, extending in all directions, and the area up to 3 feet above floor or grade level within 5 feet to 25 feet horizontally from any edge of such equipment.
<b>Outdoor equipment where flammable vapor/air mixtures could exist under normal operations</b>	1	Area within 3 feet of any edge of such equipment, extending in all directions.
	2	Area between 3 feet and 8 feet of any edge of such equipment extending in all directions, and the area up to 3 feet above floor or grade level within 3 feet to 10 feet horizontally from any edge of such equipment.
<b>Tank—Above ground</b> Shell, ends or roof and dike area	1	Area inside dike where dike height is greater than the distance from the tank to the dike for more than 50 percent of the tank circumference.
	2	Area within 10 feet from shell, ends or roof of tank. Area inside dikes to level of top of dike.
Vent	1	Area within 5 feet of open end of vent, extending in all directions.
	2	Area between 5 feet and 10 feet from open end of vent, extending in all directions.
Floating roof	1	Area above the roof and within the shell.
<b>Office and restrooms</b>	Ordinary	Where there is an opening to these rooms within the extent of an indoor classified location, the room shall be classified the same as if the wall, curb or partition did not exist.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Locations as classified in NFPA 70.

b. When classifying extent of area, consideration shall be given to the fact that tank cars or tank vehicles can be spotted at varying points. Therefore, the extremities of the loading or unloading positions shall be used.

c. The release of Class I liquids can generate vapors to the extent that the entire building, and possibly a zone surrounding it, are considered a Class I, Division 2 location.

**5703.1.2 Classified locations for combustible liquids.**

Areas where Class II or III liquids are heated above their *flash points* shall have electrical installations in accordance with Section 5703.1.1.

**Exception:** Solvent distillation units in accordance with Section 5705.4.

- ❖ Electrical systems can create sparks that can be a source of ignition. The sparks may be caused by electrical current or static electricity. Areas of a building where combustible liquids are heated to or above their flash points are treated the same as areas containing flammable liquids. Class I equipment locations, which require special installation of the wiring and equipment, are listed in Table 5703.1.1.

The exception indicates that use of a solvent distillation unit for the recovery of combustible liquids is not considered a Class I, Group D location. See the commentary to Section 2705.4 for information on solvent distillation units.

**5703.1.3 Other applications.** The *fire code official* is authorized to determine the extent of the Class I electrical equipment and wiring location where a condition is not specifically covered by these requirements or NFPA 70.

- ❖ There may be situations when the code does not specifically cover the hazardous location that should have Class I electrical equipment and wiring. The fire code official has the authority to require Class I electrical equipment and wiring in a location not specifically identified by the code for Division 1 or 2 locations.

**5703.2 Fire protection.** Fire protection for the storage, use, dispensing, mixing, handling and on-site transportation of flammable and *combustible liquids* shall be in accordance with this chapter and applicable sections of Chapter 9.

- ❖ The requirements of Chapter 9 apply to flammable and combustible liquids. Fire protection is a principal means of preventing and controlling the spread of fire.

**5703.2.1 Portable fire extinguishers and hose lines.** Portable fire extinguishers shall be provided in accordance with Section 906. Hose lines shall be provided in accordance with Section 905.

- ❖ Portable fire extinguishers and hose lines are to be installed where flammable and combustible liquids are stored, used or dispensed. These fire protection devices, operated by trained personnel, are to handle small emergencies. They are not an alternative to fire protection systems mandated by this section, Chapter 9 of the code or the IBC.

**5703.3 Site assessment.** In the event of a spill, leak or discharge from a tank system, a site assessment shall be completed by the *owner* or operator of such tank system if the *fire code official* determines that a potential fire or explosion hazard exists. Such site assessments shall be conducted to ascertain potential fire hazards and shall be completed and

submitted to the fire department within a time period established by the *fire code official*, not to exceed 60 days.

- ❖ Site assessment is to ensure that a spill, leak or discharge of flammable or combustible liquid is investigated and corrective action is taken. The corrective action may involve only cleaning the area and covering the cause of the problem during personnel safety meetings or it may require a revision to the equipment or operation procedures. The fire code official is to establish the deadline for completion of the site assessment. The maximum time for completing a site assessment is 60 days. The corrective actions may take longer than the time to complete the site assessment.

**5703.4 Spill control and secondary containment.** Where the *maximum allowable quantity per control area* is exceeded, and where required by Section 5004.2, rooms, buildings or areas used for storage, dispensing, use, mixing or handling of Class I, II and IIIA liquids shall be provided with spill control and secondary containment in accordance with Section 5004.2.

- ❖ Where the maximum allowable quantity per control area (MAQ) of flammable or Class II or IIIA combustible liquids is exceeded, spills must be controlled to prevent the spread of liquid and vapors. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled. Section 5004.3 discusses mechanical and natural exhaust systems. The exhaust system is to remove the vapors to prevent them from accumulating in concentrations in the flammable range of the vapor. See also Section 5704.3.7.3.

**5703.5 Labeling and signage.** The *fire code official* is authorized to require warning signs for the purpose of identifying the hazards of storing or using flammable liquids. Signage for identification and warning such as for the inherent hazard of flammable liquids or smoking shall be provided in accordance with this chapter and Sections 5003.5 and 5003.6.

- ❖ Signs are used to identify the flammable or combustible liquid being stored or used and to provide any warning or information necessary for its storage or use. Sections 5003.5 and 5003.6 include a reference to NFPA 704, which details the locations and construction of the signs. NFPA 704 uses a diamond with each of its four points colored either red, blue, yellow or white. Each diamond point represents a different hazard. For flammable and combustible liquids, the red diamond point (uppermost point) represents flammability. The number in this diamond point will vary from 0 (will not burn) to 4 (rapidly burn). For flammable and combustible reference, numbers 2 to 4 usually represent flammable and combustible liquids. These signs are permanent, durable signs that are to be readily visible and are not to be covered or removed.

**5703.5.1 Style.** Warning signs shall be of a durable material. Signs warning of the hazard of flammable liquids shall have white lettering on a red background and shall read: DANGER—FLAMMABLE LIQUIDS. Letters shall be not less than 3 inches (76 mm) in height and 1/2 inch (12.7 mm) in stroke.

❖ The signs used with flammable liquids are to read “DANGER—FLAMMABLE LIQUIDS.” The code defines color and size of lettering to ensure uniformity.

**5703.5.2 Location.** Signs shall be posted in locations as required by the *fire code official*. Piping containing flammable liquids shall be identified in accordance with ASME A13.1.

❖ The location of signs is discussed in Section 5003.5 for containers, tanks, entrances, etc., by reference to NFPA 704. Signage for piping containing flammable liquids is covered under ASME A13.1. The signage is in English text and requires arrows to indicate flow direction.

**5703.5.3 Warning labels.** Individual containers, packages and cartons shall be identified, marked, labeled and placarded in accordance with federal regulations and applicable state laws.

❖ The warning labels on individual containers, packages and cartons may be different than what is required under NFPA 704. Other federal and state laws may address the warning label for these individual containers, packages and cartons.

**5703.5.4 Identification.** Color coding or other *approved* identification means shall be provided on each loading and unloading riser for flammable or *combustible liquids* to identify the contents of the tank served by the riser.

❖ More than one flammable or combustible liquid may be present at a facility in addition to other liquids. The loading and unloading risers are to be color coded or identified by other approved identification means to ensure that operators know which material is being used. If color coding is not used, the fire code official is to approve any other identification means.

**5703.6 Piping systems.** Piping systems, and their component parts, for flammable and *combustible liquids* shall be in accordance with Sections 5703.6.1 through 5703.6.11.

❖ Piping must be designed to provide protection against overpressure or other conditions that could create leaks at joints or rupture the pipes.

**5703.6.1 Nonapplicability.** The provisions of Section 5703.6 shall not apply to gas or oil well installations; piping that is integral to stationary or portable engines, including aircraft, watercraft and motor vehicles; and piping in connection with boilers and pressure vessels regulated by the *International Mechanical Code*.

❖ Piping of some applications of flammable and combustible liquids is addressed under other code documents or other laws. Other state and federal agencies have laws and authority to regulate the piping for oil

and gas wells. Stationary and portable engines are manufactured under other standards that are enforced by other state and federal agencies. Because the piping associated with heating equipment (fuel oil and pressure systems) is addressed by the IMC, those requirements are not repeated.

**5703.6.2 Design and fabrication of piping systems and components.** Piping system components shall be designed and fabricated in accordance with the applicable standard listed in Table 5703.6.2 and Chapter 27 of NFPA 30, except as modified by Section 5703.6.2.1.

❖ Rather than include lengthy requirements for piping systems in the body of the code, this section provides correlation with Chapter 27 of NFPA 30, which references the ASME B31 series of piping standards, not all of which are suitable or necessary for flammable or combustible liquid piping. By including a table listing the four specific standards within ASME B31 that are applicable for flammable liquid piping, the code is made more user friendly. It is left to the code user to select the correct standard to apply.

TABLE 5703.6.2  
PIPING STANDARDS

PIPING USE	STANDARD
Power Piping	ASME B31.1
Process Piping	ASME B31.3
Pipeline Transportation Systems for Liquid Hydrocarbons and Other Liquids	ASME B31.4
Building Services Piping	ASME B31.9

❖ See the commentary to Section 5703.6.2.

**5703.6.2.1 Special materials.** Low-melting-point materials (such as aluminum, copper or brass), materials that soften on fire exposure (such as nonmetallic materials) and nonductile material (such as cast iron) shall be acceptable for use underground in accordance with the applicable standard listed in Table 5703.6.2. Where such materials are used outdoors in above-ground piping systems or within buildings, they shall be in accordance with the applicable standard listed in Table 5703.6.2 and one of the following:

1. Suitably protected against fire exposure.
2. Located where leakage from failure would not unduly expose people or structures.
3. Located where leakage can be readily controlled by operation of accessible remotely located valves.

In all cases, nonmetallic piping shall be used in accordance with Section 27.4.6 of NFPA 30.

❖ Piping that may fail under fire exposure as a result of heat reducing its material strength is limited to specific installations and locations. Pipes that have “low melting points” can fail by sagging when exposed to fire. Sagging can cause a joint to separate or the pipes to burst if piping is under pressure. These failures would result in the flammable and combustible liquids being exposed to the fire and air. The limitations on the use of these piping materials reduces their exposure to a fire, or where a failure occurs,

does not increase the potential danger. This kind of piping can also be used where the piping system can be isolated in an emergency.

**5703.6.3 Testing.** Unless tested in accordance with the applicable section of ASME B31.9, piping, before being covered, enclosed or placed in use, shall be hydrostatically tested to 150 percent of the maximum anticipated pressure of the system, or pneumatically tested to 110 percent of the maximum anticipated pressure of the system, but not less than 5 pounds per square inch gauge (psig) (34.47 kPa) at the highest point of the system. This test shall be maintained for a sufficient time period to complete visual inspection of joints and connections. For not less than 10 minutes, there shall be no leakage or permanent distortion. Care shall be exercised to ensure that these pressures are not applied to vented storage tanks. Such storage tanks shall be tested independently from the piping.

- ❖ Piping must be tested to a minimum pressure of 5 pounds per square inch gauge (psig) (34.47 kPa) or to a pressure greater than the anticipated pressure of the system. The pipe joints and connections are to be visually inspected. The test pressure is to be maintained for a minimum of 10 minutes, but not less than the time required for a visual inspection.

**5703.6.3.1 Existing piping.** Existing piping shall be tested in accordance with this section where the *fire code official* has reasonable cause to believe that a leak exists. Piping that could contain flammable or *combustible liquids* shall not be tested pneumatically. Such tests shall be at the expense of the *owner* or operator.

**Exception:** Vapor-recovery piping is allowed to be tested using an inert gas.

- ❖ The fire code official may require testing of existing piping. Existing piping is to be tested to the same criteria as new piping, except that piping containing flammable or combustible liquids is not to be pneumatically tested. The introduction of air into these pipes can create a vapor and air mixture that reaches the flammable range.

The exception allows pneumatic testing of a vapor-recovery system with an inert gas (such as nitrogen, carbon dioxide, etc.). Because vapor-recovery systems are designed to remove the flammable or combustible vapors and recycle the liquid, these vapors could be removed from the piping during the recovery process; however, the inert gas is still required to prevent the vapor and air mixture from reaching the flammable range before or during the recovery process.

**5703.6.4 Protection from vehicles.** Guard posts or other *approved* means shall be provided to protect piping, valves or fittings subject to vehicular damage in accordance with Section 312.

- ❖ Protection from vehicle impact is provided by guard posts or other approved barriers. Section 312 states

that the specifications for guard posts or the design forces required for an approved barrier should comply with the code.

**5703.6.5 Protection from external corrosion and galvanic action.** Where subject to external corrosion, piping, related fluid-handling components and supports for both underground and above-ground applications shall be fabricated from noncorrosive materials, and coated or provided with corrosion protection. Dissimilar metallic parts that promote galvanic action shall not be joined.

- ❖ Deterioration of piping and components can cause leaks and spillage of flammable and combustible liquids. Using uncorrodible materials, protective coatings, galvanic protection or a combination of these methods can protect the piping and components. Dissimilar metals are prohibited because of the localized galvanic action that could occur between them. This localized galvanic action could cause one of the metals to corrode so that the other metal is protected from corrosion. See Section 5704.2.7.9 for corrosion protection for tanks.

**5703.6.6 Valves.** Piping systems shall contain a sufficient number of manual control valves and check valves to operate the system properly and to protect the plant under both normal and emergency conditions. Piping systems in connection with pumps shall contain a sufficient number of such valves to control properly the flow of liquids in normal operation and in the event of physical damage or fire exposure.

- ❖ Valves are essential to proper operation. Check valves prevent the backflow or siphonage of flammable and combustible liquids. Other valves are used to isolate piping sections and equipment for maintenance. Valves are also used to stop the flow of flammable and combustible liquids.

**5703.6.6.1 Backflow protections.** Connections to pipelines or piping by which equipment (such as tank cars, tank vehicles or marine vessels) discharges liquids into storage tanks shall be provided with check valves or block valves for automatic protection against backflow where the piping arrangement is such that backflow from the system is possible. Where loading and unloading is done through a common pipe system, a check valve is not required. However, a block valve, located so as to be readily accessible or remotely operable, shall be provided.

- ❖ Check valves prevent the backflow or siphonage of flammable and combustible liquids. A check valve cannot be used for a common pipe used to both load and unload flammable and combustible liquids because check valves are designed to allow flow in only one direction. This type of valve would prohibit a common pipe for both loading and unloading. A block valve is to be used for this common pipe. The block valve control mechanism must be readily accessible or remotely operable in the event that the valve is needed to stop a spill or accidental discharge.

**5703.6.6.2 Manual drainage.** Manual drainage-control valves shall be located at *approved* locations remote from the tanks, diked area, drainage system and impounding basin to ensure their operation in a fire condition.

❖ In case of a fire, it may be necessary to drain the piping system. This is to be accomplished by a manual drainage-control valve. The number of manual drainage-control valves will depend on the facility. The manual drainage-control valves are to be located to isolate sections of the piping and equipment for maintenance, repair, replacement and control of flammable and combustible liquids during an emergency.

**5703.6.7 Connections.** Above-ground tanks with connections located below normal liquid level shall be provided with internal or external isolation valves located as close as practical to the shell of the tank. Except for liquids whose chemical characteristics are incompatible with steel, such valves, where external, and their connections to the tank shall be of steel.

❖ The isolation valve is located as near as practical to above-ground tanks to control the flow of flammable and combustible liquids. This location is to reduce the quantity of flammable and combustible liquids that may be discharged during an emergency. The loss of a portion of the piping system between an above-ground tank and the isolation valve may allow the discharge of the flammable and combustible liquids under gravity flow.

The isolation valve is to be of steel unless the flammable and combustible liquids are not compatible with steel. Other valve materials may be damaged and fail under the heat from a fire. If the isolation valve fails, the flammable and combustible liquids may be discharged under gravity flow and increase the fire potential.

**5703.6.8 Piping supports.** Piping systems shall be substantially supported and protected against physical damage and excessive stresses arising from settlement, vibration, expansion, contraction or exposure to fire. The supports shall be protected against exposure to fire by one of the following:

1. Draining liquid away from the piping system at a minimum slope of not less than 1 percent.
2. Providing protection with a *fire-resistance rating* of not less than 2 hours.
3. Other *approved* methods.

❖ Pipe supports are necessary to reduce stress on the pipe from both external and internal sources. Personnel are an external source of potential damage to piping, as is unattached equipment hitting the piping system. The pipe supports are to absorb these impact loads to protect the pipe from excess deflection.

Internal forces are caused by the positive and negative pressures created by the operation of pumps and valves. Pumping of flammable and combustible

liquids will generate positive pressure in the pipe. This pressure, combined with any pressure required to support the dead weight of the piping system and flammable and combustible liquids in the piping system, can cause the pipe wall to rupture.

The pumping action and the operation of the valve can cause shock waves to travel through the flammable and combustible liquids in a pipe, which can create internal pressures several times larger than normal operating pressures. One type of shock wave is caused by the fast opening and closing of a valve. This pressure wave can place high internal pressures on the piping system.

This section lists three methods of protecting pipe supports from a fire:

1. The piping is required to have a minimum slope of 1 percent to allow for drainage. The viscosity of the flammable and combustible liquids may mandate a greater drainage slope.
2. The pipe supports must support the piping in a fire for a minimum of 2 hours based on ASTM E119 test criteria. This fire protection of the supports is to keep any flammable and combustible liquids in the pipe from adding to an existing fire.
3. The code always recognizes that there may be other methods available for accomplishing the intent. The fire code official has the responsibility to review these alternative methods and the authority to approve an alternative method, but only if it has been demonstrated or documented to comply with the intent of the code requirement.

**5703.6.9 Flexible joints.** Flexible joints shall be *listed* and *approved* and shall be installed on underground liquid, vapor and vent piping at all of the following locations:

1. Where piping connects to underground tanks.
2. Where piping ends at pump islands and vent risers.
3. At points where differential movement in the piping can occur.

❖ Flexible joints are necessary to handle expansion and contraction of the piping system and control vibration. Expansion and contraction of the piping system will create stresses in the pipe and pipe joints because of the increase or decrease in pipe length. These changes in pipe length may cause the pipe to buckle, or pull or push a joint apart. The vibration of a pipe may cause a fatigue failure. Fatigue failures result from the reversal of stresses in a material. The flexing of the pipe wall or pipe joint from a positive pressure to a negative pressure over time will create a fatigue failure in the pipe wall. This fatigue can cause the pipe or pipe joint to finally break open because of internal operating pressures or external loading, such as dead weight or an impact load.

This section lists three locations where flexible joints must be used:

1. *Piping connected to an underground tank.* An underground tank is unmovable; therefore, the flexible joint connecting the piping to the tank must handle the expansion and contraction of the pipe system.
2. *Piping ending at pump islands and vent risers.* The mechanical equipment vibrations make it necessary to isolate the piping with flexible joints at a pumping island. Equipment vibrations can cause failure of vent risers or joints in vent risers. Vent risers may vibrate more than other piping because there is no liquid in the pipe to help dampen the vibrations.
3. *Points of differential movement.* Any location where differential settlement may occur will need to be isolated by a flexible joint. Differential settlement can cause the piping to become the support or to have inadequate support. Either case can cause the pipe to buckle or fail.

**5703.6.9.1 Fiberglass-reinforced plastic piping.** Fiberglass-reinforced plastic (FRP) piping is not required to be provided with flexible joints in locations where both of the following conditions are present:

1. Piping does not exceed 4 inches (102 mm) in diameter.
2. Piping has a straight run of not less than 4 feet (1219 mm) on one side of the connection where such connections result in a change of direction.

In lieu of the minimum 4-foot (1219 mm) straight run length, *approved* and *listed* flexible joints are allowed to be used under dispensers and suction pumps, at submerged pumps and tanks, and where vents extend above ground.

❖ Fiberglass-reinforced plastic piping is more flexible than metal piping. This flexibility of fiberglass-reinforced plastic piping can be used to handle expansion and contraction of piping, or vibrations that would be handled by a flexible joint under a set of conditions of pipe diameter and minimum straight section of fiberglass-reinforced plastic piping. This section lists two conditions that must be met:

1. *Maximum 4 inches (102 mm) in diameter.* Fiberglass-reinforced plastic piping greater than 4 inches (102 mm) in diameter can be too stiff to have the flexibility necessary to be an alternative to a flexible joint. The greater the diameter of the pipe, the greater the stiffness of the pipe.
2. *Minimum 4-foot (1219 mm) straight run.* Straight runs of less than 4 feet (1219 mm) are too stiff to have the flexibility necessary to be an alternative to a flexible joint. The longer a pipe run is, the more the pipe can flex without causing stresses that will damage the pipe.

These two conditions are required before fiberglass-reinforced plastic piping can be used as the flexible joint. Flexible joints can be used with fiberglass-reinforced plastic piping. There are locations where there is not sufficient space to meet the two requirements for fiberglass-reinforced plastic piping as a flexible joint or where the use of fiberglass-reinforced plastic piping is not desired. These locations can use a flexible joint.

**5703.6.10 Pipe joints.** Joints shall be liquid tight and shall be welded, flanged or threaded except that *listed* flexible connectors are allowed in accordance with Section 5703.6.9. Threaded or flanged joints shall fit tightly by using *approved* methods and materials for the type of joint. Joints in piping systems used for Class I liquids shall be welded where located in concealed spaces within buildings.

Nonmetallic joints shall be *approved* and shall be installed in accordance with the manufacturer's instructions.

Pipe joints that are dependent on the friction characteristics or resiliency of combustible materials for liquid tightness of piping shall not be used in buildings. Piping shall be secured to prevent disengagement at the fitting.

❖ Pipe joints are to be liquid tight. The code recognizes only three types of generic mechanical joints as being adequate for pipes carrying flammable and combustible liquids. Welded joints, flanged joints and threaded joints provide a liquid-tight joint. ANSI B31.3 contains criteria for the welding of piping. This reference is not in this chapter, but is cited in Chapter 50.

Flanged joints are to be made with materials that are compatible with the piping system and the flammable and combustible liquids in the pipe.

Threaded joints are to be fabricated by methods that ensure a liquid-tight joint by the selection of thread pitch and length of the threaded connection. Listed flexible joints are to be approved by the fire code official.

Pipe joints in a building's concealed space that carry Class I flammable liquids are limited to welded joints. Because Class I flammable liquids can become vapor at ambient temperature, a joint leak in a concealed space could go unnoticed. There could be no liquid escaping the concealed space for personnel to notice. A welded joint that has passed the test requirements of Section 5703.6.3 would be a liquid-tight joint that meets code requirements.

**5703.6.11 Bends.** Pipe and tubing shall be bent in accordance with ASME B31.9.

❖ Pipe direction can be changed using either fittings or bends. Bends are to be done according to ANSI B31.9. Bending a pipe can damage the pipe. An improper bend may kink the interior portion of the pipe wall and that could cause increased pipe stresses resulting from the kink restricting flow. An improper bend could stretch the outer portion of the pipe wall. The stretched portion of pipe would have a thinner wall thickness. This thinner wall could develop pinhole leaks or even cause the pipe to rupture.

## SECTION 5704 STORAGE

**5704.1 General.** The storage of flammable and *combustible liquids* in containers and tanks shall be in accordance with this section and the applicable sections of Chapter 50.

❖ This section and Chapter 50 cover the storage of flammable and combustible liquids in containers and tanks.

**5704.2 Tank storage.** The provisions of this section shall apply to:

1. The storage of flammable and *combustible liquids* in fixed above-ground and underground tanks.
2. The storage of flammable and *combustible liquids* in fixed above-ground tanks inside of buildings.
3. The storage of flammable and *combustible liquids* in portable tanks whose capacity exceeds 660 gallons (2498 L).
4. The installation of such tanks and portable tanks.

❖ The scope of this section is limited to the storage of flammable and combustible liquids in above-ground tanks, underground tanks, above-ground tanks in buildings, portable tanks exceeding 660 gallons (2498 L) and the installation of these tanks.

**5704.2.1 Change of tank contents.** Tanks subject to change in contents shall be in accordance with Section 5704.2.7. Prior to a change in contents, the *fire code official* is authorized to require testing of a tank.

Tanks that have previously contained Class I liquids shall not be loaded with Class II or Class III liquids until such tanks and all piping, pumps, hoses and meters connected thereto have been completely drained and flushed.

❖ The type of flammable or combustible liquid stored in a tank can change. When the type of flammable or combustible liquid is changed, the design and construction of the tank is to comply with NFPA 30 for the type of flammable or combustible liquid to be stored. A change in the tank contents can effect safety by altering the flashpoint of the contents through contamination. Accordingly, the fire code official has the authority to require the tank to be tested before placing the tank in operation with the new type of flammable and combustible liquid.

If the change of flammable and combustible liquid is from a Class I to a Class II or III liquid, the tank and accessory piping and equipment are to be drained and cleaned of the Class I liquid. The Class I liquid left in the tank and accessory piping and equipment can generate vapors that could create a hazard not associated with the Class II or III liquid that has replaced the Class I liquid.

**5704.2.2 Use of tank vehicles and tank cars as storage tanks.** Tank cars and tank vehicles shall not be used as storage tanks.

❖ Even if the wheels were removed and the tank supported on adequate foundations, the use of tank cars

or tank vehicles for permanent storage of flammable or combustible liquids is prohibited by this section because, in many cases, these “tanks” do not comply with the requirements of the referenced standard, NFPA 30. The U.S. Department of Transportation (DOTn) allows motor carriers to transport flammable and combustible liquids in tank vehicles constructed of aluminum. Section 5704.2.7 requires that tanks be constructed in accordance with Section 21.4 of NFPA 30, which, in turn, requires that they be constructed in accordance with good engineering practices. All of the standards adopted in NFPA 30 for shop-fabricated and field-erected above-ground storage tanks prohibit the use of aluminum as a material of construction for storage tanks because of its low melting point. In addition, it is quite possible, for example, that someone could attempt to convert a milk tanker into an above-ground storage tank for flammable or combustible liquids. Such a tank would not, for one thing, have an emergency vent, which is required by Section 5704.2.7.4 of the code. Note that this section does not include the demountable intermediate bulk containers (IBCs) frequently seen in transport secured on flatbed trucks. These portable tanks are regulated by Section 5704.3.

**5704.2.3 Labeling and signs.** Labeling and signs for storage tanks and storage tank areas shall comply with Sections 5704.2.3.1 and 5704.2.3.2.

❖ Above-ground tanks, underground tanks, above-ground tanks in buildings and portable tanks exceeding 660 gallons (2498 L) are to be provided with warning and identification signs.

**5704.2.3.1 Smoking and open flame.** Signs shall be posted in storage areas prohibiting open flames and smoking. Signs shall comply with Section 5703.5.

❖ Warning signs prohibiting smoking and open flames are to comply with NFPA 704.

**5704.2.3.2 Label or placard.** Tanks more than 100 gallons (379 L) in capacity, which are permanently installed or mounted and used for the storage of Class I, II or III liquids, shall bear a label and placard identifying the material therein. Placards shall be in accordance with NFPA 704.

### Exceptions:

1. Tanks of 300-gallon (1136 L) capacity or less located on private property and used for heating and cooking fuels in single-family *dwelling*s.
2. Tanks located underground.

❖ In order to provide warning and information on the hazards of their contents, permanently installed tanks in excess of 100-gallon (379 L) capacity used to store Class I, II or III liquids are to be labeled to identify the flammable or combustible liquid.

There are two exceptions to this labeling of storage tanks based on the use of the storage tank and its location. First, a 300-gallon (1136 L) storage tank for use by a single-family dwelling does not need to be

labeled. This exception is based on the tank's sole use for the storage of heating or cooking fuel used by the occupants of the single-family dwelling. Second, underground tanks do not need to be labeled since their location precludes it.

**5704.2.4 Sources of ignition.** Smoking and open flames are prohibited in storage areas in accordance with Section 5003.7.

**Exception:** Areas designated as smoking and hot work areas, and areas where hot work permits have been issued in accordance with this code.

❖ Smoking and open flames are strictly limited around above-ground tanks, underground tanks, above-ground tanks in buildings and portable tanks exceeding 660 gallons (2498 L). Section 5003.7 prohibits smoking or open flames within 25 feet (7620 mm) of outdoor storage of flammable and combustible liquids and indoors where there are flammable and combustible liquids or where vapors from flammable and combustible liquids may occur.

The exception allows establishment of designated smoking areas and hot work areas. Hot work may be done in areas not designated as a hot work area when a hot work permit is obtained.

**5704.2.5 Explosion control.** Explosion control shall be provided in accordance with Section 911 for indoor tanks.

❖ The vapor from flammable and combustible liquids can cause an explosion when the vapor-air mixture is in an explosive ratio. Explosion control is required for a facility storing or using Class IA liquids or for a facility that has open use or dispensing of Class IIB liquids. Section 911 requires deflagration venting to direct the force of an explosion out of the structure and into an unoccupied area. This section also references NFPA 69, which may require monitoring of gases and other methods to suppress factors affecting an explosion.

**5704.2.6 Separation from incompatible materials.** Storage of flammable and *combustible liquids* shall be separated from *incompatible materials* in accordance with Section 5003.9.8.

Grass, weeds, combustible materials and waste Class I, II or IIIA liquids shall not be accumulated in an unsafe manner at a storage site.

❖ Materials that could create a fire or explosive hazard when in contact with flammable or combustible liquids are to be separated from flammable or combustible liquids by either distance or physical barriers.

Materials that may not be incompatible with flammable or combustible liquids but may be an ignition source or a fuel source are to be removed.

**5704.2.7 Design, fabrication and construction requirements for tanks.** The design, fabrication and construction of tanks shall comply with NFPA 30. Each tank shall bear a per-

manent nameplate or marking indicating the standard used as the basis of design.

❖ Tanks are to be designed according to NFPA 30 and labeled to indicate the design standard.

**5704.2.7.1 Materials used in tank construction.** The materials used in tank construction shall be in accordance with NFPA 30. The materials of construction for tanks and their appurtenances shall be compatible with the liquids to be stored.

❖ The preferred material for tank construction is steel or concrete, materials that have high levels of resistance to heat. Because combustible and flammable liquid tanks are being used to store an ever increasing number of liquids, including gasoline/ethanol blends and diesel/biodiesels blends, this section requires that tank construction materials be compatible with the stored liquids. This is consistent with NFPA 30, Section 21.4.1.1. Petroleum products containing mixtures that are not petroleum based may be incompatible with components in the underground tank. The nonpetroleum products could attack liners, gaskets, etc., and the loss of or damage to these components may cause the underground tank or piping system to develop leaks.

**5704.2.7.2 Pressure limitations for tanks.** Tanks shall be designed for the pressures to which they will be subjected in accordance with NFPA 30.

❖ Tanks may be designed for operation under atmospheric pressure, low pressure or high pressure. The design criteria for pressure are in NFPA 30.

**5704.2.7.3 Tank vents for normal venting.** Tank vents for normal venting shall be installed and maintained in accordance with Sections 5704.2.7.3.1 through 5704.2.7.3.5.3.

❖ Tanks are vented to maintain the internal tank pressure within the design operating range. A low pressure can increase the generation of vapors while a high pressure can damage the tank or piping system. Any pressure outside of the design pressure range can have an adverse affect on the operation of the system as well as the piping and equipment.

**5704.2.7.3.1 Vent lines.** Vent lines from tanks shall not be used for purposes other than venting unless *approved*.

❖ Vent lines are to be used only as vents unless an additional use is approved by the fire code official.

**5704.2.7.3.2 Vent-line flame arresters and pressure-vacuum vents.** *Listed or approved* flame arresters or pressure-vacuum (PV) vents that remain closed unless venting under pressure or vacuum conditions shall be installed in normal vents of tanks containing Class IB and IC liquids.

**Exception:** Where determined by the *fire code official* that the use of such devices can result in damage to the tank.

Vent-line flame arresters shall be installed in accordance with their listing or API 2000 and maintained in accordance

with Section 21.8.6 of NFPA 30 or API 2000. In-line flame arresters in piping systems shall be installed and maintained in accordance with their listing or API 2028. Pressure-vacuum vents shall be installed in accordance with Section 21.4.3 of NFPA 30 or API 2000 and maintained in accordance with Section 21.8.6 of NFPA 30 or API 2000.

❖ The vapors from a vent will mix with air and become an ignitable mixture. This condition requires that measures be taken to either suppress an ignition source or to disperse the ignitable mixture with additional air to drop the vapor-air mixture below the LFL. Previously, the code required that a flame arrester or pressure-vacuum (PV) vent be installed in the normal vent of only protected above-ground tanks containing flammable or combustible liquids, but did not have a similar requirement for other above-ground tanks with a design and construction that provides significantly less protection than a protected above-ground tank. This section has been revised to be consistent with NFPA 30 in that, regardless of tank type, a listed flame arrester or PV vent is only required for tanks containing Class IB and IC liquids, which are less prone to vaporization than Class IA liquids.

Because the primary function of a flame arrester is to prevent the unrestricted propagation of flame through flammable gas or vapor mixtures, it is not necessary to install a flame arrester on tanks containing combustible liquids. Additionally, because flame arresters cannot prevent detonation or control flame propagation speeds associated with a detonation (flame speeds greater than the speed of sound), flame arresters are not effective when installed on tanks containing Class IA liquids. This revision establishes a requirement for a tank-vent flame arrester only when there is a sound technical reason to provide one. The exception allows omitting the use of a PV vent or flame arrester in situations where the properties of the liquid can cause the tank to be damaged by their use. Properties of some Class IB and IC liquids (e.g., crystallization, polymerization, corrosion) can present obstructions in flame arresters that may justify omitting the device.

This section clarifies that API 2028 addresses in-line flame arresters for piping systems. An end-of-line flame arrester is a flame arrester that is mounted at the end of a pipe (flanged or threaded inlet connection) and vents directly to the atmosphere, whereas an in-line flame arrester may be mounted upstream of a PV relief vent or may be located upstream of a specified maximum length of vent piping to the atmosphere. Both in-line and end-of-line flame arresters are acceptable devices. Not only is proper installation of these devices important, but their maintenance is critical. A blocked or corroded flame arrester can render the device ineffective and lead to catastrophic results. As such, this section also addresses maintenance of flame arresters and PV vents in accordance with NFPA 30 or API 2000.

**5704.2.7.3.3 Vent pipe outlets.** Vent pipe outlets for tanks storing Class I, II or IIIA liquids shall be located such that the vapors are released at a safe point outside of buildings and not less than 12 feet (3658 mm) above the finished ground level. Vapors shall be discharged upward or horizontally away from adjacent walls to assist in vapor dispersion. Vent outlets shall be located such that flammable vapors will not be trapped by eaves or other obstructions and shall be not less than 5 feet (1524 mm) from building openings or *lot lines* of properties that can be built upon. Vent outlets on atmospheric tanks storing Class IIIB liquids are allowed to discharge inside a building where the vent is a normally closed vent.

**Exception:** Vent pipe outlets on tanks storing Class IIIB liquid inside buildings and connected to fuel-burning equipment shall be located such that the vapors are released to a safe location outside of buildings.

❖ Vent pipes must be terminated to direct vapors away from the building. Vapors from flammable liquids are normally heavier than air so that the vapor will settle to lower levels. The termination of a vent pipe a minimum of 12 feet (3658 mm) above grade will provide space for the vapors to disperse to below the LFL. This high termination elevation also reduces the potential for the termination being close to grade-level ignition sources. Because flammable liquid vapors are heavier than air, attention needs to be placed on the building design near the termination. Building design and features that may allow the flammable liquid vapors to reenter the building or to collect on the building are to be eliminated. Because Class IIIB liquids have a relatively high boiling point, the vent termination for atmospheric tanks containing these combustible liquids may terminate inside the building, if the vent is normally closed.

Because of the increasing use of alternative fuels derived from biological mass, the requirements for above-ground storage tanks located inside of buildings and that are connected to fuel-burning equipment have been modified to address the use of biodiesel blends. Even though this section allows tanks storing Class IIIB liquids to discharge their vents inside the building, the exception applies to tanks providing fuel to fuel-burning equipment and recognizes that a facility could discover after installation that the fuel-burning equipment either isn't working as efficiently as desired with the Class IIIB liquid biofuel, or the biofuel becomes unavailable or more costly than traditional diesel fuel. Under such circumstances, the facility may elect to switch to a higher-hazard fuel such as Class II diesel fuel without a permit as required by Section 105.6.16(8) or other notification to the jurisdiction. The result of such a switch could be a significantly noncompliant tank system where the quantity of Class II liquid fuel could far exceed the code-allowed quantity of Class II liquid fuel. Such quantities of Class II diesel fuel in excess of that allowed inside of buildings in steel above-

ground tanks would otherwise require providing a Group H occupancy or a protected above-ground tank. Accordingly, tanks connected to and supplying fuel to fuel-burning equipment must be vented to an approved location outside the building.

The exception does not specify a minimum termination height for the vent opening nor a minimum separation distance from property lines or building eaves. Instead, the terminus of the normal vent is required to be at a safe location outside of buildings. Given that biodiesel and many biodiesel blends are classified as Class IIIA or IIIB liquids, it will be difficult to ignite the vapors exhausted through the normal vent opening from a storage tank inside of a building. The exception will provide flexibility to the design professional and fire code official in the placement of the termination point for a normal vent discharging Class IIIB liquid vapors.

**5704.2.7.3.4 Installation of vent piping.** Vent piping shall be designed, sized, constructed and installed in accordance with Section 5703.6. Vent pipes shall be installed such that they will drain toward the tank without sags or traps in which liquid can collect. Vent pipes shall be installed in such a manner so as not to be subject to physical damage or vibration.

❖ Section 5703.6 covers the design, installation, testing and protection of vent pipes. Vent pipes are to drain to the tank and not accumulate condensation in the vent pipe.

**5704.2.7.3.5 Manifolding.** Tank vent piping shall not be manifolded unless required for special purposes such as vapor recovery, vapor conservation or air pollution control.

❖ The combining of vent pipes into a manifold is not permitted as a function for venting unless it is required for the purposes stated in this section. Manifolding of several vents can cause pressure problems during tank-filling operations or in case of a fire in or near the tanks. When vapor recovery, vapor conservation or pollution control is necessary, the vents can be manifolded so that the same equipment can be used for multiple vents.

**5704.2.7.3.5.1 Above-ground tanks.** For above-ground tanks, manifolded vent pipes shall be adequately sized to prevent system pressure limits from being exceeded where manifolded tanks are subject to the same fire exposure.

❖ Manifolding of above-ground tanks requires the manifold to be designed to handle the additional pressure generated by the heating of the flammable or combustible liquid. This additional pressure could cause pressure to build up in other tanks or in the piping system. This additional pressure could create leaks or failure of other tanks or piping.

**5704.2.7.3.5.2 Underground tanks.** For underground tanks, manifolded vent pipes shall be sized to prevent system pressure limits from being exceeded when manifolded tanks are filled simultaneously.

❖ Manifolding of underground tanks must consider the buildup of pressure when the underground tanks are

filled simultaneously. The introduction of flammable or combustible liquids into several tanks at the same time will require the vent system to release the vapor in the tank being displaced by the flammable or combustible liquids. This displaced vapor could exceed the capacity of the vent, causing a buildup of pressure.

**5704.2.7.3.5.3 Tanks storing Class I liquids.** Vent piping for tanks storing Class I liquids shall not be manifolded with vent piping for tanks storing Class II and III liquids unless positive means are provided to prevent the vapors from Class I liquids from entering tanks storing Class II and III liquids, to prevent contamination and possible change in classification of less volatile liquid.

❖ Vapor from a Class I liquid is not to be vented with Class II or III liquid vapors unless a positive means is provided to prevent the Class I vapors from entering tanks storing Class II or III liquids. The flash point of the Class I liquid vapor may affect the flash point of the vapors in the tanks storing the Class II or III liquids.

**5704.2.7.4 Emergency venting.** Stationary, above-ground tanks shall be equipped with additional venting that will relieve excessive internal pressure caused by exposure to fires. Emergency vents for Class I, II and IIIA liquids shall not discharge inside buildings. The venting shall be installed and maintained in accordance with Section 22.7 of NFPA 30.

#### Exceptions:

1. Tanks larger than 12,000 gallons (45 420 L) in capacity storing Class IIIB liquids that are not within the diked area or the drainage path of Class I or II liquids do not require emergency relief venting.
  2. Emergency vents on protected above-ground tanks complying with UL 2085 containing Class II or IIIA liquids are allowed to discharge inside the building.
- ❖ Stationary above-ground tanks can be exposed to an external fire that will heat the tank, generating a greater volume of flammable or combustible liquid vapors in the tank. These vapors can create pressures that could damage the tank or piping system, so these tanks are vented to relieve this additional pressure. If the tank is installed inside of a building and exposed to a fire, the tank is required to vent itself, releasing flammable or combustible liquid vapors into the building, which is already involved in a fire. Since the tank will be venting flammable vapors into a fire scenario, vapor ignition would be immediate and the reaction would be continuous and uncontrolled. This hazard is mitigated by requiring that the emergency vents for Class I, II and IIIA liquid tanks discharge outside the building.

Recognizing the reduced hazard of Class IIIB liquids, Exception 1 provides that stationary above-ground tanks storing more than 12,000 gallons (45 420 L) of Class IIIB liquids do not need emergency venting if the tank is not in the same containment area or drainage path as tanks with Class I or II liq-

uids. The high boiling point of Class IIIB liquids and the high volume provide a degree of safety before the buildup of internal pressure. With the tank safety features, the volume of Class IIIB liquid and having the tank located so that it does not affect tanks storing Class I or II liquids, emergency venting is not required.

Exception 2 recognizes the higher level of protection afforded by a UL 2085-protected above-ground tank storing Class II or IIIA liquid by allowing the emergency vent to discharge inside the building. This is made possible by the fact that UL 2085 tanks are designed and constructed to withstand a 2-hour pool fire test of 2,000°F (1111°C) during which no single point temperature may exceed 400°F (204°C) and the average temperature rise throughout the internal tank can be no greater than 260°F (126.67°C). Given the stringent UL 2085 testing requirements, activation of the emergency vent is likely only under extreme fire conditions over an extended period of time. Further, NFPA 30 requires that emergency vents placed on vent pipes that extend beyond 12 inches (305 mm) from the tank be reengineered to account for the potential back pressure and ensure activation at the appropriate pressure. It is not unusual to see vent lines extending 30 or 40 feet (9.14 or 12.19 m) or more through a building in order to achieve the exterior discharge. Allowing the emergency vent to discharge inside eliminates the need to reengineer the venting and ensures proper sizing and activation of the emergency vent.

**5704.2.7.5 Tank openings other than vents.** Tank openings for other than vents shall comply with Sections 5704.2.7.5.1 through 5704.2.7.5.8.

- ❖ Tanks will have openings other than a vent opening. It will be necessary to have openings for the transfer of flammable and combustible liquids to monitor the contents, sampling, etc. These openings will need to be controlled to avoid the escape of vapors of flammable and combustible liquids or the entrance of air.

**5704.2.7.5.1 Connections below liquid level.** Connections for tank openings below the liquid level shall be liquid tight.

- ❖ Connections below the liquid level for flammable and combustible liquids are to be liquid tight. A connection that is not liquid tight may allow the flammable or combustible liquid to leak from the connection. The leakage could cause a vapor-air mixture that is between the lower flammable limit and the upper flammable limit.

**5704.2.7.5.2 Filling, emptying and vapor recovery connections.** Filling, emptying and vapor recovery connections to tanks containing Class I, II or IIIA liquids shall be located outside of buildings in accordance with Section 5704.2.7.5.6 at a location free from sources of ignition and not less than 5 feet (1524 mm) away from building openings or *lot lines* of property that can be built upon. Such openings shall be prop-

erly identified and provided with a liquid-tight cap that shall be closed when not in use.

Filling and emptying connections to indoor tanks containing Class IIIB liquids and connected to fuel-burning equipment shall be located at a finished ground level location outside of buildings. Such openings shall be provided with a liquid-tight cap that shall be closed when not in use. A sign in accordance with Section 5003.6 that displays the following warning shall be permanently attached at the filling location:

**TRANSFERRING FUEL OTHER THAN  
CLASS IIIB COMBUSTIBLE LIQUID TO  
THIS TANK CONNECTION IS A VIOLATION  
OF THE FIRE CODE AND IS STRICTLY  
PROHIBITED**

- ❖ In order to eliminate the hazards associated with inside connections, tanks for Class I, II and IIIA liquids are to have openings for filling, emptying and vapor recovery connections outside of the building and away from property lines and ignition sources in accordance with Section 5704.2.7.5.6. The flash point of the liquids creates a hazard that is not acceptable inside a building where vapors could accumulate and find their way to an ignition source.

The English-language sign complying with Section 5003.6 required by this section is to warn delivery drivers that liquids other than Class IIIB liquids are not to be delivered to the subject fill pipe. Since some tanks storing Class IIIB liquid biodiesel fuels are allowed to vent inside the building in accordance with Section 5704.2.7.3.3, this is intended to prevent the inadvertent delivery of higher hazard (i.e., lower flash point) liquids to the tank with the corresponding discharge of vapors inside the building (see comment, Section 5704.2.7.3.3).

**5704.2.7.5.3 Piping, connections and fittings.** Piping, connections, fittings and other appurtenances shall be installed in accordance with Section 5703.6.

- ❖ Section 5703.6 covers the design, installation, testing and protection of vent pipes.

**5704.2.7.5.4 Manual gauging.** Openings for manual gauging, if independent of the fill pipe, shall be provided with a liquid-tight cap or cover. Covers shall be kept closed when not gauging. If inside a building, such openings shall be protected against liquid overflow and possible vapor release by means of a spring-loaded check valve or other *approved* device.

- ❖ A manual gauge opening that has a liquid-tight cap and protection against overflow and vapor release is acceptable in tanks located inside a building. The manual gauge opening is permitted if it meets the safety requirements to prevent spillage, leakage and vapor release and has the operation feature that the opening has to be closed except when used to check the contents of the tank.

**5704.2.7.5.5 Fill pipes and discharge lines.** For top-loaded tanks, a metallic fill pipe shall be designed and installed to minimize the generation of static electricity by terminating the pipe within 6 inches (152 mm) of the bottom of the tank, and it shall be installed in a manner that avoids excessive vibration.

- ❖ The filling of a tank with flammable or combustible liquids can generate static electricity. To reduce the generation of static electricity for a top-loaded tank, the fill pipe is to be metallic and extend to within 6 inches (152 mm) of the tank bottom.

**5704.2.7.5.5.1 Class I liquids.** For Class I liquids other than crude oil, gasoline and asphalt, the fill pipe shall be designed and installed in a manner that will minimize the possibility of generating static electricity by terminating within 6 inches (152 mm) of the bottom of the tank.

- ❖ Class I liquids other than crude oil, gasoline and asphalt are to comply with Section 5704.2.7.5.5.

**5704.2.7.5.5.2 Underground tanks.** For underground tanks, fill pipe and discharge lines shall enter only through the top. Fill lines shall be sloped toward the tank. Underground tanks for Class I liquids having a capacity greater than 1,000 gallons (3785 L) shall be equipped with a tight fill device for connecting the fill hose to the tank.

- ❖ Underground tanks are to have the fill pipe and discharge pipe through the top. These fill and discharge pipes are to slope to the top to prevent the accumulation of flammable and combustible liquid. The tight fill device for tanks having a capacity of 1,000 gallons (3785 L) of Class I liquid is to ensure a liquid-tight mechanical connection of the fill hose to the tank. This connection will reduce the potential for spills or leakage and the mixing of Class I vapors with air.

**5704.2.7.5.6 Location of connections that are made or broken.** Filling, withdrawal and vapor-recovery connections for Class I, II and IIIA liquids that are made and broken shall be located outside of buildings, not more than 5 feet (1524 mm) above the finished ground level, in an *approved* location in close proximity to the parked delivery vehicle. Such location shall be away from sources of ignition and not less than 5 feet (1524 mm) away from building openings. Such connections shall be closed and liquid tight when not in use and shall be properly identified.

- ❖ The low flash point of liquids creates a hazard that is not acceptable inside of a building where vapors could accumulate. In order to eliminate the hazards associated with inside connections that are made or broken, tanks for Class I, II and IIIA liquids are to have their filling, emptying and vapor-recovery connections outside of the building and away from property lines and ignition sources in accordance with this section. The flash point of the liquids creates a hazard that is not acceptable inside a building where vapors could accumulate and find their way to an ignition source.

This section also requires that the tank-fill connection location is required to be at ground level where the fuel delivery truck driver has direct access to it.

This is to prevent designs that propose to hoist fuel delivery truck hose lines up the exterior of the building to rooftops and other building levels above the finished ground level (see also commentary, Section 5704.2.7.5.2).

**5704.2.7.5.7 Protection against vapor release.** Tank openings provided for purposes of vapor recovery shall be protected against possible vapor release by means of a spring-loaded check valve or dry-break connections, or other *approved* device, unless the opening is a pipe connected to a vapor processing system. Openings designed for combined fill and vapor recovery shall also be protected against vapor release unless connection of the liquid delivery line to the fill pipe simultaneously connects the vapor recovery line. Connections shall be vapor tight.

- ❖ Connections are to be vapor tight to prevent the release of vapor from flammable or combustible liquids into the area surrounding the tank. The release of vapor from flammable or combustible liquids could create a vapor-air mixture that exceeds the LFL. The code does permit connections that are not vapor tight if the connection is part of the vapor-recovery system. This exception is permitted because the vapor-recovery system should be operating at a pressure lower than atmospheric pressure. This lower pressure should prevent vapor from escaping the vapor-recovery system.

**5704.2.7.5.8 Overfill prevention.** An *approved* means or method in accordance with Section 5704.2.9.7.6 shall be provided to prevent the overfill of all Class I, II and IIIA liquid storage tanks. Storage tanks in refineries, bulk plants or terminals regulated by Section 5706.4 or 5706.7 shall have overfill protection in accordance with API 2350.

An *approved* means or method in accordance with Section 5704.2.9.7.6 shall be provided to prevent the overfilling of Class IIIB liquid storage tanks connected to fuel-burning equipment inside buildings.

**Exception:** Outside above-ground tanks with a capacity of 1,320 gallons (5000 L) or less.

- ❖ In the 2003 and earlier editions and drafts of the code, this section required that all above-ground storage tanks, regardless of capacity, be provided with an approved means or method of overfill prevention. For smaller tanks [less than 200- to 300-gallon (757 to 1136 L) capacity], technology exists to provide such protection. However, it must be an engineered design using a liquid-level limit switch and shutoff valve in the tank fill opening, which can cost thousands of dollars. Off-the-shelf overfill prevention devices are generally not available in the marketplace because most tank manufacturers provide fill openings that are less than 2 inches (51 mm) in diameter on smaller tanks and the off-the-shelf overfill prevention devices currently available are designed for use with tank openings 2 inches (51 mm) or larger in diameter.

A second issue relates to the frequency and size of spills. The United States Coast Guard maintains data

on spill amounts and locations in accordance with the Federal Water Pollution Control Act. A review of that data disclosed that the volume of spills has been on a downward trend since 1974. For spills of 101 to 1,000 gallons (382 to 3785 L), 1,457 events occurred in 1974, but in 2001, only 216 such spill events occurred. Also, 87.6 percent of all the spills reported to the Coast Guard are less than 100 gallons (379 L). Certainly, while no spill is acceptable, the data clearly shows that when spills do occur, they are typically less than 100 gallons (379 L).

Overfill protection is important for flammable and combustible liquids but not necessary on small tanks. Those code requirements for overfill prevention for above-ground petroleum storage tanks align with the federal requirements for Spill Prevention Control and Countermeasures (SPCC) Plans. An SPCC plan is required in accordance with the U.S. Oil Pollution Act for most sites with an aggregate tank volume of over 1,320 gallons (4996 L). Additionally, tanks over 660 gallons (2498 L) typically have 2-inch (51 mm) or larger openings that can accommodate off-the-shelf overfill prevention devices discussed above.

API 2350 includes recommended practices on prevention of overfills of above-ground tanks of greater than 1,320 gallons (4996 L) storing Class I and II liquids associated with marketing, refining, pipeline and similar facilities (see commentary, Section 5704.2.9.7.5).

Even though this section does not otherwise require overfill protection on tanks storing Class IIIB liquids, it recognizes one of the major concerns about Class IIIB liquid biodiesel tanks connected to fuel-burning equipment. That concern is that a facility could discover after installation that the fuel-burning equipment either isn't working as efficiently as desired with the Class IIIB liquid biofuel, or the biofuel becomes unavailable or more costly than traditional diesel fuel. Under such circumstances, the facility may elect to switch to a higher hazard fuel such as Class II diesel fuel without a permit as required by Section 105.6.16(8) or other notification to the jurisdiction. The result of such a switch could be a significantly noncompliant tank system where now a Class II liquid fuel storage tank exists where none did before and is without the safeguard of overfill protection. The lower flash point of the Class II liquid creates an overfill hazard potential that is not acceptable inside a building where vapors could accumulate and find their way to an ignition source.

**5704.2.7.6 Repair, alteration or reconstruction of tanks and piping.** The repair, *alteration* or reconstruction, including welding, cutting and hot tapping of storage tanks and piping that have been placed in service, shall be in accordance with NFPA 30. Hot work, as defined in Section 202, on such tanks shall be conducted in accordance with Section 3510.

❖ Tanks and piping for flammable and combustible liquids can be repaired, altered or reconstructed under the criteria of NFPA 30 and in accordance with Section 3510.

**5704.2.7.7 Design of supports.** The design of the supporting structure for tanks shall be in accordance with the *International Building Code* and NFPA 30.

❖ Footings, foundations and structural supports for tanks must comply with the IBC and NFPA 30.

**5704.2.7.8 Locations subject to flooding.** Where a tank is located in an area where it is subject to buoyancy because of a rise in the water table, flooding or accumulation of water from fire suppression operations, uplift protection shall be provided in accordance with Sections 22.14 and 23.14 of NFPA 30.

❖ The tank, with its content of flammable or combustible liquid, may weigh less than an equivalent volume of water. If this occurs and the tank is subjected to flooding, the tank will float. This will place stresses on piping systems that could fail, causing the flammable or combustible liquid to spill. The flooding may be from natural causes or from fire suppression operations. The application of water by a fire department could cause flooding in the area of the tank. Section 26.6 of NFPA 30 contains the criteria for designing anchorage for both above-ground and underground tanks. Flood hazard areas are defined in IBC Section 202.

**5704.2.7.9 Corrosion protection.** Where subject to external corrosion, tanks shall be fabricated from corrosion-resistant materials, coated or provided with corrosion protection in accordance with Section 23.3.5 of NFPA 30.

❖ Soil conditions and environmental conditions can cause tanks to deteriorate. Corrosion can weaken the tank, creating a potential for leakage. The tank is to be protected from corrosion by use of corrosion-resistant material, coatings, cathodic protection or methods described in Section 23.3.4 of NFPA 30. See Section 5703.6.5 for requirements for corrosion protection for piping.

**5704.2.7.10 Leak reporting.** A consistent or accidental loss of liquid, or other indication of a leak from a tank system, shall be reported immediately to the fire department, the *fire code official* and other authorities having jurisdiction.

❖ The leakage of flammable or combustible liquids is a serious fire hazard. This hazard is to be immediately reported to the fire department, the fire code official and other authorities having jurisdiction.

The leaking tank will have to be repaired or taken out of service. The fire code official will have to review plans and issue a permit for the repair.

**5704.2.7.10.1 Leaking tank disposition.** Leaking tanks shall be promptly emptied, repaired and returned to service, abandoned or removed in accordance with Section 5704.2.13 or 5704.2.14.

❖ Leaking tanks must be repaired, taken out of service or removed. The fire code official must review plans and issue a permit for these activities.

**5704.2.7.11 Tank lining.** Steel tanks are allowed to be lined only for the purpose of protecting the interior from corrosion or providing compatibility with a material to be stored. Only

those liquids tested for compatibility with the lining material are allowed to be stored in lined tanks.

- ❖ Tanks are lined to prevent corrosion from attacking the interior surface. Water vapor can condense inside a tank or the flammable or combustible liquid stored can be corrosive. The type of lining will limit the use of the tank to flammable and combustible liquids that are compatible with the lining.

**5704.2.8 Vaults.** Vaults shall be allowed to be either above or below grade and shall comply with Sections 5704.2.8.1 through 5704.2.8.18.

- ❖ Vaults are designed and constructed for the protection of tanks and as a secondary containment for flammable and combustible liquids. Above-ground tanks may be installed in vaults.

**5704.2.8.1 Listing required.** Vaults shall be *listed* in accordance with UL 2245.

**Exception:** Where *approved* by the *fire code official*, below-grade vaults are allowed to be constructed on site, provided that the design is in accordance with the *International Building Code* and that special inspections are conducted to verify structural strength and compliance of the installation with the *approved* design in accordance with Section 1707 of the *International Building Code*. Installation plans for below-grade vaults that are constructed on site shall be prepared by, and the design shall bear the stamp of, a professional engineer. Consideration shall be given to soil and hydrostatic loading on the floors, walls and lid; anticipated seismic forces; uplifting by groundwater or flooding; and to loads imposed from above such as traffic and equipment loading on the vault lid.

- ❖ Vaults must be listed to UL 2245. The fire code official can approve below-grade vaults that are constructed on site. These below-grade vaults must be designed by a professional engineer to comply with the IBC. The construction is to be inspected by a design professional. Flood hazard areas are defined in IBC Section 202.

**5704.2.8.2 Design and construction.** The vault shall completely enclose each tank. There shall not be openings in the vault enclosure except those necessary for access to, inspection of, and filling, emptying and venting of the tank. The walls and floor of the vault shall be constructed of reinforced concrete not less than 6 inches (152 mm) thick. The top of an above-grade vault shall be constructed of noncombustible material and shall be designed to be weaker than the walls of the vault, to ensure that the thrust of an explosion occurring inside the vault is directed upward before significantly high pressure can develop within the vault.

The top of an at-grade or below-grade vault shall be designed to relieve safely or contain the force of an explosion occurring inside the vault. The top and floor of the vault and the tank foundation shall be designed to withstand the anticipated loading, including loading from vehicular traffic, where applicable. The walls and floor of a vault installed below grade shall be designed to withstand anticipated soil and hydrostatic loading.

Vaults shall be designed to be wind and earthquake resistant, in accordance with the *International Building Code*.

- ❖ The vault is to be of noncombustible materials with openings required only for the operation and maintenance of the enclosed tank. Reinforced concrete is to be used for the walls and floor and the top is designed to vent an explosion.

**5704.2.8.3 Secondary containment.** Vaults shall be substantially liquid tight and there shall not be backfill around the tank or within the vault. The vault floor shall drain to a sump. For premanufactured vaults, liquid tightness shall be certified as part of the listing provided by a nationally recognized testing laboratory. For field-erected vaults, liquid tightness shall be certified in an *approved* manner.

- ❖ The vault is to function as a secondary containment for the tank in the event of a leak or spillage. Any leakage or spillage must be removed by draining to a sump in the vault floor. Premanufactured vaults are required to be listed in accordance with UL 2245 by Section 5704.2.8.1, and part of the analysis program performed is an evaluation during the listing process of the effectiveness of secondary containment provided by a vault. It is much more difficult to accomplish a liquid-tight installation on a field-erected vault, as evidenced by the proliferation of leaky basements found throughout the country; therefore, to enhance the quality of field-erected vaults, such units must be certified for liquid tightness to the satisfaction of the fire code official. Methods that might be used include third-party inspection/evaluation and full-scale liquid retention testing.

**5704.2.8.4 Internal clearance.** There shall be sufficient clearance between the tank and the vault to allow for visual inspection and maintenance of the tank and its appurtenances. Dispensing devices are allowed to be installed on tops of vaults.

- ❖ Maintenance and inspection of the tank requires that the clearance between the tank and the vault be sufficient for personnel to perform these functions.

**5704.2.8.5 Anchoring.** Vaults and their tanks shall be suitably anchored to withstand uplifting by ground water or flooding, including when the tank is empty.

- ❖ The tank and the vault may float if the water table is high or flooding occurs. The tank is to be anchored to the vault to prevent the tank from floating, while the vault is also to be anchored to prevent it from floating. Anchoring is also required under Section 5704.2.7.8. Flood hazard areas are defined in IBC Section 202.

**5704.2.8.6 Vehicle impact protection.** Vaults shall be resistant to damage from the impact of a motor vehicle, or vehicle impact protection shall be provided in accordance with Section 312.

- ❖ Protection from impact by vehicles is provided by guard posts or other approved barriers. Section 312 contains the specifications for guard posts or the design forces required for an approved barrier to

comply with the code. Protection from vehicle impact is also required under Section 5703.6.4.

**5704.2.8.7 Arrangement.** Tanks shall be *listed* for above-ground use, and each tank shall be in its own vault. Compartmentalized tanks shall be allowed and shall be considered as a single tank. Adjacent vaults shall be allowed to share a common wall. The common wall shall be liquid and vapor tight and shall be designed to withstand the load imposed when the vault on either side of the wall is filled with water.

- ❖ Above-ground tanks installed in vaults are to be independent of each other; a separate vault is to be constructed for each tank. The individual vaults can use a common separation wall if it does not allow the flammable and combustible liquids or their vapors from one vault to enter another vault. This common wall must be able to resist the hydrostatic loads if the adjacent vault is flooded.

**5704.2.8.8 Connections.** Connections shall be provided to permit venting of each vault to dilute, disperse and remove vapors prior to personnel entering the vault.

- ❖ Because flammable and combustible vapors are normally heavier than air, the vault must have connections for venting these vapors.

**5704.2.8.9 Ventilation.** Vaults that contain tanks of Class I liquids shall be provided with an exhaust ventilation system installed in accordance with Section 5004.3. The ventilation system shall operate continuously or be designed to operate upon activation of the vapor or liquid detection system. The system shall provide ventilation at a rate of not less than 1 cubic foot per minute (cfm) per square foot of floor area [ $0.00508 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ], but not less than 150 cfm ( $4 \text{ m}^3/\text{min}$ ). The exhaust system shall be designed to provide air movement across all parts of the vault floor. Supply and exhaust ducts shall extend to within 3 inches (76 mm), but not more than 12 inches (305 mm), of the floor. The exhaust system shall be installed in accordance with the *International Mechanical Code*.

- ❖ The removal of Class I vapors from a vault requires that a ventilation system be installed according to Section 5004.3 and the IMC. The ventilation system must have supply and exhaust ducts within 3 inches (76 mm) to 12 inches (305 mm) of the vault floor. These ducts are to provide ventilation across the entire vault floor to remove the vapors and provide breathable air.

**5704.2.8.10 Liquid detection.** Vaults shall be equipped with a detection system capable of detecting liquids, including water, and activating an alarm.

- ❖ The liquid detection system is to identify any leakage or spillage of flammable or combustible liquids. There are two concerns for liquid detection: flammable or combustible liquids and water leaking into the vault.

**5704.2.8.11 Monitoring and detection.** Vaults shall be provided with *approved* vapor and liquid detection systems and equipped with on-site audible and visual warning devices with battery backup. Vapor detection systems shall sound an

alarm when the system detects vapors that reach or exceed 25 percent of the lower explosive limit (LEL) of the liquid stored. Vapor detectors shall be located not higher than 12 inches (305 mm) above the lowest point in the vault. Liquid detection systems shall sound an alarm upon detection of any liquid, including water. Liquid detectors shall be located in accordance with the manufacturer's instructions. Activation of either vapor or liquid detection systems shall cause a signal to be sounded at an *approved*, constantly attended location within the facility serving the tanks or at an *approved* location. Activation of vapor detection systems shall also shut off dispenser pumps.

- ❖ The vault is to have liquid and vapor detection systems that sound an alarm when either is present. The systems are to have battery backup in the event of a power failure.

The liquid and vapor detection systems are to sound an alarm at a constantly attended location that is approved by the fire code official.

The vapor detection system is to sound an alarm and shut off dispensing pumps when the detection system senses a vapor concentration of 25 percent or greater of the flammable or combustible LFL.

**5704.2.8.12 Liquid removal.** Means shall be provided to recover liquid from the vault. Where a pump is used to meet this requirement, the pump shall not be permanently installed in the vault. Electric-powered portable pumps shall be suitable for use in Class I, Division 1, or Zone 0 locations, as defined in NFPA 70.

- ❖ A method for removing liquid from the vault must be provided. This can be through a gravity drain, if the site is appropriate, or by manual or portable electric pumps.

**5704.2.8.13 Normal vents.** Vent pipes that are provided for normal tank venting shall terminate not less than 12 feet (3658 mm) above ground level.

- ❖ Vault vent pipe termination must comply with Section 5704.2.7.3.3.

**5704.2.8.14 Emergency vents.** Emergency vents shall be vapor tight and shall be allowed to discharge inside the vault. Long-bolt manhole covers shall not be allowed for this purpose.

- ❖ An emergency vent is necessary to release any pressure that develops in a tank when it is exposed to fire. The fire will cause a release of vapor from the flammable or combustible liquid, greatly exceeding pressures expected during normal operation. The emergency vent on a tank is to prevent the tank from rupturing, which would expose a greater volume of flammable or combustible liquids to the fire.

**5704.2.8.15 Accessway.** Vaults shall be provided with an *approved* personnel accessway with a minimum dimension of 30 inches (762 mm) and with a permanently affixed, nonferrous ladder. Accessways shall be designed to be nonsparking. Travel distance from any point inside a vault to an accessway shall not exceed 20 feet (6096 mm). At each entry point, a warning sign indicating the need for procedures for safe entry

into confined spaces shall be posted. Entry points shall be secured against unauthorized entry and vandalism.

❖ Access to the vault must have a minimum dimension of 30 inches (762 mm) for ease of personnel passage. Because there is the possibility of vapors from flammable and combustible liquids in the vault, the accessway and ladder are to be nonsparking. Vapor from flammable and combustible liquids can replace the air in a vault. For personnel safety, the travel distance is limited and warning signs must be posted to remind personnel of potential hazards.

**5704.2.8.16 Fire protection.** Vaults shall be provided with a suitable means to admit a fire suppression agent.

❖ The fire suppression agent used to control a flammable or combustible liquid fire in a vault may be water, foam or some combination. The vault must be equipped with a suitable means for applying the fire suppression agent.

**5704.2.8.17 Classified area.** The interior of a vault containing a tank that stores a Class I liquid shall be designated a Class I, Division 1, or Zone 0 location, as defined in NFPA 70.

❖ The interior of a vault storing Class I liquid is a Class I, Division 1, location for determining the type of electrical system and components to be installed.

**5704.2.8.18 Overfill protection.** Overfill protection shall be provided in accordance with Section 5704.2.9.7.6. The use of a float vent valve shall be prohibited.

❖ Overfill protection is covered in Section 5704.2.9.7.6 and applies to all flammable and combustible liquids.

**5704.2.9 Above-ground tanks.** Above-ground storage of flammable and *combustible liquids* in tanks shall comply with Section 5704.2 and Sections 5704.2.9.1 through 5704.2.9.7.9.

❖ The storage of flammable and combustible liquids is permitted in above-ground tanks if the tanks are equipped to prevent the flammable and combustible liquid from escaping and becoming a vapor-air mixture in the flammable range. Operation of these above-ground tanks, sources of ignition, locations, security, etc., are covered to ensure a safe facility and operation.

**5704.2.9.1 Existing noncompliant installations.** Existing above-ground tanks shall be maintained in accordance with the code requirements that were applicable at the time of installation. Above-ground tanks that were installed in violation of code requirements applicable at the time of installation shall be made code compliant or shall be removed in accordance with Section 5704.2.14, regardless of whether such tank has been previously inspected (see Section 106.4).

❖ For existing, noncompliant above-ground storage tanks that constitute a hazard, such as an underground tank being used above ground, straightforward guidance and a clear-cut authorization, as provided by this section, to remove the tank is needed. These situations are different from an aban-

doned or out-of-service tank, yet require similar mitigation, such that the removal of such an unsafe tank needs to be in accordance with the safeguards otherwise required.

The reference to Section 106.4 addresses the issue of previous approvals that were mistakenly given by an inspector when a violation may have gone unnoticed.

**5704.2.9.2 Fire protection.** Fire protection for above-ground tanks shall comply with Sections 5704.2.9.2.1 through 5704.2.9.2.4.

❖ Above-ground tanks are equipped with fire protection to control exterior fire exposure, control fire from flammable and combustible liquid, protect the tank structure and protect the facility.

**5704.2.9.2.1 Required foam fire protection systems.** Where required by the *fire code official*, foam fire protection shall be provided for above-ground tanks, other than pressure tanks operating at or above 1 pound per square inch gauge (psig) (6.89 kPa) where such tank, or group of tanks spaced less than 50 feet (15 240 mm) apart measured shell to shell, has a liquid surface area in excess of 1,500 square feet (139 m<sup>2</sup>), and is in accordance with one of the following:

1. Used for the storage of Class I or II liquids.
2. Used for the storage of crude oil.
3. Used for in-process products and is located within 100 feet (30 480 mm) of a fired still, heater, related fractionating or processing apparatus or similar device at a processing plant or petroleum refinery as herein defined.
4. Considered by the *fire code official* as posing an unusual exposure hazard because of topographical conditions; nature of occupancy, proximity on the same or adjoining property, and height and character of liquids to be stored; degree of private fire protection to be provided; and facilities of the fire department to cope with flammable liquid fires.

❖ The fire code official has the authority to require a foam fire protection system for above-ground tanks when the tanks satisfy the criteria in this section. These limits are based on the capacity of the foam fire protection system.

**5704.2.9.2.2 Foam fire protection system installation.** Where foam fire protection is required, it shall be installed in accordance with NFPA 11.

❖ Foam fire protection systems are to comply with NFPA 11. Such systems are for use on flammable and combustible liquid hazards in local areas of a building, for storage tanks and for indoor or outdoor processing areas. NFPA 11 also covers systems for use on liquid fuel fires in small enclosed or partially enclosed spaces.

Foam can provide quick and effective coverage for flammable liquid spill fires where rapid vapor suppression is essential. High-expansion foams are for use on liquid fuel fires where depth of coverage is

important to fill volumes where fire exists at various levels. High-expansion foams are more effective indoors than outdoors.

**5704.2.9.2.2.1 Foam storage.** Where foam fire protection is required, foam-producing materials shall be stored on the premises.

**Exception:** Storage of foam-producing materials off the premises is allowed as follows:

1. Such materials stored off the premises shall be of the proper type suitable for use with the equipment at the installation where required.
2. Such materials shall be readily available at the storage location at all times.
3. Adequate loading and transportation facilities shall be provided.
4. The time required to deliver such materials to the required location in the event of fire shall be consistent with the hazards and fire scenarios for which the foam supply is intended.
5. At the time of a fire, these off-premises supplies shall be accumulated in sufficient quantities before placing the equipment in operation to ensure foam production at an adequate rate without interruption until extinguishment is accomplished.

❖ When the fire code official requires a foam fire protection system, the foam must be stored on site.

The exception allows the fire code official to authorize off-site foam storage if the off-site storage does not hamper the foam fire protection. Consideration must be given to type of foam, availability, time needed to get the foam material to the site and the quantity of foam material required before authorization for off-site foam storage is approved.

**5704.2.9.2.3 Fire protection of supports.** Supports or pilings for above-ground tanks storing Class I, II or IIIA liquids elevated more than 12 inches (305 mm) above grade shall have a *fire-resistance rating* of not less than 2 hours in accordance with the fire exposure criteria specified in ASTM E1529.

**Exceptions:**

1. Structural supports tested as part of a protected above-ground tank in accordance with UL 2085.
  2. Stationary tanks located outside of buildings where protected by an *approved* water-spray system designed in accordance with Chapter 9 and NFPA 15.
  3. Stationary tanks located inside of buildings equipped throughout with an *approved* automatic sprinkler system designed in accordance with Section 903.3.1.1.
- ❖ Above-ground tank supports extending more than 12 inches (305 mm) above grade must have no less than 2-hour fire protection. This fire rating is based on ASTM E1529, which is based on a hydrocarbon pool

fire instead of the ASTM E119 estimate of fuel content in a building.

The exceptions to this fire rating for the structural support are based on the fire protection provided by other means listed under UL 2085, protection provided by a waterspray system under NFPA 15 or for a tank inside a sprinklered building.

**5704.2.9.2.4 Inerting of tanks storing boilover liquids.** Liquids with boilover characteristics shall not be stored in fixed roof tanks larger than 150 feet (45 720 mm) in diameter unless an *approved* gas enrichment or inerting system is provided on the tank.

**Exception:** Crude oil storage tanks in production fields with no other exposures adjacent to the storage tank.

❖ The application of water to a liquid with boilover characteristics can cause a rapid increase in the fire. The boilover liquid may be hot enough to vaporize water that has been added to the fire or water that may be under the boilover liquid. The sudden release of steam can cause the fire to greatly increase in intensity or cause an explosion. Using an inert system to suppress a fire in a large diameter tank will reduce the potential danger from boilover.

The exception notes that where the hazard is limited to an isolated crude oil tank in a production field, the inert system is not required.

**5704.2.9.3 Supports, foundations and anchorage.** Supports, foundations and anchorages for above-ground tanks shall be designed and constructed in accordance with NFPA 30 and the *International Building Code*.

❖ Footings, foundations and structural supports for above-ground tanks must comply with the IBC and NFPA 30.

**5704.2.9.4 Stairways, platforms and walkways.** *Stairways*, platforms and walkways shall be of noncombustible construction and shall be designed and constructed in accordance with NFPA 30 and the *International Building Code*.

❖ Stairways, platforms and walkways for above-ground tanks must be of noncombustible construction and comply with the IBC and NFPA 30.

**5704.2.9.5 Above-ground tanks inside of buildings.** Above-ground tanks inside of buildings shall comply with Sections 5704.2.9.5.1 and 5704.2.9.5.2.

❖ This section introduces the requirements for above-ground storage tanks inside buildings.

**5704.2.9.5.1 Overfill prevention.** Above-ground tanks storing Class I, II and IIIA liquids inside buildings shall be equipped with a device or other means to prevent overflow into the building including, but not limited to: a float valve; a preset meter on the fill line; a valve actuated by the weight of the tank's contents; a low-head pump that is incapable of producing overflow; or a liquid-tight overflow pipe not less than one pipe size larger than the fill pipe and discharging by gravity back to the outside source of liquid or to an *approved* location. Tanks containing Class IIIB liquids and connected

to fuel-burning equipment shall be provided with a means to prevent overflow into buildings in accordance with Section 5704.2.7.5.8.

- ❖ Overfilling of tanks containing Class I, II and IIIA liquids inside a building can release vapors that could reach concentrations at or above the LFL. Devices and equipment for filling of these tanks must be designed to prevent spillage and damage to the storage tank.

Note that tanks storing Class IIIB liquids and not connected to fuel-burning equipment, such as waste motor oil, are not subject to these requirements due to the higher flash point (lower volatility) and thus the lower relative hazard of the liquid.

Tanks storing Class IIIB liquids and connected to fuel burning equipment, however, are subject to over-fill protection requirements in accordance with Section 5704.2.7.5.8 due to the potential for the creation of hazardous conditions as discussed in the commentary to that section.

**5704.2.9.5.2 Fill pipe connections.** Fill pipe connections for tanks storing Class I, II and IIIA liquids and Class IIIB liquids connected to fuel-burning equipment shall be in accordance with Section 5704.2.9.7.7.

- ❖ This section requires fill pipes on above-ground tanks located inside buildings to be equipped with a means to make a direct connection with the tank vehicle's fuel-delivery hose. Essentially, it requires a "camlock" or other similar device and prohibits filling a tank located inside a building through the use of a hand-held nozzle. This requirement exists already for protected above-ground tanks in Section 5704.2.9.7.6, so a reference in this section establishes parity between protected tanks and other types of tanks.

**5704.2.9.6 Above-ground tanks outside of buildings.** Above-ground tanks outside of buildings shall comply with Sections 5704.2.9.6.1 through 5704.2.9.6.3.

- ❖ Above-ground tanks outside of a building are separated from other tanks and facilities to minimize the exposure to fire and transfer of fire from tank to tank or to another facility.

**5704.2.9.6.1 Locations where above-ground tanks are prohibited.** Storage of Class I and II liquids in above-ground tanks outside of buildings is prohibited within the limits established by law as the limits of districts in which such storage is prohibited (see Section 3 of the Sample Legislation for Adoption of the *International Fire Code* on page xxi).

- ❖ This section enables the adopting jurisdiction to prohibit the installation of above-ground tanks in certain geographic areas of the jurisdiction by enumerating them in the adopting legislation. The code book includes a sample adopting ordinance that contains a blank space for the jurisdiction to fill in describing the particular areas where above-ground tank installations are to be prohibited.

**5704.2.9.6.1.1 Location of tanks with pressures 2.5 psig or less.** Above-ground tanks operating at pressures not exceeding 2.5 psig (17.2 kPa) for storage of Class I, II or IIIA liquids, which are designed with a floating roof, a weak roof-to-shell seam or equipped with emergency venting devices limiting pressure to 2.5 psig (17.2 kPa), shall be located in accordance with Table 22.4.1.1(a) of NFPA 30.

**Exceptions:**

1. Vertical tanks having a weak roof-to-shell seam and storing Class IIIA liquids are allowed to be located at one-half the distances specified in Table 22.4.1.1(a) of NFPA 30, provided the tanks are not within a diked area or drainage path for a tank storing Class I or II liquids.
2. Liquids with boilover characteristics and unstable liquids in accordance with Sections 5704.2.9.6.1.3 and 5704.2.9.6.1.4.
3. For protected above-ground tanks in accordance with Section 5704.2.9.7 and tanks in at-grade or above-grade vaults in accordance with Section 5704.2.8, the distances in Table 22.4.1.1(b) of NFPA 30 shall apply and shall be reduced by one-half, but not to less than 5 feet (1524 mm).

- ❖ Above-ground tanks for Class I, II and IIIA liquids are to be located at clearances specified by Table 22.4.1.1(a) of NFPA 30.

Exception 1 permits locating above-ground tanks for Class IIIA liquids at half the clearances of Table 22.4.1.1(a) of NFPA 30 if the tanks are isolated from tanks containing Class I and II liquids.

Exception 2 recognizes the special hazards of boilover and unstable liquids by deferring to Section 5704.2.9.6.1.3 or 5704.2.9.6.1.4, respectively.

Exception 3 recognizes the additional fire protection provided by protected above-ground tanks and tanks in vaults by allowing reduced separation distances.

**5704.2.9.6.1.2 Location of tanks with pressures exceeding 2.5 psig.** Above-ground tanks for the storage of Class I, II or IIIA liquids operating at pressures exceeding 2.5 psig (17.2 kPa) or equipped with emergency venting allowing pressures to exceed 2.5 psig (17.2 kPa) shall be located in accordance with Table 22.4.1.3 of NFPA 30.

**Exception:** Liquids with boilover characteristics and unstable liquids in accordance with Sections 5704.2.9.6.1.4 and 5704.2.9.6.1.5.

- ❖ Above-ground tanks for Class I, II and IIIA liquids are to be located at clearances specified by Table 22.4.1.3 of NFPA 30.

The exception prohibits this tank spacing if the tanks contain liquids with boilover characteristics and unstable liquids (see commentary, Sections 5704.2.9.6.1.4 and 5704.2.9.6.1.5).

**5704.2.9.6.1.3 Location of tanks storing boilover liquids.** Above-ground tanks for storage of liquids with boilover char-

acteristics shall be located in accordance with Table 22.4.1.4 of NFPA 30.

- ❖ Above-ground tanks containing boiler liquids are to be located at clearances specified by Table 22.4.1.4 of NFPA 30.

**5704.2.9.6.1.4 Location of tanks storing unstable liquids.** Above-ground tanks for the storage of unstable liquids shall be located in accordance with Table 22.4.1.5 of NFPA 30.

- ❖ Above-ground tanks for unstable liquids are to be located at clearances specified by Table 22.4.1.5 of NFPA 30.

**5704.2.9.6.1.5 Location of tanks storing Class IIIB liquids.** Above-ground tanks for the storage of Class IIIB liquids, excluding unstable liquids, shall be located in accordance with Table 22.4.1.6 of NFPA 30, except where located within a diked area or drainage path for a tank or tanks storing Class I or II liquids. Where a Class IIIB liquid storage tank is within the diked area or drainage path for a Class I or II liquid, distances required by Section 5704.2.9.6.1.1 shall apply.

- ❖ Above-ground tanks for Class IIIB liquids, excluding unstable liquids, are to be located at clearances specified by Table 22.4.1.6 of NFPA 30. Because of the hazards of Class I and II liquids, when an above-ground tank for Class IIIB liquids is not isolated from these liquids, the clearances specified by NFPA 30 are to apply.

**5704.2.9.6.1.6 Reduction of separation distances to adjacent property.** Where two tank properties of diverse ownership have a common boundary, the *fire code official* is authorized to, with the written consent of the *owners* of the two properties, apply the distances in Sections 5704.2.9.6.1.2 through 5704.2.9.6.1.5 assuming a single property.

- ❖ The fire code official has the authority to consider two independent properties as a single property for tank farms for determining the clearances. This authority is limited to having the written consent from both property owners. This does not reduce the clearances between above-ground tanks.

**5704.2.9.6.2 Separation between adjacent stable or unstable liquid tanks.** The separation between tanks containing stable liquids shall be in accordance with Table 22.4.2.1 of NFPA 30. Where tanks are in a diked area containing Class I or II liquids, or in the drainage path of Class I or II liquids, and are compacted in three or more rows or in an irregular pattern, the *fire code official* is authorized to require greater separation than specified in Table 22.4.2.1 of NFPA 30 or other means to make tanks in the interior of the pattern accessible for fire-fighting purposes.

**Exception:** Tanks used for storing Class IIIB liquids are allowed to be spaced 3 feet (914 mm) apart unless within a diked area or drainage path for a tank storing Class I or II liquids.

The separation between tanks containing unstable liquids shall be not less than one-half the sum of their diameters.

- ❖ NFPA 30 specifies clearances between above-ground tanks containing stable and unstable liquids.

Because the placement of tanks can create an access problem for fire department equipment, the fire code official has the authority to require a greater separation than required by Table 22.4.2.1 of NFPA 30 to ensure fire equipment access.

The exception allows a 3-foot (914 mm) clearance between above-ground tanks containing Class IIIB liquid if they meet the requirements stated.

The minimum clearance for above-ground tanks containing unstable liquids must be greater because of the greater hazard they pose.

**5704.2.9.6.3 Separation between adjacent tanks containing flammable or combustible liquids and LP-gas.** The minimum horizontal separation between an LP-gas container and a Class I, II or IIIA liquid storage tank shall be 20 feet (6096 mm) except in the case of Class I, II or IIIA liquid tanks operating at pressures exceeding 2.5 psig (17.2 kPa) or equipped with emergency venting allowing pressures to exceed 2.5 psig (17.2 kPa), in which case the provisions of Section 5704.2.9.6.2 shall apply.

An *approved* means shall be provided to prevent the accumulation of Class I, II or IIIA liquids under adjacent LP-gas containers such as by dikes, diversion curbs or grading. Where flammable or *combustible liquid* storage tanks are within a diked area, the LP-gas containers shall be outside the diked area and not less than 10 feet (3048 mm) away from the centerline of the wall of the diked area.

**Exceptions:**

1. Liquefied petroleum gas containers of 125 gallons (473 L) or less in capacity installed adjacent to fuel-oil supply tanks of 660 gallons (2498 L) or less in capacity.
2. Horizontal separation is not required between above-ground LP-gas containers and underground flammable and *combustible liquid* tanks.

- ❖ Liquefied petroleum gas (LP-gas) above-ground tanks need a minimum clearance of 20 feet (6069 mm) from above-ground tanks containing Class I, II or IIIA liquids. When the above-ground tanks containing Class I, II and IIIA liquids are under pressure exceeding 2.5 psig (17.2 kPa), the minimum clearance is according to Section 5704.2.9.6.3.

LP-gas tanks require additional protection from Class I, II and IIIA liquids. Spills and leakage of the flammable and combustible liquids are to be kept away from the LP-gas tank by not placing the tanks in a common diked area. Drainage from the above-ground tanks containing Class I, II and IIIA liquids is to be directed away from the LP-gas tank.

The exception states that small tanks of LP-gas and small fuel oil tanks need not be separated. There is no separation required between LP-gas tanks and underground tanks of flammable and combustible liquids.

**5704.2.9.7 Additional requirements for protected above-ground tanks.** In addition to the requirements of this chapter for above-ground tanks, the installation of protected above-

ground tanks shall be in accordance with Sections 5704.2.9.7.1 through 5704.2.9.7.9.

❖ Besides being located to have the required clearance between above-ground tanks and between above-ground tanks and property lines or other structures, the above-ground tanks are to be designed and constructed with safety features to protect and control flammable and combustible liquids. These features include venting, flame arresters, secondary containment, impact protection, overfill protection and antisiphon devices.

**5704.2.9.7.1 Tank construction.** The construction of a protected above-ground tank and its primary tank shall be in accordance with Section 5704.2.7.

❖ Tanks are to be designed according to NFPA 30 and labeled to indicate the design standard according to Section 5704.2.7.

**5704.2.9.7.2 Normal and emergency venting.** Normal and emergency venting for protected above-ground tanks shall be provided in accordance with Sections 5704.2.7.3 and 5704.2.7.4. The vent capacity reduction factor shall not be allowed.

❖ Tanks must be vented to maintain the internal tank pressure within the design operating range. A low pressure can increase the generation of vapors. A high pressure can damage the tank or piping system. Any pressure outside of the design pressure range can have an adverse effect on the operation of the system as well as on the piping and equipment. Vent lines are to be used solely as vents unless other uses are approved by the fire code official. The termination of a vent pipe is to direct the vapors away from the building. Vapors from flammable liquids are normally heavier than air so that the vapor will settle to lower levels. The termination of a vent pipe a minimum of 12 feet (3658 mm) above grade will provide space for the vapors to disperse to concentrations below the LFL. This high termination elevation also reduces the potential for the termination to be close to grade-level ignition sources. Because flammable liquid vapors are heavier than air, attention needs to be given to the building design near the termination. Building design and features that may allow the flammable liquid vapors to reenter the building or to collect on the building must be eliminated. Because Class IIIB has a relatively high boiling point, the vent termination for this combustible liquid may terminate inside the building if the vent is normally closed. Section 5703.6 covers the design, installation, testing and protection of vent pipes. Vent pipes must drain to the tank and not accumulate condensation in the vent pipe.

**5704.2.9.7.3 Secondary containment.** Protected above-ground tanks shall be provided with secondary containment, drainage control or diking in accordance with Section 5004.2. A means shall be provided to establish the integrity of the secondary containment in accordance with NFPA 30.

❖ Protected above-ground tanks are to be located within secondary containment according to Section

5004.2 and NFPA 30. Section 5004.2 discusses the use of liquid-tight curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled (see commentary, Section 5004.2).

**5704.2.9.7.4 Vehicle impact protection.** Where protected above-ground tanks, piping, electrical conduit or dispensers are subject to vehicular impact, they shall be protected therefrom, either by having the impact protection incorporated into the system design in compliance with the impact test protocol of UL 2085, or by meeting the provisions of Section 312, or where necessary, a combination of both. Where guard posts or other *approved* barriers are provided, they shall be independent of each above-ground tank.

❖ Above-ground tanks can be protected from vehicle impact in one of two ways. Either the above-ground tank system can be designed to satisfy the impact criteria of UL 2085 or guard posts or other approved barriers complying with Section 312 can be used for protection from vehicle impact. Section 312 contains the specifications for guard posts or the design forces required for an approved barrier to comply with the code.

**5704.2.9.7.5 Overfill prevention.** Protected above-ground tanks shall not be filled in excess of 95 percent of their capacity. An overfill prevention system shall be provided for each tank. During tank-filling operations, the system shall comply with one of the following:

1. The system shall:

1.1. Provide an independent means of notifying the person filling the tank that the fluid level has reached 90 percent of tank capacity by providing an audible or visual alarm signal, providing a tank level gauge marked at 90 percent of tank capacity, or other *approved* means; and

1.2. Automatically shut off the flow of fuel to the tank when the quantity of liquid in the tank reaches 95 percent of tank capacity. For rigid hose fuel-delivery systems, an *approved* means shall be provided to empty the fill hose into the tank after the automatic shutoff device is activated.

2. The system shall reduce the flow rate to not more than 15 gallons per minute (0.95 L/s) so that at the reduced flow rate, the tank will not overfill for 30 minutes, and automatically shut off flow into the tank so that none of the fittings on the top of the tank are exposed to product because of overfilling.

❖ To prevent spillage during filling, above-ground tanks must be limited to 95 percent of their capacity by an overfill protection system. Several methods are acceptable that provide design flexibility utilizing either an audible or visible alarm when the tank becomes 90-percent full, including draining the fill hose into the above-ground tank without exceeding the 95-percent capacity; an automatic shutoff at 95-percent full or by a means of reducing the fill rate to not more than 15

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

gallons per minute (gpm) (0.95 L/sec) so that, at that reduced flow rate, the tank will not overflow for 30 minutes, after which the fill flow will stop automatically.

**5704.2.9.7.5.1 Information signs.** A permanent sign shall be provided at the fill point for the tank, documenting the filling procedure and the tank calibration chart.

**Exception:** Where climatic conditions are such that the sign may be obscured by ice or snow, or weathered beyond readability or otherwise impaired, said procedures and chart shall be located in the office window, lock box or other area accessible to the person filling the tank.

❖ A permanent sign displaying filling instructions and a tank calibration chart must be located at the fill point. If weather conditions exist that make an outdoor permanent sign impractical, the exception allows storing the instructions and calibration charts at another location that is accessible to the individual filling the tank.

**5704.2.9.7.5.2 Determination of available tank capacity.** The filling procedure shall require the person filling the tank to determine the gallonage (literage) required to fill it to 90 percent of capacity before commencing the fill operation.

❖ As an additional safety measure, the filling procedure is to include a requirement that the operator determine the gallonage (literage) required to fill the tank to 90-percent capacity before commencing the operation.

**5704.2.9.7.6 Fill pipe connections.** The fill pipe shall be provided with a means for making a direct connection to the tank vehicle's fuel delivery hose so that the delivery of fuel is not exposed to the open air during the filling operation. Where any portion of the fill pipe exterior to the tank extends below the level of the top of the tank, a check valve shall be installed in the fill pipe not more than 12 inches (305 mm) from the fill hose connection.

❖ The filling operation could create a vapor-air mixture above the LFL. The fill hose is to be tight fitting to reduce the potential for the flammable or combustible liquid to be exposed to air.

**5704.2.9.7.7 Spill containers.** A spill container having a capacity of not less than 5 gallons (19 L) shall be provided for each fill connection. For tanks with a top fill connection, spill containers shall be noncombustible and shall be fixed to the tank and equipped with a manual drain valve that drains into the primary tank. For tanks with a remote fill connection, a portable spill container shall be allowed.

❖ To control spillage during filling, a spill container is to be provided for each above-ground tank. The spill container must have a top fill connection, be noncombustible and be permanently fixed to the tank. This spill container is to drain directly into the above-ground tank. A remote fill connection can use a portable spill container.

**5704.2.9.7.8 Tank openings.** Tank openings in protected above-ground tanks shall be through the top only.

❖ Above-ground tanks can have an opening only through the tank top.

**5704.2.9.7.9 Antisiphon devices.** *Approved* antisiphon devices shall be installed in each external pipe connected to the protected above-ground tank where the pipe extends below the level of the top of the tank.

❖ To prevent spillage by siphoning through the fill connection, an approved antisiphon device must be installed on the fill connection. An antisiphon valve is a normally closed valve used on above-ground storage tanks to help prevent a drain off of tank contents if a rupture in a line occurs below the liquid level in the tank.

**5704.2.10 Drainage and diking.** The area surrounding a tank or group of tanks shall be provided with drainage control or shall be diked to prevent accidental discharge of liquid from endangering adjacent tanks, adjoining property or reaching waterways.

### Exceptions:

1. The *fire code official* is authorized to alter or waive these requirements based on a technical report that demonstrates that such tank or group of tanks does not constitute a hazard to other tanks, waterways or adjoining property, after consideration of special features such as topographical conditions, nature of occupancy and proximity to buildings on the same or adjacent property, capacity, and construction of proposed tanks and character of liquids to be stored, and nature and quantity of private and public fire protection provided.
2. Drainage control and diking is not required for *listed* secondary containment tanks.

❖ Leaks and spills of flammable and combustible liquids must be controlled by dikes and drainage. The flammable and combustible liquids are to be collected in a manner that will not endanger other tanks, properties or waterways.

Exception 1 gives the fire code official the authority to consider installations where the use of drainage and dikes may not be necessary if technical documentation exists to show that this is practical.

Exception 2 states that listed secondary containment tanks do not require drainage control or dikes in the surrounding area. The secondary containment system in these tanks is considered equivalent to drainage and diking.

**5704.2.10.1 Volumetric capacity.** The volumetric capacity of the diked area shall be not less than the greatest amount of liquid that can be released from the largest tank within the diked area. The capacity of the diked area enclosing more than one tank shall be calculated by deducting the volume of

the tanks other than the largest tank below the height of the dike.

- ❖ The diked area must have sufficient capacity to contain the spillage of flammable and combustible liquids. The volume of flammable and combustible liquid to be held in the diked area is the greatest amount that can be released from the largest tank. This is the volume of the largest tank that is above the lowest elevation of the dike. For diked areas containing more than one tank, the volume is determined using the volume of the largest tank. This determination is based on the assumption that major leakage from more than one tank at any given time is very unlikely.

Because dike storage capacity is critical to spill control, designers must make certain they design their impoundment based on tank capacity. The fire code official, the plan reviewers and the inspectors responsible for approving the design must also be able to determine whether the design is adequate. Below are two examples to aid in understanding the calculations.

**Example 1:**

Determine the dike storage volume for a single tank.

Tank:

- Diameter = 100 feet (30 480 mm)
- Height = 30 feet (9144 mm)

Dike:

- Length = 140 feet (42 672 mm)
- Width = 140 feet (42 672 mm)
- Height = 5 feet (1524 mm)

Maximum dike storage volume:

$$(140 \text{ feet}) (140 \text{ feet}) (5 \text{ feet}) = 98,000 \text{ ft}^3 (2775 \text{ m}^3)$$

Maximum potential volume of spill:

$$(100 \text{ feet}/2)^2 (\pi) (30 \text{ feet} - 5 \text{ feet}) = 196,350 \text{ ft}^3 (5560 \text{ m}^3)$$

Tank volume below dike height:

$$(100 \text{ feet}/2)^2 (\pi) (5 \text{ feet}) = 39,270 \text{ ft}^3 (1112 \text{ m}^3)$$

Available dike storage volume for spill containment:

$$98,000 \text{ ft}^3 - 39,270 \text{ ft}^3 = 58,730 \text{ ft}^3 (1663 \text{ m}^3)$$

Available dike storage volume for spill containment is not sufficient to contain for the maximum potential spill.

$$58,730 \text{ ft}^3 (1663 \text{ m}^3) < 196,350 \text{ ft}^3 (5560 \text{ m}^3)$$

Determine the minimum size dike based on a square dike area.

$$L = \sqrt{\frac{100(\text{ feet}/2)^2(30 \text{ feet})}{5}} = 218 \text{ feet (66 446 mm)}$$

Maximum dike storage volume:

$$(218 \text{ feet}) (218 \text{ feet}) (5 \text{ feet}) = 237,620 \text{ ft}^3 (6729 \text{ m}^3)$$

Available dike storage volume for spill containment:  
 $237,620 \text{ ft}^3 - 39,270 \text{ ft}^3 = 198,350 \text{ ft}^3 (5617 \text{ m}^3)$

Available dike storage volume for spill containment is sufficient to contain for the maximum potential spill.  
 $198,350 \text{ ft}^3 (5617 \text{ m}^3) > 196,350 \text{ ft}^3 (5560 \text{ m}^3)$

**Example 2:**

Determine the dike storage volume for a dike with three tanks.

Tank 1:

- Diameter = 100 feet (30 480 mm)
- Height = 30 feet (9144 mm)

Tank 2:

- Diameter = 50 feet (15 240 mm)
- Height = 20 feet (6096 mm)

Tank 3:

- Diameter = 50 feet (15 240 mm)
- Height = 20 feet (6096 mm)

Dike:

- Length = 300 feet (91 440 mm)
- Width = 150 feet (45 720 mm)
- Height = 5 feet (1524 mm)

Maximum dike storage volume:

$$300 \text{ feet (150 feet) (5 feet)} = 225,000 \text{ ft}^3 (6371 \text{ m}^3)$$

Maximum potential volume of spill:

Tank 1:

$$(100 \text{ feet}/2)^2 (\pi) (30 \text{ feet} - 5 \text{ feet}) = 196,350 \text{ ft}^3 (5560 \text{ m}^3)$$

Tank 1 volume below dike height:

$$(100 \text{ feet}/2)^2 (\pi) (5 \text{ feet}) = 39,270 \text{ ft}^3 (1112 \text{ m}^3)$$

Tank 2 volume below dike height:

$$(50 \text{ feet}/2)^2 (\pi) (5 \text{ feet}) = 9,817 \text{ ft}^3 (278 \text{ m}^3)$$

Tank 3 volume below dike height:

$$(50 \text{ feet}/2)^2 (\pi) (5 \text{ feet}) = 9,817 \text{ ft}^3 (278 \text{ m}^3)$$

Available dike storage volume for spill containment:

$$225,000 \text{ ft}^3 - 39,270 \text{ ft}^3 - 9,817 \text{ ft}^3 - 9,817 \text{ ft}^3 = 166,095 \text{ ft}^3 (4703 \text{ m}^3)$$

Available dike storage volume for spill containment is not sufficient to contain for the maximum potential spill.  $166,095 \text{ ft}^3 (4703 \text{ m}^3) < 196,350 \text{ ft}^3 (5560 \text{ m}^3)$

Revise the dike design by increasing the dike height to 6 feet (1829 mm).

Maximum dike storage volume:

$$300 \text{ feet (150 feet) (6 feet)} = 270,000 \text{ ft}^3 (7646 \text{ m}^3)$$

Maximum potential volume of spill:

Tank 1:

$$(100 \text{ feet}/2)^2 (\pi) (30 \text{ feet} - 6 \text{ feet}) = 188,496 \text{ ft}^3 (5338 \text{ m}^3)$$

Tank 1 volume below dike height:  
 $(100 \text{ feet}/2)^2 (\pi) (6 \text{ feet}) = 47,124 \text{ ft}^3 (1334 \text{ m}^3)$

Tank 2 volume below dike height:  
 $(50 \text{ feet}/2)^2 (\pi) (6 \text{ feet}) = 11,781 \text{ ft}^3 (334 \text{ m}^3)$

Tank 3 volume below dike height:  
 $(50 \text{ feet}/2)^2 (\pi) (6 \text{ feet}) = 11,781 \text{ ft}^3 (334 \text{ m}^3)$

Available dike storage volume for spill containment:  
 $270,000 \text{ ft}^3 - 47,124 \text{ ft}^3 - 11,781 \text{ ft}^3 - 11,781 \text{ ft}^3 = 199,314 \text{ ft}^3 (5644 \text{ m}^3)$

Available dike storage volume for spill containment is sufficient to contain for the maximum potential spill.  
 $199,314 \text{ ft}^3 (5644 \text{ m}^3) > 188,496 \text{ ft}^3 (5338 \text{ m}^3)$

**5704.2.10.2 Diked areas containing two or more tanks.** Diked areas containing two or more tanks shall be subdivided in accordance with NFPA 30.

❖ Diked areas are to be subdivided according to NFPA 30 to control the flow of flammable and combustible liquids.

**5704.2.10.3 Protection of piping from exposure fires.** Piping shall not pass through adjacent diked areas or impounding basins, unless provided with a sealed sleeve or otherwise protected from exposure to fire.

❖ Piping can be damaged and fail as a result of fire exposure. A failed pipe could add fuel to a fire. To prevent a pipe from an adjacent diked area or impoundment basin from providing additional fuel, the pipe is to be protected with a sealed sleeve or otherwise protected from exposure to fire. The best method is to install piping so that it does not enter an adjacent diked area or impoundment basin whenever possible. The sealed pipe sleeve provides some protection from direct fire exposure and is also a secondary containment system.

**5704.2.10.4 Combustible materials in diked areas.** Diked areas shall be kept free from combustible materials, drums and barrels.

❖ Good housekeeping must be practiced around flammable and combustible materials, whether they are solid or liquid. Combustible materials that accumulate in diked areas are a source of ignition and fuel. These materials must be removed.

**5704.2.10.5 Equipment, controls and piping in diked areas.** Pumps, manifolds and fire protection equipment or controls shall not be located within diked areas or drainage basins or in a location where such equipment and controls would be endangered by fire in the diked area or drainage basin. Piping above ground shall be minimized and located as close as practical to the shell of the tank in diked areas or drainage basins.

**Exceptions:**

1. Pumps, manifolds and piping integral to the tanks or equipment being served, which is protected by inter-

mediate diking, berms, drainage or fire protection such as water spray, monitors or resistive coating.

2. Fire protection equipment or controls that are appurtenances to the tanks or equipment being protected, such as foam chambers or foam piping and water or foam monitors and hydrants, or hand and wheeled extinguishers.

❖ Equipment and controls must be located outside of the diked areas for fire protection. Piping must be in the diked areas to operate the facility, but the piping must be underground except at the tank. This provides as much fire protection for the piping as is practical while still allowing the facility to function.

Exception 1 allows locating equipment that is integral to the tank inside the diked area. Other service equipment that is provided with fire protection may also be in diked areas. Separation (immediate diking), water spray or coatings can accomplish this fire protection.

Exception 2 allows fire protection equipment that is part of the tank system to be in the diked area.

**5704.2.11 Underground tanks.** Underground storage of flammable and *combustible liquids* in tanks shall comply with Section 5704.2 and Sections 5704.2.11.1 through 5704.2.11.4.2.

❖ Underground tanks are exposed to conditions not associated with above-ground tanks. Leakage of flammable and combustible liquids is harder to detect. Protection from loads being placed on top of or adjacent to the underground tank is needed to prevent damage to the underground tank. The underground tank must be protected from flooding and from floating in areas having a groundwater table that may be above the bottom of the underground tank.

**5704.2.11.1 Location.** Flammable and *combustible liquid* storage tanks located underground, either outside or under buildings, shall be in accordance with all of the following:

1. Tanks shall be located with respect to existing foundations and supports such that the loads carried by the latter cannot be transmitted to the tank.
2. The distance from any part of a tank storing liquids to the nearest wall of a *basement*, pit, cellar or *lot line* shall be not less than 3 feet (914 mm).
3. A minimum distance of 1 foot (305 mm), shell to shell, shall be maintained between underground tanks.

❖ Underground tanks must be located away from a building or structure so that the tank does not support the building or structure. The loads from a building or structure can cause the underground tank to rupture.

Underground tanks are to be a minimum of 3 feet (914 mm) from the nearest below-grade wall or property line. Any leakage from an underground tank may migrate through the soil and enter a basement, cellar or pit. The accumulation of flammable and combustible liquids in this location could develop into a hazard-

ous condition. Because the owner of the underground tank does not own the adjacent property, the location of the underground tank should not affect the adjacent property or the use of this property.

To ensure that underground tanks are independent of each other, a minimum clearance of 1 foot (305 mm) is required between the shells of adjacent underground tanks.

**5704.2.11.2 Depth and cover.** Excavation for underground storage tanks shall be made with due care to avoid undermining of foundations of existing structures. Underground tanks shall be set on firm foundations and surrounded with not less than 6 inches (152 mm) of noncorrosive inert material, such as clean sand.

❖ Excavation for underground tanks must not damage existing structures and must provide a sound foundation for the underground tank. The use of 6 inches (152 mm) of a noncorrosive material (sand) around an underground tank prevents concentrated loads from being applied to the tank. These concentrated loads can be caused during backfilling when a hard solid object, such as a rock, comes in contact with the underground tank. Soil pressures on the rock can be concentrated into a small contact area with the underground tank.

**5704.2.11.3 Overfill protection and prevention systems.** Fill pipes shall be equipped with a spill container and an overfill prevention system in accordance with NFPA 30.

❖ To control spillage during filling of underground tanks, each tank must have a spill container that is noncombustible and permanently fixed to the tank. This spill container is to drain directly into the underground tank.

**5704.2.11.4 Leak prevention.** Leak prevention for underground tanks shall comply with Sections 5704.2.11.4.1 and 5704.2.11.4.2.

❖ Leakage from underground tanks is to be detected by either monitoring or an approved leak detection system.

**5704.2.11.4.1 Inventory control.** Daily inventory records for underground storage tank systems shall be maintained.

❖ Leakage detection by inventory control requires accurate records of the volume of flammable and combustible liquid dispensed into and removed from the underground tank. A discrepancy between these two volumes is used to identify a leak.

**5704.2.11.4.2 Leak detection.** Underground storage tank systems shall be provided with an *approved* method of leak detection from any component of the system that is designed and installed in accordance with NFPA 30.

❖ Leakage detection systems must comply with NFPA 30.

**5704.2.12 Testing.** Tank testing shall comply with Sections 5704.2.12.1 and 5704.2.12.2.

❖ Tanks must be tested before being placed in service.

**5704.2.12.1 Acceptance testing.** Prior to being placed into service, tanks shall be tested in accordance with Section 21.5 of NFPA 30.

❖ The acceptance test for tanks is described in Section 21.5 of NFPA 30.

**5704.2.12.2 Testing of underground tanks.** Before being covered or placed in use, tanks and piping connected to underground tanks shall be tested for tightness in the presence of the *fire code official*. Piping shall be tested in accordance with Section 5703.6.3. The system shall not be covered until it has been *approved*.

❖ The fire code official is to be present for testing of underground tanks. The tank, connections and piping are to be tested for tightness. Piping is to be tested under Section 5703.6.3.

**5704.2.13 Abandonment and status of tanks.** Tanks taken out of service shall be removed in accordance with Section 5704.2.14, or safeguarded in accordance with Sections 5704.2.13.1 through 5704.2.13.2.3 and API 1604.

❖ Tanks that are no longer in service are to be removed or secured. Abandoned tanks can develop leaks or be damaged when new construction occurs near the tank. In addition to the referenced standard, API 1604, further guidance on this subject is available in NFPA 30, Annex C.

**5704.2.13.1 Underground tanks.** Underground tanks taken out of service shall comply with Sections 5704.2.13.1.1 through 5704.2.13.1.5.

❖ The procedure for safeguarding an underground tank will depend on the period that the tank is to be out of service.

**5704.2.13.1.1 Temporarily out of service.** Underground tanks temporarily out of service shall have the fill line, gauge opening, vapor return and pump connection secure against tampering. Vent lines shall remain open and be maintained in accordance with Sections 5704.2.7.3 and 5704.2.7.4.

❖ An underground tank that will be temporarily out of service for a period of less than 90 days is to be secured from tampering. The vents are to remain in operation and are to be maintained to allow for continuous venting of the tank. The flammable or combustible liquids may remain in the underground tank.

**5704.2.13.1.2 Out of service for 90 days.** Underground tanks not used for a period of 90 days shall be safeguarded in accordance with all the following or be removed in accordance with Section 5704.2.14:

1. Flammable or *combustible liquids* shall be removed from the tank.
2. All piping, including fill line, gauge opening, vapor return and pump connection, shall be capped or plugged and secured from tampering.
3. Vent lines shall remain open and be maintained in accordance with Sections 5704.2.7.3 and 5704.2.7.4.

❖ Flammable or combustible liquid must be removed from underground tanks that are out of service for 90

days but less than a year. The tank is to be secured and vents are to be opened and maintained as required by Section 5704.2.13.1.1.

The owner also has the option to remove the underground tank according to Section 5704.2.14. The code does not provide the option for abandoning the underground tank in place because the tank could not be returned to service.

**5704.2.13.1.3 Out of service for one year.** Underground tanks that have been out of service for a period of one year shall be removed from the ground in accordance with Section 5704.2.14 or abandoned in place in accordance with Section 5704.2.13.1.4.

❖ An underground tank that is out of service for one year is to be removed or abandoned in place.

**5704.2.13.1.4 Tanks abandoned in place.** Tanks abandoned in place shall be as follows:

1. Flammable and *combustible liquids* shall be removed from the tank and connected piping.
2. The suction, inlet, gauge, vapor return and vapor lines shall be disconnected.
3. The tank shall be filled completely with an *approved* inert solid material.
4. Remaining underground piping shall be capped or plugged.
5. A record of tank size, location and date of abandonment shall be retained.
6. All exterior above-grade fill piping shall be permanently removed when tanks are abandoned or removed.

❖ An underground tank that is abandoned in place is to have the flammable or combustible liquid removed. The tank is to be stripped of any appurtenances and filled with an inert material. Piping from the underground tank is to be capped or plugged and the owner is to retain a record of the tank. This action should remove the flammable or combustible liquid from the underground tank and prevent any residue from readily mixing with air. Annex C of NFPA 30 provides additional guidance on this topic.

Note that these provisions apply to all tanks without exception, such as the one that existed in previous editions of the code for 1,100-gallon (4163 L) capacity residential heating oil tanks. The majority of those tanks were installed in the 1950s and 1960s and the estimated useful life of such unprotected, single wall, steel underground fuel oil tanks is 35 to 40 years. This raises the question of who becomes responsible when someone drives or falls into one of the empty voids left by these tanks when the steel finally corrodes away. In order to improve the safeguarding of the public's health and safety, the exception has been removed and all underground tanks abandoned in place must be filled with an approved, inert solid material.

**5704.2.13.1.5 Reinstallation of underground tanks.** Tanks that are to be reinstalled for flammable or *combustible liquid*

service shall be in accordance with this chapter, ASME *Boiler and Pressure Vessel Code* (Section VIII), API 12-P, API 1615, UL 58 and UL 1316.

❖ An underground tank that is reinstalled for flammable or combustible liquids has to comply as a new installation.

**5704.2.13.2 Above-ground tanks.** Above-ground tanks taken out of service shall comply with Sections 5704.2.13.2.1 through 5704.2.13.2.3.

❖ The procedure for safeguarding an above-ground tank will depend on the period that the tank is to be out of service.

**5704.2.13.2.1 Temporarily out of service.** Above-ground tanks temporarily out of service shall have all connecting lines isolated from the tank and be secured against tampering.

**Exception:** In-place fire protection (foam) system lines.

❖ An above-ground tank that is temporarily out of service for a period of less than 90 days is to be secured from tampering, and all lines to the tank are to be disconnected. The flammable or combustible liquids may remain in the above-ground tank.

The exception requires keeping fire protection lines intact. Disconnecting the fire protection lines would reduce the fire safety of the above-ground tank.

**5704.2.13.2.2 Out of service for 90 days.** Above-ground tanks not used for a period of 90 days shall be safeguarded in accordance with Section 5704.2.13.1.2 or removed in accordance with Section 5704.2.14.

**Exceptions:**

1. Tanks and containers connected to oil burners that are not in use during the warm season of the year or are used as a backup heating system to gas.
2. In-place, active fire protection (foam) system lines.

❖ Flammable or combustible liquid must be removed from an above-ground tank that is out of service for at least 90 days but less than one year. The tank is to be secured and vents are to be opened and maintained as required by Section 5704.2.13.1.1.

The owner has the option to remove the above-ground tank according to Section 5704.2.14.

Exception 1 exempts an above-ground tank used for seasonal heating or as a backup for a gas heater from being considered out of service.

Exception 2 requires fire protection lines to remain intact. To disconnect the fire protection lines would reduce the fire safety of the above-ground tank.

**5704.2.13.2.3 Out of service for one year.** Above-ground tanks that have been out of service for a period of one year shall be removed in accordance with Section 5704.2.14.

**Exception:** Tanks within operating facilities.

❖ Tanks that have held hazardous materials must be properly decommissioned in order to abate the residual hazards that they can present. An above-ground tank that is out of service for one year is assumed by the code to be at the end of its useful life and must be

properly removed and disposed. The exception recognizes that operating facilities such as refineries, tank farms, etc. may hold a tank in reserve out of service for more than one year. The status of tanks should be monitored through the operating permit required by Section 105.6.17(7).

**5704.2.14 Removal and disposal of tanks.** Removal and disposal of tanks shall comply with Sections 5704.2.14.1 and 5704.2.14.2.

❖ Removal and disposal of above-ground and underground tanks requires care because the vapors in the tank may be above the LFL for the flammable or combustible liquid. Operations to remove equipment or piping may involve heat that could ignite the vapor-air mixture or force the vapor-air mixture out of the tank where it may be ignited.

**5704.2.14.1 Removal.** Removal of above-ground and underground tanks shall be in accordance with all of the following:

1. Flammable and *combustible liquids* shall be removed from the tank and connected piping.
2. Piping at tank openings that is not to be used further shall be disconnected.
3. Piping shall be removed from the ground.

**Exception:** Piping is allowed to be abandoned in place where the *fire code official* determines that removal is not practical. Abandoned piping shall be capped and safeguarded as required by the *fire code official*.

4. Tank openings shall be capped or plugged, leaving a  $\frac{1}{8}$ -inch to  $\frac{1}{4}$ -inch-diameter (3.2 mm to 6.4 mm) opening for pressure equalization.
5. Tanks shall be purged of vapor and inerted prior to removal.
6. All exterior above-grade fill and vent piping shall be permanently removed.

**Exception:** Piping associated with bulk plants, terminal facilities and refineries.

❖ For tanks that will be removed and disposed, the flammable or combustible liquid is to be removed from the tank and piping and the tank must be purged. An inert gas, such as nitrogen or carbon dioxide, should be used to purge the tank, not air. Tank openings are to be capped or plugged. Vent openings are to be provided in capped tank openings as a vent for equalization of internal and atmospheric pressure. Abandoned piping above ground or in the ground is to be removed to the maximum practical extent to avoid being mistaken for active piping. Any piping approved by the fire code official to remain in the ground is to be capped.

**5704.2.14.2 Disposal.** Tanks shall be disposed of in accordance with federal, state and local regulations.

❖ Other federal, state and local regulations address the disposal of above-ground and underground tanks.

**5704.2.15 Maintenance.** Above-ground tanks, connected piping and ancillary equipment shall be maintained in a safe operating condition. Tanks shall be maintained in accordance with their listings. Damage to above-ground tanks, connected piping or ancillary equipment shall be repaired using materials having equal or greater strength and *fire resistance* or the equipment shall be replaced or taken out of service.

❖ This section addresses the general maintenance of above-ground flammable and combustible liquid tanks and associated equipment. Similar text appears in Section 5003.2.6 for general maintenance of equipment associated with hazardous materials. However, it is useful and appropriate to also have specific text to address the maintenance of above-ground flammable and combustible liquid tank systems available in Chapter 57 (see also commentary, Section 5003.2.6).

**5704.3 Container and portable tank storage.** Storage of flammable and *combustible liquids* in closed containers that do not exceed 60 gallons (227 L) in individual capacity and portable tanks that do not exceed 660 gallons (2498 L) in individual capacity, and limited transfers incidental thereto, shall comply with Sections 5704.3.1 through 5704.3.8.5.

❖ Storage containers not exceeding 60 gallons (227 L) and portable tanks not exceeding 660 gallons (2798 L) are regulated by this section. The use of these containers and portable tanks is limited to incidental transfers of flammable or combustible liquids.

**5704.3.1 Design, construction and capacity of containers and portable tanks.** The design, construction and capacity of containers for the storage of Class I, II and IIIA liquids shall be in accordance with this section and Section 9.4 of NFPA 30.

❖ Design, construction and capacity of containers and portable tanks are addressed in Section 9.4 of NFPA 30.

**5704.3.1.1 Approved containers.** Only *approved* containers and portable tanks shall be used.

❖ It is difficult at best to determine by examination that a container or portable tank complies with Section 9.4 of NFPA 30. One practical approval method is to require listed containers or portable tanks.

**5704.3.2 Liquid storage cabinets.** Where other sections of this code require that liquid containers be stored in storage cabinets, such cabinets and storage shall be in accordance with Sections 5704.3.2.1 through 5704.3.2.2.

❖ Containers and portable storage tanks are to be stored in liquid storage cabinets.

**5704.3.2.1 Design and construction of storage cabinets.** Design and construction of liquid storage cabinets shall be in accordance with Sections 5704.3.2.1.1 through 5704.3.2.1.4.

❖ Liquid storage cabinets are designed to protect containers and portable storage tanks and their contents from damage and ignition sources.

Liquid storage cabinets can be constructed of

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

metal or wood. Cabinets listed under UL 1275 and cabinets constructed according to this section are approved.

**5704.3.2.1.1 Materials.** Cabinets shall be *listed* in accordance with UL 1275, or constructed of *approved* wood or metal in accordance with the following:

1. Unlisted metal cabinets shall be constructed of steel having a thickness of not less than 0.044 inch (1.12 mm) (18 gage). The cabinet, including the door, shall be double walled with 1½-inch (38 mm) airspace between the walls. Joints shall be riveted or welded and shall be tight fitting.
  2. Unlisted wooden cabinets, including doors, shall be constructed of not less than 1-inch (25 mm) exterior grade plywood. Joints shall be rabbeted and shall be fastened in two directions with wood screws. Door hinges shall be of steel or brass. Cabinets shall be painted with an intumescent-type paint.
- ❖ Unlisted liquid storage cabinets and cabinet doors made of steel are to be double-wall cabinets with tight-fitting joints. Minimum steel thickness is 18 gage [0.044 inch (1.12 mm)].

Unlisted liquid storage cabinets and cabinet doors made of wood are to use rabbet joints fastened with wood screws in two directions to develop a tight joint. The minimum wood is to be 1-inch (25 mm) exterior-grade plywood. The cabinet is to be painted with an intumescent-type paint. The plywood grade will increase the cabinet's durability and the intumescent-type paint will reduce the ignition properties of the plywood.

**5704.3.2.1.2 Labeling.** Cabinets shall be provided with a conspicuous label in red letters on contrasting background that reads: FLAMMABLE—KEEP FIRE AWAY.

❖ Label the liquid storage cabinet to restrict ignition sources from the immediate area.

**5704.3.2.1.3 Doors.** Doors shall be well fitted, self-closing and equipped with a three-point latch.

❖ The door is to be self-closing and tight fitting. This prevents flammable or combustible liquid that has leaked or spilled in the storage cabinet from easily escaping the storage cabinet.

**5704.3.2.1.4 Bottom.** The bottom of the cabinet shall be liquid tight to a height of not less than 2 inches (51 mm).

❖ To control the flow of any spills, the cabinet is to be liquid tight for at least 2 inches (51 mm) from the bottom. This prevents flammable or combustible liquid that has leaked or spilled in the storage cabinet from easily escaping the storage cabinet.

**5704.3.2.2 Capacity.** The combined total quantity of liquids in a cabinet shall not exceed 120 gallons (454 L).

❖ The quantity of flammable and combustible liquids in a cabinet is not to exceed 120 gallons (454 L). Controlling the quantity of flammable and combustible liq-

uids in a liquid storage cabinet controls the fire hazard by limiting the amount of liquid that can be involved in a single incident.

**5704.3.3 Indoor storage.** Storage of flammable and *combustible liquids* inside buildings in containers and portable tanks shall be in accordance with Sections 5704.3.3.1 through 5704.3.3.10.

### Exceptions:

1. Liquids in the fuel tanks of motor vehicles, aircraft, boats or portable or stationary engines.
2. The storage of distilled spirits and wines in wooden barrels or casks.

❖ Indoor storage in containers or portable tanks is governed by this section with two exceptions.

The requirements of this section are not applicable to fuel in vehicles and portable engines. The small quantity of fuel and the protection provided by the fuel containers provide sufficient safety for these uses to be indoors.

Distilled spirits and wines in wooden barrels or casks are allowed indoors. This exception is covered in Section 5701.1.

**5704.3.3.1 Portable fire extinguishers.** *Approved* portable fire extinguishers shall be provided in accordance with specific sections of this chapter and Section 906.

❖ Portable fire extinguishers are useful for controlling small fires. Section 906 contains the size and spacing for portable fire extinguishers to be used on a fire involving flammable or combustible liquids that have a liquid depth of 0.25 inch (6.4 mm) or less.

**5704.3.3.2 Incompatible materials.** Materials that will react with water or other liquids to produce a hazard shall not be stored in the same room with flammable and combustible liquids except where stored in accordance with Section 5003.9.8.

❖ Materials that generate heat or become combustible when exposed to water or other liquids are not to be in the same room as flammable or combustible liquids. The exception is when one of the four methods of material separation from Section 5003.9.8 of the code is used. This is to remove a potential ignition reaction.

**5704.3.3.3 Clear means of egress.** Storage of any liquids, including stock for sale, shall not be stored near or be allowed to obstruct physically the route of egress.

❖ The means of egress must be usable to be effective. The placement of flammable or combustible liquids near or in the route used to exit the room or building produces a risk that is not acceptable.

**5704.3.3.4 Empty containers or portable tank storage.** The storage of empty tanks and containers previously used for the storage of flammable or *combustible liquids*, unless free from explosive vapors, shall be stored as required for filled containers and portable tanks. Portable tanks and containers,

when emptied, shall have the covers or plugs immediately replaced in openings.

- ❖ An empty container or portable tank is as dangerous and possibly more dangerous than a full container or portable storage tank. There is a possibility that the vapor-air mixture in the container or portable storage tank could reach the LFL. This potential danger requires that empty containers and portable tanks be handled and stored as if full of flammable or combustible liquid.

**5704.3.3.5 Shelf storage.** Shelving shall be of *approved* construction, adequately braced and anchored. Seismic requirements shall be in accordance with the *International Building Code*.

- ❖ Shelving for containers and portable tanks is to be adequate to support the container and portable tank under normal loads and seismic loads. Failure of shelving could cause damage to containers and portable tanks or leakage.

**5704.3.3.5.1 Use of wood.** Wood of not less than 1 inch (25 mm) nominal thickness is allowed to be used as shelving, racks, dunnage, scuffboards, floor overlay and similar installations.

- ❖ The minimum thickness of wood is to be 1 inch (25 mm).

**5704.3.3.5.2 Displacement protection.** Shelves shall be of sufficient depth and provided with a lip or guard to prevent individual containers from being displaced.

**Exception:** Shelves in storage cabinets or on laboratory furniture specifically designed for such use.

- ❖ Shelving must be designed and constructed to prevent containers or portable tanks from sliding off the shelving. A container or portable tank that falls from a shelf is subject to damage or leakage.

The exception covers shelving in storage cabinets, which may have locked doors or doors fitting snugly against the front of shelves to prevent containers from falling. Shelving that is part of laboratory furniture is not required to have a lip or guard because typically this kind of shelving would hold only small containers. Large containers or tanks would be floor mounted in nearly all laboratory settings. These kinds of shelves may also have other features to prevent containers or portable tanks from sliding or being knocked off the shelf.

**5704.3.3.5.3 Orderly storage.** Shelf storage of flammable and *combustible liquids* shall be maintained in an orderly manner.

- ❖ The handling of containers and portable tanks increases the possibility that an accident can occur. Containers and portable tanks arranged on shelves in an orderly manner make moving one container or portable tank to get to another unnecessary.

**5704.3.3.6 Rack storage.** Where storage on racks is allowed elsewhere in this code, a minimum 4-foot-wide (1219 mm) aisle shall be provided between adjacent rack sections and

any adjacent storage of liquids. Main aisles shall be not less than 8 feet (2438 mm) wide.

- ❖ Rack storage indicates that a larger quantity of flammable and combustible liquids is available for use. Requiring a minimum aisle width of 4 feet (1219 mm) between racks and a minimum main aisle width of 8 feet (2438 mm) provides room to access the flammable and combustible liquids while reducing interference with other racks or other containers and portable tanks. In case of a fire, these aisles are wide enough to give emergency response personnel ready access to the fire and also serve as fire breaks that help prevent fire spread from rack to rack.

**5704.3.3.7 Pile or palletized storage.** Solid pile and palletized storage in liquid warehouses shall be arranged so that piles are separated from each other by not less than 4 feet (1219 mm). Aisles shall be provided and arranged so that no container or portable tank is more than 20 feet (6096 mm) from an aisle. Main *aisles* shall be not less than 8 feet (2438 mm) wide.

- ❖ The rationale for aisle widths is similar to that for rack storage. The 20-foot (6069 mm) restriction is intended to place containers and portable tanks within easy range of on-site fire-fighting equipment as well as minimize the number of items that must be moved to get to the desired container or portable tank.

**5704.3.3.8 Limited combustible storage.** Limited quantities of combustible commodities are allowed to be stored in liquid storage areas where the ordinary combustibles, other than those used for packaging the liquids, are separated from the liquids in storage by not less than 8 feet (2438 mm) horizontally, either by open aisles or by open racks, and where protection is provided in accordance with Chapter 9.

- ❖ Combustible products may be stored in a storage facility with flammable or combustible liquids because having a separate storage facility for these combustible materials may be impractical. The storage of these combustible materials with flammable and combustible liquids results in a source of ignition that must be regulated. The code recognizes a clearance of 8 feet (2438 mm) between the combustible materials and the flammable and combustible liquids, with the building fire protection systems required by Chapter 9, as being acceptable.

**5704.3.3.9 Idle combustible pallets.** Storage of empty or idle combustible pallets inside an unprotected liquid storage area shall be limited to a maximum pile size of 2,500 square feet (232 m<sup>2</sup>) and to a maximum storage height of 6 feet (1829 mm). Storage of empty or idle combustible pallets inside a protected liquid storage area shall comply with NFPA 13. Pallet storage shall be separated from liquid storage by aisles that are not less than 8 feet (2438 mm) wide.

- ❖ The construction of combustible pallets with their large air spaces and volume of wood or plastic boards is a recipe for rapid consumption by fire. Though they present a substantial fuel load, combus-

tible pallets are often necessary for the stable storage of flammable and combustible liquids in containers. Ideally, idle combustible pallets should be stored outdoors; however, that is not always feasible and they may accumulate inside the building.

When stored indoors in unprotected (nonsprinklered) liquid storage areas, the volume of idle combustible pallets stored is regulated to limit the fire load. Note that the maximum volume of combustible pallets that are allowed to be stored is 15,000 cubic feet [2,500 square feet (232 m<sup>2</sup>) in area by 6 feet (1829 mm) (425 m<sup>3</sup>) high].

Conversely, in protected (sprinklered) liquid storage areas, when combustible pallets are no longer in use, the quantity is not controlled in light of the enhanced fire protection provided in accordance with Section 12.12 of NFPA 13.

The required separation aisles are intended to reduce the likelihood of fire spread from the pallet storage pile to rack- or pallet-stored flammable or combustible liquid containers.

**5704.3.3.10 Containers in piles.** Containers in piles shall be stacked in such a manner as to provide stability and to prevent excessive stress on container walls. Portable tanks stored more than one tier high shall be designed to nest securely, without dunnage. Material-handling equipment shall be suitable to handle containers and tanks safely at the upper tier level.

❖ The requirements in this section for stacking containers reduce the possibility of damaging the containers. Piling containers can damage them by placing loading on sides that were not intended to be loaded. Piles are subject to collapse if stress loads on containers become excessive. Collapse could cause the containers to rupture or rub against one another and bump one another, resulting in liquid spills and possibly sparking that could cause ignition. By controlling container stacks, this potential for damage is reduced.

Unless tanks are specifically designed to allow stacking, they must all be stored at ground level.

Requiring material-handling equipment to be designed specifically to handle the stored items is intended to increase safety and reduce the potential for serious accidents.

**5704.3.4 Quantity limits for storage.** Liquid storage quantity limitations shall comply with Sections 5704.3.4.1 through 5704.3.4.4.

❖ The quantity of flammable and combustible liquids in an area is limited to reduce the potential fire hazard.

**5704.3.4.1 Maximum allowable quantity per control area.** For occupancies other than Group M wholesale and retail sales uses, indoor storage of flammable and *combustible liquids* shall not exceed the *maximum allowable quantities per control area* indicated in Table 5003.1.1(1) and shall not exceed the additional limitations set forth in this section.

For Group M occupancy wholesale and retail sales uses, indoor storage of flammable and *combustible liquids* shall not

exceed the *maximum allowable quantities per control area* indicated in Table 5704.3.4.1.

Storage of hazardous production material flammable and *combustible liquids* in Group H-5 occupancies shall be in accordance with Chapter 27.

❖ Whereas Table 5003.1.1(1) lists the MAQs for occupancies other than Group M, Table 5704.3.4.1 lists the flammable and combustible liquid MAQ for Group M occupancies. The term “wholesale” is intended to eliminate the question as to whether Group M provisions apply to stores where goods are displayed and sold in bulk packaging or where bulk-packaged merchandise is kept above customer displays, such as in the popular “big box” home-improvement centers and “club” stores. Conversely, these provisions would not apply to a storage warehouse with a customer service counter or similar arrangement. Such facilities should be regulated using standard MAQs for occupancies other than Group M and would not qualify for the special MAQs of this section. It is very important to note that any time the special MAQs for Group M wholesale and retail-sale uses are applied, the limitations on container types, capacities, fire protection and storage arrangements in Section 5704.3.6 must be applied.

**TABLE 5704.3.4.1.** See page 57-35.

❖ Group M (mercantile) occupancies used for wholesale and retail sales of flammable and combustible liquids are not designed and constructed for flammable and combustible liquids. Business establishments classified in Group M must be able to display flammable and combustible liquids for sale to the public. To control the potential hazard, the quantities of flammable and combustible liquids are limited in a control area. The limitations are based on the type of flammable and combustible liquid in the control area, the type of storage of the flammable and combustible liquids and the automatic sprinkler system installed in the mercantile occupancy.

The easier the flammable or combustible liquid is to ignite, the smaller the quantity of the liquid allowed. This table shows that the quantity of Class IA liquids is smaller than any of the flammable and combustible liquids, and Class III liquids are unlimited in a building with an automatic sprinkler system.

The automatic sprinkler system must be one complying with NFPA 13. Flammable and combustible liquids displayed on shelves of 6 feet (1829 mm) or less are treated as Ordinary Hazard Group 2, which would require a minimum sprinkler density of 0.19 gpm per square foot (7.7 L/min/m<sup>2</sup>) over the most remote 1,500-square-foot (139 m<sup>2</sup>) area.

Because the flammable and combustible liquid is more exposed in individual packaging, the sprinkler system can provide better fire control. If the flammable and combustible liquids are displayed or stored in cartons, pallets or racks, the minimum sprinkler density is 0.21 gpm per square foot (8.6 L/min/m<sup>2</sup>) over

the most remote 1,500-square-foot (139 m<sup>2</sup>) area. This type of display or storage is limited to a maximum height of 4 feet, 6 inches (1372 mm). This type of packaging is more difficult for the automatic sprinkler system to handle so a greater density is required. To allow a larger quantity of flammable and combustible liquids, the mercantile occupancy can use an automatic sprinkler system that complies with Table 5704.3.6.3(4), 5704.3.6.3(5) or 5704.3.7.5.1. These tables require the automatic sprinkler system to have a greater capacity for fire fighting.

**5704.3.4.2 Occupancy quantity limits.** The following limits for quantities of stored flammable or *combustible liquids* shall not be exceeded:

1. Group A occupancies: Quantities in Group A occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
2. Group B occupancies: Quantities in drinking, dining, office and school uses within Group B occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
3. Group E occupancies: Quantities in Group E occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
4. Group F occupancies: Quantities in dining, office, and school uses within Group F occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).

5. Group I occupancies: Quantities in Group I occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
6. Group M occupancies: Quantities in dining, office, and school uses within Group M occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1). The maximum allowable quantities for storage in wholesale and retail sales areas shall be in accordance with Section 5704.3.4.1.
7. Group R occupancies: Quantities in Group R occupancies shall not exceed that necessary for maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
8. Group S occupancies: Quantities in dining and office uses within Group S occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).

❖ Flammable and combustible liquids may be used in occupancies other than Group H. These other occupancies are not designed specifically for flammable and combustible liquids, so there are limitations on the quantities that can be in use or stored in these occupancies. The use of flammable and combustible liquids must be consistent with the function of the occupancy. This prevents these other occupancies from becoming Group H occupancies. The quantities of flammable and combustible liquid are listed in Table 5003.1.1(1). The occupancies covered by these limitations are Groups A, B, E, F, I, M, R and S.

**5704.3.4.3 Quantities exceeding limits for control areas.** Quantities exceeding those allowed in *control areas* set forth

**TABLE 5704.3.4.1  
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF  
FLAMMABLE AND COMBUSTIBLE LIQUIDS IN WHOLESALE AND RETAIL SALES OCCUPANCIES<sup>a</sup>**

TYPE OF LIQUID	MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA (gallons)		
	Sprinklered <sup>b</sup> in accordance with foot-note densities and arrangements	Sprinklered in accordance with Tables 5704.3.6.3(4) through 5704.3.6.3(8) and Table 5704.3.7.5.1	Nonsprinklered
Class IA	60	60	30
Class IB, IC, II and IIIA	7,500 <sup>c</sup>	15,000 <sup>c</sup>	1,600
Class IIIB	Unlimited	Unlimited	13,200

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon = 3.785 L, 1 gallon per minute per square foot = 40.75 L/min/m<sup>2</sup>.

- a. Control areas shall be separated from each other by not less than a 1-hour *fire barrier*.
- b. To be considered as sprinklered, a building shall be equipped throughout with an approved automatic sprinkler system with a design providing minimum densities as follows:
  1. For uncartoned commodities on shelves 6 feet or less in height where the ceiling height does not exceed 18 feet, quantities are those allowed with a minimum sprinkler design density of Ordinary Hazard Group 2.
  2. For cartoned, palletized or racked commodities where storage is 4 feet 6 inches or less in height and where the ceiling height does not exceed 18 feet, quantities are those allowed with a minimum sprinkler design density of 0.21 gallon per minute per square foot over the most remote 1,500-square-foot area.
- c. Where wholesale and retail sales or storage areas exceed 50,000 square feet in area, the maximum allowable quantities are allowed to be increased by 2 percent for each 1,000 square feet of area in excess of 50,000 square feet, up to not more than 100 percent of the table amounts. A control area separation is not required. The cumulative amounts, including amounts attained by having an additional control area, shall not exceed 30,000 gallons.

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

in Section 5704.3.4.1 shall be in liquid storage rooms or liquid storage warehouses in accordance with Sections 5704.3.7 and 5704.3.8.

- ❖ It is possible to have a quantity of flammable and combustible liquids greater than allowed in Section 5704.3.4.1. To control the potential hazard, these quantities must be given additional protection by being in specifically designed liquid storage rooms.

**5704.3.4.4 Liquids for maintenance and operation of equipment.** In all occupancies, quantities of flammable and combustible liquids in excess of 10 gallons (38 L) used for maintenance purposes and the operation of equipment shall be stored in liquid storage cabinets in accordance with Section 5704.3.2. Quantities not exceeding 10 gallons (38 L) are allowed to be stored outside of a cabinet where in *approved* containers located in private garages or other *approved* locations.

- ❖ The operation of a building will require the use of flammable and combustible liquids for maintenance. A quantity of 10 gallons (38 L) or less of flammable and combustible liquids is recognized as practical to allow the use of such liquids for maintenance without requiring fire protection. See also Section 313.1 and its commentary for additional regulations on this topic.

**5704.3.5 Storage in control areas.** Storage of flammable and combustible liquids in control areas shall be in accordance with Sections 5704.3.5.1 through 5704.3.5.4.

- ❖ The location of flammable and combustible liquids in a control area can increase the fire hazard.

**5704.3.5.1 Basement storage.** Class I liquids shall be allowed to be stored in basements in amounts not exceeding the *maximum allowable quantity per control area* for use-open systems in Table 5003.1.1(1), provided that automatic suppression and other fire protection are provided in accordance with Chapter 9. Class II and IIIA liquids shall also be allowed to be stored in basements, provided that automatic suppression and other fire protection are provided in accordance with Chapter 9.

- ❖ The storage of Class I liquids in basements in amounts not exceeding the MAQ in Table 5003.1.1(1) (including the increases allowed by the table notes) is allowed by this section. Since storage is typically thought to be a safer condition than any use condition (no transport, no transfer, etc.), storage in a basement of amounts at least equal to what is allowed for use-open system MAQs in a basement (Section 5705.3.7.2) is allowed. This reflects actual practice in the field with no known loss experience indicating that it has been a problem. Compliance with control area requirements must still be achieved, the MAQ limitations must still apply and the basement must be provided with a fire suppression system and other required protection called for in Chapter 9. It also enhances the level of safety by eliminating the

need to transport Class I liquids vertically in buildings (out of the basement) after use is complete.

Class II and IIIA liquids are also permitted in a basement provided with a fire suppression system and other required protection called for in Chapter 9.

**5704.3.5.2 Storage pile heights.** Containers having less than a 30-gallon (114 L) capacity that contain Class I or II liquids shall not be stacked more than 3 feet (914.4 mm) or two containers high, whichever is greater, unless stacked on fixed shelving or otherwise satisfactorily secured. Containers of Class I or II liquids having a capacity of 30 gallons (114 L) or more shall not be stored more than one container high. Containers shall be stored in an upright position.

- ❖ The storage height of containers of flammable and combustible liquids increases the risk by having a larger quantity per floor area and possible damage to the container. The stacking operation and the weight of containers can damage the containers, creating leaks.

**5704.3.5.3 Storage distance from ceilings and roofs.** Piles of containers or portable tanks shall not be stored closer than 3 feet (914 mm) to the nearest beam, chord, girder or other obstruction, and shall be 3 feet (914 mm) below sprinkler deflectors or discharge orifices of water spray or other overhead fire protection system.

- ❖ The storage of containers or portable tanks near a ceiling or roof can create several problems. The high fire load that close to a structural member could overpower the fire protection of the structure or membrane, allowing the fire to spread to another level or cause a collapse. The height could reduce the effectiveness of the automatic sprinkler system. If the flammable and combustible liquid containers and portable tanks are stacked too high, the sprinkler heads may not be able to effectively apply water to the fire. The containers and portable tanks may be above the sprinkler spray or the containers and portable tanks may shield areas from the spray. Note that the general storage clearances contained in Section 315.3.1 are superceded by these specific requirements as provided in Section 102.9.

**5704.3.5.4 Combustible materials.** In areas that are inaccessible to the public, Class I, II and IIIA liquids shall not be stored in the same pile or rack section as ordinary combustible commodities unless such materials are packaged together as kits.

- ❖ The mixing of flammable and combustible liquid containers and portable tanks with other combustibles can place the flammable and combustible liquid in the vicinity of a possible ignition source and a fuel source.

**5704.3.6 Wholesale and retail sales uses.** Flammable and combustible liquids in Group M occupancy wholesale and retail sales uses shall be in accordance with Sections 5704.3.6.1 through 5704.3.6.5, or Sections 10.10.2, 12.3.8,

16.4.1 through 16.4.3, 16.5.1 through 16.5.2.12, Tables 16.5.2.1 through 16.5.2.12, and Figures 16.4.1(a) through 16.14.1(c) of NFPA 30.

- ❖ A mercantile (Group M) occupancy is not designed to address the fire hazards associated with flammable and combustible liquids, so the limited quantities, specific packing requirements and handling are used to control the fire hazard.

**5704.3.6.1 Container type.** Containers for Class I liquids shall be metal.

**Exception:** In sprinklered buildings, an aggregate quantity of 120 gallons (454 L) of water-miscible Class IB and Class IC liquids is allowed in nonmetallic containers, each having a capacity of 16 ounces (0.473 L) or less.

- ❖ Metal containers are required for Class I liquids. Class II and III liquids may be stored in any container designed for that specific liquid.

The exception recognizes that the additional fire protection provided by an automatic sprinkler system will allow an aggregate quantity of 120 gallons (454 L) of Class IB and IC liquids to be in individual non-combustible containers of 16 ounces (0.473 L) or less. The lower flash point of these Class I liquids, combined with the individual packaging in an automatic sprinkler building, is the rationale for this exception.

**5704.3.6.2 Container capacity.** Containers for Class I liquids shall not exceed a capacity of 5 gallons (19 L).

**Exception:** Metal containers not exceeding 55 gallons (208 L) are allowed to store up to 240 gallons (908 L) of the *maximum allowable quantity per control area* of Class IB and IC liquids in a control area. The building shall be equipped throughout with an *approved* automatic sprinkler system in accordance with Table 5704.3.4.1. The containers shall be provided with plastic caps without cap seals and shall be stored upright. Containers shall not be stacked or stored in racks and shall not be located in areas accessible to the public.

- ❖ Limiting the capacity of containers in a wholesale or retail establishment reduces the size of a potential spill or fire.

The lengthy and detailed exception recognizes that sprinklers provide additional protection so that a greater quantity of flammable and combustible liquids can be placed in the wholesale or retail establishment. Even with this greater fire protection, the flammable and combustible liquids must have the physical property that would allow them to be mixed with water. This ability will allow the sprinkler system to dilute the flammable and combustible liquid. Restrictions on the size of individual containers control the volume of Class IB and IC liquids that can be exposed at one time.

**5704.3.6.3 Fire protection and storage arrangements.** Fire protection and container storage arrangements shall be in accordance with Table 5704.3.6.3(1) or the following:

1. Storage on shelves shall not exceed 6 feet (1829 mm) in height, and shelving shall be metal.
2. Storage on pallets or in piles greater than 4 feet 6 inches (1372 mm) in height, or where the ceiling exceeds 18 feet (5486 mm) in height, shall be protected in accordance with Table 5704.3.6.3(4), and the storage heights and arrangements shall be limited to those specified in Table 5704.3.6.3(2).
3. Storage on racks greater than 4 feet 6 inches (1372 mm) in height, or where the ceiling exceeds 18 feet (5486 mm) in height shall be protected in accordance with Tables 5704.3.6.3(5), 5704.3.6.3(6), and 5704.3.6.3(7) as appropriate, and the storage heights and arrangements shall be limited to those specified in Table 5704.3.6.3(3).

Combustible commodities shall not be stored above flammable and *combustible liquids*.

- ❖ The methods and the maximum height of storage are intended to control the flammable and combustible liquids so that damage to containers is limited and fire protection equipment adequately protects flammable and combustible liquids and controls fire.

**TABLE 5704.3.6.3(1).** See page 57-41.

- ❖ The storage height of flammable and combustible liquids has an effect on the ability of the automatic sprinkler system to control a fire. The first to be considered is storage: the higher the storage, the greater the quantity. By limiting the height of storage, the code limits the volume of flammable and combustible liquids under a sprinkler head. Because the automatic sprinkler system is designed to deliver a minimum density of water per square foot of area, the less flammable and combustible the liquid is, the easier it will be for the automatic sprinkler system to control the fire.

The second function of limiting the height of storage is to make certain the automatic sprinkler system will cover the flammable and combustible liquids. The upper containers of flammable and combustible liquids could act as a shield for lower containers. This shielding could divert the water spray from the sprinkler head away from the fire. With the automatic sprinkler system shielded during early development of the fire, the fire could develop to a stage that the automatic sprinkler system would not be effective.

Note a helps to ensure that storage heights will not exceed the capabilities of the level of sprinkler protection provided. It also clarifies that protection schemes demonstrated with metallic containers and portable tanks are not suitable for nonmetallic containers and

portable tanks, which present a much more significant fire challenge. Without this clarification, which correlates with NFPA 30, the height limits established by the tables place sprinklered buildings at risk of having the sprinkler system fail to control a fire because the protection scheme might not be properly matched with stored commodities.

**TABLE 5704.3.6.3(2).** See page 57-42.

❖ The palletized or solid-pile storage of flammable and combustible liquids in liquid storage rooms and warehouses is regulated by floor, type of container, maximum storage height, maximum quantity per pile and maximum quantity per room. The table restricts the storage by floor to require that the basement not be used for the storage of Class I liquids. The accumulation of vapors from Class I liquids in a basement with a low ignition point for these vapors is not an acceptable situation.

The type of container is regulated to control the problem of leakage and damage to the container caused by handling.

The storage height is used to control the quantity of flammable and combustible liquids and to provide access to the flammable and combustible liquids for water spray from the automatic sprinkler system.

The maximum quantity per pile is to limit the volume of flammable and combustible liquids so that the automatic sprinkler system can control a fire based on the design density of the automatic sprinkler system.

The maximum quantity per room of flammable and combustible liquids is to control the volume of flammable and combustible liquids with the automatic sprinkler system.

The sprinkler system is designed for a minimum flow rate. If the volume of flammable and combustible liquids in a room is not regulated, the room could contain more flammable and combustible liquids than the design flow rate of the automatic sprinkler system could handle.

Note a recognizes that since liquid storage warehouses are dedicated to storage of those materials only, unlimited quantities are acceptable based on Section 5704.3.8.1. See the commentary to Section 5704.3.8.1 for further discussion. This is consistent with Table 5704.3.6.3(3), Note a.

Note b helps to ensure that storage heights will not exceed the capabilities of the level of sprinkler protection provided. It also clarifies that protection schemes demonstrated with metallic containers and portable tanks are not suitable for nonmetallic containers and portable tanks, which present a much more significant fire challenge. Without this clarification, which correlates with NFPA 30, the height limits established by the tables place sprinklered buildings at risk of having the sprinkler system fail to control a fire because the protection scheme might not be properly matched with stored commodities.

Note c recognizes the enhanced level of safety provided by smaller containers.

Note d recognizes that low-flash point, unsaturated polyester resins (UPRs) have a fire behavior more closely resembling that of Class IIIB liquids than Class I liquids, and that sprinkler protection schemes more closely associated with protection of Class III liquids can satisfactorily protect UPRs packaged in relieving-style metal drums. The American Composites Manufacturing Association recently completed a full-scale, two-phase fire test series to demonstrate the safety of UPR storage when protected in that manner.

Phase I of the test program, which included three tests, was conducted at Omega Point Laboratories in San Antonio, Texas. These tests involved totally engulfing single 55-gallon (208 L) relieving-style drums containing a representative UPR in a UPR liquid pool fire to determine the behavior of the commodity in extreme fire conditions. The results of the Phase I tests were considered successful in demonstrating that UPRs are a unique commodity that do not behave like “typical” flammable or combustible liquids in a fire condition because of their high viscosity and density. During the Phase I tests, no significant increases in internal drum pressure were observed in any case even though drum contents completely polymerized during the tests, changing from a liquid to a dense jelly-like consistency.

Phase II tests were conducted at Southwest Research Institute in San Antonio, Texas, in a simulated warehouse environment, and included arrangements ranging in size from a single pallet load to a three-high pallet array. These tests successfully demonstrated that UPRs respond better to the application of sprinkler water than “typical” low-flash point flammable liquids. The unique fire behavior, which resembled that of a Class IIIB liquid as opposed to a Class IC liquid (which is the true classification based on the flash point), can be attributed to at least two factors. First, UPRs are more viscous than typical fluids, which tends to limit the size of associated pool fires, and second, UPRs are heavier than water, which allows sprinkler discharge to cool the surface of a burning pool fire more efficiently than with typical liquids.

Given that the testing conducted clearly demonstrated that a 10-foot-high (3048 mm) array of UPR can be satisfactorily protected with a water-only sprinkler system discharging at a rate of 0.45 gpm per square foot (18 L/min/m<sup>2</sup>); and the testing clearly demonstrated that pile length and width and the associated liquid volume were not factors in determining the effectiveness of sprinkler protection, it is appropriate to allow limits on storage arrays of UPRs to parallel the code requirements for Class III liquids, rather than Class I liquids. Accordingly, the pile quantity limits for UPRs in containers are those currently listed in this table for Class III liquids. However, the recom-

mended height limit is restricted to 10 feet (3048 mm) because that was the height limit utilized in the referenced fire tests.

It is also important to note that there is a code-based precedence for UPRs to be uniquely regulated as a Class IIIB liquid, even though the actual flash point-based classification is ordinarily Class IC. Under NFPA 30, UPRs were generally regarded as “viscous” liquids, which allowed them to be protected as Class IIIB liquids even though the actual designation was Class IC.

**TABLE 5704.3.6.3(3).** See page 57-42.

❖ The storage of flammable and combustible liquids in liquid storage rooms and warehouses is regulated by floor, type of rack, maximum storage height and maximum quantity per room. The table restricts the storage by floor to ensure that the basement is not used for the storage of Class I liquids. The accumulation of vapors from Class I liquids in a basement with a low ignition point for these vapors is not an acceptable situation.

The storage height is used to control the quantity of flammable and combustible liquids and to provide access to the flammable and combustible liquids for water spray from the automatic sprinkler system.

The maximum quantity per room of flammable and combustible liquids is to control the volume of flammable and combustible liquids with the automatic sprinkler system.

The automatic sprinkler system is designed for a minimum flow rate. If the volume of flammable and combustible liquids in a room is not regulated, the room could contain more flammable and combustible liquids than the design flow rate of the automatic sprinkler system could handle.

Note a recognizes that since liquid storage warehouses are dedicated to storage of those materials only, unlimited quantities are acceptable based on Section 5704.3.8.1. See the commentary to Section 5704.3.8.1 for further discussion. This is consistent with Table 5704.3.6.3(2), Note a.

Note b helps to ensure that storage heights will not exceed the capabilities of the level of sprinkler protection provided. It also clarifies that protection schemes demonstrated with metallic containers and portable tanks are not suitable for nonmetallic containers and portable tanks, which present a much more significant fire challenge. Without this clarification, which correlates with NFPA 30, the height limits established by the tables place sprinklered buildings at risk of having the sprinkler system fail to control a fire because the protection scheme might not be properly matched with stored commodities.

**TABLE 5704.3.6.3(4).** See page 57-43.

❖ The quantity of flammable and combustible liquids can be increased if they are in containers and arranged as described in this table and the sprinkler system criteria are increased to comply with this

table. The containers and arrangements control the quantity of flammable and combustible liquid that is exposed. The sprinkler system criteria have been increased to provide a higher density, larger water demand and longer duration than normally required under NFPA 13. These additional sprinkler requirements permit an increase in quantity of flammable and combustible liquids that are permitted per control area in wholesale and retail uses.

Note that the provisions in this table are based on fire tests or historic protection schemes that were based on protection of metal containers and portable tanks. The schemes are inadequate for protection of liquids in containers and portable tanks constructed of other materials, such as plastic. NFPA 30 includes a limited number of protection schemes for nonmetal containers, and those schemes, which require far more protection than the code prescribes in Tables 5704.3.6.3(4) through (8), can still be recognized through the application of Section 5704.3.7.5.1 or 5704.3.8.4. Storage configurations that do not have demonstrated or code-recognized protection schemes, such as putting plastic containers into an area protected for metallic containers, should not be permitted.

**TABLE 5704.3.6.3(5).** See page 57-44.

❖ Rack storage is designed for easy access by personnel and to contain huge quantities of goods that are stored to great heights. The rack storage arrangement maximizes the fuel surface area accessible to flames. Fire can rapidly spread up between containers. Heat from flames burning on one surface augments the heat transfer from the flames burning on the opposing surface. Rack storage geometry can be the most hazardous of all fire geometries. High-rack storage is often protected with in-rack sprinklers inside or on the face of the high-rack storage. The storage of flammable and combustible liquids can be as high as 25 feet (7620 mm) because the containers have been limited in size to control volume in individual containers, and the sprinkler system requirements have been increased to provide more fire protection.

Note that the provisions in this table are based on fire tests or historic protection schemes that were based on protection of metal containers and portable tanks. The schemes are inadequate for protection of liquids in containers and portable tanks constructed of other materials, such as plastic. NFPA 30 includes a limited number of protection schemes for nonmetal containers, and those schemes, which require far more protection than the code prescribes in Tables 5704.3.6.3(4) through (8), can still be recognized through the application of Section 5704.3.7.5.1 or 5704.3.8.4. Storage configurations that do not have demonstrated or code-recognized protection schemes, such as putting plastic containers into an area protected for metallic containers, should not be permitted.

**TABLE 5704.3.6.3(6).** See page 57-45.

❖ Rack storage is designed for easy access by personnel and to contain huge quantities of goods that are stored to great heights. The rack storage arrangement maximizes the fuel surface area accessible to flames. Fire can rapidly spread up between containers. Heat from flames burning on one surface augments the heat transfer from the flames burning on the opposing surface. Rack storage geometry can be the most hazardous of all fire geometries. High-rack storage is often protected with in-rack sprinklers inside or on the face of the high-rack storage. The storage of Class I and II liquids up to 25 feet (7620 mm) and for Class III liquids up to 40 feet (12 192 mm) in containers larger than 5-gallon (19 L) capacity is similar to Table 5704.3.6.3(5), except the sprinkler system requirements have been increased to provide more fire protection.

Note that the provisions in this table are based on fire tests or historic protection schemes that were based on protection of metal containers and portable tanks. The schemes are inadequate for protection of liquids in containers and portable tanks constructed of other materials, such as plastic. NFPA 30 includes a limited number of protection schemes for nonmetal containers, and those schemes, which require far more protection than the code prescribes in Tables 5704.3.6.3(4) through (8), can still be recognized through the application of Section 5704.3.7.5.1 or 5704.3.8.4. Storage configurations that do not have demonstrated or code-recognized protection schemes, such as putting plastic containers into an area protected for metallic containers, should not be permitted.

**TABLE 5704.3.6.3(7).** See page 57-46.

❖ Rack storage is designed for easy access by personnel and to contain huge quantities of goods that are stored to great heights. The rack storage arrangement maximizes the fuel surface area accessible to flames. Fire can rapidly spread up between containers. Heat from flames burning on one surface augments the heat transfer from the flames burning on the opposing surface. Rack storage geometry can be the most hazardous of all fire geometries. High-rack storage (see also Chapter 23) is often protected with in-rack sprinklers inside or on the face of the high-rack storage. Aqueous film-forming foam (AFFF) is effective because the film forms a barrier that starves the fire for oxygen, cools the hydrocarbon and suppresses the release of flammable vapors. The increased fire protection provided by the additional requirements on the AFFF above that required under NFPA 13 allows the storage of flammable and combustible liquids with in-rack storage.

Note that the provisions in this table are based on fire tests or historic protection schemes that were based on protection of metal containers and portable tanks. The schemes are inadequate for protection of

liquids in containers and portable tanks constructed of other materials, such as plastic. NFPA 30 includes a limited number of protection schemes for nonmetal containers, and those schemes, which require far more protection than the code prescribes in Tables 5704.3.6.3(4) through (8), can still be recognized through the application of Section 5704.3.7.5.1 or 5704.3.8.4. Storage configurations that do not have demonstrated or code-recognized protection schemes, such as putting plastic containers into an area protected for metallic containers, should not be permitted.

**TABLE 5704.3.6.3(8).** See page 57-46.

❖ Group M (mercantile) occupancies used for wholesale and retail sales of flammable and combustible liquids are not designed and constructed for flammable and combustible liquids. Table 5704.3.4.1 permits the display and storage of Class I liquid if the automatic fire protection system complies with this table. The limited container size, the limited volume under Table 5704.3.4.1 and the sprinkler protection provided under this table permit display and storage in racks up to 6 feet, 6 inches (1981 mm) high.

Rack storage is designed for easy access by personnel and to contain huge quantities of goods that are stored to great heights. The rack storage arrangement maximizes the fuel surface area accessible to flames. Fire can rapidly spread up between containers. Heat from flames burning on one surface augments the heat transfer from the flames burning on the opposing surface. Rack storage geometry can be the most hazardous of all fire geometries. High-rack storage is often protected with in-rack sprinklers inside or on the face of the high-rack storage. Double-row racks are rack storage that has two racks placed back to back. The double-row rack storage requires additional sprinkler heads to control fire between containers within the rack storage. This table provides the requirements for the additional sprinkler heads and increases the sprinkler density.

Note that the provisions in this table are based on fire tests or historic protection schemes that were based on protection of metal containers and portable tanks. The schemes are inadequate for protection of liquids in containers and portable tanks constructed of other materials, such as plastic. NFPA 30 includes a limited number of protection schemes for nonmetal containers, and those schemes, which require far more protection than the code prescribes in Tables 5704.3.6.3(4) through (8), can still be recognized through the application of Sections 5704.3.7.5.1 or 5704.3.8.4. Storage configurations that do not have demonstrated or code-recognized protection schemes, such as putting plastic containers into an area protected for metallic containers, should not be permitted.

**5704.3.6.4 Warning for containers.** Cans, containers and vessels containing flammable liquids or flammable liquid

compounds or mixtures offered for sale shall be provided with a warning indicator, painted or printed on the container and stating that the liquid is flammable, and shall be kept away from heat and an open flame.

- ❖ Individual containers and their packaging must bear labels warning handling personnel and the public of flammable and combustible liquids. This warning is to prevent the containers from being accidentally or deliberately exposed to heat or open flame.

**5704.3.6.5 Storage plan.** Where required by fire the code official, *aisle* and storage plans shall be submitted in accordance with Chapter 50.

- ❖ The storage plan would be needed if there are conditions that the fire code official believes would lead to the mishandling of flammable and combustible liquids. Such conditions include, but are not limited to, quantity of flammable and combustible liquids, the turnover rate of flammable and combustible liquids and the turnover rate of personnel.

**5704.3.7 Liquid storage rooms.** Liquid storage rooms shall comply with Sections 5704.3.7.1 through 5704.3.7.5.2.

- ❖ Liquid storage rooms are protected locations for the storage of flammable and combustible liquids in occupancies normally not associated with the use and storage of flammable and combustible liquids. Liquid storage rooms are intended to store flammable and combustible liquids that exceed the quantities permitted in a control area.

**5704.3.7.1 General.** Quantities of liquids exceeding those set forth in Section 5704.3.4.1 for storage in *control areas* shall be stored in a liquid storage room complying with this section and constructed and separated as required by the *International Building Code*.

- ❖ Liquid storage rooms are intended to store flammable and combustible liquids that exceed the quantities permitted in a control area.

**5704.3.7.2 Quantities and arrangement of storage.** The quantity limits and storage arrangements in liquid storage rooms shall be in accordance with Tables 5704.3.6.3(2) and

5704.3.6.3(3) and Sections 5704.3.7.2.1 through 5704.3.7.2.3.

- ❖ Liquid storage rooms are limited in the quantity of flammable and combustible liquids and the method of storage of flammable and combustible liquids. The maximum height and maximum volume per pile are limited by Tables 5704.3.6.3(2) and 5704.3.6.3(3).

**5704.3.7.2.1 Mixed storage.** Where two or more classes of liquids are stored in a pile or rack section, both of the following shall apply:

1. The quantity in that pile or rack shall not exceed the smallest of the maximum quantities for the classes of liquids stored in accordance with Table 5704.3.6.3(2) or 5704.3.6.3(3).
2. The height of storage in that pile or rack shall not exceed the smallest of the maximum heights for the classes of liquids stored in accordance with Table 5704.3.6.3(2) or 5704.3.6.3(3).

- ❖ A liquid storage room is intended for the storage of a maximum quantity of flammable and combustible liquid. When more than one class of flammable and combustible liquid is stored in the same room, the aggregate quantity of flammable and combustible liquids cannot exceed the smallest quantity allowed in Table 5704.3.6.3(2) or 5704.3.6.3(3) for the flammable and combustible liquids being stored:

1. Because the liquid storage room is adequate for a maximum volume of a flammable or combustible liquid, the liquid storage room will be adequate for the aggregate quantity based on the allowable volume of the most hazardous flammable and combustible liquid being stored.
2. Because the liquid storage room is adequate for a maximum height of a flammable or combustible liquid, the liquid storage room will be adequate for the height based on the allowable height of the most hazardous flammable and combustible liquid being stored.

TABLE 5704.3.6.3(1)  
MAXIMUM STORAGE HEIGHT IN CONTROL AREA

TYPE OF LIQUID	NONSPRINKLERED AREA (feet)	SPRINKLERED AREA <sup>a</sup> (feet)	SPRINKLERED WITH IN-RACK PROTECTION <sup>a, b</sup> (feet)
Flammable liquids:			
Class IA	4	4	4
Class IB	4	8	12
Class IC	4	8	12
Combustible liquids:			
Class II	6	8	12
Class IIIA	8	12	16
Class IIIB	8	12	20

For SI: 1 foot = 304.8 mm.

- a In buildings protected by an automatic sprinkler system, the storage height for containers and portable tanks shall not exceed the maximum storage height permitted for the fire protection scheme set forth in NFPA 30 or the maximum storage height demonstrated in a full-scale fire test, whichever is greater. NFPA 30 criteria and fire test results for metallic containers and portable tanks shall not be applied to nonmetallic containers and portable tanks.
- b In-rack protection shall be in accordance with Table 5704.3.6.3(5), 5704.3.6.3(6) or 5704.3.6.3(7).

**TABLE 5704.3.6.3(2)**  
**STORAGE ARRANGEMENTS FOR PALLETIZED OR SOLID-PILE STORAGE IN LIQUID STORAGE ROOMS AND WAREHOUSES**

CLASS	STORAGE LEVEL	MAXIMUM STORAGE HEIGHT			MAXIMUM QUANTITY PER PILE (gallons)		MAXIMUM QUANTITY PER ROOM <sup>a</sup> (gallons)	
		Drums	Containers <sup>b</sup> (feet)	Portable tanks <sup>b</sup> (feet)	Containers	Portable tanks	Containers	Portable tanks
IA	Ground floor	1	5	Not Allowed	3,000	Not Allowed	12,000	Not Allowed
	Upper floors	1	5	Not Allowed	2,000	Not Allowed	8,000	Not Allowed
	Basements	0	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed
IB	Ground floor	1	6.5	7	5,000	20,000	15,000	40,000
	Upper floors	1	6.5	7	3,000	10,000	12,000	20,000
	Basements	0	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed
IC	Ground floor <sup>d</sup>	1	6.5 <sup>c</sup>	7	5,000	20,000	15,000	40,000
	Upper floors	1	6.5 <sup>c</sup>	7	3,000	10,000	12,000	20,000
	Basements	0	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed	Not Allowed
II	Ground floor <sup>d</sup>	3	10	14	10,000	40,000	25,000	80,000
	Upper floors	3	10	14	10,000	40,000	25,000	80,000
	Basements	1	5	7	7,500	20,000	7,500	20,000
III	Ground floor	5	20	14	15,000	60,000	50,000	100,000
	Upper floors	5	20	14	15,000	60,000	50,000	100,000
	Basements	3	10	7	10,000	20,000	25,000	40,000

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

- a. See Section 5704.3.8.1 for unlimited quantities in liquid storage warehouses.
- b. In buildings protected by an automatic sprinkler system, the storage height for containers and portable tanks shall not exceed the maximum storage height permitted for the fire protection scheme set forth in NFPA 30 or the maximum storage height demonstrated in a full-scale fire test, whichever is greater. NFPA 30 criteria and fire test results for metallic containers and portable tanks shall not be applied to nonmetallic containers and portable tanks.
- c. These height limitations are allowed to be increased to 10 feet for containers having a capacity of 5 gallons or less.
- d. For palletized storage of unsaturated polyester resins (UPR) in relieving-style metal containers with 50 percent or less by weight Class IC or II liquid and no Class IA or IB liquid, height and pile quantity limits shall be permitted to be 10 feet and 15,000 gallons, respectively, provided that such storage is protected by sprinklers in accordance with NFPA 30 and that the UPR storage area is not located in the same containment area or drainage path for other Class I or II liquids.

**TABLE 5704.3.6.3(3)**  
**STORAGE ARRANGEMENTS FOR RACK STORAGE IN LIQUID STORAGE ROOMS AND WAREHOUSES**

CLASS	TYPE RACK	STORAGE LEVEL	MAXIMUM STORAGE HEIGHT <sup>b</sup> (feet)	MAXIMUM QUANTITY PER ROOM <sup>a</sup> (gallons)
			Containers	Containers
IA	Double row or Single row	Ground floor	25	7,500
		Upper floors	15	4,500
		Basements	Not Allowed	Not Allowed
IB IC	Double row or Single row	Ground floor	25	15,000
		Upper floors	15	9,000
		Basements	Not Allowed	Not Allowed
II	Double row or Single row	Ground floor	25	24,000
		Upper floors	25	24,000
		Basements	15	9,000
III	Multirow Double row Single row	Ground floor	40	48,000
		Upper floors	20	48,000
		Basements	20	24,000

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

- a. See Section 5704.3.8.1 for unlimited quantities in liquid storage warehouses.
- b. In buildings protected by an automatic sprinkler system, the storage height for containers and portable tanks shall not exceed the maximum storage height permitted for the fire protection scheme set forth in NFPA 30 or the maximum storage height demonstrated in a full-scale fire test, whichever is greater. NFPA 30 criteria and fire test results for metallic containers and portable tanks shall not be applied to nonmetallic containers and portable tanks.

TABLE 5704.3.6.3(4) AUTOMATIC SPRINKLER PROTECTION FOR SOLID-PILE AND PALLETIZED STORAGE OF LIQUIDS IN METAL CONTAINERS AND PORTABLE TANKS<sup>a</sup>

STORAGE CONDITIONS		CEILING SPRINKLER DESIGN AND DEMAND				MINIMUM HOSE STREAM DEMAND (gpm)	MINIMUM DURATION SPRINKLERS AND HOSE STREAMS (hours)
Class liquid	Container size and arrangement	Density (gpm/ft <sup>2</sup> )	Area (square feet)		Maximum spacing (square feet)		
			High temperature sprinklers	Ordinary temperature sprinklers			
IA	5 gallons or less, with or without cartons, palletized or solid pile <sup>b</sup>	0.30	3,000	5,000	100	750	2
	Containers greater than 5 gallons, on end or side, palletized or solid pile	0.60	5,000	8,000	80	750	
IB, IC and II	5 gallons or less, with or without cartons, palletized or solid pile <sup>b</sup>	0.30	3,000	5,000	100	500	2
	Containers greater than 5 gallons on pallets or solid pile, one high	0.25	5,000	8,000	100		
II	Containers greater than 5 gallons on pallets or solid pile, more than one high, on end or side	0.60	5,000	8,000	80	750	2
	Portable tanks, one high	0.30	3,000	5,000	100	500	2
III	Portable tanks, two high	0.60	5,000	8,000	80	750	2
	5 gallons or less, with or without cartons, palletized or solid pile	0.25	3,000	5,000	120	500	1
III	Containers greater than 5 gallons on pallets or solid pile, on end or sides, up to three high	0.25	3,000	5,000	120	500	1
	Containers greater than 5 gallons, on pallets or solid pile, on end or sides, up to 18 feet high	0.35	3,000	5,000	100	750	2
III	Portable tanks, one high	0.25	3,000	5,000	120	500	1
	Portable tanks, two high	0.50	3,000	5,000	80	750	2

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L, 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min/m<sup>2</sup>.  
 a. The design area contemplates the use of Class II standpipe systems. Where Class I standpipe systems are used, the area of application shall be increased by 30 percent without revising density.  
 b. For storage heights above 4 feet or ceiling heights greater than 18 feet, an approved engineering design shall be provided in accordance with Section 104.7.2.

TABLE 5704.3.6.3(5)  
**AUTOMATIC SPRINKLER PROTECTION REQUIREMENTS FOR RACK STORAGE OF LIQUIDS IN METAL CONTAINERS OF 5-GALLON CAPACITY OR LESS WITH OR WITHOUT CARTONS ON CONVENTIONAL WOOD PALLETS<sup>a</sup>**

CLASS LIQUID	CEILING SPRINKLER DESIGN AND DEMAND			IN-RACK SPRINKLER ARRANGEMENT AND DEMAND				MINIMUM HOSE STREAM DEMAND (gpm)	MINIMUM DURATION SPRINKLER AND HOSE STREAM (hours)	
	Density (gpm/ft <sup>2</sup> )	Area (square feet)		Racks up to 9 feet deep	Racks more than 9 feet to 12 feet deep	30 psi (standard orifice)				
		High-temperature sprinklers	Ordinary temperature sprinklers			14 psi (large orifice)	Number of sprinklers operating			
I (maximum 25-foot height) Option 1	0.40	3,000	5,000	80 ft <sup>2</sup> /head	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. One line sprinklers above each level of storage 3. Locate in longitudinal flue space, staggered vertical 4. Shields required where multilevel	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	1. Eight sprinklers if only one level 2. Six sprinklers each on two levels if only two levels 3. Six sprinklers each on top three levels, if three or more levels 4. Hydraulically most remote	750	2
I (maximum 25-foot height) Option 2	0.55	2,000 <sup>b</sup>	Not Applicable	100 ft <sup>2</sup> /head	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	See 1 through 4 above	500	2
I and II (maximum 14-foot storage height) (maximum three tiers)	0.55 <sup>c</sup>	2,000 <sup>d</sup>	Not Applicable	100 ft <sup>2</sup> /head	Not Applicable None for maximum 6-foot-deep racks	Not Applicable	Not Applicable	Not Applicable	500	2
II (maximum 25-foot height)	0.30	3,000	5,000	100 ft <sup>2</sup> /head	1. Ordinary temperature sprinklers 8 feet apart horizontally 2. One line sprinklers between levels at nearest 10-foot vertical intervals 3. Locate in longitudinal flue space, staggered vertical 4. Shields required where multilevel	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. See 2 above 3. See 3 above 4. See 4 above	Hydraulically most remote—six sprinklers at each level, up to a maximum of three levels	750	2
III (40-foot height)	0.25	3,000	5,000	120 ft <sup>2</sup> /head	Same as for Class II liquids	Same as for Class II liquids	Same as for Class II liquids	Same as for Class II liquids	500	2

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch = 6.895 kPa, 1 gallon = 3.785 L, 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min·m<sup>2</sup>.

a. The design area contemplates the use of Class II standpipe systems. Where Class I standpipe systems are used, the area of application shall be increased by 30 percent without revising density.

b. Using listed or approved extra-large orifices, high-temperature quick-response or standard element sprinklers under a maximum 30-foot ceiling with minimum 7.5-foot aisles.

c. For friction lid cans and other metal containers equipped with plastic nozzles or caps, the density shall be increased to 0.65 gpm per square foot using listed or approved extra-large orifice, high-temperature quick-response sprinklers.

d. Using listed or approved extra-large orifice, high-temperature quick-response or standard element sprinklers under a maximum 18-foot ceiling with minimum 7.5-foot aisles and metal containers.

TABLE 5704.3.6.3(6) AUTOMATIC SPRINKLER PROTECTION REQUIREMENTS OR RACK STORAGE OF LIQUIDS IN METAL CONTAINERS GREATER THAN 5-GALLON CAPACITY<sup>a</sup>

CLASS LIQUID	CEILING SPRINKLER DESIGN AND DEMAND			IN-RACK SPRINKLER ARRANGEMENT AND DEMAND					MINIMUM HOSE STREAM DEMAND (gpm)	MINIMUM DURATION SPRINKLER AND HOSE STREAM (hours)
	Density (gpm/ft <sup>2</sup> )	Area (square feet)		Maximum spacing	On-side storage racks up to 9-foot-deep racks	On-end storage (on pallets) up to 9-foot-deep racks	Minimum nozzle pressure	Number of sprinklers operating		
		High-temperature sprinklers	Ordinary temperature sprinklers							
IA (maximum 25-foot height)	0.60	3,000	5,000	80 ft <sup>2</sup> /head	1. Ordinary temperature sprinklers 8 feet apart horizontally 2. One line sprinklers above each tier of storage 3. Locate in longitudinal flue space, staggered vertical 4. Shields required where multilevel	1. Ordinary temperature sprinklers 8 feet apart horizontally 2. One line sprinklers above each tier of storage 3. Locate in longitudinal flue space, staggered vertical 4. Shields required where multilevel	30 psi	Hydraulically most remote—six sprinklers at each level	1,000	2
IB, IC and II (maximum 25-foot height)	0.60	3,000	5,000	100 ft <sup>2</sup> /head	1. See 1 above 2. One line sprinklers every three tiers of storage 3. See 3 above 4. See 4 above	1. See 1 above 2. See 2 above 3. See 3 above 4. See 4 above	30 psi	Hydraulically most remote—six sprinklers at each level	750	2
III (maximum 40-foot height)	0.25	3,000	5,000	120 ft <sup>2</sup> /head	1. See 1 above 2. One line sprinklers every sixth level (maximum) 3. See 3 above 4. See 4 above	1. See 1 above 2. One line sprinklers every third level (maximum) 3. See 3 above 4. See 4 above	15 psi	Hydraulically most remote—six sprinklers at each level	500	1

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch = 6.895 kPa, 1 gallon = 3.785 L, 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min/m<sup>2</sup>.  
 a. The design assumes the use of Class II standpipe systems. Where a Class I standpipe system is used, the area of application shall be increased by 30 percent without revising density.

TABLE 5704.3.6.3(7) AUTOMATIC AFF WATER PROTECTION REQUIREMENTS FOR RACK STORAGE OF LIQUIDS IN METAL CONTAINERS GREATER THAN 5-GALLON CAPACITY<sup>a,b</sup>

CLASS LIQUID	CEILING SPRINKLER DESIGN AND DEMAND		IN-RACK SPRINKLER ARRANGEMENT AND DEMAND <sup>c</sup>				DURATION AFF SUPPLY (minimum)	DURATION WATER SUPPLY (hours)	
	Density (gpm/ft <sup>2</sup> )	Area (square feet)		Minimum nozzle pressure (psi)	Number of sprinklers operating	Hose stream demand <sup>d</sup> (gpm)			
		High-temperature sprinklers	Ordinary temperature sprinklers						
IA, IB, IC and II	0.30	1,500	2,500	On-end storage of drums on pallets, up to 25 feet	30	Three sprinklers per level	500	15	2

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch = 6.895 kPa, 1 gallon = 3.785 L, 1 gallon per minute = 3.785 L/m, 1 gallon per square foot = 40.75 L/min/m<sup>2</sup>.

a. System shall be a closed-head wet system with *approved* devices for proportioning aqueous film-forming foam.

b. Except as modified herein, in-rack sprinklers shall be installed in accordance with NFPA 13.

c. The height of storage shall not exceed 25 feet.

d. Hose stream demand includes 1½-inch inside hose connections, where required.

TABLE 5704.3.6.3(8) AUTOMATIC SPRINKLER PROTECTION REQUIREMENTS FOR CLASS I LIQUID STORAGE IN METAL CONTAINERS OF 1-GALLON CAPACITY OR LESS WITH UNCARTONED OR CASE-CUT SHELF DISPLAY UP TO 6.5 FEET, AND PALLETIZED STORAGE ABOVE IN A DOUBLE-ROW RACK ARRAY<sup>a</sup>

STORAGE HEIGHT	CEILING SPRINKLER DESIGN AND DEMAND			IN-RACK SPRINKLER ARRANGEMENT AND DEMAND				MINIMUM HOSE STREAM DEMAND (gpm)	MINIMUM DURATION SPRINKLERS AND HOSE STREAM (hours)	
	Density (gpm/ft <sup>2</sup> )	Area (square feet)		Racks 9 to 12 feet	Racks up to 9 feet deep	Minimum nozzle pressure	Number of sprinklers operating			
		High temperature	Ordinary temperature							
Maximum 20-foot storage height	0.60	2,000 <sup>b</sup>	Not Applicable	100 ft <sup>2</sup> /head	1. Ordinary temperature, quick-response sprinklers, maximum 8 feet 3 inches horizontal spacing 2. One line of sprinklers at the 6-foot level and the 11.5-foot level of storage 3. Locate in longitudinal flue space, staggered vertical space, staggered vertical 4. Shields required where multilevel	Not Applicable	30 psi (standard orifice) or 14 psi (large remote 12 sprinklers)	1. Six sprinklers each on two levels 2. Hydraulically most remote 12 sprinklers	500	2

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch = 6.895 kPa, 1 gallon = 3.785 L, 1 gallon per minute = 3.785 L/m, 1 gallon per square foot = 40.75 L/min/m<sup>2</sup>.

a. This table shall not apply to racks with solid shelves.

b. Using extra-large orifice sprinklers under a ceiling 30 feet or less in height. Minimum aisle width is 7.5 feet.

**5704.3.7.2.2 Separation and aisles.** Piles shall be separated from each other by not less than 4-foot (1219 mm) aisles. Aisles shall be provided so that all containers are 20 feet (6096 mm) or less from an aisle. Where the storage of liquids is on racks, a minimum 4-foot-wide (1219 mm) aisle shall be provided between adjacent rows of racks and adjacent storage of liquids. Main aisles shall be not less than 8 feet (2438 mm) wide.

Additional aisles shall be provided for access to doors, required windows and ventilation openings, standpipe connections, mechanical equipment and switches. Such aisles shall be not less than 3 feet (914 mm) in width, unless greater widths are required for separation of piles or racks, in which case the greater width shall be provided.

❖ Aisles in a liquid storage room are designed to the same aisle criteria as for rack storage. A minimum aisle width of 4 feet (1219 mm) between piles and a minimum main aisle of 8 feet (2438 mm) is to provide clearance for personnel to access the flammable and combustible liquids without interference with other piles.

Egress from the room for evacuation and access to fire protection and other facilities within the room must be maintained.

**5704.3.7.2.3 Stabilizing and supports.** Containers and piles shall be separated by pallets or dunnage to provide stability and to prevent excessive stress to container walls. Portable tanks stored over one tier shall be designed to nest securely without dunnage.

Requirements for portable tank design shall be in accordance with Chapters 9 and 12 of NFPA 30. Shelving, racks, dunnage, scuffboards, floor overlay and similar installations shall be of noncombustible construction or of wood not less than a 1-inch (25 mm) nominal thickness. Adequate material-handling equipment shall be available to handle tanks safely at upper tier levels.

❖ The requirements of this section are intended to prevent piles from collapsing and causing container damage or liquid spills. Requiring pallets or dunnage spreads stress loads over broad surfaces, reducing stresses in container walls that could lead to damage or leakage.

Requirements for portable tank design are intended to result in stability that will prevent tanks from toppling. Having materials-handling equipment that is designed to handle the tanks also helps to ensure safe storage and handling.

**5704.3.7.3 Spill control and secondary containment.** Liquid storage rooms shall be provided with spill control and secondary containment in accordance with Section 5004.2.

❖ Spills must be contained and controlled to prevent the spread of the liquid and the vapors. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled. Storage rooms shall be ventilated in accordance with

Section 5004.3, which discusses mechanical and natural exhaust systems. The exhaust system is to remove the vapors to prevent them from accumulating in concentrations in the flammable range of the vapor.

**5704.3.7.4 Ventilation.** Liquid storage rooms shall be ventilated in accordance with Section 5004.3.

❖ See the commentary to Section 5004.3 for discussions of ventilation requirements.

**5704.3.7.5 Fire protection.** Fire protection for liquid storage rooms shall comply with Sections 5704.3.7.5.1 and 5704.3.7.5.2.

❖ This section introduces the fire protection requirements for liquid storage rooms.

**5704.3.7.5.1 Fire-extinguishing systems.** Liquid storage rooms shall be protected by *automatic sprinkler systems* installed in accordance with Chapter 9 and Tables 5704.3.6.3(4) through 5704.3.6.3(7) and Table 5704.3.7.5.1. In-rack sprinklers shall also comply with NFPA 13.

Automatic foam-water systems and automatic aqueous film-forming foam (AFFF) water sprinkler systems shall not be used except where *approved*.

Protection criteria developed from fire modeling or full-scale fire testing conducted at an *approved* testing laboratory are allowed in lieu of the protection as shown in Tables 5704.3.6.3(2) through 5704.3.6.3(7) and Table 5704.3.7.5.1 where *approved*.

❖ The fire protection system must be designed to handle anticipated fires. For a liquid storage room that contains a variety of flammable and combustible liquids, the fire protection needs to be selected from Tables 5704.3.6.3(4) through 5704.3.6.3(7) and Table 5704.3.7.5.1. These tables address the classification of flammable and combustible liquids, container size and the method of storing the liquids. The installation of this fire protection is to comply with Chapter 9. For liquid storage rooms that use rack storage not covered in the tables, use NFPA 13 for the fire protection requirements.

Automatic foam-water systems and AFFF are to be used if approved by the fire code official. These fire protection systems starve the fire for oxygen by forming a barrier between the hydrocarbon and the air, by cooling the hydrocarbon and by suppressing the release of flammable vapors.

These fire protection systems, however, can be harmful to the environment. Containment of the foam solution should be considered when using these systems.

The code is designed to reflect that there may be other methods available for meeting code requirements. The fire code official is responsible for reviewing proposed alternative methods and has the authority to approve them when they have been demonstrated or documented to comply with the code.

**TABLE 5704.3.7.5.1.** See below.

❖ Solid-pile or palletized storage of flammable and combustible liquids, except for Class IA liquids, in metal containers is allowed when AFFF is installed. The storage system permits these flammable and combustible liquids to either be in cartons or uncartoned. Flammable and combustible liquids in carton packaging can be piled 11 feet (3353 mm) high while uncartoned containers can be piled 12 feet (3658 mm) high. The higher storage is allowed for containers out of cartons because the combustible cartons have been removed, reducing the fire load.

AFFF is effective fire protection for this storage because it forms a barrier that starves the fire for oxygen, cools the hydrocarbon and suppresses the release of flammable vapors. The 5-gallon (19 L) metal containers provide some protection from ignition as well as limit the quantity of flammable and combustible liquids that can be exposed. The cartons and pallets are a source of combustibles.

The AFFF provides fire prevention and fire protection in case of a liquid spill or pool fire. The AFFF will also provide protection for the metal containers if the cartons or pallets become involved in a fire. The increased fire protection provided by using 5-gallon (19 L) containers or less with the additional requirements on the AFFF above that required under NFPA 13 permit the storage of flammable and combustible liquids in solid-piled and palletized storage.

**5704.3.7.5.2 Portable fire extinguishers.** Not less than one approved portable fire extinguisher complying with Section 906 and having a rating of not less than 20-B shall be located not less than 10 feet (3048 mm) or more than 50 feet (15 240 mm) from any Class I or II liquid storage area located outside of a liquid storage room.

Not less than one portable fire extinguisher having a rating of not less than 20-B shall be located outside of, but not more than 10 feet (3048 mm) from, the door opening into a liquid storage room.

❖ Portable fire extinguishers are to be available outside of the liquid storage room because a fire in the liquid storage room could prevent personnel from getting to portable fire extinguishers in the room. The 20-B por-

table fire extinguisher is for the control of small flammable liquid fires.

**5704.3.8 Liquid storage warehouses.** Buildings used for storage of flammable or combustible liquids in quantities exceeding those set forth in Section 5704.3.4 for control areas and Section 5704.3.7 for liquid storage rooms shall comply with Sections 5704.3.8.1 through 5704.3.8.5 and shall be constructed and separated as required by the *International Building Code*.

❖ Liquid storage warehouses, as defined in Section 5702.1, are buildings that are designed to store flammable and combustible liquids in quantities that exceed the quantities allowed in a control area or a liquid storage room. A liquid storage warehouse is classified in Group H-2 or H-3 depending on whether the liquid is (H-2) or is not (H-3) under pressure. It can be a separate, detached building or it can be an attached building separated from other parts of the structure by a fire wall complying with IBC Section 706. This section establishes the applicability of Sections 5704.3.8.1 through 5704.3.8.5 to these unique buildings. See the commentary to Section 5702.1 and definition of “Liquid storage warehouse” for further information.

**5704.3.8.1 Quantities and storage arrangement.** The total quantities of liquids in a liquid storage warehouse shall not be limited. The arrangement of storage shall be in accordance with Table 5704.3.6.3(2) or 5704.3.6.3(3).

❖ Liquid storage warehouses are not restricted in the quantity of flammable and combustible liquids that may be stored; however, the maximum height and maximum volume per pile is limited by Tables 5704.3.6.3(2) and 5704.3.6.3(3), which effectively limit the quantity of flammable or combustible liquids that can be stored in a given space. Aisle width requirements further restrict quantities.

**5704.3.8.1.1 Mixed storage.** Mixed storage shall be in accordance with Section 5704.3.7.2.1.

❖ Liquid storage warehouses have to meet the same criteria as a liquid storage room. Liquid storage warehouses are intended for the storage of a maximum quantity of flammable and combustible liquid. When

**TABLE 5704.3.7.5.1**  
**AUTOMATIC AFFF-WATER PROTECTION REQUIREMENTS FOR SOLID-PILE AND**  
**PALLETIZED STORAGE OF LIQUIDS IN METAL CONTAINERS OF 5-GALLON CAPACITY OR LESS<sup>a, b</sup>**

PACKAGE TYPE	CLASS LIQUID	CEILING SPRINKLER DESIGN AND DEMAND					STORAGE HEIGHT (feet)	HOSE DEMAND (gpm) <sup>c</sup>	DURATION AFFF SUPPLY (minimum)	DURATION WATER SUPPLY (hours)
		Density (gpm/ft <sup>2</sup> )	Area (square feet)	Temperature rating	Maximum spacing	Orifice size (inch)				
Cartoned	IB, IC, II and III	0.40	2,000	286°F	100 ft <sup>2</sup> /head	0.531	11	500	15	2
Uncartoned	IB, IC, II and III	0.30	2,000	286°F	100 ft <sup>2</sup> /head	0.5 or 0.531	12	500	15	2

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min/m<sup>2</sup>, °C = [(°F)-32]/1.8.

a. System shall be a closed-head wet system with approved devices for proportioning aqueous film-forming foam.

b. Maximum ceiling height of 30 feet.

c. Hose stream demand includes 1½-inch inside hose connections, where required.

more than one class of flammable and combustible liquid is stored in the same liquid storage warehouse, the aggregate quantity of flammable and combustible liquids cannot exceed the smallest quantity allowed in Table 5704.3.6.3(2) or 5704.3.6.3(3) for the flammable and combustible liquids being stored.

Because the liquid storage warehouse is adequate for a maximum volume of a flammable or combustible liquid, the liquid storage warehouse will be adequate for the aggregate quantity based on the allowable volume of the most hazardous flammable and combustible liquid being stored.

Because the liquid storage warehouse is adequate for a maximum height of a flammable or combustible liquid, the liquid storage warehouse will be adequate for the height based on the allowable height of the most hazardous flammable and combustible liquid being stored.

**5704.3.8.1.2 Separation and aisles.** Separation and *aisles* shall be in accordance with Section 5704.3.7.2.2.

❖ Liquid storage warehouses must meet the same criteria as a liquid storage room. A liquid storage warehouse is designed to the same aisle criteria as rack storage. A minimum aisle width of 4 feet (1219 mm) between piles and a minimum main aisle of 8 feet (2438 mm) provide clearance for personnel and materials-handling equipment to access the flammable and combustible liquids without interference with other piles. The aisles are also intended for ready access by emergency responders.

Egress from the warehouse for evacuation and access to fire protection and other facilities within the warehouse need to be maintained.

**5704.3.8.2 Spill control and secondary containment.** Liquid storage warehouses shall be provided with spill control and secondary containment as set forth in Section 5004.2.

❖ The spill must be controlled to prevent the spread of liquid. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled.

**5704.3.8.3 Ventilation.** Liquid storage warehouses storing containers greater than 5 gallons (19 L) in capacity shall be ventilated at a rate of not less than 0.25 cfm per square foot (0.075 m<sup>3</sup>/s · m<sup>2</sup>) of floor area over the storage area.

❖ This section specifies the ventilation rate for liquid warehouses storing containers whose capacity exceeds 5 gallons (19 L). Note that the provisions of Section 5004.3 do not apply. The exhaust system is to remove the vapors to prevent them from accumulating in concentrations in the flammable range of the vapor.

**5704.3.8.4 Automatic sprinkler systems.** Liquid storage warehouses shall be protected by *automatic sprinkler systems* installed in accordance with Chapter 9 and Tables 5704.3.6.3(4) through 5704.3.6.3(7) and Table 5704.3.7.5.1, or Sections 16.4.1 through 16.4.3, 16.5.1 through 16.5.2.12,

and Tables 16.5.2.1 through 16.5.2.12 and Figures 16.4.1(a) through 16.4.1(c) of NFPA 30. In-rack sprinklers shall also comply with NFPA 13.

Automatic foam-water systems and automatic AFFF water sprinkler systems shall not be used except where *approved*.

Protection criteria developed from fire modeling or full-scale fire testing conducted at an *approved* testing laboratory are allowed in lieu of the protection as shown in Tables 5704.3.6.3(2) through 5704.3.6.3(7) and Table 5704.3.7.5.1 where *approved*.

❖ The fire protection system must be designed to cope with anticipated fires. For a liquid storage warehouse that contains a variety of flammable and combustible liquids, the fire protection needs to be selected from Tables 5704.3.6.3(4) through 5704.3.6.3(7) and Table 5704.3.7.5.1. These tables address the classification of flammable and combustible liquids, container size and the method of storing the liquids. The installation of this fire protection is to comply with Chapter 9. For liquid storage warehouses that use rack storage not covered in the tables, use NFPA 13 for the fire protection requirements.

Automatic foam-water systems and AFFF are to be used if approved by the fire code official. These fire protection systems starve the fire for oxygen by forming a barrier between the hydrocarbon and the air, by cooling the hydrocarbon and by suppressing the release of flammable vapors.

These fire protection systems, however, can be harmful to the environment. Containment of the foam solution should be considered when using these systems.

The code always recognizes that there may be other methods available for accomplishing its intent. The fire code official is responsible for reviewing these alternative methods and has the authority to approve them if they have been demonstrated or documented to comply with the intent of the code requirement.

**5704.3.8.5 Warehouse hose lines.** In liquid storage warehouses, either 1<sup>1</sup>/<sub>2</sub>-inch (38 mm) lined or 1-inch (25 mm) hard rubber hose lines shall be provided in sufficient number to reach all liquid storage areas and shall be in accordance with Section 903 or 905.

❖ The requirements for hose lines stated in this section are consistent with the requirements of Chapter 9. They may be supplied by either the automatic sprinkler system in accordance with Section 903 or a standpipe system in accordance with Section 905.

**5704.4 Outdoor storage of containers and portable tanks.** Storage of flammable and *combustible liquids* in closed containers and portable tanks outside of buildings shall be in accordance with Section 5703 and Sections 5704.4.1 through 5704.4.8. Capacity limits for containers and portable tanks shall be in accordance with Section 5704.3.

❖ Outdoor storage in containers and portable tanks is regulated to prevent ignition sources from coming in

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

contact with containers and portable tanks, to prevent damage to containers and portable tanks and to protect property and buildings.

**5704.4.1 Plans.** Storage shall be in accordance with *approved* plans.

❖ The fire code official must approve the layout of the outdoor storage. The clearances between tanks, buildings and property lines are to ensure that ignition sources are not in the immediate vicinity of the outdoor storage area.

**5704.4.2 Location on property.** Outdoor storage of liquids in containers and portable tanks shall be in accordance with Table 5704.4.2. Storage of liquids near buildings located on the same lot shall be in accordance with this section.

❖ Restrictions on pile size, required pile separation distances and required distances from lot lines, structures and public thoroughways are intended to result in improved fire safety. Limiting quantities that can be stored in a single pile limits the potential fuel load in any fire. Keeping piles away from structures, lot lines and public ways protects the piles from stray ignition sources as well as keeping buildings, personnel and the general public safe from the hazards of a possible fire.

**TABLE 5704.4.2.** See below.

❖ The outdoor storage of flammable and combustible liquids in containers and portable tanks is limited to control the size and location of a fire. The volume of flammable and combustible liquids is limited based on the type of liquid. The lower the ignition point of the liquid, the smaller the volume of the liquid permitted in a pile. The same approach is taken in determining the maximum height of a pile. These two features control the size of a fire.

Separation is used to control the spread of fire from pile to pile and from a pile to a structure or other property. The distance between piles is the same for all classes of flammable and combustible liquids. The

distance between a pile and a structure or property line serves several functions. The clearance is greater for flammable or combustible liquids with a lower ignition point to protect the flammable and combustible liquid from an ignition source as well as protecting the surrounding area from a pool fire of flammable or combustible liquid.

**5704.4.2.1 Mixed liquid piles.** Where two or more classes of liquids are stored in a single pile, the quantity in the pile shall not exceed the smallest of maximum quantities for the classes of material stored.

❖ When more than one class of flammable and combustible liquid is stored in the same pile, the aggregate quantity of flammable and combustible liquids cannot exceed the smallest quantity allowed in Table 5704.4.2.

Because the pile is adequate for a maximum volume of a flammable or combustible liquid, the pile will be adequate for the aggregate quantity based on the allowable volume of the most hazardous flammable and combustible liquid being stored.

Because the pile is adequate for a maximum height of a flammable or combustible liquid, the pile will be adequate for the height based on the allowable height of the most hazardous flammable and combustible liquid being stored.

**5704.4.2.2 Access.** Storage of containers or portable tanks shall be provided with fire apparatus access roads in accordance with Chapter 5.

❖ Access roads for fire department apparatus must be maintained in the outdoor storage so that fire department apparatus can gain access to any pile storage. Access may involve more than one access point. Consideration must be given to the turning radius of fire apparatus, dead-end lanes and entrance through security gates or locked gates.

**5704.4.2.3 Security.** The storage area shall be protected against tampering or trespassers where necessary and shall be

**TABLE 5704.4.2  
OUTDOOR LIQUID STORAGE IN CONTAINERS AND PORTABLE TANKS**

CLASS OF LIQUID	CONTAINER STORAGE— MAXIMUM PER PILE		PORTABLE TANK STORAGE— MAXIMUM PER PILE		MINIMUM DISTANCE BETWEEN PILES OR RACKS (feet)	MINIMUM DISTANCE TO LOT LINE OF PROP- ERTY THAT CAN BE BUILT UPON <sup>c, d</sup> (feet)	MINIMUM DISTANCE TO PUBLIC STREET, PUB- LIC ALLEY OR PUBLIC WAY <sup>d</sup> (feet)
	Quantity <sup>a, b</sup> (gallons)	Height (feet)	Quantity <sup>a, b</sup> (gallons)	Height (feet)			
IA	1,100	10	2,200	7	5	50	10
IB	2,200	12	4,400	14	5	50	10
IC	4,400	12	8,800	14	5	50	10
II	8,800	12	17,600	14	5	25	5
III	22,000	18	44,000	14	5	10	5

For SI: 1 foot = 304.8 mm, 1 gallon 3.785 L.

a. For mixed class storage, see Section 5704.4.2.

b. For storage in racks, the quantity limits per pile do not apply, but the rack arrangement shall be limited to not more than 50 feet in length and two rows or 9 feet in depth.

c. If protection by a public fire department or private fire brigade capable of providing cooling water streams is not available, the distance shall be doubled.

d. When the total quantity stored does not exceed 50 percent of the maximum allowed per pile, the distances are allowed to be reduced 50 percent, but not less than 3 feet.

kept free from weeds, debris and other combustible materials not necessary to the storage.

- ❖ Unauthorized personnel may not know the potential dangers associated with flammable and combustible liquids. By controlling access to the outdoor storage facility, the owner will be able to monitor sources of heat and open flame. Security will be able to monitor the accumulation of combustibles and take appropriate action to remove these fuel sources.

**5704.4.2.4 Storage adjacent to buildings.** Not more than 1,100 gallons (4163 L) of liquids stored in closed containers and portable tanks is allowed adjacent to a building located on the same premises and under the same management, provided that:

1. The building does not exceed one story in height. Such building shall be of fire-resistance-rated construction with noncombustible exterior surfaces or noncombustible construction and shall be used principally for the storage of liquids; or
2. The exterior building wall adjacent to the storage area shall have a *fire-resistance rating* of not less than 2 hours, having no openings to above-grade areas within 10 feet (3048 mm) horizontally of such storage and no openings to below-grade areas within 50 feet (15 240 mm) horizontally of such storage.

The quantity of liquids stored adjacent to a building protected in accordance with Item 2 is allowed to exceed 1,100 gallons (4163 L), provided that the maximum quantity per pile does not exceed 1,100 gallons (4163 L) and each pile is separated by a 10-foot-minimum (3048 mm) clear space along the common wall.

Where the quantity stored exceeds 1,100 gallons (4163 L) adjacent to a building complying with Item 1, or the provisions of Item 1 cannot be met, a minimum distance in accordance with Table 5704.4.2, column 7 (“Minimum Distance to Lot Line of Property That Can Be Built Upon”) shall be maintained between buildings and the nearest container or portable tank.

- ❖ Storage of flammable and combustible liquid next to a building can expose the flammable and combustible liquid or the building to a fire; however, placing flammable and combustible liquids next to a building may be necessary for the operation of the facility. To control the fire exposure, both the flammable and combustible liquid next to the building and the building itself must be on the same property and under the same management. Two types of buildings may have flammable and combustible liquid stored adjacent to them.

A building of noncombustible construction not more than one story in height used for the storage of flammable and combustible liquid that is of noncombustible construction and not more than one story in height can have outdoor storage next to it. This building has fire protection features installed to protect the building and its contents from an interior fire, but is

not designed for the exterior fire exposure. Limiting the quantity of flammable and combustible liquid to 1,100 gallons (4136 L) in closed containers reduces the exterior fire exposure. If the exterior quantity of flammable and combustible liquid exceeds 1,100 gallons (4136 L) in closed containers, or this building does not meet the criteria for construction, height or use as storage for flammable and combustible liquids, the fire protection must be increased by using the distance between the building and the pile. The clearance required between the class of flammable and combustible liquid and the property line is to be used.

A building can have outdoor storage next to it when the building exterior wall adjacent to the storage of flammable and combustible liquid has a minimum 2-hour fire-resistance rating and protected openings. The restriction on openings above grade is to prevent an interior or exterior fire from bypassing the 2-hour fire-resistance-rated wall construction. The restriction on an opening below grade is to prevent flammable or combustible liquid or vapors from entering the building. The maximum quantity of flammable and combustible liquid is limited to 1,100 gallons (4136 L) in closed containers per pile. More than one pile can be located adjacent to this fire-resistant construction if the piles are located a minimum of 10 feet (3480 mm) from the building.

**5704.4.3 Spill control and secondary containment.** Storage areas shall be provided with spill control and secondary containment in accordance with Section 5703.4.

**Exception:** Containers stored on *approved* containment pallets in accordance with Section 5004.2.3 and containers stored in cabinets and lockers with integral spill containment.

- ❖ Outdoor storage of flammable or Class II combustible liquids must be controlled to prevent the spread of liquid. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled.

The exception allows use of approved containment pallets as an acceptable alternative to an integral spill containment for containers. Section 5004.2.3 requires containment pallets to have a liquid-tight sump that is accessible for visible inspection with a minimum capacity of 66 gallons (250 L). The containment pallet must be designed to prevent the collection of rainwater in the sump.

**5704.4.4 Security.** Storage areas shall be protected against tampering or trespassers by fencing or other *approved* control measures.

- ❖ Unauthorized personnel may not know the potential dangers associated with flammable and combustible liquids. By controlling access to the outdoor storage facility, the owner will be able to monitor sources of heat and open flame.

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

**5704.4.5 Protection from vehicles.** Guard posts or other means shall be provided to protect exterior storage tanks from vehicular damage. Where guard posts are installed, the posts shall be installed in accordance with Section 312.

- ❖ Protection from vehicle impact is provided by guard posts or other approved barriers. Section 312 contains the specifications for guard posts or the design forces required for an approved barrier to comply with the code.

**5704.4.6 Clearance from combustibles.** The storage area shall be kept free from weeds, debris and combustible materials not necessary to the storage. The area surrounding an exterior storage area shall be kept clear of such materials for a minimum distance of 15 feet (4572 mm).

- ❖ This is the same requirement as in Section 5704.4.2.3, with the additional focus that combustible materials be cleared for a minimum of 15 feet (4572 mm) around the storage area. Keeping combustibles a minimum of 15 feet (4572 mm) from each pile removes a fuel source from the immediate area.

**5704.4.7 Weather protection.** Weather protection for outdoor storage shall be in accordance with Section 5004.13.

- ❖ Weather protection is not required for outdoor storage; however, where an overhead structure is erected, it must conform to the requirements of Section 5004.13, which refers to the requirements of the IBC. The code reference notes that an open structure consisting of only a noncombustible roof structure does not change the storage facility to indoor storage. Natural airflow through a structure with no walls and only a noncombustible roof has sufficient ventilation for the storage area to be treated as outdoor storage for flammable and combustible liquids.

**5704.4.8 Empty containers and tank storage.** The storage of empty tanks and containers previously used for the storage of flammable or *combustible liquids*, unless free from explosive vapors, shall be stored as required for filled containers and tanks. Tanks and containers when emptied shall have the covers or plugs immediately replaced in openings.

- ❖ An empty container or portable tank is at least as dangerous as and possibly more dangerous than a full container or portable storage tank. There is a possibility that a vapor-air mixture in the container or portable storage tank could reach the LFL. This potential danger requires that empty containers and portable tanks be handled and stored as if full of flammable or combustible liquid.

## SECTION 5705

### DISPENSING, USE, MIXING AND HANDLING

**5705.1 Scope.** Dispensing, use, mixing and handling of flammable liquids shall be in accordance with Section 5703 and this section. Tank vehicle and tank car loading and unloading

and other special operations shall be in accordance with Section 5706.

**Exception:** Containers of organic coatings having no fire point and which are opened for pigmentation are not required to comply with this section.

- ❖ The dispensing, use, mixing and handling of flammable and combustible liquids provide opportunities for flammable and combustible liquids to become mixed with air. These operations can create a vapor-air mixture between the LFL and the UFL.

This section does not cover organic coating with no fire point used for pigmentation. This exception is also covered in Section 5701.1.

**5705.2 Liquid transfer.** Liquid transfer equipment and methods for transfer of Class I, II and IIIA liquids shall be *approved* and be in accordance with Sections 5705.2.1 through 5705.2.6.

- ❖ The low flash points for Class I, II and IIIA liquids require restrictions on transferring flammable and combustible liquids.

**5705.2.1 Pumps.** Positive-displacement pumps shall be provided with pressure relief discharging back to the tank, pump suction or other *approved* location, or shall be provided with interlocks to prevent over-pressure.

- ❖ Positive-displacement pumps are used because the pumping action is forward only and is a good pump for viscous fluids. The positive-displacement pump will create pressure waves in the fluid. A buildup of pressure can damage the pump and the piping system. This pressure buildup must be relieved by discharging the excess pressure into the tank or the pump suction (intake) or other approved location.

**5705.2.2 Pressured systems.** Where gases are introduced to provide for transfer of Class I liquids, or Class II and III liquids transferred at temperatures at or above their *flash points* by pressure, only inert gases shall be used. Controls, including pressure relief devices, shall be provided to limit the pressure so that the maximum working pressure of tanks, containers and piping systems cannot be exceeded. Where devices operating through pressure within a tank or container are used, the tank or container shall be a pressure vessel *approved* for the intended use. Air or oxygen shall not be used for pressurization.

**Exception:** Air transfer of Class II and III liquids at temperatures below their *flash points*.

- ❖ Compressed inert gas can be used to transfer flammable and combustible liquids. The inert gas prevents a vapor-air mixture from entering the LFL. The pressure system must be designed to prevent overloading any component of the system. An overload could create a leak or failure in the system.

The use of air as the compressed gas is permitted for Class II and III liquids under limited conditions. If the Class II and III liquids are to be dispensed at a

temperature below their flash points, there is no ignition source.

**5705.2.3 Piping, hoses and valves.** Piping, hoses and valves used in liquid transfer operations shall be *approved* or *listed* for the intended use.

❖ Piping, hoses and valves must be designed to function with the flammable or combustible liquid being transferred and at the temperatures and pressures of the dispensing system.

**5705.2.4 Class I, II and III liquids.** Class I liquids or, when heated to or above their flash points, Class II and Class III liquids, shall be transferred by one of the following methods:

1. From safety cans complying with UL 30.
2. Through an *approved* closed piping system.
3. From containers or tanks by an *approved* pump taking suction through an opening in the top of the container or tank.
4. For Class IB, IC, II and III liquids, from containers or tanks by gravity through an *approved* self-closing or automatic-closing valve where the container or tank and dispensing operations are provided with spill control and secondary containment in accordance with Section 5703.4. Class IA liquids shall not be dispensed by gravity from tanks.
5. *Approved* engineered liquid transfer systems.

**Exception:** Liquids in original shipping containers not exceeding a 5.3-gallon (20 L) capacity.

❖ This section correlates with Section 5701.5 and similar provisions in Section 18.4.2 of NFPA 30. The lower flash points for Class I liquids require that dispensing be done by an approved procedure to avoid the development of a vapor-air mixture above the LFL. Class II and III liquids, when they are heated up to or above their flash point, become as readily ignitable as Class I liquids.

The exception exempts original shipping containers no larger than 5.3 gallons (20 L) from the limitations of this section with the intent of preventing the use of temporary, single-use containers.

**5705.2.5 Manual container filling operations.** Class I liquids or Class II and Class III liquids that are heated up to or above their *flash points* shall not be transferred into containers unless the nozzle and containers are electrically interconnected. Acceptable methods of electrical interconnection include either of the following:

1. Metallic floor plates on which containers stand while filling, where such floor plates are electrically connected to the fill stem.
2. Where the fill stem is bonded to the container during filling by means of a bond wire.

❖ Flammable and combustible liquids being transferred near or above their flash points will generate vapors

and are near the point of ignition. Transferring these liquids to a container must be done in a manner to prevent a static spark. Grounding the container and the nozzle will remove the potential for an electrical hazard and the possibility for a spark to jump.

**5705.2.6 Automatic container-filling operations for Class I liquids.** Container-filling operations for Class I liquids involving conveyor belts or other automatic-feeding operations shall be designed to prevent static accumulations.

❖ The conveyor belts and other automatic-feeding equipment can develop a static charge. This static charge must be discharged by grounding the equipment so that no electrical potential can develop.

**5705.3 Use, dispensing and mixing inside of buildings.** Indoor use, dispensing and mixing of flammable and *combustible liquids* shall be in accordance with Section 5705.2 and Sections 5705.3.1 through 5705.3.5.3.

❖ The use, dispensing and mixing of flammable and combustible liquids creates an environment where vapor may accumulate. These vapors must be controlled to keep the vapor-air mixture from reaching the LFL.

**5705.3.1 Closure of mixing or blending vessels.** Vessels used for mixing or blending of Class I liquids and Class II or III liquids heated up to or above their *flash points* shall be provided with self-closing, tight-fitting, noncombustible lids that will control a fire within such vessel.

**Exception:** Where such devices are impractical, *approved* automatic or manually controlled fire-extinguishing devices shall be provided.

❖ Flammable and combustible liquids being mixed or blended near or above their flash points will generate vapors and are near the point of ignition. Using a vessel with a self-closing, tight-fitting, noncombustible lid will allow a fire to be contained within the vessel and for the fire to be cut off from any source of additional air.

The exception covers situations in which the use of a vessel to contain and extinguish the fire may be impractical. These processes can use a fire-extinguishing device that operates automatically or manually.

**5705.3.2 Bonding of vessels.** Where differences of potential could be created, vessels containing Class I liquids or liquids handled at or above their *flash points* shall be electrically connected by bond wires, ground cables, piping or similar means to a static grounding system to maintain equipment at the same electrical potential to prevent sparking.

❖ Static electricity will spark between surfaces with different electrical potential. This spark is an ignition source for Class I liquids. Vessels used to contain Class I liquids near or above their flash points are to be bonded using wires, ground cables, metal piping or other similar means that will carry current.

**5705.3.3 Heating, lighting and cooking appliances.** Heating, lighting and cooking appliances that utilize Class I liquids shall not be operated within a building or structure.

**Exception:** Operation in single-family *dwelling*s.

- ❖ The use of Class I liquids for the operation of heating, lighting and cooking appliances is not permitted inside of a building or structure except for a single-family dwelling.

**5705.3.4 Location of processing vessels.** Processing vessels shall be located with respect to distances to *lot lines* of adjoining property that can be built on, in accordance with Tables 5705.3.4(1) and 5705.3.4(2).

**Exception:** Where the exterior wall facing the adjoining *lot line* is a blank wall having a *fire-resistance rating* of not less than 4 hours, the *fire code official* is authorized to modify the distances. The distance shall be not less than that set forth in the *International Building Code*, and where Class IA or unstable liquids are involved, explosion control shall be provided in accordance with Section 911.

- ❖ Adjacent property is protected from processing vessels by separation. The three factors to be considered in determining the minimum clearance to protect property are the processing vessel operating pressure, the processing vessel capacity and the stability of the flammable or combustible liquid. The larger these factors become, the greater the clearance needed for safety. Processing an unstable flammable or combustible liquid will require a greater clearance than a similar operation using a stable flammable or combustible liquid. Tables 5705.3.4(1) and 5705.3.4(2) are used together to determine the minimum clearance required to protect adjacent property or important buildings on the same property.

The exception allows fire-resistant construction to be substituted for clearance to a property. A 4-hour fire-resistant exterior wall without any openings may be used to reduce the clearance to as little as 30 feet (9144 mm). The fire code official can use the requirements in IBC Section 415.6.1, along with a 4-hour fire-resistance-rated exterior wall without any openings, to approve smaller clearance to a property line. The clearances in IBC Section 415.6.1 establish the minimum clearance.

For process vessels using Class I liquids, this exception requires that the building be designed for explosion control as well as having a 4-hour fire-resistant exterior wall without any openings to take advantage of the smaller clearance.

Here are some sample problems to determine the separation for processing vessels:

**Example 1:**

Processing vessel:  
 Tank capacity = 800 gallons (3028 L)  
 Emergency relief venting = 2 psig (14 kPa)

Flammable liquid is stable.

Factors from Table 5705.3.4(1):  
 Emergency relief venting under 2.5 psig (17 kPa)  
 with stable liquid = 1

Minimum distance from Table 5705.3.4(2):  
 Distance from lot line or opposite side of public way = 15 feet (4572 mm)  
 Distance to nearest side of public way or important building = 5 feet (1524 mm)

Adjustment to the minimum distance resulting from emergency relief venting and stability of flammable liquid:

Distance from lot line or opposite side of public way:  
 1 (15 feet) = 15 feet (4572 mm)  
 Distance to nearest side of public way or important building:  
 1 (5 feet) = 5 feet (1524 mm)

**Example 2:**

Processing vessel:  
 Tank capacity = 800 gallons (3028 L)  
 Emergency relief venting = 3 psig (21 kPa)

Flammable liquid is stable.

Factors from Table 5705.3.4(1):  
 Emergency relief venting over 2.5 psig (17 kPa)  
 with stable liquid = 2.5

Minimum distance from Table 5705.3.4(2):  
 Distance from lot line or opposite side of public way = 15 feet (4572 mm)  
 Distance to nearest side of public way or important building = 5 feet (1524 mm)

Adjustment to the minimum distance resulting from emergency relief venting and stability of flammable liquid:

Distance from lot line or opposite side of public way:  
 2.5 (15 feet) = 37.5 feet (11 430 mm)  
 Distance to nearest side of public way or important building: 2.5 (5 feet) = 12.5 feet (3810 mm)

**Example 3:**

Processing vessel:  
 Tank capacity = 800 gallons (3028 L)  
 Emergency relief venting = 2 psig (14 kPa)

Flammable liquid is stable.

Factors from Table 5705.3.4(1):  
 Emergency relief venting under 2.5 psig (17 kPa)  
 with stable liquid = 1.5

Minimum distance from Table 5705.3.4(2):  
 Distance from lot line or opposite side of public way = 15 feet (4572 mm)  
 Distance to nearest side of public way or important building = 5 feet (1524 mm)

Adjustment to the minimum distance resulting from emergency relief venting and stability of flammable liquid:

Distance from lot line or opposite side of public way:  
1.5 (15 feet) = 22.5 feet (6858 mm)

Distance to nearest side of public way or important building: 1.5 (5 feet) = 7.5 feet (2286 mm)

**Example 4:**

Processing vessel:  
Tank capacity = 800 gallons (3028 L)  
Emergency relief venting = 3 psig (17 kPa)

Flammable liquid is unstable.

Factors from Table 5705.3.4(1):  
Emergency relief venting over 2.5 psig (17 kPa) with unstable liquid = 4

Minimum distance from Table 5705.3.4(2):  
Distance from lot line or opposite side of public way = 15 feet (4572 mm)  
Distance to nearest side of public way or important building = 5 feet (1524 mm)

Adjustment to the minimum distance resulting from emergency relief venting and stability of flammable liquid:

Distance from lot line or opposite side of public way:  
4 (15 feet) = 60 feet (18 288 mm)  
Distance to nearest side of public way or important building: 4 (5 feet) = 20 feet (6096 mm)

**TABLE 5705.3.4(1).** See below.

- ❖ Processing vessels containing flammable and combustible liquids must be located a minimum distance from property lines. The clearance is to protect flammable and combustible liquids from ignition sources that are not under the control of facility operators. This clearance also protects the property adjacent to the facility.

The separation varies depending on the type of flammable and combustible liquid and operating pressure of the processing vessel. The table divides flammable and combustible liquids into two categories: stable and unstable. An unstable liquid can self-react when exposed to heat. This autoignition property requires that the separation distance for an unstable flammable or combustible liquid be several times greater than for a stable flammable or combustible liquid.

The operating pressure of the processing vessel is divided into two categories: 2.5 psig (17 kPa) or less and over 2.5 psig (17 kPa). Pressure can be the cause of damage to the processing system, and this damage could result in a vapor or liquid leak of flammable or combustible liquid. A higher pressure would also force more vapor or liquid out of the system during a leak. To provide protection from a processing vessel with an operating pressure greater than 2.5 psig (17 kPa), the separation distance is several times greater than for a processing vessel with an operating pressure 2.5 psig (17 kPa) or less. These two factors are cumulative. One or both of these factors may increase the separation distance. This table provides the factor to be used to calculate the separation distance listed in Table 5705.3.4(2).

**TABLE 5705.3.4(2).** See page 57-56.

- ❖ The separation distance from the processing vessel is affected by the tank capacity of the processing vessel and the object. The larger the tank capacity, the greater the separation distance. This greater separation distance is to handle the potential pool fire with the tank capacity. The separation distance is greater to a property line to protect the processing vessel from ignition sources that are not under control of the facility operators, as well as to protect the adjacent property from a potential fire. The separation distance to an important building on the property or to a public way is the same or less than for a property line. Because buildings on the property are under the control and operation of the facility operators, these buildings should be maintained and operated to prevent an ignition source. The separation from a public way is handled the same as from an important building on the property. The public way does not have buildings that have ignition sources, so the potential is not as great as from an adjacent property.

**5705.3.5 Quantity limits for use.** Liquid use quantity limitations shall comply with Sections 5705.3.5.1 through 5705.3.5.3.

- ❖ The volume of flammable and combustible liquid is controlled to limit the potential fire. The smaller the quantity, the smaller the potential fire. The dispensing and mixing of flammable and combustible liquids indoors can generate a vapor-air mixture. If this vapor-air mixture is ignited, the size of the fire could increase because of the availability of flammable and combustible liquid in the area. Limiting the volume will help control the overall size of any fire.

**TABLE 5705.3.4(1)**  
**SEPARATION OF PROCESSING VESSELS FROM LOT LINES**

PROCESSING VESSELS WITH EMERGENCY RELIEF VENTING	LOCATION <sup>a</sup>	
	Stable liquids	Unstable liquids
Not in excess of 2.5 psig	Table 5705.3.4(2)	2.5 times Table 5705.3.4(2)
Over 2.5 psig	1.5 times Table 5705.3.4(2)	4 times Table 5705.3.4(2)

For SI: 1 pound per square inch gauge = 6.895 kPa.

a. Where protection of exposures by a public fire department or private fire brigade capable of providing cooling water streams on structures is not provided, distances shall be doubled.

**FLAMMABLE AND COMBUSTIBLE LIQUIDS**

**5705.3.5.1 Maximum allowable quantity per control area.**

Indoor use, dispensing and mixing of flammable and *combustible liquids* shall not exceed the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) and shall not exceed the additional limitations set forth in Section 5705.3.5.

**Exception:** Cleaning with Class I, II and IIIA liquids shall be in accordance with Section 5705.3.6.

Use of hazardous production material flammable and *combustible liquids* in Group H-5 occupancies shall be in accordance with Chapter 27.

❖ The maximum quantity per control area for use, dispensing and mixing of flammable and combustible liquids indoors is identical to that for indoor storage (see Section 5704.3.3) with some additional limits caused by the processing operation. Table 5003.1.1(1) contains the quantity permitted per control area. By limiting the quantity per control area, the flammable and combustible liquid hazard is reduced to a level that the fire protection can handle and that will not interfere with egress requirements, which results in a building that can function and provide a reasonable degree of safety.

Cleaning with Class I, II, and IIIA liquids is covered in Section 5705.3.6.

The use of flammable and combustible liquids in a semiconductor fabrication facility is covered by Chapter 27.

**5705.3.5.2 Occupancy quantity limits.** The following limits for quantities of flammable and *combustible liquids* used, dispensed or mixed based on occupancy classification shall not be exceeded:

**Exception:** Cleaning with Class I, II, or IIIA liquids shall be in accordance with Section 5705.3.6.

1. Group A occupancies: Quantities in Group A occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance

purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).

2. Group B occupancies: Quantities in drinking, dining, office and school uses within Group B occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
3. Group E occupancies: Quantities in Group E occupancies shall not exceed that necessary for demonstration, treatment, laboratory work, maintenance purposes and operation of equipment and shall not exceed quantities set forth in Table 5003.1.1(1).
4. Group F occupancies: Quantities in dining, office and school uses within Group F occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
5. Group I occupancies: Quantities in Group I occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
6. Group M occupancies: Quantities in dining, office and school uses within Group M occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).
7. Group R occupancies: Quantities in Group R occupancies shall not exceed that necessary for maintenance purposes and operation of equipment, and shall not exceed quantities set forth in Table 5003.1.1(1).

**TABLE 5705.3.4(2)  
REFERENCE TABLE FOR USE WITH TABLE 5705.3.4(1)**

TANK CAPACITY (gallons)	MINIMUM DISTANCE FROM LOT LINE OF A LOT WHICH IS OR CAN BE BUILT UPON, INCLUDING THE OPPOSITE SIDE OF A PUBLIC WAY (feet)	MINIMUM DISTANCE FROM NEAREST SIDE OF ANY PUBLIC WAY OR FROM NEAREST IMPORTANT BUILDING ON THE SAME PROPERTY (feet)
275 or less	5	5
276 to 750	10	5
751 to 12,000	15	5
12,001 to 30,000	20	5
30,001 to 50,000	30	10
50,001 to 100,000	50	15
100,001 to 500,000	80	25
500,001 to 1,000,000	100	35
1,000,001 to 2,000,000	135	45
2,000,001 to 3,000,000	165	55
3,000,001 or more	175	60

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

8. Group S occupancies: Quantities in dining and office uses within Group S occupancies shall not exceed that necessary for demonstration, laboratory work, maintenance purposes and operation of equipment and shall not exceed quantities set forth in Table 5003.1.1(1).

❖ Flammable and combustible liquids may be used in occupancies other than Group H. The control of these liquids is based on the quantity in that occupancy.

The limitations for occupancies are based on the quantity limits for the storage of flammable and combustible liquids in containers and portable tanks in other occupancies. These other occupancies are not designed for flammable and combustible liquids so there are limitations on the quantity of flammable and combustible liquids that can be stored or used in these occupancies.

The use of flammable and combustible liquids must be consistent with the function of the occupancy. This prevents these other occupancies from being converted into Group H. The MAQs of flammable and combustible liquids are listed in Table 5003.1.1(1). The occupancies covered by these limitations are Groups A, B, E, F, I, M, R and S.

**5705.3.5.3 Quantities exceeding limits for control areas.**

Quantities exceeding the *maximum allowable quantity per control area* indicated in Sections 5705.3.5.1 and 5705.3.5.2 shall be in accordance with the following:

1. For *open systems*, indoor use, dispensing and mixing of flammable and *combustible liquids* shall be within a room or building complying with the *International Building Code* and Sections 5705.3.7.1 through 5705.3.7.5.
2. For *closed systems*, indoor use, dispensing and mixing of flammable and *combustible liquids* shall be within a room or building complying with the *International Building Code* and Sections 5705.3.7 through 5705.3.7.4 and Section 5705.3.7.6.

❖ It is possible to have a quantity of flammable and combustible liquids greater than allowed in Sections 5704.3.5 and 5705.3.5.2. To use, dispense and mix flammable and combustible liquids indoors in quantities larger than approved in this section, the building or room must be designed and constructed to provide additional protection. The design and construction requirements are based on the potential for the use, dispensing and mixing to generate vapors.

**5705.3.6 Cleaning with flammable and combustible liquids.** Cleaning with Class I, II and IIIA liquids shall be in accordance with Sections 5705.3.6.1 through 5705.3.6.2.7.

**Exceptions:**

1. Dry cleaning shall be in accordance with Chapter 21.
2. Spray-nozzle cleaning shall be in accordance with Section 2403.3.5.

❖ Cleaning machines using flammable or combustible liquids may generate a vapor-air mixture in the flammable range.

The use of cleaning machines using flammable or combustible liquids is regulated to control the vapor-air mixture, ignition sources and quantity of flammable or combustible liquids in the machines and the work area.

The exception directs the reader to other chapters for a detailed discussion of dry cleaning operations and spray nozzle cleaning.

**5705.3.6.1 Cleaning operations.** Class IA liquids shall not be used for cleaning. Cleaning with Class IB, IC or II liquids shall be conducted as follows:

1. In a room or building in accordance with Section 5705.3.7; or
2. In a parts cleaner *listed, labeled* and approved for the purpose in accordance with Section 5705.3.6.2.

**Exception:** Materials used in commercial and industrial process-related cleaning operations in accordance with other provisions of this code and not involving facilities maintenance cleaning operations.

❖ The lower flash point for a Class IA liquid is the reason for prohibiting its use as a cleaning solution. Class IB, IC and II liquids can be used in rooms designed and constructed with adequate fire protection, spillage control and ventilation, or in a machine that is designed to protect and control the liquid. The exception is provided to make it clear that process-related cleaning operations not considered part of facility maintenance cleaning and having a good safety history are not included in the operations regulated by this section.

**5705.3.6.2 Listed and approved machines.** Parts cleaning and degreasing conducted in *listed* and *approved* machines in accordance with Section 5705.3.6.1 shall be in accordance with Sections 5705.3.6.2.1 through 5705.3.6.2.7.

❖ Prior to the development of parts-washing machines, the typical method of washing automotive or other machinery parts was primitive and dangerous and typically consisted of allowing parts to soak in an open bucket of gasoline or low-flash-point solvent. Labeled machines used for the washing of parts are similar to the spray equipment cleaning machines discussed in the commentary to Section 2403.3.5.1. Such machines consist of a sink-like open container set upon a solvent reservoir or connected to it by approved hoses. A noncombustible lid on the sink is typically held in the open position by a fusible element that will melt and allow the lid to close in the event of a fire in the sink [see Commentary Figure 5705.3.6.2(1)].

Some labeled parts washing machines do not include a solvent reservoir but are simply a solvent-filled, sink-like rinsing tank in which parts may be soaked, manually agitated or scrubbed with a brush, but in which circulation of the solvent does not occur [see Commentary Figure 5705.3.6.2(2)]. The manufacturers' installation instructions are evaluated as part of the labeling process and, thus, must be care-

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

fully followed when setting up and using these machines.

**5705.3.6.2.1 Solvents.** Solvents shall be classified and shall be compatible with the machines within which they are used.

❖ Manufacturers of labeled parts-washing machines either manufacture and market or recommend specific solvents that may be used in their machines in order to maintain the level of safety contemplated in the design of the machine. The testing and labeling process is based on only the manufacturer-recommended solvents being used in the machines. Typically, these are Class II or III solvents.

**5705.3.6.2.2 Machine capacities.** The quantity of solvent shall not exceed the *listed* design capacity of the machine for the solvent being used with the machine.

❖ The machine listing states the quantity of solvent permitted. The listing agency tests the machine to determine the maximum capacity of flammable or combustible liquid. The listing indicates that the machine is safe for use based on the quantities permitted.

**5705.3.6.2.3 Solvent quantity limits.** Solvent quantities shall be limited as follows:

1. Machines without remote solvent reservoirs shall be limited to quantities set forth in Section 5705.3.5.
2. Machines with remote solvent reservoirs using Class I liquids shall be limited to quantities set forth in Section 5705.3.5.
3. Machines with remote solvent reservoirs using Class II liquids shall be limited to 35 gallons (132 L) per machine. The total quantities shall not exceed an aggregate

of 240 gallons (908 L) per *control area* in buildings not equipped throughout with an *approved* automatic sprinkler system and an aggregate of 480 gallons (1817 L) per *control area* in buildings equipped throughout with an *approved* automatic sprinkler system in accordance with Section 903.3.1.1.

4. Machines with remote solvent reservoirs using Class IIIA liquids shall be limited to 80 gallons (303 L) per machine.

❖ This section lists four restrictions on solvent quantities in machines:

1. A machine without a remote solvent reservoir is under the quantity limitations for a control area. The quantity of solvent in the machine and any other flammable and combustible liquids in the control area cannot exceed the maximum quantity permitted under Table 5003.1.1(1). These quantities can be increased by the application of Section 5705.3.5.3.
2. A machine with a remote solvent reservoir using Class IB or IC liquids is treated the same as a machine without a remote solvent reservoir.
3. A machine with a remote solvent reservoir using Class II liquid is permitted to have larger quantities than Table 5003.1.1(1) allows. The allowable quantity is increased even more if the control area has an automatic sprinkler system. The safety features built into the machine permit the increase in Class II solvent quantities for each machine and for the control area.

- 4. A machine with a remote solvent reservoir using Class IIIA liquid is permitted to have 80 gallons (303 L) per machine.

**5705.3.6.2.4 Immersion soaking of parts.** Work areas of machines with remote solvent reservoirs shall not be used for immersion soaking of parts.

- ❖ The action of immersion soaking of parts for a machine with a remote reservoir would have the effect of changing the machine from having a remote reservoir to a machine without a remote reservoir. This function of immersion soaking of parts changes the justification for permitting machines with a remote reservoir to have greater quantities of solvent than machines without a remote reservoir.

**5705.3.6.2.5 Separation.** Multiple machines shall be separated from each other by a distance of not less than 30 feet (9144 mm) or by a *fire barrier* with a minimum 1-hour *fire-resistance rating*.

- ❖ Machines are isolated from one another to reduce the potential of a fire from one machine affecting an adjacent machine. The isolation can be by a clearance of 30 feet (9144 mm) or by a 1-hour fire-resistant barrier.

**5705.3.6.2.6 Ventilation.** Machines shall be located in areas adequately ventilated to prevent accumulation of vapors.

- ❖ The machines are to be located in areas having mechanical or natural ventilation complying with Section 5004.3 to remove the vapors in order to prevent

the vapor-air mixture from accumulating in concentrations above the LFL.

**5705.3.6.2.7 Installation.** Machines shall be installed in accordance with their listings.

- ❖ Listed machines normally have written installation instructions that must be followed to make certain the machine is installed correctly. A machine installed incorrectly could generate vapors, leaks or sparks.

**5705.3.7 Rooms or buildings for quantities exceeding the maximum allowable quantity per control area.** Where required by Section 5705.3.5.3 or 5705.3.6.1, rooms or buildings used for the use, dispensing or mixing of flammable and *combustible liquids* in quantities exceeding the maximum allowable quantity per control area shall be in accordance with Sections 5705.3.7.1 through 5705.3.7.6.3.

- ❖ Some uses of flammable and combustible liquids may require a quantity that is greater than the MAQ. These sections state requirements for a room or building so that a greater quantity of flammable and combustible liquid may be used.

**5705.3.7.1 Construction, location and fire protection.** Rooms or buildings classified in accordance with the *International Building Code* as Group H-2 or H-3 occupancies based on use, dispensing or mixing of flammable or *combustible liquids* shall be constructed in accordance with the *International Building Code*.

- ❖ Group H-2 occupancy is the classification for a facility that uses or stores Class I, II or III liquids in open con-

tainers and systems, or in closed containers or systems under a pressure greater than 15 psig (103 kPa). Group H-3 occupancy is the classification for a facility that uses or stores Class I, II or III liquids in closed containers or systems under a pressure of 15 psig (103 kPa) or less. IBC Sections 414 and 415 give guidance for determining the construction requirements for these two occupancies.

**5705.3.7.2 Basements.** In rooms or buildings classified in accordance with the *International Building Code* as Group H-2 or H-3, dispensing or mixing of flammable or *combustible liquids* shall not be conducted in *basements*.

❖ The mixing and dispensing of flammable and combustible liquids may generate vapors. The accumulation of flammable and combustible liquids or vapors in a basement could develop into a hazardous condition. These operations are prohibited in a basement of a Group H-2 or H-3 occupancy.

**5705.3.7.3 Fire protection.** Rooms or buildings classified in accordance with the *International Building Code* as Group H-2 or H-3 occupancies shall be equipped with an *approved* automatic fire-extinguishing system in accordance with Chapter 9.

❖ Group H-2 and H-3 occupancies must have an automatic sprinkler system according to Section 903.2.5.1 of the code. Any building that can be classified as a Group H-2 or H-3 occupancy that is not equipped with an automatic sprinkler system is in violation of the code.

**5705.3.7.4 Doors.** Interior doors to rooms or portions of such buildings shall be self-closing fire doors in accordance with the *International Building Code*.

❖ Interior fire-resistance-rated wall construction used to separate or isolate portions of a building must have fire-resistance-rated doors in the openings in the wall. A fire-resistance-rated interior door consists of the door, door frame, latches, locks, hinges, closers and any other hardware that is necessary for the door to function. The door is to be self-closing to ensure that the door is not open during a fire. IBC Section 716 contains the criteria for the fire-resistance-rated door. Any obstruction to the operation of or damage to this door that prevents the door from forming a barrier with the fire-resistance-rated wall must be removed or repaired.

**5705.3.7.5 Open systems.** Use, dispensing and mixing of flammable and *combustible liquids* in *open systems* shall be in accordance with Sections 5705.3.7.5.1 through 5705.3.7.5.3.

❖ Rooms and buildings where flammable and combustible liquids are dispensed, mixed or used in open containers or open systems must be designed and constructed to control the potential fire hazard created by the liquid and its vapor.

**5705.3.7.5.1 Ventilation.** Continuous mechanical ventilation shall be provided at a rate of not less than 1 cfm per square

foot [0.00508 m<sup>3</sup>/(s · m<sup>2</sup>)] of floor area over the design area. Provisions shall be made for introduction of makeup air in such a manner to include all floor areas or pits where vapors can collect. Local or spot ventilation shall be provided where needed to prevent the accumulation of hazardous vapors. Ventilation system design shall comply with the *International Building Code* and *International Mechanical Code*.

**Exception:** Where natural ventilation can be shown to be effective for the materials used, dispensed or mixed.

❖ The requirements of this section for a mechanical ventilation system are identical to those in Section 5004.3. The mechanical ventilation system must remove the vapors to prevent accumulation in concentrations in the flammable range for the flammable and combustible liquids being used.

The exception allows use of natural ventilation complying with Section 5004.3 that can be demonstrated to be effective for the flammable and combustible liquids being used.

**5705.3.7.5.2 Explosion control.** Explosion control shall be provided in accordance with Section 911.

❖ Refer to Section 911 for deflagration venting to direct the force of an explosion out of the structure into an unoccupied area. That section also references NFPA 69, which may require monitoring of gases and other methods to suppress factors affecting an explosion.

**5705.3.7.5.3 Spill control and secondary containment.** Spill control shall be provided in accordance with Section 5703.4 where Class I, II or IIIA liquids are dispensed into containers exceeding a 1.3-gallon (5 L) capacity or mixed or used in open containers or systems exceeding a 5.3-gallon (20 L) capacity. Spill control and secondary containment shall be provided in accordance with Section 5703.4 where the capacity of an individual container exceeds 55 gallons (208 L) or the aggregate capacity of multiple containers or tanks exceeds 100 gallons (378.5 L).

❖ Spill control complying with Section 5703.4 must be built into a room or a building where Class I, II or IIIA liquids are used in open containers or open systems that dispense the liquid into containers greater than 1.3 gallons (5 L), or mixed or used in quantities greater than 5.3 gallons (20 L). In addition, secondary containment must be provided for individual containers greater than 55 gallons or multiple containers with an aggregate capacity greater than 100 gallons. This section references Section 5004.2, which discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled.

**5705.3.7.6 Closed systems.** Use or mixing of flammable or *combustible liquids* in *closed systems* shall be in accordance with Sections 5705.3.7.6.1 through 5705.3.7.6.3.

❖ Rooms and buildings where flammable and combustible liquids are dispensed, mixed or used in closed systems must be designed and constructed to control the potential fire hazard created by the liquid and its vapor.

**5705.3.7.6.1 Ventilation.** *Closed systems* designed to be opened as part of normal operations shall be provided with ventilation in accordance with Section 5705.3.7.5.1.

❖ The requirements of this section for a mechanical ventilation system are identical to those in Section 5004.3. The mechanical ventilation system must remove the vapors to prevent accumulation in concentrations in the flammable range for the flammable and combustible liquids being used. Natural ventilation complying with Section 5004.3 that can be demonstrated to be effective for the flammable and combustible liquids being used is an acceptable alternative.

**5705.3.7.6.2 Explosion control.** Explosion control shall be provided where an explosive environment can occur as a result of the mixing or use process. Explosion control shall be designed in accordance with Section 911.

**Exception:** Where process vessels are designed to contain fully the worst-case explosion anticipated within the vessel under process conditions considering the most likely failure.

❖ Refer to Section 911 for deflagration venting to direct the force of an explosion out of the structure into an unoccupied area. This section also references NFPA 69, which may require monitoring of gases and other methods to suppress factors affecting an explosion.

The exception recognizes that a closed system can be designed to absorb the forces from an internal explosion. If the closed system is designed to resist the worst-case explosion, the room or building does not have to be designed to comply with Section 911.

**5705.3.7.6.3 Spill control and secondary containment.** Spill control shall be provided in accordance with Section 5703.4 where flammable or *combustible liquids* are dispensed into containers exceeding a 1.3-gallon (5 L) capacity or mixed or used in open containers or systems exceeding a 5.3-gallon (20 L) capacity. Spill control and secondary containment shall be provided in accordance with Section 5703.4 where the capacity of an individual container exceeds 55 gallons (208 L) or the aggregate capacity of multiple containers or tanks exceeds 1,000 gallons (3785 L).

❖ Spill control complying with Section 5703.4 must be designed into a room or a building where flammable or combustible liquids are used in closed systems that dispense the liquid into containers greater than 1.3 gallons (5 L), or mixed or used in quantities greater than 5.3 gallons (20 L). In addition, secondary containment must be provided for individual containers greater than 55 gallons or multiple containers with an aggregate capacity greater than 1,000 gallons. This section references Section 5004.2, which discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled. This is identical to the requirement for an open system except that the aggregate quantity for a closed sys-

tem is 1,000 gallons (3785 L) and only 100 gallons (379 L) for an open system.

**5705.3.8 Use, dispensing and handling outside of buildings.** Outside use, dispensing and handling shall be in accordance with Sections 5705.3.8.1 through 5705.3.8.4.

Dispensing of liquids into motor vehicle fuel tanks at motor fuel-dispensing facilities shall be in accordance with Chapter 23.

❖ Dispensing and handling of flammable and combustible liquids outside of a building requires that the location be protected from ignition sources by separating it from structures, property lines, streets, etc. Spill control and drainage control must be designed into the outside location to prevent flammable and combustible liquids from affecting other areas. Dispensing into motor vehicle fuel tanks is covered in Chapter 23.

**5705.3.8.1 Spill control.** Outside use, dispensing and handling areas shall be provided with spill control as set forth in Section 5703.4.

❖ Outside use, dispensing and handling areas must have spill control according to Section 5703.4. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled.

**5705.3.8.2 Location on property.** Dispensing activities that exceed the quantities set forth in Table 5705.3.8.2 shall not be conducted within 15 feet (4572 mm) of buildings or combustible materials or within 25 feet (7620 mm) of building openings, *lot lines*, public streets, public alleys or *public ways*. Dispensing activities that exceed the quantities set forth in Table 5705.3.8.2 shall not be conducted within 15 feet (4572 mm) of storage of Class I, II or III liquids unless such liquids are stored in tanks that are *listed* and *labeled* as 2-hour protected tank assemblies in accordance with UL 2085.

#### Exceptions:

1. The requirements shall not apply to areas where only the following are dispensed: Class III liquids; liquids that are heavier than water; water-miscible liquids; and liquids with viscosities greater than 10,000 centipoise (cp) (10 Pa • s).
  2. Flammable and *combustible liquid* dispensing in refineries, chemical plants, process facilities, gas and crude oil production facilities and oil-blending and packaging facilities, terminals and bulk plants.
- ❖ The dispensing of flammable and combustible liquids can generate vapors. Flammable and combustible liquid exceeding the quantities in Table 5705.3.8.2 must be separated from combustibles, buildings, other property, public property, etc. The separation allows the vapor to disperse to a vapor-air mixture below its LFL. The clearance isolates the dispensing area from ignition sources and other fuel sources. When the quantity of flammable and combustible liquid exceeds the quantity in Table 5705.3.8.2, the

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

storage tank for the flammable or combustible liquid must be protected by separation from the dispensing area. The clearance between the storage tank and the dispensing area can be reduced if the storage tank is a 2-hour protected tank in accordance with UL 2085.

Exception 1 is based on the viscosity of the hazardous liquid. Class III liquids, liquids heavier than water, water-miscible liquids and liquids with a viscosity greater than 10,000 cp need not be isolated. The isolation is not necessary for liquids with higher flash points, liquids that can be mixed with water, liquids that can be covered by a barrier of water or liquids that are slow moving. These liquids can be controlled by other procedures rather than mandate a clearance.

Exception 2 exempts facilities that are designed specifically for processing, manufacturing, storage or transfer of large quantities of flammable and combustible liquids.

**Table 5705.3.8.2.** See below.

- ❖ The quantities of flammable and combustible liquids dispensed outdoors are limited when the dispensing is near a building. This table contains the maximum volume of flammable and combustible liquids that can be dispensed in an outdoor control area. An outdoor control area is defined as the area within 15 feet (4572 mm) of a building, combustible materials or a Class I, II or III liquid storage tank unless the storage tanks have 2-hour fire protection, or within 25 feet (7620 mm) of a building opening, a property line, a street, an alley or a public way. This quantity limit protects the vapor of flammable or combustible liquids from ignition sources. It also protects the building and adjacent property from a fire involving flammable or combustible liquids.

**TABLE 5705.3.8.2**  
**MAXIMUM ALLOWABLE QUANTITIES FOR**  
**DISPENSING OF FLAMMABLE AND COMBUSTIBLE**  
**LIQUIDS IN OUTDOOR CONTROL AREAS<sup>a, b</sup>**

CLASS OF LIQUID	QUANTITY (gallons)
Flammable	
Class IA	10
Class IB	15
Class IC	20
Combination Class IA, IB and IC	30 <sup>c</sup>
Combustible	
Class II	30
Class IIIA	80
Class IIIB	3,300

For SI: 1 gallon = 3.785 L.

- a. For definition of "Outdoor Control Area," see Section 5002.1.
- b. The fire code official is authorized to impose special conditions regarding locations, types of containers, dispensing units, fire control measures and other factors involving fire safety.
- c. Containing not more than the maximum allowable quantity per control area of each individual class.

**5705.3.8.3 Location of processing vessels.** Processing vessels shall be located with respect to distances to *lot lines* that can be built on in accordance with Table 5705.3.4(1).

**Exception:** In refineries and distilleries.

- ❖ Processing vessels outside of a building must be treated the same as a processing vessel inside a building. The exception covers refineries and distilleries, which are designed specifically for the processing of large quantities of hazardous liquids.

**5705.3.8.4 Weather protection.** Weather protection for outdoor use shall be in accordance with Section 5005.3.9.

- ❖ Weather protection is not required for outdoor use; however, where an overhead protective structure is erected, it must conform to the requirements of Section 5004.13. That section also notes that an open structure consisting of only a noncombustible roof structure does not change the storage facility to being considered as indoor storage, provided that the roof structure is constructed in accordance with the construction requirements of IBC Section 414.6.1. Natural airflow through a structure with no walls and only a noncombustible roof is considered sufficient ventilation for the storage area to be treated as outdoor storage for flammable and combustible liquids.

**5705.4 Solvent distillation units.** Solvent distillation units shall comply with Sections 5705.4.1 through 5705.4.9.

- ❖ Distillation units generate vapors by heating the flammable and combustible liquids. This process must be controlled to prevent the vapor-air mixture from reaching the LFL or an ignition source from coming into contact with the mixture.

**5705.4.1 Unit with a capacity of 60 gallons or less.** Solvent distillation units used to recycle Class I, II or IIIA liquids having a distillation chamber capacity of 60 gallons (227 L) or less shall be *listed, labeled* and installed in accordance with Section 5705.4 and UL 2208.

**Exceptions:**

1. Solvent distillation units used in continuous through-put industrial processes where the source of heat is remotely supplied using steam, hot water, oil or other heat transfer fluids, the temperature of which is below the auto-ignition point of the solvent.
  2. *Approved* research, testing and experimental processes.
- ❖ Distillation equipment with a distillation chamber (sometimes called a "still pot") of the stated size can be manufactured so that the design, construction and operation can be tested for safety. These units are tested, listed and labeled according to this section and UL 2208. There are two exceptions to these requirements: Exception 1 exempts solvent distillation units that are in continuous operation, do not use heat from fluid transfer and the heat transfer fluid

temperature is below the autoignition point. Exception 2 exempts solvent distillation units that are approved for research or experimental processes from complying with this section or UL 2208.

**5705.4.2 Units with a capacity exceeding 60 gallons.** Solvent distillation units used to recycle Class I, II or IIIA liquids, having a distillation chamber capacity exceeding 60 gallons (227 L) shall be used in locations that comply with the use and mixing requirements of Section 5705 and other applicable provisions in this chapter.

- ❖ Distillation units with a distillation chamber (sometimes called a “still pot”) of the stated size must be treated as if the unit was for mixing and blending. The operation involves vapor concentrations from flammable or combustible liquid that may be in the flammable range.

**5705.4.3 Prohibited processing.** Class I, II and IIIA liquids that are also classified as unstable (reactive) shall not be processed in solvent distillation units.

**Exception:** Appliances *listed* for the distillation of unstable (reactive) solvents.

- ❖ Flammable and combustible liquids that are also unstable are prohibited from being processed by a solvent distillation unit. An unstable liquid can self-react when exposed to heat. By removing the heat source, the code is reducing the potential danger.

The exception recognizes that some equipment is designed for the safe distillation of unstable flammable and combustible liquids and is listed for that function.

**5705.4.4 Labeling.** A permanent label shall be affixed to the unit by the manufacturer. The label shall indicate the capacity of the distillation chamber, and the distance the unit shall be placed away from sources of ignition. The label shall indicate the products for which the unit has been *listed* for use or refer to the instruction manual for a list of the products.

- ❖ The distillation unit is to be permanently labeled to provide information for its safe operation. At minimum, the label must indicate capacity, clearance from ignition sources and information on products the unit is designed to process.

**5705.4.5 Manufacturer’s instruction manual.** An instruction manual shall be provided. The manual shall be readily available for the user and the *fire code official*. The manual shall include installation, use and servicing instructions. It shall identify the liquids for which the unit has been *listed* for distillation purposes along with each liquid’s *flash point* and auto-ignition temperature. For units with adjustable controls, the manual shall include directions for setting the heater temperature for each liquid to be instilled.

- ❖ Manufacturers of listed and labeled equipment normally prepare an instruction manual for their equipment. The instruction manual is to be available for use by installation personnel and the fire code official. The instruction manual should include not only installation instructions, but also operating procedures and the products the unit can distill.

**5705.4.6 Location.** Solvent distillation units shall be used in locations in accordance with the listing. Solvent distillation units shall not be used in *basements*.

- ❖ The label and instruction manual will include information on acceptable locations, separation from ignition sources, light sources, ventilation, etc. Regardless of the instruction manual, the distillation unit cannot be located in a basement. Vapors that may escape during distillation will normally be heavier than air and settle to the lower levels, making their removal from a basement location difficult.

**5705.4.7 Storage of liquids.** Distilled liquids and liquids awaiting distillation shall be stored in accordance with Section 5704.

- ❖ Distilled liquids governed by this section will always present storage hazards. It is therefore important that all the liquids, both before and after distillation, be handled as prescribed in Section 5704.

**5705.4.8 Storage of residues.** Hazardous residue from the distillation process shall be stored in accordance with Section 5704 and Chapter 50.

- ❖ The residue from the distillation process may be a flammable or combustible material, or some other hazardous material. The instruction manual must include information on the products that the distillation unit is designed to process and identify the residue. If the residue is hazardous, it must be handled according to Section 5704 and Chapter 50.

**5705.4.9 Portable fire extinguishers.** *Approved* portable fire extinguishers shall be provided in accordance with Section 906. Not less than one portable fire extinguisher having a rating of not less than 40-B shall be located not less than 10 feet (3048 mm) or more than 30 feet (9144 mm) from any solvent distillation unit.

- ❖ Portable fire extinguishers must be located in clear view and within 30 feet (9144 mm) of the distillation unit. The 40-B portable fire extinguisher is for the control of small flammable liquid fires.

**5705.5 Alcohol-based hand rubs classified as Class I or II liquids.** The use of wall-mounted dispensers containing alcohol-based hand rubs classified as Class I or II liquids shall be in accordance with all of the following:

1. The maximum capacity of each dispenser shall be 68 ounces (2 L).
2. The minimum separation between dispensers shall be 48 inches (1219 mm).
3. The dispensers shall not be installed above, below, or closer than 1 inch (25 mm) to an electrical receptacle, switch, appliance, device or other ignition source. The wall space between the dispenser and the floor or intervening counter top shall be free of electrical receptacles, switches, appliances, devices or other ignition sources.
4. Dispensers shall be mounted so that the bottom of the dispenser is not less than 42 inches (1067 mm) and not

more than 48 inches (1219 mm) above the finished floor.

5. Dispensers shall not release their contents except when the dispenser is manually activated. Facilities shall be permitted to install and use automatically activated “touch free” alcohol-based hand-rub dispensing devices with the following requirements:

- 5.1. The facility or persons responsible for the dispensers shall test the dispensers each time a new refill is installed in accordance with the manufacturer’s care and use instructions.

- 5.2. Dispensers shall be designed and must operate in a manner that ensures accidental or malicious activations of the dispensing device are minimized. At a minimum, all devices subject to or used in accordance with this section shall have the following safety features:

- 5.2.1. Any activations of the dispenser shall only occur when an object is placed within 4 inches (98 mm) of the sensing device.

- 5.2.2. The dispenser shall not dispense more than the amount required for hand hygiene consistent with label instructions as regulated by the United States Food and Drug Administration (USFDA).

- 5.2.3. An object placed within the activation zone and left in place will cause only one activation.

6. Storage and use of alcohol-based hand rubs shall be in accordance with the applicable provisions of Sections 5704 and 5705.

7. Dispensers installed in occupancies with carpeted floors shall only be allowed in smoke compartments or *fire areas* equipped throughout with an *approved* automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

❖ Alcohol-based hand rubs are essential in health care occupancies for controlling the spread of unwanted infectious microorganisms. Numerous studies conducted on their use have found that they provide a vastly improved efficacy against numerous pathogens and are more effective for a longer time period when compared to simple hand-washing with soap and water.

In 2003, the American Hospital Association (AHA) approached the International Code Council® (ICC®) regarding the safety issues related to the use of alcohol-based hand rub products in health care occupancies. Specifically, they were concerned that some code officials had prohibited the installation of alcohol-based hand rub dispensers in corridors. The ICC Board of Directors appointed an ad hoc committee with broad representation to address the issue and develop appropriate code change proposals.

Alcohol-based hand rub solution is typically pack-

aged in pump bottles or soft bladders for insertion into a pump dispenser. They are closed to the atmosphere with no mixing or refilling of containers. The likelihood of ignition is extremely remote. But if, somehow, a dispenser were to ignite, the burn characteristics must be understood to better determine the risks. The American Society of Healthcare Engineering (ASHE) commissioned a fire modeling analysis to study the overall effects of placing dispensers in corridors and suites of rooms. The Fire Dynamics Simulator (FDS) Version 3.1, published by the National Institute of Standards and Technology (NIST), was used for the modeling. The results of the FDS model were used to evaluate the potential hazards and characteristics including:

- Tenability of the space.
- Ignition of adjacent fuel loads/combustibles.
- Sprinkler activation.

Because the modeling was for sick patients incapable of self-preservation, the tenability value (temperature, visibility, and carbon monoxide) was chosen to be conservative (factor of safety of 10).

Several fire scenarios were modeled with variables of dispenser volume, spacing and space configuration. In each scenario, a “worst case” was simulated that consisted of a complete rupture of the dispenser and simultaneous ignition resulting in a pool fire. The results indicated that both ethyl and isopropyl alcohol-based products met the tenability criteria when controlled in volume (1.2-L container in a corridor and 2 L in a room) and in dispenser placement [6-foot wide (1829 mm) corridor]. The results showed that with adequate horizontal spacing [48 inches (1219 mm)], none of the fuel targets put into the models would ignite, indicating that the proposed spacing was reasonable to prevent additional ignition. Sprinkler activation was not predicted for most of the scenarios modeled (activation only occurred with the larger 2-L spills). Additionally, the results indicate the scenario with a carpeted floor is a concern because of visibility problems.

This section and Section 5705.5.1 are the result of the ICC ad hoc committee’s consensus proposals and also reflect the opinion of the *International Fire Code*® (IFC®) Code Development Committee and the ICC membership as to the appropriate level of regulation necessary in allowing the use of alcohol-based hand rubs in buildings. The intent of this section is to provide a means to avoid the code being utilized as a barrier to infection control while maintaining an appropriate level of safety in health care and other environments where alcohol-based hand rubs are an important public health tool. It should be noted that, while the AHA approached the ICC specifically regarding health care occupancies, these provisions are not occupancy-specific because the ad hoc committee recognized that the use of alcohol-based

hand rubs affects more than a single occupancy group. Section 5001.1 also provides the necessary cross reference to these new provisions to prevent the alcohol-based hand rub dispensers from being considered the same as other flammable liquids, thereby exempting them from the MAQs in Table 5003.1.1(1).

This section outlines seven criteria that are necessary, based in large part on fire modeling tests, to safely utilize alcohol-based hand rubs in buildings of any occupancy. These include regulating fuel load by controlling dispenser volume based on established industry practices (Criterion 1), minimizing the potential for ignition of other dispensers by establishing horizontal spacing requirements (Criterion 2), minimizing the potential for ignition of dispensers by establishing clearance requirements to ignition sources (Criterion 3), access to dispensers consistent with accessibility requirements (Criterion 4), control of dripping (Criterion 5), regulation of alcohol-based hand rub storage and use (Criterion 6) and mitigation of concerns over the visibility of leakage on carpeting by requiring sprinkler protection (Criterion 7). When combined, these controls effectively manage and minimize fire risk while allowing personnel ready access to these hand hygiene products.

It should be noted that, originally, Criterion 5 of this section allowed only manual activation of hand-rub dispensers by actual physical contact with the unit, which did not include operation by means of an infrared sensor. Infrared sensor operation has gained in popularity as use of hand rubs has grown, resulting in a revised Criterion 5 that allows “touch-free” operation. Touch-free dispensers have been developed to eliminate the need for persons to touch the dispenser, which creates a potential path for passing of microorganisms. (See Commentary Figure 5705.5) The devices are generally activated by passing hands in front of or under an optical scanner, which dispenses a specified dose of ethanol or isopropanol. In addition to compliance with all seven of the requirements of this section, these particular dispensers are required by Item 5.1 to be tested each time the dispenser is refilled in accordance the manufacturer’s care and use instructions. Item 5.2 requires that dispenser design be such that accidental or malicious activations are minimized. To prevent accidental activation of the device, such as when a cart or gurney is pushed near a touch-free dispenser, Item 5.2.1 only allows dispenser activation to occur when an object is placed within 4 inches (102 mm) of the device. Item 5.2.2 requires the discharged dose to be limited to the amount necessary for hand hygiene. Finally, if a cart or other object is “parked” close enough to activate the dispenser, Item 5.2.3 only allows the device to dispense a single dose, i.e., the dispenser must be designed so that it does not

continue to cycle and dispense additional doses of alcohol.

**5705.5.1 Corridor installations.** In addition to the provisions of Section 5705.5, where wall-mounted dispensers containing alcohol-based hand rubs are installed in *corridors* or rooms and areas open to the corridor, they shall be in accordance with all of the following:

1. Level 2 and 3 aerosol containers shall not be allowed in *corridors*.
2. The maximum capacity of each Class I or II liquid dispenser shall be 41 ounces (1.21 L) and the maximum capacity of each Level 1 aerosol dispenser shall be 18 ounces (0.51 kg).
3. The maximum quantity allowed in a *corridor* within a *control area* shall be 10 gallons (37.85 L) of Class I or II liquids or 1135 ounces (32.2 kg) of Level 1 aerosols, or a combination of Class I or II liquids and Level 1 aerosols not to exceed, in total, the equivalent of 10 gallons (37.85 L) or 1,135 ounces (32.2 kg) such that the sum of the ratios of the liquid and aerosol quantities divided by the allowable quantity of liquids and aerosols, respectively, shall not exceed one.
4. The minimum *corridor* width shall be 72 inches (1829 mm).
5. Projections into a *corridor* shall be in accordance with Section 1003.3.3.

❖ Though these provisions are not occupancy specific, in health care occupancies, hand rub dispensers are often located in the patient room. But due to a variety of clinical issues, including patient population (psychiatric and pediatric patients), care delivery models (teaching hospitals with multiple residents in contact with patients) and patient room space constraints

**Figure 5705.5**  
**TOUCH-FREE ALCOHOL-BASED**  
**HAND RUB DISPENSER**  
 (Credit: Gojo Industries, Akron, OH)

(lack of available space for mounting a dispenser away from constricted traffic flow, electric outlets and electric switches), mounting the dispenser in the patient room may not be possible or may compromise effective patient care. In these instances, dispensers mounted in the corridor best meet the clinical needs.

Because of life safety hazards in health care occupancies, various medical professional associations approached the ASHE to address the challenge of understanding, and if possible, allowing the installation of a number of dispensers containing a small quantity of alcohol-based hand rubs (Class 1B flammable liquid) in egress corridors of health care facilities. Concerned that the introduction of alcohol-based hand rubs may simply be reducing one risk while creating another (fire safety), ASHE responded by investigating the current use of alcohol-based hand rub solutions and analyzing the risks presented by them. The ad hoc committee reviewed the results of the fire modeling in corridors and recommended the five safeguards contained in this section.

Item 1 prohibits the use of Level 2 and 3 aerosol alcohol-based hand rub dispensers in exit access corridors because aerosol containers were not considered in the fire modeling for the original project. This exclusion is appropriate for Level 2 and 3 aerosols but not for Level 1 aerosols, because they are treated as ordinary combustibles by the code. Their alcohol content is equal to that currently permitted in Class I and II liquid or gel hand sanitizers. The aerosol industry was asked to conduct its own study and testing to show that aerosols could also be allowed in the same application. The study determined that the hazard of level 1 aerosols was less than that of the allowed Class I and II liquid or gel hand sanitizers and that the aerosol can would not release its contents before the temperatures in the corridor became untenable.

Item 2 is based on the fact that the fire modeling and aerosol industry test results indicated that both ethyl and isopropyl alcohol-based products and aerosols met the tenability criteria when controlled in volume to 41-ounce (1158 g) liquid and 18-ounce (509 g) aerosol dispenser containers in corridors. For aerosols, the capacity is based on typical industry containers.

In arriving at Item 3, based on usage patterns, primarily in health care occupancies, it was felt that establishing a 10-gallon (38 L) allowable amount or combined liquid and aerosol equivalent allowable amount, which is well below the MAQs for Class I or II liquids in Table 5003.1.1(1), is reasonable and safe for any occupancy. A simple method of calculating the maximum allowable quantity of combined liquids and aerosols is provided and is based on IBC Section 508.4.2. For example, if 4 gallons (15 L) of liquids and 500 ounces (14 175 g) of aerosols were present, 4/10 plus 500/1135 is less than one and, therefore, below the maximum combined allowable quantity.

Item 4 is based on the performance of the dis-

penser containers in the fire modeling scenarios.

Item 5 is intended to prevent dispensers from projecting into areas over walking surfaces as regulated in Section 1003.3.3. See the commentary for Section 1003.3.3 for further discussion of projections into the required width of corridors.

## SECTION 5706 SPECIAL OPERATIONS

**5706.1 General.** This section shall cover the provisions for special operations that include, but are not limited to, storage, use, dispensing, mixing or handling of flammable and *combustible liquids*. The following special operations shall be in accordance with Sections 5701, 5703, 5704 and 5705, except as provided in Section 5706.

1. Storage and dispensing of flammable and *combustible liquids* on farms and construction sites.
2. Well drilling and operating.
3. Bulk plants or terminals.
4. Bulk transfer and process transfer operations utilizing tank vehicles and tank cars.
5. Tank vehicles and tank vehicle operation.
6. Refineries.
7. Vapor recovery and vapor-processing systems.

❖ This section covers uses of flammable and combustible liquids for specific occupancies. The requirements of Sections 5701, 5703, 5704 and 5705 apply to these occupancies except as specifically directed by Section 5706.

**5706.2 Storage and dispensing of flammable and combustible liquids on farms and construction sites.** Permanent and temporary storage and dispensing of Class I and II liquids for private use on farms and rural areas and at construction sites, earth-moving projects, gravel pits or borrow pits shall be in accordance with Sections 5706.2.1 through 5706.2.8.1.

**Exception:** Storage and use of fuel oil and containers connected with oil-burning equipment regulated by Section 603 and the *International Mechanical Code*.

❖ These provisions cover both temporary and permanent storage and dispensing of Class I and II liquids, primarily in outdoor locations.

The exception covers storage and use of fuel oil for building service equipment, which is governed by other sections of the code as well as other codes.

**5706.2.1 Combustibles and open flames near tanks.** Storage areas shall be kept free from weeds and extraneous combustible material. Open flames and smoking are prohibited in flammable or *combustible liquid* storage areas.

❖ The area around storage tanks is to be free of combustibles and ignition sources.

**5706.2.2 Marking of tanks and containers.** Tanks and containers for the storage of liquids above ground shall be conspicuously marked with the name of the product that they

contain and the words: FLAMMABLE—KEEP FIRE AND FLAME AWAY. Tanks shall bear the additional marking: KEEP 50 FEET FROM BUILDINGS.

- ❖ When hazardous liquids are stored in above-ground storage tanks, signs containing safety information and warnings to keep ignition sources from the tanks are to be placed on the tanks.

**5706.2.3 Containers for storage and use.** Metal containers used for storage of Class I or II liquids shall be in accordance with DOTn requirements or shall be of an *approved* design.

Discharge devices shall be of a type that do not develop an internal pressure on the container. Pumping devices or *approved* self-closing faucets used for dispensing liquids shall not leak and shall be well-maintained. Individual containers shall not be interconnected and shall be kept closed when not in use.

Containers stored outside of buildings shall be in accordance with Section 5704 and the *International Building Code*.

- ❖ Individual containers for the storage of Class I and II liquids are to be DOT approved or approved for use with these liquids. To prevent leaks and spills, the discharge devices must be designed for use with Class I and II liquids. The storage of individual containers outside of a building is to be treated as outside storage under Section 5704.

**5706.2.4 Permanent and temporary tanks.** The capacity of permanent above-ground tanks containing Class I or II liquids shall not exceed 1,100 gallons (4164 L). The capacity of temporary above-ground tanks containing Class I or II liquids shall not exceed 10,000 gallons (37 854 L). Tanks shall be of the single-compartment design.

**Exception:** Permanent above-ground tanks of greater capacity that meet the requirements of Section 5704.2.

- ❖ Above-ground, single-compartment storage tanks must be used for permanent or temporary storage of Class I and II liquids. Permanent storage is limited to 1,100 gallons (3785 L) where temporary storage is limited to 10,000 gallons (37 854 L).

The exception covers permanent storage of quantities larger than 1,100 gallons (3785 L). Requirements for permanent storage of larger quantities are contained in Section 5704.2.

**5706.2.4.1 Fill-opening security.** Fill openings shall be equipped with a locking closure device. Fill openings shall be separate from vent openings.

- ❖ Security to prevent the dispensing of flammable and combustible liquids is provided by a locking device on the fill opening. Fill openings are separated from vent openings so that locking does not affect the operation of the vent openings.

**5706.2.4.2 Vents.** Tanks shall be provided with a method of normal and emergency venting. Normal vents shall be in accordance with Section 5704.2.7.3.

Emergency vents shall be in accordance with Section 5704.2.7.4. Emergency vents shall be arranged to discharge

in a manner that prevents localized overheating or flame impingement on any part of the tank in the event that vapors from such vents are ignited.

- ❖ The need for normal venting and emergency venting is no different than required on other storage tanks. The requirements of Sections 5702.7.3 and 5702.7.4 apply to venting the storage tanks.

**5706.2.4.3 Location.** Tanks containing Class I or II liquids shall be kept outside and not less than 50 feet (15 240 mm) from buildings and combustible storage. Additional distance shall be provided where necessary to ensure that vehicles, equipment and containers being filled directly from such tanks will not be less than 50 feet (15 240 mm) from structures, haystacks or other combustible storage.

- ❖ The clearance required between above-ground storage tanks containing Class I and II liquids, combustible storage and other structures is 50 feet (15 240 mm). Vehicles, equipment or containers using the storage tank are to have a clearance of 50 feet (15 240 mm) from these same ignition sources and fuel sources.

**5706.2.4.4 Locations where above-ground tanks are prohibited.** The storage of Class I and II liquids in above-ground tanks is prohibited within the limits established by law as the limits of districts in which such storage is prohibited (see Section 3 of the Sample Legislation for Adoption of the *International Fire Code* on page xxi).

- ❖ This section enables the adopting jurisdiction to prohibit the installation of above-ground tanks in certain geographic areas by enumerating them in the adopting legislation. Page xxi of the code (ix in this volume) shows a sample ordinance containing blank space for the jurisdiction to fill in describing the particular areas where above-ground tank installations are to be prohibited.

**5706.2.5 Type of tank.** Tanks shall be provided with top openings only or shall be elevated for gravity discharge.

- ❖ Above-ground storage tanks are to be top-opening or gravity discharge tanks.

**5706.2.5.1 Tanks with top openings only.** Tanks with top openings shall be mounted in accordance with either of the following:

1. On well-constructed metal legs connected to shoes or runners designed so that the tank is stabilized and the entire tank and its supports can be moved as a unit.
2. For stationary tanks, on a stable base of timbers or blocks approximately 6 inches (152 mm) in height that prevents the tank from contacting the ground.

- ❖ Above-ground storage tanks with top openings must be on stable supports of metal or wood. The above-ground storage tank shell is not to be in contact with the ground. Stability is extremely important because movement of the tank could damage the tank shell or connected piping, creating a leak.

**5706.2.5.1.1 Pumps and fittings.** Tanks with top openings only shall be equipped with a tightly and permanently

attached, *approved* pumping device having an *approved* hose of sufficient length for filling vehicles, equipment or containers to be served from the tank. Either the pump or the hose shall be equipped with a padlock to its hanger to prevent tampering. An effective antisiphoning device shall be included in the pump discharge unless a self-closing nozzle is provided. Siphons or internal pressure discharge devices shall not be used.

❖ Above-ground storage tanks with top openings must be equipped with an approved, permanently attached tight-fitting pump and hose. Pumps must be secured against unauthorized use and designed to prevent siphoning through the pump.

**5706.2.5.2 Tanks for gravity discharge.** Tanks with a connection in the bottom or the end for gravity-dispensing liquids shall be mounted and equipped as follows:

1. Supports to elevate the tank for gravity discharge shall be designed to carry all required loads and provide stability.
2. Bottom or end openings for gravity discharge shall be equipped with a valve located adjacent to the tank shell that will close automatically in the event of fire through the operation of an effective heat-activated releasing device. Where this valve cannot be operated manually, it shall be supplemented by a second, manually operated valve.

The gravity discharge outlet shall be provided with an *approved* hose equipped with a self-closing valve at the discharge end of a type that can be padlocked to its hanger.

❖ Above-ground storage tanks for gravity discharge must be elevated on stable supports capable of supporting all required loads. Valves for bottom and end openings must be located adjacent to the tank shell. These valves are to be heat-activated valves that must close in case of a fire. The valve is to prevent the tank from dispensing its content through one of the tank openings. If the heat-activated valve cannot be manually operated, a second manually operable valve must be installed. The hose must be secured to prevent unauthorized operation.

**5706.2.6 Spill control drainage control and diking.** Indoor storage and dispensing areas shall be provided with spill control and drainage control as set forth in Section 5703.4. Outdoor storage areas shall be provided with drainage control or diking as set forth in Section 5704.2.10.

❖ Indoor above-ground storage tanks must be equipped to control leaks and spills to prevent the spread of liquid and vapors. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled. Section 5004.3 discusses mechanical and natural exhaust systems. The exhaust system is to remove the vapors to prevent them from accumulating in concentrations in the flammable range of the vapor.

Outdoor above-ground storage tanks must use

dikes and drainage to control leaks or spills from a tank. The flammable and combustible liquids must be collected in a manner that will not endanger other tanks, properties or waterways.

The fire code official has the authority to consider installations where the use of drainage and dikes may not be necessary, such as listed secondary containment tanks in lieu of drainage control or dikes. The secondary containment system in these tanks is considered equivalent to drainage and diking.

**5706.2.7 Portable fire extinguishers.** Portable fire extinguishers with a minimum rating of 20-B:C and complying with Section 906 shall be provided where required by the *fire code official*.

❖ Portable fire extinguishers must be in clear view and within 50 feet (15 240 mm) of the storage tank. The 20-B:C portable fire extinguisher is for the control of small flammable liquid fires and electrical fires.

**5706.2.8 Dispensing from tank vehicles.** Where *approved*, liquids used as fuels are allowed to be transferred from tank vehicles into the tanks of motor vehicles or special equipment, provided:

1. The tank vehicle's specific function is that of supplying fuel to motor vehicle fuel tanks.
2. The dispensing hose does not exceed 100 feet (30 480 mm) in length.
3. The dispensing nozzle is an *approved* type.
4. The dispensing hose is properly placed on an *approved* reel or in a compartment provided before the tank vehicle is moved.
5. Signs prohibiting smoking or open flames within 25 feet (7620 mm) of the vehicle or the point of refueling are prominently posted on the tank vehicle.
6. Electrical devices and wiring in areas where fuel dispensing is conducted are in accordance with NFPA 70.
7. Tank vehicle-dispensing equipment is operated only by designated personnel who are trained to handle and dispense motor fuels.
8. Provisions are made for controlling and mitigating unauthorized discharges.

❖ The dispensing of fuel at a farm or construction site may be from a tanker to a vehicle or equipment. Dispensing fuel using a tanker requires the tanker to be designed and equipped specifically for fueling other vehicles and equipment. The dispensing line cannot exceed 100 feet (30 480 mm). The tanker operator is responsible for the dispensing line and the tanker, so these two items need to be in the same area. The dispensing cannot be done around an ignition source, such as smoking, or electrical equipment that is not classified for use in hazardous locations. Note that these provisions apply to all classes of liquid fuel, not Class II and III only, as in Section 5706.5.4.5.

**5706.2.8.1 Location.** Dispensing from tank vehicles shall be conducted not less than 50 feet (15 240 mm) from structures or combustible storage.

- ❖ Fuel must be dispensed at least 50 feet (15 240 mm) from a structure or combustible storage to prevent the accumulation of vapor-air mixtures, control ignition sources and to minimize the potential loss of property.

**5706.3 Well drilling and operating.** Wells for oil and natural gas shall be drilled and operated in accordance with Sections 5706.3.1 through 5706.3.8.

- ❖ The drilling and operation of a well may allow the escape of vapors from petroleum products. Well drilling and operation are essential for the extraction of petroleum products. The requirements are to prevent the vapor-air mixture from reaching the LFL, to prevent ignition sources from being in the immediate vicinity and other functions to control the hazard.

**5706.3.1 Location.** The location of wells shall comply with Sections 5706.3.1.1 through 5706.3.1.3.2.

- ❖ The location of wells is regulated to permit the dilution of any vapor-air mixtures that may escape the well head or facilities, prevent ignition sources from being in close proximity and other safety and security to control the hazards created by the well drilling and production operation.

**5706.3.1.1 Storage tanks and sources of ignition.** Storage tanks or boilers, fired heaters, open-flame devices or other sources of ignition shall not be located within 25 feet (7620 mm) of well heads. Smoking is prohibited at wells or tank locations except as designated and in *approved* posted areas.

**Exception:** Engines used in the drilling, production and serving of wells.

- ❖ Sources of ignition from equipment and open flame must be kept a minimum of 25 feet (7620 mm) from a well head. The distance provides an area for any vapors leaking from the well head to dilute to a vapor-air mixture below the LFL.

Only equipment necessary for the drilling, installation and production of the well is permitted. These engines are designed for this use.

**5706.3.1.2 Streets and railways.** Wells shall not be drilled within 75 feet (22 860 mm) of any dedicated public street, highway or nearest rail of an operating railway.

- ❖ Sources of ignition from vehicle and rail traffic are to be kept a minimum of 75 feet (22 860 mm) from a well head. Vehicle traffic can produce sources of ignition from either the vehicle or the passengers. The rail traffic can produce sources of ignition by engine, brakes or personnel. The distance provides an area for any vapors leaking from the well head to dilute to a vapor-air mixture below the LFL.

**5706.3.1.3 Buildings.** Wells shall not be drilled within 100 feet (30 480 mm) of buildings not necessary to the operation of the well.

- ❖ Sources of ignition from buildings are to be kept a minimum of 100 feet (30 480 mm) from a well head. Building equipment and occupancy can become sources of ignition. The building also represents a potential for loss of life and property. The distance provides an area for any vapors leaking from the well head to dilute to a vapor-air mixture below the LFL.

The separation distance also protects buildings and their occupants from hazards associated with the well and its operation.

A building necessary for operation of a well need not be remote from the well head, but it should be constructed and maintained to prevent it from becoming an ignition source.

**5706.3.1.3.1 Group A, E or I buildings.** Wells shall not be drilled within 300 feet (91 440 mm) of buildings with an occupancy in Group A, E or I.

- ❖ Sources of ignition from a Group A, E, or I occupancy must be kept a minimum of 300 feet (91 440 mm) from a well head. Building equipment and occupancy can become sources of ignition. Because these occupancies also represent a potential for loss of life and property, the clearance has been increased over that required for other occupancies. The distance provides an area for any vapors leaking from the well head to dilute to a vapor-air mixture below the LFL.

**5706.3.1.3.2 Existing wells.** Where wells are existing, buildings shall not be constructed within the distances set forth in Section 5706.3.1 for separation of wells or buildings.

- ❖ The same problems exist regardless of whether the well head is installed first or the building is constructed first. The code regulates whichever is built second. The well head clearance to the building is to be maintained.

**5706.3.2 Waste control.** Control of waste materials associated with wells shall comply with Sections 5706.3.2.1 and 5706.3.2.2.

- ❖ Liquids containing petroleum or its products are to be disposed of according to federal and state laws and any local ordinances.

**5706.3.2.1 Discharge on a street or water channel.** Liquids containing crude petroleum or its products shall not be discharged into or on streets, highways, drainage canals or ditches, storm drains or flood control channels.

- ❖ The discharge of liquids containing petroleum or its products is prohibited. The unregulated discharge of liquids containing petroleum or its products can place flammable or combustible liquids and gases into contact with ignition sources. The liquids and their vapors also can become environmental problems and can cause health concerns.

**5706.3.2.2 Discharge and combustible materials on ground.** The surface of the ground under, around or near wells, pumps, boilers, oil storage tanks or buildings shall be kept free from oil, waste oil, refuse or waste material.

❖ The discharge of liquids containing petroleum or its products is prohibited. The unregulated discharge of liquids containing petroleum or its products can place flammable or combustible liquids and gases into contact with ignition sources and become a source of environmental contamination and health hazards.

**5706.3.3 Sumps.** Sumps associated with wells shall comply with Sections 5706.3.3.1 through 5706.3.3.3.

❖ Sumps and basins may be necessary to temporarily store drilling materials that may contain petroleum products. The use of sumps and basins is regulated to control their size, service life and security.

**5706.3.3.1 Maximum width.** Sumps or other basins for the retention of oil or petroleum products shall not exceed 12 feet (3658 mm) in width.

❖ The maximum width of 12 feet (3658 mm) for a sump or basin keeps the surface area of the sump or basin at a size that will help in diluting the vapor-air mixture to below the LFL and that is readily accessible to fire-fighting equipment. The narrow width allows the vapors of the petroleum products to diffuse with a greater volume of air than if the sump or basin were allowed to be larger.

**5706.3.3.2 Backfilling.** Sumps or other basins for the retention of oil or petroleum products larger than 6 feet by 6 feet by 6 feet (1829 mm by 1829 mm by 1829 mm) shall not be maintained longer than 60 days after the cessation of drilling operations.

❖ The temporary storage of oil or petroleum products in sumps or basins larger than 6 feet by 6 feet by 6 feet (1829 mm by 1829 mm by 1829 mm) is restricted to no more than 60 days. Drilling operations may require that materials containing petroleum products be stored in a sump or basin. This open storage may allow the vapors from the petroleum products to mix with air, creating a hazard. To control the hazard, the use of a sump or basin is restricted to a maximum of 60 days. The storage of oil or petroleum products in volumes greater than the capacity of these sumps or basins needs to be equipped with safety features to control the hazard.

**5706.3.3.3 Security.** Sumps, diversion ditches and depressions used as sumps shall be securely fenced or covered.

❖ Security for the open storage of oil or petroleum products in sumps, basins and ditches is needed to prevent unauthorized access. Individuals may not realize the hazard presented by this open storage and accidentally introduce ignition sources.

**5706.3.4 Prevention of blowouts.** Protection shall be provided to control and prevent the blowout of a well. Protection

equipment shall meet federal, state and other applicable jurisdiction requirements.

❖ A blowout is the uncontrolled release of oil, gas or water from a well. Pressure relief equipment must be installed and maintained on a drilling apparatus to reduce the likelihood of an uncontrolled release of oil, gas or water. Oil vapor or gas escaping in an uncontrolled manner poses an extreme hazard and can generate enough energy to ignite during its release, which can lead to the destruction of the drilling apparatus or the site itself with a corresponding potential for loss of life. Federal and state regulations govern the protective equipment required to prevent blowouts.

**5706.3.5 Storage tanks.** Storage of flammable or *combustible liquids* in tanks shall be in accordance with Section 5704. Oil storage tanks or groups of tanks shall have posted in a conspicuous place, on or near such tank or tanks, an *approved* sign with the name of the *owner* or operator, or the lease number and the telephone number where a responsible person can be reached at any time.

❖ The storage requirements for flammable and combustible liquids at a well head are identical to those for any other storage of flammable and combustible liquids. Clearances, security, corrosion protection, drainage, diking, signing, etc., are to control ignition sources, combustibles, leaks, spills, etc.

**5706.3.6 Soundproofing.** Where soundproofing material is required during oil field operations, such material shall be noncombustible.

❖ The operation of drilling, pumping and dispensing equipment may create noise that needs to be reduced. Soundproofing material must not add a fuel source around the flammable or combustible liquids. Combustible soundproofing is to be used only at locations that are beyond the distances for the clearance between flammable and combustible liquids and combustibles.

**5706.3.7 Signs.** Well locations shall have posted in a conspicuous place on or near such tank or tanks an *approved* sign with the name of the *owner* or operator, name of the leasee or the lease number, the well number and the telephone number where a responsible person can be reached at any time. Such signs shall be maintained on the premises from the time materials are delivered for drilling purposes until the well is abandoned.

❖ Well heads may or may not have personnel on site, so it may be necessary to contact the operator/owner. The signs need to provide sufficient information so the operator/owner can be notified of any problems with the site.

**5706.3.8 Field-loading racks.** Field-loading racks shall be in accordance with Section 5706.5.

❖ See the commentary to Section 5706.5.

**5706.4 Bulk plants or terminals.** Portions of properties where flammable and *combustible liquids* are received by tank vessels, pipelines, tank cars or tank vehicles and stored or blended in bulk for the purpose of distribution by tank vessels, pipelines, tanks cars, tank vehicles or containers shall be in accordance with Sections 5706.4.1 through 5706.4.10.4.

❖ Bulk plants and terminals are used for the blending or transferring of large volumes of flammable and combustible liquids. Besides normally involving large quantities of flammable and combustible liquids, these facilities can create numerous opportunities for leaks, spills and the escape of vapors.

**5706.4.1 Building construction.** Buildings shall be constructed in accordance with the *International Building Code*.

❖ These facilities are hazardous occupancies divided into Group H-2 or H-3. Sections 414 and 415 of the IBC contain guidance for determining the construction requirements for these two occupancies.

**5706.4.2 Means of egress.** Rooms in which liquids are stored, used or transferred by pumps shall have *means of egress* arranged to prevent occupants from being trapped in the event of fire.

❖ The means of egress from rooms where flammable or combustible liquids are present must be an escape route for personnel that cannot be blocked in case of a fire. This may require having more than one independent escape route or having a short travel distance to a door exiting the room. Doors exiting rooms should swing in the direction of exit travel.

**5706.4.3 Heating.** Rooms in which Class I liquids are stored or used shall be heated only by means not constituting a source of ignition, such as steam or hot water. Rooms containing heating appliances involving sources of ignition shall be located and arranged to prevent entry of flammable vapors.

❖ Heating units that use open flames and other ignition sources must be separated from areas where flammable or combustible liquids are present or where vapors from these liquids can migrate. The low flash point for Class I liquids requires that where Class I liquid is present, either steam or hot water must be used as the heat source.

**5706.4.4 Ventilation.** Ventilation shall be provided for rooms, buildings and enclosures in which Class I liquids are pumped, used or transferred. Design of ventilation systems shall consider the relatively high specific gravity of the vapors. Where natural ventilation is used, adequate openings in outside walls at floor level, unobstructed except by louvers or coarse screens, shall be provided. Where natural ventilation is inadequate, mechanical ventilation shall be provided in accordance with the *International Mechanical Code*.

❖ The low flash point for Class I liquids requires that where Class I liquid is present the area be ventilated to prevent the accumulation of a vapor-air mixture above the LFL. Ventilation can be either mechanical

or natural. Because the vapors from Class I liquids are heavier than air, the ventilation must remove the air at the floor level. Natural ventilation must be to the outdoors.

**5706.4.4.1 Basements and pits.** Class I liquids shall not be stored or used within a building having a *basement* or pit into which flammable vapors can travel, unless such area is provided with ventilation designed to prevent the accumulation of flammable vapors therein.

❖ The vapors from Class I liquids are heavier than air, so these vapors can settle from the upper floors and accumulate in a basement or pit. In a building with a basement or pit that has any connection between the basement or pit and upper floors, the basement or pit is not to be used for the storage or mixing of Class I liquids. The vapors from Class I liquids may settle in the basement or pit through openings for mechanical systems or that are part of an egress path, creating a hazard. Unless there is a mechanical or natural ventilation system that is adequate for removing accumulated vapors from the basement or pit, the building cannot be used for the storage or mixing of Class I liquids.

**5706.4.4.2 Dispensing of Class I liquids.** Containers of Class I liquids shall not be drawn from or filled within buildings unless a provision is made to prevent the accumulation of flammable vapors in hazardous concentrations. Where mechanical ventilation is required, it shall be kept in operation while flammable vapors could be present.

❖ Containers of Class I liquids cannot be dispensed or filled in a building unless ventilation is installed to remove accumulated vapors. To make certain that vapors do not accumulate, any mechanical ventilation system must operate continuously or whenever containers of Class I liquids are open.

**5706.4.5 Storage.** Storage of Class I, II and IIIA liquids in bulk plants shall be in accordance with the applicable provisions of Section 5704.

❖ The potential hazards of storing Class I, II and IIIA liquids are the same for bulk plants and terminals as for any other facility. The requirements for storage are covered in Section 5704.

**5706.4.6 Overfill protection of Class I and II liquids.** Manual and automatic systems shall be provided to prevent overfill during the transfer of Class I and II liquids from mainline pipelines and marine vessels in accordance with API 2350.

❖ Overfill protection must comply with API 2350. This standard is limited to above-ground tanks that receive liquids from main pipelines or marine vessels. The standard accomplishes overfill protection by awareness of available tank capacity and inventory and careful monitoring and control of product movement.

**5706.4.7 Wharves.** This section shall apply to all wharves, piers, bulkheads and other structures over or contiguous to navigable water having a primary function of transferring liq-

uid cargo in bulk between shore installations and tank vessels, ships, barges, lighter boats or other mobile floating craft.

**Exception:** Marine motor fuel-dispensing facilities in accordance with Chapter 23.

❖ This section regulates the transfer of flammable and combustible liquids in bulk quantities between a shore installation and any marine vessel or other floating craft, except for marine motor fuel-dispensing facilities, which are covered in Chapter 23.

**5706.4.7.1 Transferring approvals.** Handling packaged cargo of liquids, including full and empty drums, bulk fuel and stores, over a wharf during cargo transfer shall be subject to the approval of the wharf supervisor and the senior deck officer on duty.

❖ The handling and transferring of flammable and combustible liquids, including any container that contains or has contained these liquids, must be approved by the personnel responsible for the wharf. This will usually be the wharf supervisor or senior deck officer. Because these materials represent a potential hazard if mishandled, the person in authority must be aware of the potential hazard and approve the process being used.

**5706.4.7.2 Transferring location.** Wharves at which liquid cargoes are to be transferred in bulk quantities to or from tank vessels shall be not less than 100 feet (30 480 mm) from any bridge over a navigable waterway; or from an entrance to, or superstructure of, any vehicular or railroad tunnel under a waterway. The termination of the fixed piping used for loading or unloading at a wharf shall be not less than 200 feet (60 960 mm) from a bridge or from an entrance to, or superstructures of, a tunnel.

❖ Transportation facilities on a wharf must be protected by separation from public thoroughways. The separation distance required for vessel loading or unloading is 100 feet (30 480 mm). Fixed piping must terminate 200 feet (60 960 mm) from the same thoroughways.

**5706.4.7.3 Superstructure and decking material.** Superstructure and decking shall be designed for the intended use. Decking shall be constructed of materials that will afford the desired combination of flexibility, resistance to shock, durability, strength and *fire resistance*.

❖ The wharf superstructure and decking materials have to be selected to withstand normal loads, impact loads, fire exposure, environmental factors, etc.

**5706.4.7.4 Tanks allowed.** Tanks used exclusively for ballast water or Class II or III liquids are allowed to be installed on suitably designed wharves.

❖ Tanks other than tanks used for Class I liquids can be installed on a wharf if the wharf is designed for this purpose.

**5706.4.7.5 Transferring equipment.** Loading pumps capable of building up pressures in excess of the safe working pressure of cargo hose or loading arms shall be provided with bypasses, relief valves or other arrangements to protect the

loading facilities against excessive pressure. Relief devices shall be tested not less than annually to determine that they function satisfactorily at their set pressure.

❖ Pump systems must be designed so that excess pressure cannot be created in the piping and storage system. If excess pressure develops and is not relieved, the equipment or piping and storage system can be damaged. A damaged system could develop a leak.

**5706.4.7.6 Piping, valves and fittings.** Piping valves and fittings shall be in accordance with Section 5703.6 except as modified by the following:

1. Flexibility of piping shall be ensured by appropriate layout and arrangement of piping supports so that motion of the wharf structure resulting from wave action, currents, tides or the mooring of vessels will not subject the pipe to repeated excessive strain.
2. Pipe joints that depend on the friction characteristics of combustible materials or on the grooving of pipe ends for mechanical continuity of piping shall not be used.
3. Swivel joints are allowed in piping to which hoses are connected and for articulated, swivel-joint transfer systems, provided the design is such that the mechanical strength of the joint will not be impaired if the packing materials fail such as by exposure to fire.
4. Each line conveying Class I or II liquids leading to a wharf shall be provided with a readily accessible block valve located on shore near the approach to the wharf and outside of any diked area. Where more than one line is involved, the valves shall be grouped in one location.
5. Means shall be provided for easy access to cargo line valves located below the wharf deck.
6. Piping systems shall contain a sufficient number of valves to operate the system properly and to control the flow of liquid in normal operation and in the event of physical damage.
7. Piping on wharves shall be bonded and grounded where Class I and II liquids are transported. Where excessive stray currents are encountered, insulating joints shall be installed. Bonding and grounding connections on piping shall be located on the wharf side of hose riser insulating flanges, where used, and shall be accessible for inspection.
8. Hose or articulated swivel-joint pipe connections used for cargo transfer shall be capable of accommodating the combined effects of change in draft and maximum tidal range, and mooring lines shall be kept adjusted to prevent surge of the vessel from placing stress on the cargo transfer system.
9. Hoses shall be supported to avoid kinking and damage from chafing.

❖ The general requirements of Section 5703.6 apply to the piping on a wharf, with the exception of specific

requirements that are unique to the design and operation of a wharf, as indicated in this section:

1. Wharves, especially floating wharves, need flexible piping that can withstand wharf movement.
2. Slip-joint pipe connections and threaded connections are prohibited. The flexible piping required to handle the wharf's movement may move enough to cause these types of joints to loosen. A loose joint can create a leak or a spill.
3. Swivel joints are necessary for connections between wharves, between the wharf and land, and between the wharf and marine vessels. These joints are to be designed to withstand loads placed on them even if the packing material used to seal the joint fails.
4. Lines carrying Class I and II liquids require a block valve on each line feeding the wharf. The block valve is to be near the wharf and outside of the dike area. A block valve is used to isolate the line from the wharf.
5. Piping under a wharf used to transfer flammable and combustible liquids must be accessible. If these lines are not accessible, it may be difficult or impossible to inspect, maintain or provide fire protection to these lines.
6. Valves must be installed in the piping system so that sections of the system can be isolated for maintenance or repairs or to stop the transfer of flammable and combustible liquids in case of leaks, spills or fire.
7. Piping must be bonded to prevent static sparks or sparks from the electrical equipment.
8. Swivel joints must be protected from loads caused by movement of the wharf relative to movement of the marine vessel.
9. Hoses must be maintained to prevent damage.

**5706.4.7.7 Loading and unloading.** Loading or discharging shall not commence until the wharf superintendent and officer in charge of the tank vessel agree that the tank vessel is properly moored and connections are properly made.

❖ Section 5706.4.7.1 requires approval from the individual responsible for the wharf for transferring flammable and combustible liquids over the wharf. This section requires that this same individual approve the mooring of the marine vessel before transfer begins. Failure of the moorings or excessive movement of the marine vessel can damage the piping.

**5706.4.7.8 Mechanical work.** Mechanical work shall not be performed on the wharf during cargo transfer, except under special authorization by the *fire code official* based on a

review of the area involved, methods to be employed and precautions necessary.

❖ Work on the wharf or transfer equipment and piping are prohibited during the transfer of flammable or combustible liquids. Work can introduce an ignition source or possible damage to the equipment or piping system.

**5706.4.8 Sources of ignition.** Class I, II or IIIA liquids shall not be used, drawn or dispensed where flammable vapors can reach a source of ignition. Smoking shall be prohibited except in designated locations. "No Smoking" signs complying with Section 310 shall be conspicuously posted where a hazard from flammable vapors is normally present.

❖ One of the principal safety measures for using flammable and combustible liquids is to keep sources of ignition away from the liquids.

**5706.4.9 Drainage control.** Loading and unloading areas shall be provided with drainage control in accordance with Section 5704.2.10.

❖ Flammable and combustible liquids that leak or spill from a tank must be controlled by dikes and drainage. The flammable and combustible liquids are to be collected in a manner that will not endanger other tanks, properties or waterways. The fire code official has the authority to consider installations where the use of drainage and dikes may not be necessary. Listed secondary containment tanks need not be surrounded by drainage control or dikes. The secondary containment system in these tanks is considered equivalent to drainage and diking.

**5706.4.10 Fire protection.** Fire protection shall be in accordance with Chapter 9 and Sections 5706.4.10.1 through 5706.4.10.4.

❖ Fire protection complying with Chapter 9 is required for wharves.

**5706.4.10.1 Portable fire extinguishers.** Portable fire extinguishers with a rating of not less than 20-B and complying with Section 906 shall be located within 75 feet (22 860 mm) of hose connections, pumps and separator tanks.

❖ Portable fire extinguishers must be located within 75 feet (22 860 mm) of hose connections, pumps and separator tanks. These locations are where a possible leak can occur and a portable fire extinguisher may be adequate in preventing a fire or controlling a small, flammable-liquid fire. The 20-B portable fire extinguisher is for the control of a small, flammable-liquid fire.

**5706.4.10.2 Fire hoses.** Where piped water is available, ready-connected fire hose in a size appropriate for the water supply shall be provided in accordance with Section 905 so that manifolds where connections are made and broken can be reached by not less than one hose stream.

❖ If the fire control system uses piped water, a fire hose of adequate size for the piped water and complying

with Section 905 must be available. The fire hose must be capable of washing down manifolds in case of a leak or spill or for fighting a fire at the manifold.

**5706.4.10.3 Obstruction of equipment.** Material shall not be placed on wharves in such a manner that would obstruct access to fire-fighting equipment or important pipeline control valves.

- ❖ Access for fire equipment and to valves for isolating and controlling flammable and combustible liquids must be kept clear. Obstruction would prevent or slow any response to a leak, spill or fire.

**5706.4.10.4 Fire apparatus access.** Where the wharf is accessible to vehicular traffic, an unobstructed fire apparatus access road to the shore end of the wharf shall be maintained in accordance with Chapter 5.

- ❖ Wharves that are accessible to vehicle traffic are to be made accessible for fire department equipment. The access requirements are in Chapter 5. Where vehicle access to the wharf does not exist, fire department equipment access is not required.

**5706.5 Bulk transfer and process transfer operations.** Bulk transfer and process transfer operations shall be *approved* and be in accordance with Sections 5706.5.1 through 5706.5.4.5. Motor fuel-dispensing facilities shall comply with Chapter 23.

- ❖ This section gives the fire code official the authority to require approval of bulk transfer and process transfer operations.

**5706.5.1 General.** The provisions of Sections 5706.5.1.1 through 5706.5.1.18 shall apply to bulk transfer and process transfer operations; Sections 5706.5.2 and 5706.5.2.1 shall apply to bulk transfer operations; Sections 5706.5.3 through 5706.5.3.3 shall apply to process transfer operations and Sections 5706.5.4 through 5706.5.4.5 shall apply to dispensing from tank vehicles and tank cars.

- ❖ Facilities that are used for bulk transferring, bulk processing and bulk dispensing to tank vehicles and tank cars are covered by these sections.

**5706.5.1.1 Location.** Bulk transfer and process transfer operations shall be conducted in *approved* locations. Tank cars shall be unloaded only on private sidings or railroad-siding facilities equipped for transferring flammable or *combustible liquids*. Tank vehicle and tank car transfer facilities shall be separated from buildings, above-ground tanks, combustible materials, *lot lines*, public streets, public alleys or *public ways* by a distance of 25 feet (7620 mm) for Class I liquids and 15 feet (4572 mm) for Class II and III liquids measured from the nearest position of any loading or unloading valve. Buildings for pumps or shelters for personnel shall be considered part of the transfer facility.

- ❖ The volume of flammable and combustible liquids being transferred and processed requires that the location be protected from ignition sources. This is accomplished by maintaining minimum clearance

between the transfer and process operation and buildings, property lines, streets, etc.

**5706.5.1.2 Weather protection canopies.** Where weather protection canopies are provided, they shall be constructed in accordance with Section 5004.13. Weather protection canopies shall not be located within 15 feet (4572 mm) of a building or combustible material or within 25 feet (7620 mm) of building openings, *lot lines*, public streets, public alleys or *public ways*.

- ❖ This section makes clear that an open structure consisting of only a noncombustible roof structure is considered outdoor storage. A structure with no walls and only a noncombustible roof provides sufficient ventilation for the storage area to be treated as outdoor storage. Separation from buildings and openings is needed to prevent the vapors from flammable and combustible liquids from being exposed to an ignition source. These separation requirements also limit potential property and life losses.

**5706.5.1.3 Ventilation.** Ventilation shall be provided to prevent accumulation of vapors in accordance with Section 5705.3.7.5.1.

- ❖ The requirements of this section for a mechanical ventilation system are identical to those in Section 5004.3. The mechanical ventilation system must remove vapors to prevent accumulation in concentrations in the flammable range for the flammable and combustible liquids being used. Natural ventilation complying with Section 5004.3 that can be demonstrated to be effective for the flammable and combustible liquids being used is an acceptable alternative.

**5706.5.1.4 Sources of ignition.** Sources of ignition shall be controlled or eliminated in accordance with Section 5003.7.

- ❖ Smoking and open flames are strictly limited around flammable and combustible liquids. Section 5003.7 prohibits smoking or open flames within 25 feet (7620 mm) of outdoor storage of flammable and combustible liquids and anywhere indoors where there are flammable and combustible liquids or where vapors from flammable and combustible liquids may occur.

**5706.5.1.5 Spill control and secondary containment.** Areas where transfer operations are located shall be provided with spill control and secondary containment in accordance with Section 5703.4. The spill control and secondary containment system shall have a design capacity capable of containing the capacity of the largest tank compartment located in the area where transfer operations are conducted. Containment of the rainfall volume specified in Section 5004.2.2.6 is not required.

- ❖ Where flammable or combustible liquids are present, spills must be controlled to prevent the spread of liquid and vapors. Section 5004.2 discusses the use of liquid-tight floors, curbs, dikes and drainage systems to divert the liquid to a location where it can be contained and safely handled. Section 5004.3 discusses

mechanical and natural exhaust systems for indoor facilities. The exhaust system must remove the vapors to prevent them from accumulating in concentrations in the flammable range. The diked area must have sufficient capacity to contain the largest spillage of flammable and combustible liquids that can be released from the largest tank. This would be the volume of the largest tank that extends above the top of the dike.

**5706.5.1.6 Fire protection.** Fire protection shall be in accordance with Section 5703.2.

❖ The requirements of Chapter 9 apply to flammable and combustible liquids. Fire protection is a principal means of preventing and controlling the spread of a fire.

**5706.5.1.7 Static protection.** Static protection shall be provided to prevent the accumulation of static charges during transfer operations. Bonding facilities shall be provided during the transfer through open domes where Class I liquids are transferred, or where Class II and III liquids are transferred into tank vehicles or tank cars that could contain vapors from previous cargoes of Class I liquids.

Protection shall consist of a metallic bond wire permanently electrically connected to the fill stem. The fill pipe assembly shall form a continuous electrically conductive path downstream from the point of bonding. The free end of such bond wire shall be provided with a clamp or equivalent device for convenient attachment to a metallic part in electrical contact with the cargo tank of the tank vehicle or tank car. For tank vehicles, protection shall consist of a flexible bond wire of adequate strength for the intended service and the electrical resistance shall not exceed 1 megohm. For tank cars, bonding shall be provided where the resistance of a tank car to ground through the rails is 25 ohms or greater.

Such bonding connection shall be fastened to the vehicle, car or tank before dome covers are raised and shall remain in place until filling is complete and all dome covers have been closed and secured.

**Exceptions:**

1. Where vehicles and cars are loaded exclusively with products not having a static-accumulating tendency, such as asphalt, cutback asphalt, most crude oils, residual oils and water-miscible liquids.
2. Where Class I liquids are not handled at the transfer facility and the tank vehicles are used exclusively for Class II and III liquids.
3. Where vehicles and cars are loaded or unloaded through closed top or bottom connections whether the hose is conductive or nonconductive.

Filling through open domes into the tanks of tank vehicles or tank cars that contain vapor-air mixtures within the flammable range, or where the liquid being filled can form such a mixture, shall be by means of a downspout which extends to near the bottom of the tank.

❖ Static electricity will spark between surfaces with different electrical potential. Vehicles that are or may

have been used to carry Class I liquids are to be bonded. Vehicles with open domes are to be bonded before the dome is opened. Bonding to control static electricity can be done using wires, ground cables, metal piping or other similar means that will carry current. Open dome tanks must use a downspout that extends to near the bottom of the tank. This downspout will reduce the mixing of the flammable or combustible liquid with air.

Bonding to control static electricity is not necessary where static electricity is not an issue or a static spark would not act as an ignition source. Three exceptions are given to this section:

1. Combustible liquids whose viscosity prevents the accumulation of static electricity.
2. Facilities and vehicles that do not handle Class I liquids.
3. Vehicles that use a closed system for loading and unloading flammable and combustible liquids. These closed systems prevent the vapors of flammable and combustible liquids from mixing with air to form a vapor-air mixture that can reach the LFL.

**5706.5.1.8 Stray current protection.** Tank car loading facilities where Class I, II or IIIA liquids are transferred through open domes shall be protected against stray currents by permanently bonding the pipe to not less than one rail and to the transfer apparatus. Multiple pipes entering the transfer areas shall be permanently electrically bonded together. In areas where excessive stray currents are known to exist, all pipes entering the transfer area shall be provided with insulating sections to isolate electrically the transfer apparatus from the pipelines.

❖ Bonding of piping to the transfer apparatus and to a rail prevents any stray current from arcing. Any electrical equipment can develop stray current. Grounding of electrical equipment, dispensing piping and vehicles will prevent the accumulation of electrical potential, which will prevent the stray current from arcing and forming an ignition source.

**5706.5.1.9 Top loading.** When top loading a tank vehicle with Class I and II liquids without vapor control, valves used for the final control of flow shall be of the self-closing type and shall be manually held open except where automatic means are provided for shutting off the flow when the tank is full. Where used, automatic shutoff systems shall be provided with a manual shutoff valve located at a safe distance from the loading nozzle to stop the flow if the automatic system fails.

When top loading a tank vehicle with vapor control, flow control shall be in accordance with Section 5706.5.1.10. Self-closing valves shall not be tied or locked in the open position.

❖ A top-loading tank vehicle for use with Class I and II flammable and combustible liquids must have either a self-closing valve, a control valve that is manually held open or an automatic shutoff control valve to prevent overfilling and spillage. The automatic shutoff

control valve is to have a manual backup control valve located a safe distance from the loading nozzle.

If the dispensing system includes vapor control, the top loading is to comply with Section 5706.5.1.10.

**5706.5.1.10 Bottom loading.** When bottom loading a tank vehicle or tank car with or without vapor control, a positive means shall be provided for loading a predetermined quantity of liquid, together with an automatic secondary shutoff control to prevent overflow. The connecting components between the transfer equipment and the tank vehicle or tank car required to operate the secondary control shall be functionally compatible.

- ❖ Spillage is prevented when filling a bottom-loading tank vehicle by using a loading system that loads a predetermined quantity of flammable or combustible liquid. An automatic secondary shutoff control valve is required for a bottom-loading tank vehicle.

**5706.5.1.10.1 Dry disconnect coupling.** When bottom loading a tank vehicle, the coupling between the liquid loading hose or pipe and the truck piping shall be a dry disconnect coupling.

- ❖ To prevent spillage when disconnecting the dispensing system from the bottom-loading vehicle, the system is to use a dry connection.

**5706.5.1.10.2 Venting.** When bottom loading a tank vehicle or tank car that is equipped for vapor control and vapor control is not used, the tank shall be vented to the atmosphere to prevent pressurization of the tank. Such venting shall be at a height equal to or greater than the top of the cargo tank.

- ❖ Pressure is relieved in a bottom-loading tank during the loading process by venting the tank to the atmosphere. The tank vent is to be above the top of the upper limit to which flammable and combustible liquid can be loaded. This prevents the vent from spilling flammable or combustible liquid.

**5706.5.1.10.3 Vapor-tight connection.** Connections to the plant vapor control system shall be designed to prevent the escape of vapor to the atmosphere when not connected to a tank vehicle or tank car.

- ❖ Vapor recovery systems must be designed so that when they are not in use, vapors cannot escape the connection to the tank vehicle.

**5706.5.1.10.4 Vapor-processing equipment.** Vapor-processing equipment shall be separated from above-ground tanks, warehouses, other plant buildings, transfer facilities or nearest *lot line* of adjoining property that can be built on by a distance of not less than 25 feet (7620 mm). Vapor-processing equipment shall be protected from physical damage by remote location, guard rails, curbs or fencing.

- ❖ Vapor recovery is the most dangerous component of flammable or combustible liquid transfer. To protect property and life, the vapor recovery equipment is to be separated from other buildings, equipment, property lines, etc. The vapor recovery equipment must be protected from physical damage either by separa-

tion or by physical barriers. Any damage to the vapor recovery equipment could create a vapor-air mixture that is flammable. The same damage could generate an ignition source.

**5706.5.1.11 Switch loading.** Tank vehicles or tank cars that have previously contained Class I liquids shall not be loaded with Class II or III liquids until such vehicles and all piping, pumps, hoses and meters connected thereto have been completely drained and flushed.

- ❖ Class I liquids and their vapors must be cleaned from a tank vehicle before loading it with Class II or III combustible liquids. The vapors from Class I liquids can affect the response to Class II or III liquids by being the source of ignition and the initial fuel source to start a Class II or III liquid fire.

**5706.5.1.12 Loading racks.** Where provided, loading racks, *stairways* or platforms shall be constructed of noncombustible materials. Buildings for pumps or for shelter of loading personnel are allowed to be part of the loading rack. Wiring and electrical equipment located within 25 feet (7620 mm) of any portion of the loading rack shall be in accordance with Section 5703.1.1.

- ❖ Loading racks and buildings that are part of the loading rack and used to shelter pumps and loading personnel are to be noncombustible. This reduces the fuel sources in the vicinity of the flammable and combustible liquids. Electrical equipment within 25 feet (7620 mm) of the loading racks is to be classified as a hazardous location. This removes an ignition source from the immediate vicinity.

**5706.5.1.13 Transfer apparatus.** Bulk and process transfer apparatus shall be of an *approved* type.

- ❖ This section gives the fire code official the authority to approve any transfer apparatus.

**5706.5.1.14 Inside buildings.** Tank vehicles and tank cars shall not be located inside a building while transferring Class I, II or IIIA liquids, unless *approved* by the *fire code official*.

**Exception:** Tank vehicles are allowed under weather protection canopies and canopies of automobile motor vehicle fuel-dispensing stations.

- ❖ Tank vehicles are to be loaded outside of a building unless approved by the fire code official. The potential for the accumulation of vapors in a building where the bulk loading of tank vehicles takes place produces an unacceptable hazard.

The exception allows loading tank vehicles under a canopy because a canopy structure is considered to be outdoor usage.

**5706.5.1.15 Tank vehicle and tank car certification.** Certification shall be maintained for tank vehicles and tank cars in accordance with DOTn 49 CFR Parts 100-185.

- ❖ Tank vehicles for use with flammable and combustible liquids are regulated under DOTn 49 CFR, Parts 100-185. Tank vehicles and tank cars not having a current certification are not to be used.

**5706.5.1.16 Tank vehicle and tank car stability.** Tank vehicles and tank cars shall be stabilized against movement during loading and unloading in accordance with Sections 5706.5.1.16.1 through 5706.5.1.16.3.

❖ The stability of tank vehicles and tank cars is to be maintained during loading and unloading. The movement of a tank vehicle or tank car during loading or unloading could cause a spill.

**5706.5.1.16.1 Tank vehicles.** When the vehicle is parked for loading or unloading, the cargo trailer portion of the tank vehicle shall be secured in a manner that will prevent unintentional movement.

❖ Cargo trailers must be secured to prevent movement during loading and unloading.

**5706.5.1.16.2 Chock blocks.** Not less than two chock blocks not less than 5 inches by 5 inches by 12 inches (127 mm by 127 mm by 305 mm) in size and dished to fit the contour of the tires shall be used during transfer operations of tank vehicles.

❖ Tank vehicles are to use chock blocks that conform to the wheels to prevent movement. Movement of the tank vehicle could cause a spill.

**5706.5.1.16.3 Tank cars.** Brakes shall be set and the wheels shall be blocked to prevent rolling.

❖ Tank cars are to use both the tank car brakes and blocks to prevent movement. Movement of the tank car could cause a spill.

**5706.5.1.17 Monitoring.** Transfer operations shall be monitored by an *approved* monitoring system or by an attendant. Where monitoring is by an attendant, the operator or other competent person shall be present at all times.

❖ To prevent spillage, the transfer operations are to be continually monitored by an individual at the site.

**5706.5.1.18 Security.** Transfer operations shall be surrounded by a noncombustible fence not less than 5 feet (1524 mm) in height. Tank vehicles and tank cars shall not be loaded or unloaded unless such vehicles are entirely within the fenced area.

**Exceptions:**

1. Motor fuel-dispensing facilities complying with Chapter 23.
2. Installations where adequate public safety exists because of isolation, natural barriers or other factors as determined appropriate by the *fire code official*.
3. Facilities or properties that are entirely enclosed or protected from entry.

❖ Transfer operations must take place in a fenced-in area to prevent access by unauthorized personnel and the possibility of introduction of ignition sources around the transfer operation.

The three exceptions cover special sets of circumstances:

1. Motor fuel-dispensing facilities that comply with Chapter 23.

2. Installation approved by the fire code official that provides security complying with the intent of the code.
3. Facilities or properties that are completely enclosed or protected from entry by unauthorized persons.

**5706.5.2 Bulk transfer.** Bulk transfer shall be in accordance with Sections 5706.5.1 and 5706.5.2.1.

❖ The operation of a motor vehicle is prohibited during bulk transfer to prevent the presence of an ignition source.

**5706.5.2.1 Vehicle motor.** Motors of tank vehicles or tank cars shall be shut off during the making and breaking of hose connections and during the unloading operation.

**Exception:** Where unloading is performed with a pump deriving its power from the tank vehicle motor.

❖ The engine of a motor vehicle is a source of ignition. This source of ignition is to be turned off during transfer of flammable or combustible liquids.

The exception allows the engine of a motor vehicle to operate during transfer of flammable or combustible liquids only if the pump to move the flammable or combustible liquids is powered by the vehicle engine.

**5706.5.3 Process transfer.** Process transfer shall be in accordance with Section 5706.5.1 and Sections 5706.5.3.1 through 5706.5.3.3.

❖ Safety features are installed in the processing system to protect the system from failure. The failure may be caused by operational procedures or equipment. The process transfer is to be designed and operated to prevent leaks, spills, overpressure buildup, siphonage, accumulation of vapors, exposure to ignition sources, etc.

**5706.5.3.1 Piping, valves, hoses and fittings.** Piping, valves, hoses and fittings that are not a part of the tank vehicle or tank car shall be in accordance with Section 5703.6. Caps or plugs that prevent leakage or spillage shall be provided at all points of connection to transfer piping.

❖ Piping complying with Section 5703.6 provides protection against leaks and overpressures that may create leaks at joints or rupture of the pipes. To prevent any residue from leaking or spilling from the piping system, caps or plugs are to be available for all openings.

**5706.5.3.1.1 Shutoff valves.** *Approved* automatically or manually activated shutoff valves shall be provided where the transfer hose connects to the process piping, and on both sides of any exterior fire-resistance-rated wall through which the piping passes. Manual shutoff valves shall be arranged so that they are accessible from grade. Valves shall not be locked in the open position.

❖ Shutoff valves must be installed to isolate portions of the piping system. The valves must be located where the flammable or combustible liquids connect to the process equipment. Valves are to be located on both

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

sides of exterior fire-resistance-rated walls. Valves are not to be locked in the open position.

**5706.5.3.1.2 Hydrostatic relief.** Hydrostatic pressure-limiting or relief devices shall be provided where pressure buildup in trapped sections of the system could exceed the design pressure of the components of the system.

Devices shall relieve to other portions of the system or to another *approved* location.

❖ Pressure relief valves must be installed to prevent damage to the system by releasing the pressure either into another portion of the system or to an *approved* location. This prevents any vapors from the flammable and combustible liquids from being released into the atmosphere of the building or facility.

**5706.5.3.1.3 Antisiphon valves.** Antisiphon valves shall be provided where the system design would allow siphonage.

❖ To prevent leakage or spillage by siphoning flammable or combustible liquids from one portion of the process system to another, an *approved* antisiphon device must be installed.

**5706.5.3.2 Vents.** Normal and emergency vents shall be maintained operable at all times.

❖ Vents are installed to help prevent overpressurization of tanks and transfer piping. If these vents fail to operate as designed, serious damage to the system could result.

**5706.5.3.3 Motive power.** Motors of tank vehicles or tank cars shall be shut off during the making and breaking of hose connections and during the unloading operation.

**Exception:** When unloading is performed with a pump deriving its power from the tank vehicle motor.

❖ Because there is always a possibility that vapors or minor liquid spillage could present a fire hazard, it is important to remove all possible sources of ignition from the vicinity. Requiring internal combustion engines to be shut off before connections are made or broken removes an ignition source from the vicinity.

The exception acknowledges that some pumps are powered by the engine of the tank vehicle involved in the liquid transfer operation.

**5706.5.4 Dispensing from tank vehicles and tank cars.** Dispensing from tank vehicles and tank cars into the fuel tanks of motor vehicles shall be prohibited unless allowed by and conducted in accordance with Sections 5706.5.4.1 through 5706.5.4.5.

❖ The dispensing of flammable or combustible liquids from a tank vehicle or tank car into the fuel tank of a motor vehicle is covered by this section.

**5706.5.4.1 Marine craft and special equipment.** Liquids intended for use as motor fuels are allowed to be transferred from tank vehicles into the fuel tanks of marine craft and spe-

cial equipment where *approved* by the *fire code official*, and where:

1. The tank vehicle's specific function is that of supplying fuel to fuel tanks.
2. The operation is not performed where the public has access or where there is unusual exposure to life and property.
3. The dispensing line does not exceed 50 feet (15 240 mm) in length.
4. The dispensing nozzle is *approved*.

❖ Transfer of motor fuel into marine craft and special equipment is covered by this section.

The tank vehicle or tank car must be designed and equipped specifically for fueling other vehicles and equipment and the dispensing equipment must be *approved* for this use. The dispensing line cannot be more than 50 feet (15 240 mm) long. The dispensing must be done in a controlled area where there is minimal exposure to life or property.

**5706.5.4.2 Emergency refueling.** Where *approved* by the *fire code official*, dispensing of motor vehicle fuel from tank vehicles into the fuel tanks of motor vehicles is allowed during emergencies. Dispensing from tank vehicles shall be in accordance with Sections 5706.2.8 and 5706.6.

❖ Emergency refueling of vehicles is permitted only when *approved* by the *fire code official*.

**5706.5.4.3 Aircraft fueling.** Transfer of liquids from tank vehicles to the fuel tanks of aircraft shall be in accordance with Chapter 20.

❖ Chapter 20 covers the requirements for aircraft fueling.

**5706.5.4.4 Fueling of vehicles at farms, construction sites and similar areas.** Transfer of liquid from tank vehicles to motor vehicles for private use on farms and rural areas and at construction sites, earth-moving projects, gravel pits and borrow pits is allowed in accordance with Section 5706.2.8.

❖ Fueling of vehicles at farms, construction sites and similar areas is covered by Section 5706.2.8. The dispensing of fuel at a farm or construction site may be from a tanker to a vehicle or equipment. Dispensing using a tanker requires that the tanker be designed and equipped specifically for fueling other vehicles and equipment. The dispensing equipment must be *approved* for this use. The dispensing line cannot be more than 100 feet (30 480 mm) long.

The tanker operator is responsible for the dispensing line and the tanker, so these two items need to be in the same area. The dispensing cannot be done around an ignition source, such as smoking, or electrical equipment that is not classified for use in hazardous locations.

**5706.5.4.5 Commercial, industrial, governmental or manufacturing.** Dispensing of Class II and III motor vehicle fuel

from tank vehicles into the fuel tanks of motor vehicles located at commercial, industrial, governmental or manufacturing establishments is allowed where permitted, provided such dispensing operations are conducted in accordance with the following:

1. Dispensing shall occur only at sites that have been issued a permit to conduct mobile fueling.
2. The *owner* of a mobile fueling operation shall provide to the jurisdiction a written response plan which demonstrates readiness to respond to a fuel spill and carry out appropriate mitigation measures, and describes the process to dispose properly of contaminated materials.
3. A detailed site plan shall be submitted with each application for a permit. The site plan shall indicate: all buildings, structures and appurtenances on site and their use or function; all uses adjacent to the lot lines of the site; the locations of all storm drain openings, adjacent waterways or wetlands; information regarding slope, natural drainage, curbing, impounding and how a spill will be retained upon the site property; and the scale of the site plan.

Provisions shall be made to prevent liquids spilled during dispensing operations from flowing into buildings or off-site. Acceptable methods include, but shall not be limited to, grading driveways, raising doorsills or other *approved* means.

4. The *fire code official* is allowed to impose limits on the times and days during which mobile fueling operations is allowed to take place, and specific locations on a site where fueling is permitted.
5. Mobile fueling operations shall be conducted in areas not accessible to the public or shall be limited to times when the public is not present.
6. Mobile fueling shall not take place within 15 feet (4572 mm) of buildings, property lines, combustible storage or storm drains.

**Exceptions:**

1. The distance to storm drains shall not apply where an *approved* storm drain cover or an *approved* equivalent that will prevent any fuel from reaching the drain is in place prior to fueling or a fueling hose being placed within 15 feet (4572 mm) of the drain. Where placement of a storm drain cover will cause the accumulation of excessive water or difficulty in conducting the fueling, such cover shall not be used and the fueling shall not take place within 15 feet (4572 mm) of a drain.
2. The distance to storm drains shall not apply for drains that direct influent to *approved* oil interceptors.
7. The tank vehicle shall comply with the requirements of NFPA 385 and local, state and federal require-

ments. The tank vehicle's specific functions shall include that of supplying fuel to motor vehicle fuel tanks. The vehicle and all its equipment shall be maintained in good repair.

8. Signs prohibiting smoking or open flames within 25 feet (7620 mm) of the tank vehicle or the point of fueling shall be prominently posted on three sides of the vehicle including the back and both sides.
9. A portable fire extinguisher with a minimum rating of 40:BC shall be provided on the vehicle with signage clearly indicating its location.
10. The dispensing nozzles and hoses shall be of an *approved* and *listed* type.
11. The dispensing hose shall not be extended from the reel more than 100 feet (30 480 mm) in length.
12. Absorbent materials, nonwater-absorbent pads, a 10-foot-long (3048 mm) containment boom, an *approved* container with lid and a nonmetallic shovel shall be provided to mitigate a minimum 5-gallon (19 L) fuel spill.
13. Tank vehicles shall be equipped with a "fuel limit" switch such as a count-back switch, to limit the amount of a single fueling operation to not more than 500 gallons (1893 L) before resetting the limit switch.

**Exception:** Tank vehicles where the operator carries and can utilize a remote emergency shut-off device which, when activated, immediately causes flow of fuel from the tank vehicle to cease.

14. Persons responsible for dispensing operations shall be trained in the appropriate mitigating actions in the event of a fire, leak or spill. Training records shall be maintained by the dispensing company.
15. Operators of tank vehicles used for mobile fueling operations shall have in their possession at all times an emergency communications device to notify the proper authorities in the event of an emergency.
16. The tank vehicle dispensing equipment shall be constantly attended and operated only by designated personnel who are trained to handle and dispense motor fuels.
17. Fuel dispensing shall be prohibited within 25 feet (7620 mm) of any source of ignition.
18. The engines of vehicles being fueled shall be shut off during dispensing operations.
19. Nighttime fueling operations shall only take place in adequately lighted areas.
20. The tank vehicle shall be positioned with respect to vehicles being fueled to prevent traffic from driving over the delivery hose.
21. During fueling operations, tank vehicle brakes shall be set, chock blocks shall be in place and warning lights shall be in operation.
22. Motor vehicle fuel tanks shall not be topped off.

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

23. The dispensing hose shall be properly placed on an *approved* reel or in an *approved* compartment prior to moving the tank vehicle.
  24. The *fire code official* and other appropriate authorities shall be notified when a reportable spill or unauthorized discharge occurs.
  25. Operators shall place a drip pan or an absorbent pillow under each fuel fill opening prior to and during dispensing operations. Drip pans shall be liquid-tight. The pan or absorbent pillow shall have a capacity of not less than 3 gallons (11.36 L). Spills retained in the drip pan or absorbent pillow need not be reported. Operators, when fueling, shall have on their person an absorbent pad capable of capturing diesel fuel overfills. Except during fueling, the nozzle shall face upward and an absorbent pad shall be kept under the nozzle to catch drips. Contaminated absorbent pads or pillows shall be disposed of regularly in accordance with local, state and federal requirements.
- ❖ This section codifies minimum safety requirements for the regulation of certain mobile fueling operations, provides administrative controls over fueling sites, specifies the types of tank vehicles required in such operations and specifies training and licensing requirements for persons engaged in mobile fueling operations.

Regardless of previous allowances or restrictions by the legacy model fire codes (i.e., national, standard and uniform), mobile fueling is flourishing nationally and is welcomed in many jurisdictions. In fact, a number of local jurisdictions have developed regulations specifically allowing for expanded mobile fueling operations. The regulations in this section are consistent with those local regulations as well as those contained in NFPA 30A and provide an international model for jurisdictions to follow.

The greatest operational uses of mobile fueling are in conjunction with fueling of fleets, such as trucking companies, bus companies, delivery companies, municipal fleets, the U.S. Postal Service fleets and similar operations. Nationwide, the annual mobile fueling volume is conservatively estimated to exceed 500,000,000 gallons (18,992,500,000 L) and it is increasing at a rate exceeding 30 percent per year. It is a business carried out by both public and private entities. One private company alone delivers over 120,000,000 gallons (454,200,000 L) per year. There are several other companies that deliver from 500,000 to 3,000,000 gallons (1,892,500 to 11,355,000 L) per month. These operations are occurring in all regions of the United States since the early 1990s and in some areas, even longer.

Mobile fueling thrives because it meets several needs:

1. It is more cost efficient to bring delivery of fuel to high-volume consuming vehicles versus having each of those vehicles go to the fuel source.

2. Fueling is a safer operation when carried out by a trained, focused specialist who is familiar with the dispensing equipment and safety regulations, is trained in spill control and mitigation and knows what steps to take should an incident occur.
3. Fuel-consuming fleet operators recognize both safety and cost benefits by not involving a multitude of employees in a fueling operation for which they are not trained and are not likely to develop an overriding concern for safety.
4. Additional safety controls are evolving through the use of technology systems. Some systems are not economically feasible unless they include additional services. For example, some mobile fueling operations bring cost-saving advantages to their clients through the provision of a data-capturing system. In addition to having instant remote fuel-flow stopping capabilities, the system frees the operator to concentrate solely on the task of safe dispensing.
5. On-site mobile fueling eliminates the traffic hazards and air pollution problems associated with driving fleets of vehicles to a fixed fueling facility.

There is no known adverse fire incident history associated with mobile fueling. Given the length of time that mobile fueling has been occurring, the data points to an outstanding safety record. There is no safety-related reason that mobile fueling operations should not be allowed, provided such operations are carried out in keeping with reasonable safety requirements, including those designed to protect water supply and environment, as provided in this section.

**5706.6 Tank vehicles and vehicle operation.** Tank vehicles shall be designed, constructed, equipped and maintained in accordance with NFPA 385 and Sections 5706.6.1 through 5706.6.4.

❖ This section sets forth rules for the operation of tank vehicles used for the transportation of flammable and combustible liquids. Included are parking and garaging regulations, fire extinguisher requirements and regulations for the discharge of flammable and combustible liquids into underground storage tanks. These requirements are intended to apply to the extent that they do not conflict with federal requirements detailed in DOTn 49 CFR and other federal transportation regulations.

NFPA 385 details requirements for materials and methods of construction for flammable and combustible liquid tank vehicles to provide protection for their cargo under highway conditions. Design and construction of these vehicles must also conform to the requirements set forth in DOTn 49 CFR.

**5706.6.1 Operation of tank vehicles.** Tank vehicles shall be utilized and operated in accordance with NFPA 385 and Sections 5706.6.1.1 through 5706.6.1.11.

- ❖ NFPA 385 outlines the requirements for the operation of tank vehicles. These requirements detail required practices during transit, parking, loading and unloading, maintenance and repair designed to reduce the potential for accidental release of the vehicle cargo.

**5706.6.1.1 Vehicle maintenance.** Tank vehicles shall not be operated unless they are in proper state of repair and free from accumulation of grease, oil or other flammable substance, and leaks.

- ❖ Good housekeeping practices extend to tank vehicles just as much as they do to permanent facilities. Keeping vehicles clean and in good repair reduces the possibility for accumulations of flammable materials to become a fuel source for a fire.

**5706.6.1.2 Leaving vehicle unattended.** The driver, operator or attendant of a tank vehicle shall not remain in the vehicle cab and shall not leave the vehicle while it is being filled or discharged. The delivery hose, when attached to a tank vehicle, shall be considered to be a part of the tank vehicle.

- ❖ The tank vehicle driver, operator or attendant must be prepared to immediately suspend dispensing, loading or unloading operations; control a spill; or extinguish a fire should an incident occur. This section and NFPA 385 emphasize that the driver, operator or attendant must be outside the cab of the vehicle in order to be in compliance. It further clarifies that the driver, operator or attendant may be no further away from the vehicle than the length of the delivery hose connected to the vehicle. These restrictions are especially important in climates subject to extreme weather, where drivers are often tempted to sit in the truck cab or go into a building to keep cool or warm. Keeping the person most qualified to take prompt emergency action in the best possible location to do so reduces the likelihood of a major spill in the event of an equipment failure or accident.

**5706.6.1.3 Vehicle motor shutdown.** Motors of tank vehicles or tractors shall be shut down during the making or breaking of hose connections. If loading or unloading is performed without the use of a power pump, the tank vehicle or tractor motor shall be shut down throughout such operations.

- ❖ Motors must be shut down when not required to operate unloading equipment. When the vehicle motor is required to operate transfer pumps, it must be shut off when loading or unloading is commencing or is completed and before hose connections are made or broken in order to control it as a source of ignition.

**5706.6.1.4 Outage.** A cargo tank or compartment thereof used for the transportation of flammable or *combustible liquids* shall not be loaded to absolute capacity. The vacant space in a cargo tank or compartment thereof used in the transportation of flammable or *combustible liquids* shall be not less than 1 percent. Sufficient space shall be left vacant to prevent leakage from or distortion of such tank or compart-

ment by expansion of the contents caused by rise in temperature in transit.

- ❖ To allow for the thermal expansion of flammable or combustible liquids, the maximum allowable capacity of a cargo tank or compartment is 99 percent of the actual capacity. The expansion of flammable or combustible liquids in a confined space will create internal pressures, which may damage the cargo tank or compartment, possibly creating a leak.

**5706.6.1.5 Overfill protection.** The driver, operator or attendant of a tank vehicle shall, before making delivery to a tank, determine the unfilled capacity of such tank by a suitable gauging device. To prevent overfilling, the driver, operator or attendant shall not deliver in excess of that amount.

- ❖ The individual responsible for the operation of the tank vehicle is also responsible for overfill protection. This individual is to calculate the fill quantity. This is the maximum quantity that the individual responsible for the operation of the tank vehicle is to deliver.

**5706.6.1.6 Securing hatches.** During loading, hatch covers shall be secured on all but the receiving compartment.

- ❖ To ensure that the minimum amount of flammable and combustible liquids is exposed to air or to an ignition source, only hatches in actual use during dispensing are to be opened.

**5706.6.1.7 Liquid temperature.** Materials shall not be loaded into or transported in a tank vehicle at a temperature above the material's ignition temperature unless safeguarded in an *approved* manner.

- ❖ Loading and transporting of flammable and combustible liquids above their ignition temperature are prohibited unless the loading operation and the transporting process are protected from the hazards involved in this process. Risks are increased significantly when the liquid is at an elevated temperature.

**5706.6.1.8 Bonding to underground tanks.** An external bond-wire connection or bond-wire integral with a hose shall be provided for the transferring of flammable liquids through open connections into underground tanks.

- ❖ Static electricity will spark between surfaces with different electrical potential. This spark is an ignition source for flammable and combustible liquids. Bonding of the dispensing hose to the underground tank is required, if the transfer is through an open connection. Bonding can be done using wires, ground cables, metal piping or other similar means that will carry current.

**5706.6.1.9 Smoking.** Smoking by tank vehicle drivers, helpers or other personnel is prohibited while they are driving, making deliveries, filling or making repairs to tank vehicles.

- ❖ Smoking is prohibited in the vicinity of the tank vehicle. This eliminates a source of ignition.

**5706.6.1.10 Hose connections.** Delivery of flammable liquids to underground tanks with a capacity of more than 1,000 gallons (3785 L) shall be made by means of *approved* liquid

## FLAMMABLE AND COMBUSTIBLE LIQUIDS

and vapor-tight connections between the delivery hose and tank fill pipe. Where underground tanks are equipped with any type of vapor recovery system, all connections required to be made for the safe and proper functioning of the particular vapor recovery process shall be made. Such connections shall be made liquid and vapor tight and remain connected throughout the unloading process. Vapors shall not be discharged at grade level during delivery.

❖ The delivery of Class I liquids to either an above-ground or underground storage tank that exceeds 1,000 gallons (3785 L) in capacity must be through a liquid- and vapor-tight fitting to reduce the potential for the escape of flammable liquid or vapors at the point of connection. These fittings include liquid transfer lines and vapor recovery lines, which are designed to prevent the release of polluting, flammable vapors during transfer. These requirements prohibit the extremely dangerous, but not uncommon, practice of delivery tanker operators not connecting vapor return hoses, thus allowing the vapors displaced during delivery to escape at grade level from the unmade connections. Incidents have been reported where the vapors have traveled to nearby buildings, found an ignition source and exploded (see also commentary, Section 2305.1.3).

**5706.6.1.10.1 Simultaneous delivery.** Simultaneous delivery to underground tanks of any capacity from two or more discharge hoses shall be made by means of mechanically tight connections between the hose and fill pipe.

❖ The simultaneous delivery of flammable and combustible liquids to an underground tank using two or more hoses requires a mechanically tight connection for

each delivery hose to the tank fill pipe. The pressure generated by the delivery could cause one or more of the delivery hoses to leak or to disconnect if the connections are not tight.

**5706.6.1.11 Hose protection.** Upon arrival at a point of delivery and prior to discharging any flammable or *combustible liquids* into underground tanks, the driver, operator or attendant of the tank vehicle shall ensure that all hoses utilized for liquid delivery and vapor recovery, where required, will be protected from physical damage by motor vehicles. Such protection shall be provided by positioning the tank vehicle to prevent motor vehicles from passing through the area or areas occupied by hoses, or by other *approved* equivalent means.

❖ Whenever possible, fill connections for new underground storage tanks should be located where tank vehicle hose lines will be out of the way of traffic during liquid transfer operations. Otherwise, the tank vehicle should be positioned to minimize the likelihood of damage to the discharge line (which could result in a large spill and potentially a large fire), or traffic cones or pylons should be placed to warn approaching vehicles (see Commentary Figure 5706.6.1.11).

**5706.6.2 Parking.** Parking of tank vehicles shall be in accordance with Sections 5706.6.2.1 through 5706.6.2.3.

**Exception:** In cases of accident, breakdown or other emergencies, tank vehicles are allowed to be parked and left unattended at any location while the operator is obtaining assistance.

❖ The parking of tank vehicles is as important as above-ground tank storage. The quantity of flamma-

**Figure 5706.6.1.11**  
**TANK VEHICLE POSITIONING DURING UNLOADING**

ble and combustible liquids can be substantial in a tank vehicle and exposure to ignition sources is more problematic than in a secured area. The facilities adjacent to the tank vehicle may represent a potential for large loss of life or large property damage. The spread of fire from a tank vehicle is not contained by dikes or a similar containment and drainage system. The fire can spread to areas outside of the tank vehicle location and fire-fighting operations may not be effective if the fire goes into an underground drainage system.

The restrictions on parking do not apply in case of a vehicle breakdown. Because it is impossible to predict or prevent all vehicle failures, the code does not make temporary parking resulting from mechanical failure of the tank vehicle a violation.

**5706.6.2.1 Parking near residential, educational and institutional occupancies and other high-risk areas.** Tank vehicles shall not be left unattended at any time on residential streets, or within 500 feet (152 m) of a residential area, apartment or hotel complex, educational facility, hospital or care facility. Tank vehicles shall not be left unattended at any other place that would, in the opinion of the fire chief, pose an extreme life hazard.

❖ Tank vehicles must not be parked or left unattended in residential districts or near schools, nursing homes, hospitals or similar buildings where the hazards to life may be high and the occupants are more vulnerable.

Maintaining a distance of 500 feet (152 400 mm) to the listed premises provides a spatial buffer between the tank vehicle and the high life-risk property in case of a spill, accident or ignition. This section also allows the fire chief to declare certain other areas of the jurisdiction as being off limits to parking, based on the hazard exposures present. Some jurisdictions have, by local ordinance, specified certain road routes to be used by hazardous cargo vehicles, further reducing the likelihood of a major hazardous materials incident or fire.

**5706.6.2.2 Parking on thoroughfares.** Tank vehicles shall not be left unattended on a public street, highway, public avenue or public alley.

**Exceptions:**

1. The necessary absence in connection with loading or unloading the vehicle. During actual fuel transfer, Section 5706.6.1.2 shall apply. The vehicle location shall be in accordance with Section 5706.6.2.1.
2. Stops for meals during the day or night, where the street is well lighted at the point of parking. The vehicle location shall be in accordance with Section 5706.6.2.1.

❖ Leaving a tank vehicle parked or unattended in a public way invites malicious vandalism to the vehicle or an accidental collision by another vehicle, either of which could cause a release of the cargo, creating a large-scale spill or possible large-area fire if ignition were to occur. The exceptions in this section are very

specific in describing the limited conditions under which the vehicle operator may be absent from the vehicle. The locations where such absence is permitted may be expected to be generally off limits to the public (i.e., unauthorized personnel) or, in the case of meal breaks, sufficiently lighted so as to discourage vandalism and reduce the likelihood of accidental collision.

**5706.6.2.3 Duration exceeding 1 hour.** Tank vehicles parked at one point for longer than 1 hour shall be located off of public streets, highways, public avenues or alleys, and in accordance with either of the following:

1. Inside of a bulk plant and either 25 feet (7620 mm) or more from the nearest *lot line* or within a building *approved* for such use.
2. At other *approved* locations not less than 50 feet (15 240 mm) from the buildings other than those *approved* for the storage or servicing of such vehicles.

❖ In order to prevent the tank vehicle from being subject to accidents or vandalism, this section requires tank vehicles that are parked for durations exceeding 1 hour to be located off streets, highways, avenues or alleys, and either inside of a bulk plant or at other approved locations as specified in the code.

Security should be a major consideration in approving an off-street location for overnight parking. If a satisfactory location cannot be found, as an alternative method based on Section 104.9, the fire code official could consider designating areas in a parking lot for tank vehicles that provide the maximum available separation from buildings and are well-lighted, away from traffic areas, drained away from buildings, etc.

**5706.6.3 Garaging.** Tank vehicles shall not be parked or garaged in buildings other than those specifically *approved* for such use by the *fire code official*.

❖ This section prohibits the parking or garaging of tank vehicles inside of buildings. There is an exception, although it is not shown in the code style, that allows the fire code official to specifically approve a building for the parking or garaging of tank vehicles. Criteria for such specific approval could include a requirement that all liquid cargo be off-loaded (outside the building), and the tank vehicle's cargo tank, piping and hoses cleaned and purged of vapors or made inert in an approved manner before moving into any building or structure.

An alternative criterion for specific approval could be that the building or structure be specifically designed for that purpose and classified in Group H-3 (assuming that the cargo tank is at atmospheric pressure). Group H buildings used for the garaging of tank vehicles would include all code-required safety features for the indoor storage of flammable or combustible liquids, including safety features for control of leaks, spills and ignition sources; fire and fire containment and higher levels of ventilation that are not found in other buildings.

In a Group H-3 scenario, the cargo would not need to be off-loaded and the tank and appurtenances purged or inerted; however, the length of time that a tank vehicle is allowed to be kept inside of a building must be included in the approval and permit process since Section 5704.2.2 very specifically prohibits the use of tank vehicles as storage tanks, whether inside or outside of a building.

**5706.6.4 Portable fire extinguisher.** Tank vehicles shall be equipped with a portable fire extinguisher complying with Section 906 and having a minimum rating of 2-A:20-B:C.

During unloading of the tank vehicle, the portable fire extinguisher shall be out of the carrying device on the vehicle and shall be 15 feet (4572 mm) or more from the unloading valves.

- ❖ A fire extinguisher (2-A:20-B:C) must be available to control a small fire. The fire extinguisher is designed for use on ordinary combustible fires, flammable liquid fires and electrical fires. The extinguisher is to be at least 15 feet (4572 mm) from the unloading valve. This location is convenient for the attendant to close the valve, control the flow of the flammable or combustible liquid and have access to the fire extinguisher to control a fire.

**5706.7 Refineries.** Plants and portions of plants in which flammable liquids are produced on a scale from crude petroleum, natural gasoline or other hydrocarbon sources shall be in accordance with Sections 5706.7.1 through 5706.7.3. Petroleum-processing plants and facilities or portions of plants or facilities in which flammable or *combustible liquids* are handled, treated or produced on a commercial scale from crude petroleum, natural gasoline, or other hydrocarbon sources shall also be in accordance with API 651, API 653, API 752, API 1615, API 2001, API 2003, API 2009, API 2015, API 2023, API 2201 and API 2350.

- ❖ Refineries process crude petroleum or other hydrocarbon sources into flammable or combustible liquids on a commercial scale. These facilities are covered by American Petroleum Institute (API) standards:

*API RP 651:* The standard describes corrosion problems characteristic to above-ground storage tanks and associated piping systems. The standard covers the two current methods used to provide cathodic protection against corrosion.

*API STD 653:* The standard covers the inspection, repair, alteration and reconstruction of steel above-ground storage tanks and includes the minimum requirements for maintaining the integrity of welded or riveted, nonrefrigerated, atmospheric pressure, above-ground storage tanks that have been placed in service.

*API RP 752:* The guide describes a methodology for assessing and evaluating the hazards associated with the location of process plant buildings.

*API RP 1615:* The guide contains the procedures and lists equipment needed for the proper installation of

underground petroleum storage systems. The guide applies to underground storage tank systems that store petroleum products for retail and commercial facilities.

*API RP 2001:* The publication provides an understanding of the fire protection problems and the steps needed to ensure the safe storage, handling and processing of petroleum products in refineries and the safe shipment of petroleum products.

*API RP 2003:* The publication describes some of the conditions that have resulted in fires caused by electrical sparks and arcs from natural causes. The publication describes methods currently used to prevent ignition from these sources.

*API Publ. 2009:* The publication contains suggested precautions for the protection of personnel from injury and property from damage by fire that may arise during the operation of gas and electric cutting and welding equipment in and around petroleum operations.

*API STD 2015:* The standard contains safety procedures for preparing, emptying, isolating, ventilating, atmospheric testing, cleaning, entry, hot work and recommissioning activities in, on and around atmospheric and low pressure [15 psig (103 kPa) or less] above-ground storage tanks. The standard applies to stationary tanks used in petroleum and petrochemical plants and terminals.

*API RP 2023:* The publication is a recommended practice that describes the phenomena that can occur and precautions to be taken in the storage of asphalt products and residue derived from crude oil petroleum. The recommendations apply when these materials are stored in heated tanks at refineries and bulk storage facilities and transported in tank vehicles.

*API RP 2201:* The publication covers the safety aspects to be considered when hot tapping or welding without hot tapping on in-service piping or equipment.

*API RP 2350:* The publication is a recommended practice to prevent petroleum storage tanks from being overfilled. Tank overfill can be effectively reduced by developing and implementing practical and safe operating procedures for storage facilities and by providing for careful selection and application of equipment, scheduled maintenance programs and personnel training. The publication covers overfill protection for above-ground storage tanks in petroleum facilities, including refineries, terminals, bulk plants and pipeline terminals for Class I liquids from main-line pipelines or marine vessels.

**5706.7.1 Corrosion protection.** Above-ground tanks and piping systems shall be protected against corrosion in accordance with API 651.

- ❖ Above-ground tanks must have corrosion protection complying with API 651. Soil and environmental con-

ditions can cause the deterioration of tanks. Corrosion can weaken the tank, creating a potential for leakage.

Cathodic protection uses a sacrificial metal to prevent the corrosion of the metal storage tank. The sacrificial metal is bonded to the tank so the electrochemical reaction of the sacrificial metal prevents the corrosion of the steel storage tank. The sacrificial metal is the anode, the steel storage tank is the cathode and a power supply connects the two. Replacement of the anode will depend on the rate of corrosion.

**5706.7.2 Cleaning of tanks.** The safe entry and cleaning of petroleum storage tanks shall be conducted in accordance with API 2015.

- ❖ The safe entry and cleaning of tanks must comply with API 2015. The environment in a storage tank can be hostile for personnel because the air may not be breathable or may contain a vapor-air mixture within the flammable range. The standard provides mitigation protocols for personnel hazards. See the commentary to Section 5706.7 for a more detailed description of the standard.

**5706.7.3 Storage of heated petroleum products.** Where petroleum-derived asphalts and residues are stored in heated tanks at refineries and bulk storage facilities or in tank vehicles, such products shall be in accordance with API 2023.

- ❖ The storage of heated petroleum products must comply with API 2023. The guide describes the phenomena that can occur and the precautions to be taken in the storage and handling of asphalt products and residue derived from crude-oil petroleum. The heating of these flammable and combustible liquids can result in the release of vapors as well as increase the potential for ignition.

**5706.8 Vapor recovery and vapor-processing systems.** Vapor-processing systems in which the vapor source operates at pressures from vacuum, up to and including 1 psig (6.9 kPa) or in which a potential exists for vapor mixtures in the flammable range, shall comply with Sections 5706.8.1 through 5706.8.5.

**Exceptions:**

1. Marine systems complying with federal transportation waterway regulations such as DOTn 33 CFR Parts 154 through 156, and CGR 46 CFR Parts 30, 32, 35 and 39.
  2. Motor fuel-dispensing facility systems complying with Chapter 23.
- ❖ Vapor-recovery systems must function to prevent the release of vapors and protect the vapor-recovery system during operation in the flammable range.
 

Exception 1 covers marine systems complying with federal regulations. A marine system not complying with federal regulations is in violation of the code and should be reported to the appropriate federal authority for enforcement of federal regulations. Exception 2 addresses service station systems complying with

Chapter 23. A service station system not complying with Chapter 23 is in violation of the code. The motor fuel-dispensing facility system is to be brought into compliance with Chapter 23.

**5706.8.1 Over-pressure/vacuum protection.** Tanks and equipment shall have independent venting for over-pressure or vacuum conditions that might occur from malfunction of the vapor recovery or processing system.

**Exception:** For tanks, venting shall comply with Section 5704.2.7.3.

- ❖ A vapor-recovery system must be equipped with an independent system for venting overpressure or a vacuum. An overpressure condition can damage the vapor-recovery system, creating leaks or other damage. The leak or damage could allow the vapor from a flammable or combustible liquid to escape and generate a vapor-air mixture in the flammable range.

A vacuum condition can result in the introduction of air into the vapor-recovery system. The introduction of air could generate a vapor-air mixture in the flammable range within the vapor-recovery system.

The exception recognizes that tank venting complying with Section 5704.2.7.3 is exempt from this requirement. Tanks are vented to maintain the internal tank pressure within the design operating range. A low pressure can increase the generation of vapors. A high pressure can damage the tank or piping system. Any pressure outside of the design pressure range can have an adverse affect on the operation of the system as well as the piping and equipment.

**5706.8.2 Vent location.** Vents on vapor-processing equipment shall be not less than 12 feet (3658 mm) from adjacent ground level, with outlets located and directed so that flammable vapors will disperse to below the lower flammable limit (LFL) before reaching locations containing potential ignition sources.

- ❖ The termination of a vent pipe must direct vapors away from the building. Vapors from flammable liquids are normally heavier than air so that the vapor will settle to lower levels. The termination of a vent pipe a minimum of 12 feet (3658 mm) above grade will provide space for the vapors to disperse to below the LFL. This high termination elevation also reduces the potential for the termination being in close proximity to grade-level ignition sources. Because flammable liquid vapor is heavier than air, attention must be given to the building design near the termination.

**5706.8.3 Vapor collection systems and overfill protection.** The design and operation of the vapor collection system and overfill protection shall be in accordance with this section and Section 19.5 of NFPA 30.

- ❖ The vapor collection system and overfill protection are to comply with Section 7.10 of NFPA 30. This section addresses the same topics as Section 5706.8. Section 7.10 of NFPA 30 contains additional requirements not specifically listed in Section 5706.8. These requirements are in other sections of this

chapter, but not specifically contained in this section.

These additional requirements are: 1. The vapor collection system is to be designed not to trap liquid in the vapor collection piping; 2. Unless the vapor-recovery system is designed to handle flammable or combustible liquid, the system is to be designed to eliminate any liquid from the vapor-recovery system; 3. Provide protection from ignition sources; 4. Classification of locations for electrical system; 5. Protection from static electricity; 6. Precautions against spontaneous ignition; 7. Prevent friction heat or sparks from mechanical equipment; 8. Prevent the propagation of flame through the vapor-recovery system; 9. When necessary, provisions for explosion prevention; and 10. Requirements for an emergency shutdown system.

**5706.8.4 Liquid-level monitoring.** A liquid knock-out vessel used in the vapor collection system shall have means to verify the liquid level and a high-liquid-level sensor that activates an alarm. For unpopulated facilities, the high-liquid-level sensor shall initiate the shutdown of liquid transfer into the vessel and shutdown of vapor recovery or vapor-processing systems.

❖ Liquid monitoring is necessary to prevent the liquid knockout vessel from overfilling. The liquid-level monitor must sound an alarm or shut down the vapor-recovery process before the liquid knockout vessel is overfilled. Overfill of the liquid knockout vessel could cause a spill of the flammable or combustible liquid.

**5706.8.5 Overfill protection.** Storage tanks served by vapor recovery or processing systems shall be equipped with overfill protection in accordance with Section 5704.2.7.5.8.

❖ Section 5704.2.7.5.8 requires compliance with Sections 5704.2.9.6.6 through 5704.2.9.6.6.2 for tanks storing Class I, II and IIIA liquids. To prevent spillage of liquid from storage tanks served by a vapor-recovery or processing system, the tanks are limited to 95 percent of their capacity by an overfill protection system. Several methods are acceptable. The protection system must include provisions for draining the vapor-recovery or processing system into the storage tank without exceeding the 95-percent capacity.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code.* Washington, DC: International Code Council, 2014.

NFPA 30-12, *Flammable and Combustible Liquids Code.* Quincy, MA: National Fire Protection Association, 2011.

# Chapter 58: Flammable Gases and Flammable Cryogenic Fluids

## General Comments

The requirements of Chapter 58 address flammable gases and flammable cryogenic fluids, principally bulk hydrogen gas stored as either a compressed gas or as a cryogenic fluid. Note that, while Chapter 55 is intended to apply to all cryogenic fluids regardless of classification, the flammable characteristics will now be regulated by Chapter 58.

Excluding liquefied petroleum gases whose requirements are contained in Chapter 61, this chapter aggregates all of the requirements for flammable gases that are compressed, liquefied compressed or stored as a cryogenic fluid. Section 5806 is divided into two major subsections: Section 5806.3 addresses requirements for above-ground liquid hydrogen vessels and Section 5806.4 addresses the requirements for underground liquid hydrogen vessels. Sections 5806.3.1 and 5806.4.1 require above-ground liquid hydrogen tanks that are not U.S. Department of Transportation (DOT) cylinders and underground liquid hydrogen tanks to be constructed to the requirements of the American Society of Mechanical Engineers (ASME) *Boiler and Pressure Vessel Code* (BPVC), Section VIII, Division 1 for unfired pressure vessels. Section 5807 provides regulation of metal hydride storage systems.

Of the three physical states of matter, only gas will ignite without preheating. In order to burn, all other materials must be transformed into a vaporous or gaseous state, regardless of their initial phase. The principal hazard posed by flammable gas and flammable cryogenic fluids is ready ignitability, or even explosivity, when mixed with air in the proper proportions. The question in a release usually is not whether the mixture will ignite, but rather when or how it will ignite if not controlled. Consequently, occupancies storing or handling more than 1,000 cubic feet (28 m<sup>3</sup>) of flammable gas or 30 gallons (114 L) of liquefied flammable gas per control area or 45 gallons (170 L) of flammable cryogenic fluid are classified as Group H-2 (high hazard) by the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>).

## Purpose

Chapter 58 sets requirements for the storage and use of flammable gases and flammable cryogenic fluids. For safety purposes, there is a limit on the quantities allowed per control area. Exceeding these limitations increases the possibility of damage to both property and individuals.

## SECTION 5801 GENERAL

**5801.1 Scope.** The storage and use of flammable gases and flammable cryogenic fluids shall be in accordance with this chapter and NFPA 55. Compressed gases shall also comply with Chapter 53 and cryogenic fluids shall also comply with Chapter 55. Flammable cryogenic fluids shall comply with Section 5806. Hydrogen motor fuel-dispensing stations and repair garages and their associated above-ground hydrogen storage systems shall also be designed, constructed and maintained in accordance with Chapter 23 and NFPA 2.

### Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
2. Liquefied petroleum gases and natural gases regulated by Chapter 61.

3. Fuel-gas systems and appliances regulated under the *International Fuel Gas Code* other than gaseous hydrogen systems and appliances.
4. Pyrophoric gases in accordance with Chapter 64.

❖ This section establishes the scope of Chapter 58 with respect to the storage and use of flammable and non-flammable gases, cryogenic fluids and flammable cryogenic fluids. The requirements of this chapter and the referenced standards are applicable in addition to the general storage requirements of Chapter 23 for flammable gas motor fuel dispensing facilities and Chapter 50 for hazardous materials.

**5801.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regu-

late hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Sections 105.6.9 and 105.6.11 for discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

**SECTION 5802  
DEFINITIONS**

**5802.1 Definitions.** The following terms are defined in Chapter 2:

**FLAMMABLE GAS.**

**FLAMMABLE LIQUEFIED GAS.**

**GASEOUS HYDROGEN SYSTEM.**

**HYDROGEN FUEL GAS ROOM.**

**METAL HYDRIDE.**

**METAL HYDRIDE STORAGE SYSTEM.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

**SECTION 5803  
GENERAL REQUIREMENTS**

**5803.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of flammable gases in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003, 5801 and 5803.

❖ When the amounts stored or used do not exceed the maximum allowable quantities per control area (MAQs), certain factors that must be adhered to include systems and processes, release of hazardous materials into the air, Material Safety Data Sheets (MSDS), hazard identification signs, sources of ignition and construction requirements.

**5803.1.1 Special limitations for indoor storage and use.** Flammable gases shall not be stored or used in Group A, E, I or R occupancies or in offices in Group B occupancies.

**Exceptions:**

1. Cylinders of nonliquefied *compressed gases* not exceeding a capacity of 250 cubic feet (7.08 m<sup>3</sup>) or

liquefied gases not exceeding a capacity of 40 pounds (18 kg) each at *normal temperature and pressure (NTP)* used for maintenance purposes, patient care or operation of equipment.

2. Food service operations in accordance with Section 6103.2.1.7.
3. Hydrogen gas systems located in a hydrogen fuel gas room constructed in accordance with Section 421 of the *International Building Code*.

❖ Flammable gases must not be stored or used where an accident could cause a large loss of life. They must be stored and used in accordance with preventive guidelines for safety purposes. The limitation to office spaces in Group B occupancies allows small laboratories, doctor or dental spaces or other nonoffice uses classified as Group B to store and use quantities up to the MAQs of flammable or oxidizing gases.

Exception 1 provides that small quantities of liquefied or nonliquefied gases are allowed for maintenance of buildings, taking care of patients and equipment operation. Flammable gas systems are not allowed for these purposes because the large volume would create the potential for a catastrophic event with large loss of life and property.

Exception 2 refers the code user to the code provisions for use of liquefied petroleum gas (LP-gas) in cooking operations in buildings.

Starting with the 2003 editions of the code and the IBC, there existed provisions for the use of a "hydrogen cutoff room" as an incidental use for the storage and use of hydrogen. The purpose was to provide rules for the indoor application of the then-new hydrogen fuel technology. Though language was added to Chapter 23 pointing to the "hydrogen cutoff room" provisions for indoor motor fuel dispensing operations, no pointer was provided for other uses of the new technology, such as the use of hydrogen fuel cells with hydrogen gas cylinders as a fuel supply for clean energy backup power systems. The use of the hydrogen fuel cell for backup power supplies is not occupancy group specific and, though Exception 1 permits the use of hydrogen for operation of equipment, the allowed hydrogen capacity is insufficient for the backup power application. Exception 3 provides a needed pointer to the use of the "hydrogen cutoff room" (renamed "hydrogen fuel gas room") and allows use of this technology in the occupancy groups otherwise restricted by this section. The limiting factor would be the MAQ for flammable gas currently specified by the code. See the commentary to Section 5808.

**5803.1.1.1 Medical gases.** Medical gas system supply cylinders shall be located in medical gas storage rooms or gas cabinets as set forth in Section 5306.

❖ Section 5306 gives requirements for storage rooms and gas cabinets. Storage rooms are to be of 1-hour-

rated construction and be either interior or exterior rooms. Gas cabinets must be connected to an exhaust system, sprinklered internally and meet certain air velocity ventilation requirements.

**5803.1.1.2 Aggregate quantity.** The aggregate quantities of flammable gases used for maintenance purposes and operation of equipment shall not exceed the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1).

❖ Table 5003.1.1(1) contains categories of storage, use-closed systems and use-open systems. Flammable gas is categorized only in the storage and use-closed systems. Because gas is in closed containers and systems, use-open systems do not apply. The base MAQ for either storage or use-closed systems is 1,000 cubic feet (28 m<sup>3</sup>); however, increases for sprinklers and using approved storage cabinets may be applied.

**5803.1.2 Storage containers.** Cylinders and pressure vessels for flammable gases shall be designed, constructed, installed, tested and maintained in accordance with Chapter 53.

❖ Sections 5303 and 5304 give requirements for storage containers, such as markings on tanks, securing the tanks to prevent dislodging, protection of the valves, separation from hazards, electrical wiring, exposure to fire, unauthorized use, leak prevention, overhead protection and grounding to properly prevent a lightning hazard.

**5803.1.3 Emergency shutoff.** *Compressed gas* systems conveying flammable gases shall be provided with *approved* manual or automatic emergency shutoff valves that can be activated at each point of use and at each source.

❖ In order to maintain control over the flow of flammable gases under emergency conditions, each supply source, as well as each point of use of flammable compressed gas, must have an approved emergency shutoff valve. These valves must be excess flow control valves to regulate the rate of flow of hazardous materials within the piping system, fail-safe valves or other approved types that will operate automatically, or there must be a manual means of operation to give the fire department or other responsible persons the ability to stop the flow of hazardous materials in an emergency. The valves must be readily accessible and comply with Section 5003.2.2.1. See also the commentary to the definitions of “Emergency shutoff valve,” “Emergency shutoff valve, manual” and “Emergency shutoff valve, automatic” in Section 202.

**5803.1.3.1 Shutoff at source.** A manual or automatic fail-safe emergency shutoff valve shall be installed on supply piping at the cylinder or bulk source. Manual or automatic cylinder valves are allowed to be used as the required emergency shutoff valve where the source of supply is limited to unmanifolded cylinder sources.

❖ Where the source of the gas is limited to cylinder sources that are not manifolded, the shutoff valve can be the cylinder valve itself. If cylinders are manifolded

or if the source is other than cylinders, an independent shutoff valve is required to be installed in the piping system.

**5803.1.3.2 Shutoff at point of use.** A manual or automatic emergency shutoff valve shall be installed on the supply piping at the point of use or at a point where the equipment using the gas is connected to the supply system.

❖ Emergency shutoff valves are to be installed on the supply piping either at the use point or where equipment is connected. Either manual or automatic valves are allowed to be used. For example, it is common in some installations to have gas piped to a room for use with portable or fixed equipment. Emergency shutoff valves are typically provided at the point where the piping first enters the room. Equipment may not be connected to the valve; however, the valve represents the point of connection for use. When equipment is connected to the supply system, a valve that isolates the equipment is required. It may or may not be the same valve as that used at the point of penetration. Either valve is allowed to be manual or automatic, and either valve serves as an emergency shutoff valve.

**5803.1.4 Ignition source control.** Ignition sources in areas containing flammable gases in storage or in use shall be controlled in accordance with Section 5003.7.

**Exception:** Fuel gas systems connected to building service utilities in accordance with the *International Fuel Gas Code*.

❖ As discussed in the commentary to Chapter 3, an ignition source is needed to ignite a fuel load and cause a fire. Making sure electrical equipment located in gas storage areas is properly grounded is one of the primary ways to control ignition sources. The exception exempts flammable gas systems that are used primarily as a source of fuel furnished by a public utility service. The term “service utilities” is used in IBC Section 112 to describe those utilities that are used to provide building service. Without this exception, any area in which a fuel gas is used would be required to be posted.

The exception is focused on building services and as such is not intended to address the use of flammable gases such as hydrogen that may be generated on site, or otherwise supplied to an area of dispensing or use.

**5803.1.4.1 Static-producing equipment.** Static-producing equipment located in flammable gas storage areas shall be grounded.

❖ This requirement is intended to reduce the likelihood of a buildup of static electricity that could produce a spark that may become an ignition source for flammable gas. This requirement is similar to grounding requirements for electrical equipment in other hazardous material storage and handling areas, such as flammable liquids or LP-gas, and in combustible dust-producing environments. Although the text of this

section is the same as that of Section 5803.1.5.2, the applicability here is to equipment other than electrical wiring and equipment.

**5803.1.4.2 Signs.** “No Smoking” signs shall be posted at entrances to rooms and in areas containing flammable gases in accordance with Section 5003.7.1.

❖ Establishing no-smoking zones in, around and at the entrance to flammable gas storage and use areas is another means of controlling a common ignition source. Section 5003.7.1, Item 4 requires signage in the room or area where flammable materials are stored, dispensed or used. Even if the entire facility is designated as a “No Smoking” facility, entrance doors to flammable gas areas are required to be posted (see Section 5003.7.1, Item 3). With the development of provisions for the use of hydrogen as an alternative fuel, hydrogen cutoff rooms have been created. These rooms are to be used for compression, generation, storage and dispensing of hydrogen. See IBC Section 421 for further information on hydrogen cutoff rooms.

There are a multitude of other instances where posting should be provided to warn users of the potential presence of flammable gases prior to entering a room or area. Posting at the entrance to the room or area in which flammable gases are compressed or generated provides early warning of the hazard prior to entering the space. Signage on the outside entrances to such areas, as well as inside the area, is warranted. Signs should be in accordance with Section 310.

**5803.1.5 Electrical.** Electrical wiring and equipment shall be installed and maintained in accordance with Section 605 and NFPA 70.

❖ This section establishes the applicability of NFPA 70 to all electrical wiring and equipment in flammable gas occupancies. In order to control the ignition and personnel hazards of electrical wiring located where flammable gas might be released by malfunctioning equipment, rupture or breakage, they are typically classified as Class I, Division 2 wiring methods and equipment under the provisions of NFPA 70.

**5803.1.5.1 Bonding of electrically conductive materials and equipment.** Exposed noncurrent-carrying metal parts, including metal gas piping systems, that are part of flammable gas supply systems located in a hazardous (electrically classified) location shall be bonded to a grounded conductor in accordance with the provisions of NFPA 70.

❖ NFPA 70 requires bonding and grounding of metal gas piping systems and other noncurrent-carrying metal parts that are likely to become energized. Flammable gas piping and supply and transfer systems are subject to differences in electrical potential as gas is transferred from one portion of the system to another. By bonding the system and connecting the bond to ground, the system will be brought to a common potential. The limitation is placed on sys-

tems located in hazardous or electrically classified areas, because in these areas ignition is likely and differences in electrical potential represent the greatest hazard.

**5803.1.5.2 Static-producing equipment.** Static-producing equipment located in flammable gas storage or use areas shall be grounded.

❖ This requirement is intended to reduce the likelihood of a buildup of static electricity that could produce a spark that may become an ignition source for flammable gas. This requirement is similar to grounding requirements for electrical equipment in other hazardous material storage and handling areas, such as flammable liquids or LP-gas, and in combustible dust-producing environments. Although the text of this section is the same as that of Section 5803.1.4.1, the applicability here is to electrical wiring and equipment as sources of static electricity.

**5803.1.6 Liquefied flammable gases and flammable gases in solution.** Containers of liquefied flammable gases and flammable gases in solution shall be positioned in the upright position or positioned so that the pressure relief valve is in direct contact with the vapor space of the container.

**Exceptions:**

1. Containers of flammable gases in solution with a capacity of 1.3 gallons (5 L) or less.
2. Containers of flammable liquefied gases, with a capacity not exceeding 1.3 gallons (5 L), designed to preclude the discharge of liquid from safety relief devices.

❖ This section requires that pressure relief valves communicate with the container vapor space where there is a liquid component to the flammable gas storage method. Pressure relief valves are designed on the basis of gas flow, not liquid flow. As such, in the event of an abnormal increase in container pressure that could cause the pressure relief valve to operate, a pressure relief valve that is in contact with and attempts to pass liquid will operate much more slowly to reduce container pressure, thus increasing the potential for container failure. Passing liquid through a pressure relief valve to the atmosphere can also lead to a sudden vaporization of the liquid into a much larger quantity of flammable gas than would be released had the valve communicated with the vapor space. The magnitude of the vaporization depends upon the expansion ratio [from liquid to gas at 14.7 psia (101 kPa)] of the liquefied gas being stored. Propane, for example, has an expansion ratio of 1 to 270.

The exceptions recognize the lesser hazard of small containers used in everyday commerce, such as torch cylinders, table-top grill cylinders, etc. Exception 1 focuses on small containers containing gases that are dissolved in solution (such as acetylene dissolved in acetone). Exception 2 focuses on similar small containers that are designed specifically

to prevent liquid discharge through the pressure relief valve.

**5803.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of flammable gases in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

❖ Section 5003.1.4 addresses quantities that exceed the MAQ. The MAQs are located in Tables 5003.1.1(1) through 5003.1.1(4).

### SECTION 5804 STORAGE

**5804.1 Indoor storage.** Indoor storage of flammable gases in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1), shall be in accordance with Sections 5001, 5003 and 5004, and this chapter.

❖ Sections 5003.1 through 5003.11 give the requirements for the indoor storage of flammable gases, including design and construction; equipment; maintenance; markings and signs.

**5804.1.1 Explosion control.** Buildings or portions thereof containing flammable gases shall be provided with explosion control in accordance with Section 911.

❖ Table 911.1 gives the barricade and explosion control requirements for flammable gases. Section 911 gives deflagration, explosion venting and barricade requirements.

**5804.2 Outdoor storage.** Outdoor storage of flammable gases in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003 and 5004, and this chapter.

❖ Section 5001 covers the classification of the hazard of flammable gases. The MAQs of the gases are given in Table 5003.1.1(3). Section 5004 deals with the storage of flammable gases. The section covers ventilation, separation, fire-extinguishing systems, emergency power, limit controls, supervision and weather protection.

### SECTION 5805 USE

**5805.1 General.** The use of flammable gases in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall be in accordance with Sections 5001, 5003 and 5005, and this chapter.

❖ Section 5005 addresses separation, spill control, limit controls, lighting, fire-extinguishing systems, open systems, ventilation, outdoor dispensing and handling of flammable gases.

### SECTION 5806 FLAMMABLE CRYOGENIC FLUIDS

**5806.1 General.** The storage and use of flammable *cryogenic fluids* shall be in accordance with Sections 5806.2 through 5806.4.8.3 and Chapter 55.

❖ This section introduces the following sections that address the requirements for the storage and use of flammable cryogenic fluids. In addition to these hazard-specific requirements, the general provisions applicable to cryogenic fluids in Chapter 55 also apply. Note that Sections 5806.4 through 5806.4.8.3 were formerly contained in Chapter 55.

**5806.2 Limitations.** Storage of flammable *cryogenic fluids* in stationary containers outside of buildings is prohibited within the limits established by law as the limits of districts in which such storage is prohibited (see Section 3 of the Sample Legislation for Adoption of the *International Fire Code* on page xxi).

❖ This section reminds users that there may be an ordinance in the jurisdiction that would limit the location or amount of cryogenic fluid that could be stored outside of buildings. Generally, such restrictions will be based on locations in densely populated areas or similar factors. This section does not limit the amount that can be stored; it is simply a note to the code user to review any local rules or ordinances for restrictions before investing time and money in designing a facility that may not be usable. If such areas do exist in the adopting community, they must be enumerated in the adopting ordinance.

**5806.3 Above-ground tanks for liquid hydrogen.** Above-ground tanks for the storage of liquid hydrogen shall be in accordance with Sections 5806.3 through 5806.3.2.1.

❖ This section introduces the following sections that address the requirements for above-ground tank construction in a more specific manner than that described in Section 5003.2.1. The requirements for construction for above-ground tanks parallel those found for underground tanks with the exception that the vacuum jacket (outer tank) is not required to be constructed to meet requirements of the ASME BPVC. The vacuum jacket is designed to provide an insulated layer around the inner vessel through the use of vacuum and an insulating layer. It is also designed to contain and relieve a release of hydrogen should a leak occur in the annular space. The jacket is designed to a safety factor of two. For underground tanks, the safety factor is increased due to potential loading by the use of ASME requirements where the safety factor of three and a half is used.

The design criteria are found in CGA H-3 which, while not referenced in the code, is available for use by those that seek to establish more detailed design requirements than would otherwise be available through the use of Section 5003.2.1. The minimum design requirements established by Section 5806.3

coupled with the general requirements of Chapter 55 applicable to all cryogenics result in greater consistency and an increase in public safety.

**5806.3.1 Construction of the inner vessel.** The inner vessel of storage tanks in liquid hydrogen service shall be designed and constructed in accordance with Section VIII, Division 1, of the ASME *Boiler and Pressure Vessel Code* and shall be vacuum jacketed in accordance with Section 5806.3.2.

❖ Hydrogen in a liquid state must be stored at very low temperatures in tanks insulated to maintain that temperature. The inner vessel of the assembly must be constructed as a pressure vessel in accordance with the ASME BPVC, Section VIII, Division 1 to withstand the liquid hydrogen pressures.

Liquid hydrogen storage tanks are designed and manufactured as double-walled tanks equipped with a layer of insulation between the inner tank and the outer jacket. Additionally, the annular space between the inner tank and outer jacket is held under a vacuum for further insulation. Leakage of either the outer jacket through external corrosion or the inner tank through an internal crack will result in a loss of vacuum and early detection of the leak.

**5806.3.2 Construction of the vacuum jacket (outer vessel).**

The vacuum jacket used as an outer vessel for storage tanks in liquid hydrogen service shall be of welded steel construction designed to withstand the maximum internal and external pressure to which it will be subjected under operating conditions to include conditions of emergency pressure relief of the annular space between the inner and outer vessel. The jacket shall be designed to withstand a minimum collapsing pressure differential of 30 psi (207 kPa).

❖ The construction requirements for the vacuum jacket will be different depending on whether the vessel will be installed above ground or underground. For above-ground liquid hydrogen vessels, the requirements in this section are applicable and for underground vessels, Section 5806.4.8.

Above-ground vacuum-jacketed vessels must be designed to withstand the maximum internal and external pressure to which they may be subjected. Because the primary inner vessel is designed as a pressure vessel, the vacuum jacket must be designed to withstand a collapse due to the loss of vacuum and be capable of withstanding the pressure that can result in the event the liquid hydrogen vessel becomes involved in a fire or is subjected to the radiation energy of an exposure fire. While the probability of such an event is low, it is possible that hydrogen could leak from the primary pressure vessel into the annular space created by the vacuum jacket. This section requires that the outer vessel be designed for a minimum collapse pressure differential of 30 psig (207 kPa) and with a means of pressure relief to ensure that the inner primary vessel and the outer jacket safely relieve any pressure in the event the vessel is subjected to fire exposure.

**5806.3.2.1 Vacuum-level monitoring.** A connection shall be provided on the exterior of the vacuum jacket to allow measurement of the pressure within the annular space between the inner and outer vessel. The connection shall be fitted with a bellows-sealed or diaphragm-type valve equipped with a vacuum gauge tube that is shielded to protect against damage from impact.

❖ This section and Section 5806.4.8.3 require a means of monitoring the underground and above-ground liquid hydrogen tanks to ensure that vacuum pressure is maintained. Loss of vacuum pressure will result in the increased heating of the primary vessel, which will increase the pressure inside of the container. Eventually the pressure will reach and exceed the vessel's maximum allowable working pressure, which will result in the operation of the pressure relief device. For above-ground liquid hydrogen tanks, a connection with a tube or pipe terminated into the vacuum space is required by this section to terminate at a valve equipped with a vacuum pressure gauge so the pressure can be monitored. This section specifies the use of a bellows-sealed or diaphragm valve. A bellows valve is constructed with a steel bellows that is welded to the valve stem and the valve bonnet. This bellows creates a multiple layer barrier that prevents the release of any product around the valve packing or the valve gasket. Bellows valves are generally specified based on the number of cycles the valve can anticipate over its service life, which can vary from 2,000 to 10,000 cycles. A diaphragm valve is constructed in a similar manner in that the internal diaphragm isolates the working parts of the valve from the cryogenic hydrogen and isolates the valve inlet from the valve outlet. Regarding underground liquid hydrogen containers, Section 5806.4.8.3 requires that the method of monitoring the vacuum pressure be approved.

**5806.4 Underground tanks for liquid hydrogen.** Underground tanks for the storage of liquid hydrogen shall be in accordance with Sections 5806.4.1 through 5806.4.8.3.

❖ Underground storage of fuel is a common practice at consumer sites such as motor fuel-dispensing facilities. The benefits of underground storage include reduced risk of fire and hazards resulting from damage caused by vehicles or vandals. Also, unlike underground fuel storage tanks containing petroleum products, liquid hydrogen tanks present no known risk to groundwater should a leak, spill or overflow occur. Released hydrogen will evaporate to the atmosphere and will not contaminate groundwater.

Cryogenic liquid storage tanks traditionally have been installed above ground. This practice is documented in CGA P-12, which states, "Bulk storage tanks and vessels should be installed above ground and out-of-doors so that they are readily accessible to mobile supply equipment at ground level and to authorized personnel." Further, CGA G-5.4 states, "Liquid hydrogen piping shall not be installed underground."

The current interest in hydrogen vehicle fueling stations in locations similar to present gasoline-fueling stations demonstrates an increased need to place liquid hydrogen tanks at sites with limited space for a typical above-ground installation. Based on the compressed gas industry's extensive experience with cryogenic liquid storage tanks and their associated piping systems, installing cryogenic liquid storage tanks underground with proper engineering and controls is thought to be a safe alternative to the traditional practice of limiting installations to above ground only.

Underground tanks require special care and attention in design and installation because they are exposed to conditions not associated with above-ground tanks. Leakage is harder to detect and protection from loads being placed on top of or adjacent to the underground tank is needed to prevent damage to it. Additionally, the underground tank must be protected from flooding and from floating in areas having a groundwater table that may be above the bottom of the underground tank. Safeguards to mitigate these effects are contained in Sections 5806.4.1 through 5806.4.8.3.

**5806.4.1 Construction.** Storage tanks for liquid hydrogen shall be designed and constructed in accordance with ASME *Boiler and Pressure Vessel Code* (Section VIII, Division 1) and shall be vacuum jacketed in accordance with Section 5806.4.8.

❖ Hydrogen in a liquid state must be stored at very low temperatures, usually at or below -423°F (-253°C), in tanks insulated to maintain that temperature and constructed to withstand the liquid hydrogen pressures.

Liquid hydrogen storage tanks, designed, built and stamped in accordance with ASME BPVC, Section VIII, Division 1, can be installed underground as long as certain minimum criteria are met. Liquid hydrogen tanks are designed and manufactured as double-walled tanks equipped with a layer of insulation between the inner tank and the outer jacket. Additionally, the annular space between the tanks is held under a vacuum for further insulation. Leakage of either the outer jacket through external corrosion or the inner tank through an internal crack will result in a loss of vacuum and early detection of the leak.

**5806.4.2 Location.** Storage tanks shall be located outside in accordance with the following:

1. Tanks and associated equipment shall be located with respect to foundations and supports of other structures such that the loads carried by the latter cannot be transmitted to the tank.
2. The distance from any part of the tank to the nearest wall of a *basement*, pit, cellar or *lot line* shall be not less than 3 feet (914 mm).

3. A minimum distance of 1 foot (305 mm), shell to shell, shall be maintained between underground tanks.

❖ Underground tanks must be located away from a building or structure so that the tank does not support the building or structure since such loads can cause the underground tank to rupture.

Underground tanks are to be a minimum of 3 feet (914 mm) from the nearest below-grade wall or property line because any leakage from an underground tank may migrate through the soil and enter an adjacent basement, cellar or pit. The accumulation of hydrogen gas in such locations could develop into a hazardous condition. Because the owner of the underground tank does not own the adjacent property, the location of the underground tank should not have the potential to affect the adjacent property or the use of this property.

To provide physical independence between underground tanks so that they share no common or projected loads, a minimum shell-to-shell clearance of 1 foot (305 mm) is required between adjacent underground tanks.

**5806.4.3 Depth, cover and fill.** The tank shall be buried such that the top of the vacuum jacket is covered with not less than 1 foot (305 mm) of earth and with concrete not less than 4 inches (102 mm) thick placed over the earthen cover. The concrete shall extend not less than 1 foot (305 mm) horizontally beyond the footprint of the tank in all directions. Underground tanks shall be set on firm foundations constructed in accordance with the *International Building Code* and surrounded with not less than 6 inches (152 mm) of noncorrosive inert material, such as sand.

**Exception:** The vertical extension of the vacuum jacket as required for service connections.

❖ Excavation for underground tanks must not damage existing adjacent structures and must provide a sound foundation for the underground tank. The use of 6 inches (152 mm) of well-tamped, noncorrosive material (e.g., sand or clean pea gravel) around an underground tank prevents concentrated loads from being applied to the tank. These concentrated loads can be caused during backfilling when a hard solid object, such as a rock, comes in contact with the underground tank. Soil pressures on the rock can be concentrated into a small contact area with the underground tank and lead to a leak in the vacuum jacket.

While the 1 foot (305 mm) of earth cover plus a 4-inch (102 mm) concrete slab will provide physical protection for the tank from most predictable load scenarios, it would not alone provide adequate protection from the imposition of vehicular loads upon the tank. However, the provisions of this section and those for vacuum jacket construction in Section 5806.4.8 of the code are intended to work together to provide adequate protection from all anticipated loads, including vehicle loads.

The exception recognizes the practical limitations of maintaining the required burial depth and cover on vertical vacuum jacket extensions used to provide above-ground control and monitoring points, such as for vacuum and liquid level gauges, manually operated valves, controls, pressure relief devices and instrumentation, which need to be readily accessible to mobile supply equipment at ground level and to authorized personnel.

**5806.4.4 Anchorage and security.** Tanks and systems shall be secured against accidental dislodgement in accordance with this chapter.

❖ Sections 5503.5.2 and 5504.3.1.1.4 of the code detail the provisions for security of cryogenic fluid containers. See the commentary to those sections for further information.

**5806.4.5 Venting of underground tanks.** Vent pipes for underground storage tanks shall be in accordance with Section 5503.3.

❖ Section 5503.3 regulates pressure relief vent piping. Additional venting requirements were formerly contained in Section 2309.5.4 but were removed in the 2012 edition. For additional pressure relief device venting, the provisions of Chapter 8 of NFPA 2 apply in accordance with Section 5801.1. See the commentary to Sections 5503.3 through 5503.3.2.

**5806.4.6 Underground liquid hydrogen piping.** Underground liquid hydrogen piping shall be vacuum jacketed or protected by *approved* means and designed in accordance with Chapter 55.

❖ Piping associated with underground liquid hydrogen storage tanks must be provided with the same level of design integrity as the tank that it serves. If the piping is not designed with a vacuum jacket, an engineered design complying with the performance requirements of Chapter 55 and approved by the fire code official must be provided.

**5806.4.7 Overfill protection and prevention systems.** An *approved* means or method shall be provided to prevent the overfill of all storage tanks.

❖ The purpose of spill and overfill protection equipment is to reduce the potential for a hydrogen release during deliveries by stopping product flow, reducing product flow or alerting the delivery person during delivery before the tank becomes full and begins releasing hydrogen into the environment. The equipment must be maintained in proper working order and used properly to provide adequate protection from overfills.

**5806.4.8 Vacuum jacket construction.** The vacuum jacket shall be designed and constructed in accordance with Section VIII of ASME *Boiler and Pressure Vessel Code* and shall be designed to withstand the anticipated loading, including loading from vehicular traffic, where applicable. Portions of the

vacuum jacket installed below grade shall be designed to withstand anticipated soil, seismic and hydrostatic loading.

❖ This section, along with Section 5806.4.3, requires that the design of the tank's vacuum jacket and the tank's burial depth and cover work together to provide a tank installation unlikely to be affected by any anticipated loading conditions, including the possibility of vehicles being driven over the installation site.

**5806.4.8.1 Material.** The vacuum jacket shall be constructed of stainless steel or other *approved* corrosion-resistant material.

❖ Soil conditions and environmental conditions can cause tanks to deteriorate. Corrosion can weaken the tank, creating a potential for leakage. The tank must be protected from corrosion by use of corrosion-resistant material, coatings, cathodic protection or alternative methods approved by the fire code official.

**5806.4.8.2 Corrosion protection.** The vacuum jacket shall be protected by *approved* or *listed* corrosion-resistant materials or an engineered cathodic protection system. Where cathodic protection is utilized, an *approved* maintenance schedule shall be established. Exposed components shall be inspected not less than twice a year. Records of maintenance and inspection events shall be maintained.

❖ Deterioration of tanks, piping and components caused by corrosion can allow leaks and spillage of liquid hydrogen. Using noncorrodible materials of construction or cathodic (galvanic) protection can protect the tank, piping and components from deterioration and failure from corrosive effects.

Cathodic protection uses a sacrificial anode to prevent the corrosion of the metal vacuum jacket of the storage tank. The sacrificial anode is electrically bonded to the tank, so the electrochemical reaction of the sacrificial anode reduces or prevents the corrosion of the steel vacuum jacket of the storage tank. The sacrificial anode and the steel vacuum jacket of the storage tank, acting as a cathode, are interconnected with a power supply. The need to replace the anode will depend on the rate of corrosion.

While not specifically prohibited by this section, the joining of dissimilar metals in system construction should be avoided because of the localized galvanic action that could occur between them. This localized galvanic action could cause one of the metals to corrode to failure so that the other metal is protected from corrosion.

Because cathodic protection systems are more complex than other corrosion protection methodologies and in order to verify that the system is functioning properly, a fire code official's approved maintenance and inspection schedule must be established with all activities recorded. Records must be retained and should be made available for examination by the fire code official or a duly authorized representative of the fire code official when requested.

**5806.4.8.3 Vacuum-level monitoring.** An *approved* method shall be provided to indicate loss of vacuum within the vacuum jacket(s).

- ❖ In order for vacuum-jacketed tanks to be effective in maintaining liquid hydrogen at the required subzero temperature, the vacuum must be maintained at the manufacturer's design level. This section requires that an approved method of monitoring the integrity of the vacuum jacket be provided. Though no alarm system is required to be activated upon loss of the interstitial vacuum, it is important that administrative procedures require regular checking of the monitoring method to reduce the likelihood of loss of the liquid hydrogen (see also commentary, Section 5806.3.2.1).

## SECTION 5807 METAL HYDRIDE STORAGE SYSTEMS

**5807.1 General requirements.** The storage and use of metal hydride storage systems shall be in accordance with Sections 5801, 5803, 5804, 5805 and 5807. Those portions of the system that are used as a means to store or supply hydrogen shall also comply with Chapters 50 and 53 as applicable.

- ❖ Metal hydride storage systems (MHSS) are subject to the requirements in Section 5003.1.1 and IBC Sections 414 and 415 for hazardous materials, in addition to the indicated provisions of this chapter. The requirements include that the total volume of hydrogen in the fuel cells cannot exceed the compressed flammable gas MAQ of 1,000 cubic feet (28 m<sup>3</sup>) at NTP in a single control area located at the grade plane of a building.

**5807.1.1 Classification.** The hazard classification of the metal hydride storage system, as required by Section 5001.2.2, shall be based on the hydrogen stored without regard to the metal hydride content.

- ❖ When classifying the metals and hydrogen contained in an MHSS, this section prescribes that only the compressed hydrogen be considered in the classification and determination of the amount of compressed gas. The type and amount of metal used to adsorb the hydrogen is not considered when classifying hazardous materials contained in a MHSS. For the purpose of determining the MAQ, Section 5807.1.1 specifies all MHSSs should only be evaluated based on the amount of compressed flammable gas.

**5807.1.2 Listed or approved systems.** Metal hydride storage systems shall be *listed* or *approved* for the application and designed in a manner that prevents the addition or removal of the metal hydride by other than the original equipment manufacturer.

- ❖ The design of an MHSS must prevent the addition or removal of the metal hydride by unauthorized individuals. Some metal hydrides can present other physical and health hazards. This section requires that MHSS

be either listed or approved by the code official and any addition or removal of metal hydrides is to be performed by the original equipment manufacturer. When being filled, Section 5807.1.9.2 requires that the hydrogen be of a purity specified by the manufacturer.

**5807.1.3 Containers, design and construction.** *Compressed gas* containers, cylinders and tanks shall be designed and constructed in accordance with Section 5303.2.

- ❖ Containers, tanks and cylinders used in MHSS are to be constructed in accordance with U.S. DOT and Compressed Gas Association (CGA) requirements for cylinders or in accordance with Section VIII, Division 1 of the ASME BPVC. This section requires all cylinders, containers or tanks used for the primary containment of metal hydrides and hydrogen to meet the requirements of Section 5303.2. See the commentary to that section for further information.

**5807.1.4 Service life and inspection of containers.** Metal hydride storage system cylinders, containers or tanks shall be inspected, tested and requalified for service at not less than 5-year intervals.

- ❖ To ensure that hydrogen and metal hydrides are safely contained, the cylinders, tanks and containers are also subject to periodic inspection and requalification in accordance with U.S. DOT requirements and this section. This section establishes a maximum requalification frequency of 5 years.

**5807.1.5 Marking and labeling.** Marking and labeling of cylinders, containers, tanks and systems shall be in accordance with Section 5303.4 and Sections 5807.1.5.1 through 5807.1.5.4.

- ❖ The requirements for MHSS include marking and labeling of important system components to confirm that the design complies with the requirements of Chapters 50 and 53, as well as those in Section 5807.

**5807.1.5.1 System marking.** Metal hydride storage systems shall be marked with all of the following:

1. Manufacturer's name.
2. Service life indicating the last date the system can be used.
3. A unique code or serial number specific to the unit.
4. System name or product code that identifies the system by the type of chemistry used in the system.
5. Emergency contact name, telephone number or other contact information.
6. Limitations on refilling of containers to include rated charging pressure and capacity.

- ❖ The marking requirements in this section for various components of the assembled MHSS are intended to ensure that the MHSS is properly filled and the design pressure and temperature of the system is not exceeded. The markings must also identify the basic chemistry of the MHSS in the unlikely event a metal

hydride is released from a container. Markings are required for the cylinder valve in accordance with Section 5807.1.5.2, the pressure relief device in accordance with the requirements in Section 5807.1.5.3 and the cylinder or pressure vessel containing the metal hydride and hydrogen in accordance with Section 5807.1.5.4.

**5807.1.5.2 Valve marking.** Metal hydride storage system valves shall be marked with all of the following:

1. Manufacturer's name.
2. Service life indicating the last date the valve can be used.
3. Metal hydride service in which the valve can be used, or a product code that is traceable to this information.

❖ See the commentary to Section 5807.1.5.1.

**5807.1.5.3 Pressure relief device marking.** Metal hydride storage system pressure relief devices shall be marked with all of the following:

1. Manufacturer's name.
2. Metal hydride service in which the device can be used, or a product code that is traceable to this information.
3. Activation parameters to include temperature, pressure or both.

❖ See the commentary to Section 5807.1.5.1.

**5807.1.5.3.1 Pressure relief devices integral to container valves.** The required markings for pressure relief devices that are integral components of valves used on cylinders, containers and tanks shall be allowed to be placed on the valve.

❖ See the commentary to Section 5807.1.5.1.

**5807.1.5.4 Pressure vessel markings.** Cylinders, containers and tanks used in metal hydride storage systems shall be marked with all of the following:

1. Manufacturer's name.
2. Design specification to which the vessel was manufactured.
3. Authorized body approving the design and initial inspection and test of the vessel.
4. Manufacturer's original test date.
5. Unique serial number for the vessel.
6. Service life identifying the last date the vessel can be used.
7. System name or product code that identifies the system by the type of chemistry used in the system.

❖ See the commentary to Section 5807.1.5.1.

**5807.1.6 Temperature extremes.** Metal hydride storage systems, whether full or partially full, shall not be exposed to artificially created high temperatures exceeding 125°F (52°C) or subambient (low) temperatures unless designed for use under the exposed conditions.

❖ The intent of this section is to prevent damage to the MHSS or the accidental release of hydrogen due to the cylinder exceeding its design pressure. As such,

this section requires that MHSS be located in an area where they are not subject to artificially high or low temperatures. It prohibits any MHSS from exposure to temperatures in excess of 125°F (52°C) or excessively low temperatures unless it is designed for use in such environments.

**5807.1.7 Falling objects.** Metal hydride storage systems shall not be placed in areas where they are capable of being damaged by falling objects.

❖ The intent of this section is to prevent damage to the MHSS from falling objects. As such, this section requires that MHSS be located in an area where they are not subject to being struck by falling objects. In climates subject to freezing, this could include keeping the MHSS well clear of buildings or other structures where accumulated ice could fall from the structure and strike the MHSS.

**5807.1.8 Piping systems.** Piping, including tubing, valves, fittings and pressure regulators, serving metal hydride storage systems, shall be maintained gas tight to prevent leakage.

❖ All apparatus, connected and part of the MHSS, shall comply with this section and Chapter 50. Proper maintenance of all the components ensures that gas leaks with possible ignition are prevented.

**5807.1.8.1 Leaking systems.** Leaking systems shall be removed from service.

❖ Accidental spills create a vapor release that can quickly travel from the spill point to an ignition source. Because spills need immediate attention to neutralize and remove the hazard, the local fire department should be notified; it is the agency best prepared to deal with the immediate hazards of a spill.

Leaks can indicate a developing problem with equipment or piping needing immediate repair. Until repairs are made, the equipment or piping must be taken out of service.

**5807.1.9 Refilling of containers.** The refilling of *listed* or *approved* metal hydride storage systems shall be in accordance with the listing requirements and manufacturer's instructions.

❖ MHSS that are listed or approved in accordance with Section 5807.1.2 must be refilled strictly in accordance with their manufacturer's instructions which are considered part of the listing of a system. MHSS that are approved but not listed must also be refilled in accordance with their manufacturer's instructions, which were included in the fire code official's approval. Approval records should also be reviewed for any additional conditions for refilling of the system.

**5807.1.9.1 Industrial trucks.** The refilling of metal hydride storage systems serving powered industrial trucks shall be in accordance with Section 309.

❖ One MHSS application is fuel cells powering material-handling equipment such as forklifts or motorized pallet jacks. At locations where industrial trucks are fueled, this section requires that the fueling area comply with the requirements of Section 309, which, in

turn, includes requirements for proper refilling of equipment.

**5807.1.9.2 Hydrogen purity.** The purity of hydrogen used for the purpose of refilling containers shall be in accordance with the listing and the manufacturer's instructions.

❖ Keeping the hydrogen as pure as possible in keeping with the MHSS's listing is critical for the efficient operation of a turbine. Every 2-percent reduction in the purity of the hydrogen coolant increases windage losses in the turbine and the cost of running an 800-megawatt generator is increased significantly. Contaminants in the hydrogen can also be very dangerous and air is the most common impurity due to leaks. When the oxygen in the air is mixed with hydrogen, a potentially explosive condition can be created. However, hydrogen does not support combustion in a nearly pure state (greater than 90 percent) with the balance being air. By using a continuous gas analyzer transmitter to constantly monitor the hydrogen purity, any potentially hazardous condition can be avoided, enhancing safety and maximizing efficiency and profitability (see also commentary to Section 5807.1.9).

**5807.1.10 Electrical.** Electrical components for metal hydride storage systems shall be designed, constructed and installed in accordance with NFPA 70.

❖ NFPA 70 regulates the design and installation of electrical systems, components and equipment. All electrical work must also be in compliance with any specific electrical classifications and conditions contained in the listing or approval for each MHSS.

**5807.2 Portable containers or systems.** Portable containers or systems shall comply with Sections 5807.2.1 through 5807.2.2.

❖ This section introduces the provisions for portable metal hydride containers or MHSS.

**5807.2.1 Securing containers.** Containers, cylinders and tanks shall be secured in accordance with Section 5303.5.3.

❖ See the commentary to Section 5303.5.3.

**5807.2.1.1 Use on mobile equipment.** Where a metal hydride storage system is used on mobile equipment, the equipment shall be designed to restrain containers, cylinders or tanks from dislodgement, slipping or rotating when the equipment is in motion.

❖ This section requires MHSS installed on mobile equipment to be designed for such an application and be capable of restraining cylinders from movement while in motion so as to avoid damage to the equipment.

**5807.2.1.2 Motorized equipment.** Metal hydride storage systems used on motorized equipment, shall be installed in a manner that protects valves, pressure regulators, fittings and controls against accidental impact.

❖ This section requires MHSS installed on motorized equipment to be designed to be capable of restrain-

ing cylinders from movement, dislodgement or impact with other objects while the equipment is in operation so as to avoid damage to the equipment.

**5807.2.1.2.1 Protection from damage.** Metal hydride storage systems, including cylinders, containers, tanks and fittings, shall not extend beyond the platform of the mobile equipment.

❖ To protect MHSS components such as cylinders, regulators, pipe, valves and fittings from impact, the MHSS and its components must be installed so they do not extend beyond the platform of the mobile equipment.

**5807.2.2 Valves.** Valves on containers, cylinders and tanks shall remain closed except when containers are connected to *closed systems* and ready for use.

❖ In order to reduce the likelihood of hydrogen leakage from containers, cylinders and tanks when they are not connected to or in use in a closed system, their valves must be kept closed.

## SECTION 5808 HYDROGEN FUEL GAS ROOMS

**5808.1 General.** Where required by this code, hydrogen fuel gas rooms shall be designed and constructed in accordance with Sections 5808.1 through 5808.7 and the *International Building Code*.

❖ This section is simply stating that all hydrogen fuel gas rooms are to be constructed in accordance with the provisions contained in this section and IBC Section 421. Hydrogen fuel gas rooms were created to address the increasing and emerging concepts of fuel cells that use hydrogen and actually generate hydrogen on site to run the fuel cells. The provisions of this section and IBC Section 421 address construction-related issues for hydrogen cutoff rooms such as location, fire-resistance-rated separation, ventilation and safety features such as gas detection and explosion control. The provisions of Section 5808 are intended to be consistent with those of the referenced standard, NFPA 2.

**5808.2 Location.** Hydrogen fuel gas rooms shall not be located below grade.

❖ Restrictions against installation of hydrogen fuel gas rooms below grade are similar to those restricting the location of flammable and combustible liquids in basements. Explosion hazards are the primary concern, and placement of materials that have an ability to cause an explosion in below-grade spaces is not appropriate. Such spaces are more difficult to evacuate, create a fire and explosion hazard to the structure above and are very difficult for the fire department to access.

**5808.3 Design and construction.** Hydrogen fuel gas rooms not exceeding the *maximum allowable quantity per control area* in Table 5003.1.1(1) shall be separated from other areas

of the building in accordance with Section 509.1 of the *International Building Code*.

- ❖ Hydrogen fuel gas rooms are required to be separated by not less than 1-hour fire-resistance-rated fire barriers or horizontal assemblies, or both, which is consistent with the requirements in IBC Table 509 for incidental uses. In addition, the classification of the space will affect the separation requirements. Hydrogen fuel gas rooms can contain any amount of hydrogen up to the maximum allowable quantities per control area (MAQ). However, if the MAQs are exceeded, the room can no longer be considered an incidental use and instead must be classified as a separated Group H-2 occupancy. In all cases, separation in accordance with IBC Table 508.4 would apply in addition to the applicable occupancy-specific requirements.

**5808.3.1 Pressure control.** Hydrogen fuel gas rooms shall be provided with a ventilation system designed to maintain the room at a negative pressure in relation to surrounding rooms and spaces.

- ❖ This section requires hydrogen fuel gas rooms to be maintained at a negative pressure with regard to surrounding spaces to provide some level of protection against a flammable mixture being attained in other parts of the building.

**5808.3.2 Windows.** Operable windows in interior walls shall not be permitted. Fixed windows shall be permitted where in accordance with Section 716 of the *International Building Code*.

- ❖ Operable windows are prohibited in order to further reduce the likelihood of allowing hydrogen to escape from the room into other portions of the building that may not be properly ventilated. An operable window could inadvertently be left in the open or partially open position and go unnoticed. Fixed window openings must meet the requirements of IBC Section 716 to ensure that the requirements for opening protectives are met. More specifically, the proper fire protection ratings for openings in fire barriers are required.

**5808.4 Exhaust ventilation.** Hydrogen fuel gas rooms shall be provided with mechanical exhaust ventilation in accordance with the applicable provisions of Section 2311.7.1.1.

- ❖ The purpose of this section is to prevent a dangerous accumulation of flammable gas in the room through the use of an exhaust ventilation system. The ventilation must be at the rate of 1 cfm per 12 cubic feet of room volume, which is as required for ventilation of motor vehicle repair shops that repair hydrogen-fueled vehicles and is consistent with the requirements in Chapter 5 of the *International Mechanical Code*® (IMC®). See the commentary to Section 2311.7.1.1.

**5808.5 Gas detection system.** Hydrogen fuel gas rooms shall be provided with an approved flammable gas detection system in accordance with Sections 5808.5.1 through 5808.5.4.

- ❖ Some gases contain additives that produce pungent odors for easy recognition. Systems using nonodorized gases, such as hydrogen and liquefied natural gas (LNG), must utilize gas detection systems to detect leaks. This section specifically requires such detection due to the hazards associated with a build-up of hydrogen at hazardous levels within a building.

**5808.5.1 System design.** The flammable gas detection system shall be *listed* for use with hydrogen and any other flammable gases used in the hydrogen fuel gas room. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammable limit (LFL) for the gas or mixtures present at their anticipated temperature and pressure.

- ❖ The detection system must initiate the operations specified in Section 5808.5.3 at any time that the flammable gas concentration exceeds one-fourth of the concentration necessary to support combustion. Early detection of the presence of a flammable gas will allow adequate mitigation procedures to be taken. Hydrogen fires are not normally extinguished until the supply of hydrogen has been shut off because of the danger of reignition or explosion. A gas detection system in the room or space housing a gaseous hydrogen system results in early notification of a leak that is occurring before the escaping gas reaches a hazardous concentration.

**5808.5.2 Gas detection system components.** Gas detection system control units shall be *listed* and *labeled* in accordance with UL 864 or UL 2017. Gas detectors shall be *listed* and *labeled* in accordance with UL 2075 for use with the gases and vapors being detected.

- ❖ This section requires gas detection equipment to be listed in accordance with UL 2075 for use with the different gases it will detect. Under UL 2075, a set of flammable gases and concentrations, measured in parts per million (ppm), is developed for each detector or sensor, and the manufacturer is required to provide information as to what gases and the concentrations the device is designed to detect. Tests under the standard then verify the performance of each detector or sensor for each gas it is designed to detect. The gases that the equipment will detect may be shown in the manufacturer's instructions rather than on the product. This section also is intended to ensure that gas detection system control components are listed in accordance with nationally recognized safety standards. These standards include a comprehensive set of construction and performance requirements that are used to evaluate and list gas detection system control units and gas detectors.

**5808.5.3 Operation.** Activation of the gas detection system shall result in both of the following:

1. Initiation of distinct audible and visual alarm signals both inside and outside of the hydrogen fuel gas room.
  2. Activation of the mechanical exhaust ventilation system.
- ❖ The required local alarm is intended to alert the occupants to an emerging hazardous condition in the vicinity. The monitor control equipment must also initiate operation of the mechanical ventilation system in the event of a leak or rupture in the gaseous hydrogen system to prevent an accumulation of flammable gas.
- In addition to causing alarms to activate the detection system must also activate the mechanical ventilation system required by Section 5808.4.

**5808.5.4 Failure of the gas detection system.** Failure of the gas detection system shall result in activation of the mechanical exhaust ventilation system, cessation of hydrogen generation and the sounding of a trouble signal in an approved location.

- ❖ Gas detection systems must be designed to be self-monitoring and fail-safe in that all safety systems are activated to alert any occupants that a problem exists and to prevent more hydrogen from being generated by any appliances in the room when hazardous conditions cannot be monitored.

**5808.6 Explosion control.** Explosion control shall be provided where required by Section 911.

- ❖ The requirements of this section are intended to address the circumstance resulting from a catastrophic failure of the hydrogen fuel gas room. These requirements are the final safeguard in case safety features such as interlocked doors, ventilation and gas detection systems should fail. An ignited hydrogen mixture produces large quantities of heat, causing a rapid expansion of the surrounding air. This can cause a pressure increase in a confined space and a catastrophic failure. Explosion control methods are identified in Section 911 to prevent such a catastrophic failure. The explosion control requirements for gaseous and liquefied hydrogen are consistent with the requirements in Section 6.9 of NFPA 2.

**5808.7 Standby power.** Mechanical ventilation and gas detection systems shall be connected to a standby power system in accordance with Section 604.

- ❖ The ventilation system and gas detection system are life safety systems and, therefore, must be dependable. Both safety systems must remain active in the event of a failure of the primary power supply. Hydrogen is a colorless, odorless gas; a release might go undetected if detection systems are not functioning. The accumulation of hydrogen in an unventilated area can lead to mixtures in the flammable range if safety systems and mechanical ventilation systems are not in operation. Section 604 and Chapter 50 address standby power requirements for essential

systems. Chapter 50 also allows for systems that are fail-safe in Sections 5004.7.2 and 5005.1.5.1 in hydrogen fuel gas rooms where hydrogen is either generated or stored.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 59: Flammable Solids

## General Comments

This chapter addresses magnesium almost to the exclusion of all other flammable solids; however, it is important to know that several other solid materials, primarily metals, are also flammable and under the right conditions can be explosion hazards. It should also be noted that, although the definition of “Flammable solid” could be literally interpreted as being applicable to a much wider variety of common materials having an ignition temperature below 212°F (100°C), it is not the intent of this chapter to regulate such materials. See the commentary for “Flammable solid” in Chapter 2.

The list of other metals that can become fire hazards consists of titanium, zirconium, hafnium, calcium, zinc, sodium, lithium, potassium, sodium/potassium alloys, aluminum, iron and steel, uranium, thorium and plutonium. Some of these metals have a few highly specialized commercial uses; they are almost exclusively laboratory materials. But because of where they are used, both plant and fire service personnel must be trained to handle emergency situations. Because uranium, thorium and plutonium are also radioactive materials, they present still more specialized problems for plant fire brigades and local fire service personnel.

The form of the material being used (powder, sheets, castings or billets) also is critical to the way fire services respond to an incident. Fine powders of any of the materials listed can ignite or even explode under various atmospheres, including nitrogen. Some molten metals can ignite or explode under certain conditions. Castings of some of these metals can ignite or detonate if they are not handled properly. Even bulky billets can be ignited if there is sufficient heat to bring the metal to its ignition temperature, resulting in self-sustained burning.

Conventional fire-extinguishing agents may only increase the intensity of the fire being fought. Magnesium, for example, burns fiercely in a steam atmosphere. Likewise, carbon dioxide, foam and dry

chemical extinguishers are not effective on titanium fires. Additionally, water, foam and vaporizing liquids should never be used on lithium, sodium and potassium fires. Each material is different and requires different extinguishing treatment.

The National Fire Protection Association (NFPA) has developed standards for handling several of the listed materials, which are included in the bibliography at the end of this chapter. Most industry associations and companies manufacturing primary metals and alloys also have available recommended practices for storage, handling, use and scrap disposal that are based on extensive testing and usage history. The fire code official should require any person or business storing, handling or processing any of these materials to demonstrate a thorough knowledge of safe practices in both facility design and operating procedures.

## Purpose

This chapter sets general requirements for storage and handling of flammable solids in the first five sections before addressing the subject of magnesium in Section 5906.

A word of caution is necessary when applying the general requirements stated in Sections 5901 through 5905. Each of the flammable metals mentioned in the “General Comments” section requires special precautions. What works with one material may cause a major disaster with another. It is always best to make certain the building, facility and operating conditions proposed by the owner, architect or builder are based on the latest safety information available from the suppliers of the materials to be used or stored. The fire code official should verify that the emergency plan prepared for use by the owner or tenant is workable and compatible with the emergency response personnel and equipment available to the jurisdiction.

## SECTION 5901 GENERAL

**5901.1 Scope.** The storage and use of flammable solids shall be in accordance with this chapter.

❖ This section establishes the applicability of this chapter to all materials meeting the definition of and classified as flammable solids.

**5901.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is

issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.6.21 for discussion of specific operational permits for hazardous materials, Section 105.7 for a general discussion of activities requiring a construction permit and Section 105.7.10 for discussion of specific construction permits for hazardous materials. The permit process also notifies the fire department of the need for pre-fire planning for hazardous properties.

**SECTION 5902  
DEFINITIONS**

**5902.1 Definitions.** The following terms are defined in Chapter 2:

**FLAMMABLE SOLID.  
MAGNESIUM.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

**SECTION 5903  
GENERAL REQUIREMENTS**

**5903.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of flammable solids in amounts not exceeding the *maximum allowable quantity per control area* as indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5901.

❖ This section complements the requirements of Chapter 50 in structures occupied for the storage, handling or use of flammable solids. The regulations assume that the quantity of flammable solids in a given building is limited to the maximum allowable quantity per control area (MAQ) as established in Section 5003.1; thus, the building is not classified in Occupancy Group H. The general requirements of Sections 5001 and 5003 are fully applicable to the storage and use of flammable solids, in addition to the requirements of this chapter.

**5903.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of flammable solids exceeding the *maximum allowable quantity per control area* as indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

❖ This section complements the requirements of Chapter 50 for structures occupied for the storage, handling or use of flammable solids. The regulations contained in this section assume that the quantity of flammable solids in a given building is in excess of the MAQ as established in Section 5003.1; thus, the

building is classified in Occupancy Group H. The requirements of Chapter 50 apply to the storage and use of flammable solids, in addition to the requirements of this chapter.

**SECTION 5904  
STORAGE**

**5904.1 Indoor storage.** Indoor storage of flammable solids in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

❖ This section regulates the indoor storage of flammable solids when in excess of the MAQ in buildings or portions of buildings classified in Occupancy Group H. The general and storage requirements of Chapter 50 are applicable in addition to the requirements of this section. Storage of flammable solids inside of structures must comply with Sections 5904.1.1 through 5904.1.3 to prevent exposure to conditions that may result in a fire or explosion.

**5904.1.1 Pile size limits and location.** Flammable solids stored in quantities greater than 1,000 cubic feet (28 m<sup>3</sup>) shall be separated into piles each not larger than 1,000 cubic feet (28 m<sup>3</sup>).

❖ Storage piles are restricted to 1,000 cubic feet (28 m<sup>3</sup>) in size to limit the quantity of flammable solids exposed to a single fire and to facilitate fire-fighting operations. Aisles must be provided on all sides to permit access for fire fighting and reduce the likelihood of the spread of fire to adjacent piles if a pile collapse occurs.

**5904.1.2 Aisles.** Aisle widths between piles shall not be less than the height of the piles or 4 feet (1219 mm), whichever is greater.

❖ As with all other storage, aisles allow fire response personnel ready access to the immediate area of the fire. The requirement that aisle width depends on pile height acknowledges the effectiveness of physical separation in preventing fire spread as well as making room for more or larger fire-fighting equipment that may be needed to fight fires in large storage piles of flammable solids. Additionally, keeping aisle widths the same as the pile heights reduces the likelihood of the spread of fire to adjacent piles or creating a “domino effect” in the event of a pile collapse, since a pile will generally not tip over intact.

**5904.1.3 Basement storage.** Flammable solids shall not be stored in *basements*.

❖ Basement storage is prohibited because of the limited access for fire suppression and ventilation operations in most basements and the hazards associated with the vigorous and persistent fires that can occur in flammable solids.

**5904.2 Outdoor storage.** Outdoor storage of flammable solids in amounts exceeding the *maximum allowable quantities per control area* indicated in Table 5003.1.1(1) shall be in

accordance with Sections 5001, 5003, 5004 and this chapter. Outdoor storage of magnesium shall be in accordance with Section 5906.

- ❖ This section regulates the outdoor storage of flammable solids when in excess of the MAQ established by Table 5003.1.1(3). The general and storage requirements of Chapter 50 are applicable, in addition to the requirements of this section. Storage of flammable solids in outdoor control areas must comply with Sections 5904.2.1 and 5904.2.2 to reduce the likelihood of uncontrolled release or exposure to conditions that may result in a fire or explosion.

**5904.2.1 Distance from storage to exposures.** Outdoor storage of flammable solids shall not be located within 20 feet (6096 mm) of a building, *lot line*, public street, public alley, *public way* or *means of egress*. A 2-hour *fire barrier* without openings or penetrations and extending 30 inches (762 mm) above and to the sides of the storage area is allowed in lieu of such distance. The wall shall either be an independent structure, or the *exterior wall* of the building adjacent to the storage area.

- ❖ The required separation distance is intended to minimize radiant heat transfer between exposures. Separation distances provide a measure of protection against the possibility of fire spread if a fire occurs involving either the stored material or another exposure, such as a building located on the same or an adjacent lot or a vehicle in the public right-of-way.

An alternative to the 20-foot (6069 mm) distance is offered in this section. Essentially, it would allow the use of a 2-hour fire barrier, constructed in accordance with Section 707 of the *International Building Code*® (IBC®) and without openings, that extends 30 inches (763 mm) above and to the sides of the storage.

**5904.2.2 Pile size limits.** Outdoor storage of flammable solids shall be separated into piles not larger than 5,000 cubic feet (141 m<sup>3</sup>) each. Piles shall be separated by aisles with a minimum width of not less than one-half the pile height or 10 feet (3048 mm), whichever is greater.

- ❖ Outside storage piles may be increased in size (over inside storage) to 5,000 cubic feet (141 m<sup>3</sup>) based on the reduced danger to people and property associated with outdoor storage. Required aisles are intended to facilitate fire-fighting access and prevent the spread of fire to adjacent piles if a pile collapse occurs. Aisles should permit unobstructed access to the pile on all sides, as well as permit approach from more than one direction.

## SECTION 5905 USE

**5905.1 General.** The use of flammable solids in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5005 and this chapter.

The use of magnesium shall be in accordance with Section 5906.

- ❖ This section applies to all indoor and outdoor use and handling operations involving flammable solids, except magnesium, when the amounts being used or handled are in excess of the MAQ [buildings or portions of buildings classified in Occupancy Group H and outdoor control area indicated in Tables 5003.1.1(1) and 5003.1.1(3), respectively]. The administrative, general use and handling provisions of Chapter 50 are applicable, in addition to the requirements of this chapter.

## SECTION 5906 MAGNESIUM

**5906.1 General.** Storage, use, handling and processing of magnesium, including the pure metal and alloys of which the major part is magnesium, shall be in accordance with Chapter 50 and Sections 5906.2 through 5906.5.8.

- ❖ This section establishes the applicability of Section 5906 and Chapter 50 to the production, storage, processing and disposal of magnesium products. These requirements are applicable not only to pure magnesium but also to alloys having a magnesium content in excess of 50 percent.

**5906.2 Storage of magnesium articles.** The storage of magnesium shall comply with Sections 5906.2.1 through 5906.4.3.

- ❖ The requirements of Sections 5906.2.1 through 5906.4.3 apply to the storage of any quantity of magnesium based on the various physical forms of the material and the fire hazard and extinguishing problems it poses.

**5906.2.1 Storage of greater than 50 cubic feet.** Magnesium storage in quantities greater than 50 cubic feet (1.4 m<sup>3</sup>) shall be separated from storage of other materials that are either combustible or in combustible containers by aisles. Piles shall be separated by aisles with a minimum width of not less than the pile height.

- ❖ This is a general criterion applicable to all forms of magnesium. As is noted in the following sections, storage requirements and allowable quantities vary with the form of the product being stored.

Isolation of magnesium from other combustible materials of any kind helps reduce the amount of magnesium exposed to a single fire originating outside of the magnesium pile and protects materials outside the magnesium pile from exposure to it. Properly established and maintained aisles provide fire suppression personnel ready access to the immediate area of the fire as well as proper egress circulation in the storage area. The requirement that aisle width depends on pile height acknowledges the effectiveness of physical separation in preventing fire spread.

**5906.2.2 Storage of greater than 1,000 cubic feet.** Magnesium storage in quantities greater than 1,000 cubic feet (28 m<sup>3</sup>) shall be separated into piles not larger than 1,000 cubic feet (28 m<sup>3</sup>) each. Piles shall be separated by aisles with a minimum width of not less than the pile height. Such storage shall not be located in nonsprinklered buildings of Type III, IV or V construction, as defined in the *International Building Code*.

❖ Again, this is a general criterion applicable to all forms of magnesium and establishes the maximum pile size at 1,000 cubic feet (28 m<sup>3</sup>) of material (see also the discussion in the commentary to Section 5906.2.1). In this scenario, a pile could be approximately 10 feet long by 10 feet wide by 10 feet high (3048 mm by 3048 mm by 3048 mm) with an established aisle width between piles of 10 feet (3048 mm). Note that when the quantity of stored magnesium exceeds 1,000 cubic feet (28 m<sup>3</sup>), this section requires that the storage building be of Type I or II construction, or when equipped throughout with an automatic sprinkler system, of Type III, IV or V construction.

**5906.2.3 Storage in combustible containers or within 30 feet of other combustibles.** Where in nonsprinklered buildings of Type III, IV or V construction, as defined in the *International Building Code*, magnesium shall not be stored in combustible containers or within 30 feet (9144 mm) of other combustibles.

❖ This section recognizes the increased hazard of storing magnesium in nonsprinklered buildings of Type III, IV and V construction by requiring that any containers used for the storage of magnesium be constructed of noncombustible material to provide a layer of shielding to the magnesium in the event of a fire. To further isolate magnesium piles, reduce the likelihood of fire spread among adjacent piles and enhance the effectiveness of the shielding provided by noncombustible storage containers where used, this section requires a substantial increase in the spatial separation between the magnesium and any other combustible materials. Note that this increased separation is not related to pile height.

**5906.2.4 Storage in foundries and processing plants.** The size of storage piles of magnesium articles in foundries and processing plants shall not exceed 1,250 cubic feet (25 m<sup>3</sup>). Piles shall be separated by aisles with a minimum width of not less than one-half the pile height.

❖ Allowing storage of an increased quantity of flammable solids in foundries and processing plants acknowledges that ignition of pigs, ingots and billets is unlikely under conditions normally found in foundries and other processing buildings where ordinary combustible materials are rarely found in any significant quantity.

**5906.3 Storage of pigs, ingots and billets.** The storage of magnesium pigs, ingots and billets shall comply with Sections 5906.3.1 and 5906.3.2.

❖ The requirements of Sections 5906.3.1 and 5906.3.2 apply to the storage of any quantity of magnesium in the forms of pigs (a mass of magnesium that has been run into a mold while molten), ingots (a mass of magnesium cast in a convenient form for further processing) and billets (a bar of magnesium forged from an ingot) and the hazards they pose. The quantities allowed again indicate that ignition of these large shapes is unlikely under the conditions required.

**5906.3.1 Indoor storage.** Indoor storage of pigs, ingots and billets shall only be on floors of noncombustible construction. Piles shall not be larger than 500,000 pounds (226.8 metric tons) each. Piles shall be separated by aisles with a minimum width of not less than one-half the pile height.

❖ This section establishes maximum quantity for single piles, but does not restrict the number of piles that can be located in one building or structure. The requirement for aisles that are at least half the pile height allows adequate clearance for both materials-handling equipment and emergency response equipment and personnel. Where pile heights are kept low, the aisles must still be maintained at a width that will allow for equipment travel between piles. Requiring storage on a noncombustible surface reduces the likelihood that the floor would contribute any fuel or contribute to the spread of a fire involving magnesium.

**5906.3.2 Outdoor storage.** Outdoor storage of magnesium pigs, ingots and billets shall be in piles not exceeding 1,000,000 pounds (453.6 metric tons) each. Piles shall be separated by aisles with a minimum width of not less than one-half the pile height. Piles shall be separated from combustible materials or buildings on the same or adjoining property by a distance of not less than the height of the nearest pile.

❖ This section recognizes the inherently higher level of safety provided by the storage of materials outdoors by doubling the amount of magnesium per pile that can be stored. The required separation distance is intended to minimize radiant heat transfer between exposures. Separation distances provide a measure of protection against the possibility of fire spread if a fire occurs either in the stored material or in another exposure, such as a building located on the same or an adjacent lot. Separation also serves the purpose of allowing passage of materials-handling equipment and emergency response equipment.

**5906.4 Storage of fine magnesium scrap.** The storage of scrap magnesium shall comply with Sections 5906.4.1 through 5906.4.3.

❖ The requirements of Sections 5906.4.1 through 5906.4.3 apply to the storage of any quantity of mag-

nesium in the form of scrap chips, fines and dust and the hazards they pose. These less-dense forms of magnesium, typically produced in machine processing and recovered for subsequent reuse, present a substantial fire and explosion risk, which is addressed in the following sections.

**5906.4.1 Separation.** Magnesium fines shall be kept separate from other combustible materials.

❖ Separation of stored magnesium fines from ordinary combustible materials is required because fines are extremely combustible and easily ignitable. A small pile of fines can be ignited by a common match flame. Section 5906.2.1 contains minimum separation criteria for all types of magnesium storage.

**5906.4.2 Storage of 50 to 1,000 cubic feet.** Storage of fine magnesium scrap in quantities greater than 50 cubic feet (1.4 m<sup>3</sup>) [six 55-gallon (208 L) steel drums] shall be separated from other occupancies by an open space of not less than 50 feet (15 240 mm) or by a *fire barrier* constructed in accordance with Section 707 of the *International Building Code*.

❖ Because fines are usually wet with coolant from the processing operation, there is a possibility of hydrogen generation. For this reason, fines must be stored in approved steel containers with vented lids to prevent hydrogen buildup. Because there is also a possibility of spontaneous heating of fines, they must be stored separately from combustible materials, including other storage piles of magnesium. The required separation distance is intended to minimize radiant heat transfer between the stored magnesium and other materials and provide a measure of protection against the possibility of spread if a fire occurs.

An alternative to the 20-foot (6069 mm) distance is offered in this section. Essentially, it would allow the use of a 2-hour fire barrier, constructed in accordance with IBC Section 707 and without openings, that extends 30 inches (763 mm) above and to the sides of the storage.

**5906.4.3 Storage of greater than 1,000 cubic feet.** Storage of fine magnesium scrap in quantities greater than 1,000 cubic feet (28 m<sup>3</sup>) shall be separated from all buildings other than those used for magnesium scrap recovery operations by a distance of not less than 100 feet (30 480 mm).

❖ This section recognizes the increased risk associated with the storage of significant quantities of magnesium fines by establishing a blanket 100-foot (30 480 mm) separation distance to any building that is not specifically part of a magnesium recovery operation.

**5906.5 Use of magnesium.** The use of magnesium shall comply with Sections 5906.5.1 through 5906.5.8.

❖ The requirements of Sections 5906.5.1 through 5906.5.8 apply to the use, handling and processing of

any quantity of magnesium and the processing hazards it poses.

**5906.5.1 Melting pots.** Floors under and around melting pots shall be of noncombustible construction.

❖ This requirement should seem obvious for any operation that involves melting any quantity of any metal. It is particularly important with flammable metals, however, because of the possibility of fire from an overheated melting pot or an explosion caused by the addition of alloying metal to the molten magnesium that has not been thoroughly dried before being added to the pot. Any quantity of absorbed moisture on the added metal will turn instantly to steam and cause a violent eruption of molten metal from the pot.

Eruptions of molten metal present a serious burn hazard to personnel as well as the potential for the hot metal to ignite combustible construction under or near the pot.

When molten magnesium is handled according to standard industry safety practices, it is not a serious hazard. Magnesium has been used for well over 50 years in both military and commercial applications with very few serious fires. This long history of safe operations suggests that safety rules and precautions developed by both suppliers and users are effective. The fire code official must require that a user of molten magnesium have safe operating procedures in place as well as an emergency response plan that includes both plant fire brigades and jurisdiction emergency response units.

**5906.5.2 Heat-treating ovens.** *Approved* means shall be provided for control of magnesium fires in heat-treating ovens.

❖ Heat-treating ovens present a significant potential for fires. Some of the heat treatments required to obtain the physical properties necessary for certain applications are done at temperatures very close to the ignition temperature of magnesium. Accordingly, this section requires that fire control means approved by the fire code official be readily available to the heat-treating process. Large castings that have thick sections are not as likely to ignite, but fine fins or very thin sections can ignite if overheated, as can dust or fine chips. For this reason, oven controls are critical to safe operation. Making sure items to be heat treated are free of dust and chips is also essential. Fire control can also be achieved in higher temperature ovens by operating them with an inert gas atmosphere to reduce the risk of magnesium ignition.

Although not stated specifically in this section, the requirement for keeping the heat-treating area clear of scrap and other combustibles should be obvious.

**5906.5.3 Dust collection.** Magnesium grinding, buffing and wire-brushing operations, other than rough finishing of cast-

## FLAMMABLE SOLIDS

ings, shall be provided with *approved* hoods or enclosures for dust collection that are connected to a liquid-precipitation type of separator that converts dust to sludge without contact (in a dry state) with any high-speed moving parts.

❖ The potential for fires and explosions involving magnesium dust and other fines has already been stated. The dust from grinding, buffing and wire brushing operations must be collected and contained in a closed system that is equipped with a water spray dust precipitator and an exhaust blower. The exhaust system is required because wet magnesium fines will generate hydrogen gas that must be diluted below its lower flammable limit (LFL).

Equipment used for grinding, buffing and wire-brushing must be dedicated for use on magnesium only. Commentary Figure 5906.5.3 shows a typical grinding machine setup.

**5906.5.3.1 Duct construction.** Connecting ducts or suction tubes shall be completely grounded, as short as possible, and without bends. Ducts shall be fabricated and assembled with a smooth interior, with internal lap joints pointing in the direction of airflow and without unused capped side outlets, pockets or other dead-end spaces that allow an accumulation of dust.

❖ Although the requirements stated in this section are applicable to magnesium manufacturing operations, they are virtually the same as the requirements for handling any other kind of flammable or detonable dust and fine particles. The construction specifications are intended to prevent fines from accumulating in sufficient quantities to become a hazard. Grounding is required to prevent sparking that could become a source of ignition. See the commentary to Sections 510 and 511 of the *International Mechanical Code*® (IMC®) for a discussion of hazardous exhaust systems and dust conveying systems.

**5906.5.3.2 Independent dust separators.** Each machine shall be equipped with an individual dust-separating unit.

### Exceptions:

1. One separator is allowed to serve two dust-producing units on multiunit machines.
2. One separator is allowed to serve not more than four portable dust-producing units in a single enclosure or stand.

❖ This requirement complements Section 5906.5.3.1, which mandates that ducts be straight and of minimum length in order to reduce the likelihood of static buildup and dust buildup in the duct.

Exception 1 does allow two units working in tandem to be served by one collector; however, the ducts must still meet the specifications in Section 5906.5.3.1.

Exception 2 allows one collector to serve up to four small units if they are operated in an enclosure that would prevent dust from escaping into the general work area. The collector would function in approximately the same way as a vacuum system in a paint booth. The requirements for exhausting, water spray and ductwork would still apply.

Chapter 22 regulates combustible dusts and includes a reference to NFPA 484, *Standard for Combustible Metals*. See the commentary to that chapter for further information.

**5906.5.4 Power supply interlock.** Power supply to machines shall be interlocked with exhaust airflow, and liquid pressure level or flow. The interlock shall be designed to shut down the machine it serves when the dust removal or separator system is not operating properly.

❖ Allowing magnesium dust-producing operations to continue when the dust collection system required by Section 5906.5.3 is malfunctioning could allow the

dangerous buildup of extremely flammable magnesium fines at the machines. The ready ignitability of this collected material creates a hazard that this section is intended to mitigate by interlocking the dust-producing machines with the exhaust system so that the production of dust and flyings will halt if the exhaust is not performing as designed.

**5906.5.5 Electrical equipment.** Electric wiring, fixtures and equipment in the immediate vicinity of and attached to dust-producing machines, including those used in connection with separator equipment, shall be of *approved* types and shall be *approved* for use in Class II, Division 1 hazardous locations in accordance with NFPA 70.

❖ This requirement for classified electrical equipment is intended to reduce the likelihood that any fixed or portable electrical wiring and electrical equipment attached to or located or used near dust-producing and dust-collecting machines will become an ignition source.

**5906.5.6 Grounding.** Equipment shall be securely grounded by permanent ground wires in accordance with NFPA 70.

❖ As with Section 5906.5.5, this requirement is intended to reduce the likelihood of a buildup of static electricity that could produce a spark that would be an ignition source for flammable solids dust. This requirement is similar to grounding requirements for electrical equipment in other dust-producing environments.

**5906.5.7 Fire-extinguishing materials.** Fire-extinguishing materials shall be provided for every operator performing machining, grinding or other processing operation on magnesium in accordance with either of the following:

1. Within 30 feet (9144 mm), a supply of extinguishing materials in an *approved* container with a hand scoop or shovel for applying the material.
2. Within 75 feet (22 860 mm), a portable fire extinguisher complying with Section 906.

All extinguishing materials shall be *approved* for use on magnesium fires. Where extinguishing materials are stored in cabinets or other enclosed areas, the enclosures shall be openable without the use of a key or special knowledge.

❖ Magnesium fires present unusual fire suppression challenges because none of the common extinguishing materials can be used safely. The problem of using water has already been mentioned, but it must be emphasized again. Water sprayed on a magnesium fire will do two things. First, if the fire involves small pieces such as chips, fines or dust, the reaction of the burning metal with water can be explosive, causing burning brands to fly onto surrounding materials and equipment. Second, the extraordinary heat generated by burning magnesium can break the chemical bonds between hydrogen and oxygen atoms in the water molecule. Once this occurs, the hydrogen will be burned and the oxygen will support continued combustion, making the fire that much more intense; however, the danger of a hydrogen explosion under

fire conditions is generally slight. If magnesium burns in the open, an excess of oxygen will be available to burn any hydrogen as rapidly as it is generated, thus preventing formation of an explosive accumulation of gas. Despite the noted dangers, however, magnesium fires can be extinguished by cooling the metal below its melting point using relatively large amounts of water carefully applied from a safe distance.

The use of sand can produce a similar reaction to the use of water. Sand is composed of silicon dioxide (SiO<sub>2</sub>) molecules that will break down, allowing the oxygen to support the combustion of the magnesium.

Carbon dioxide cannot be used on magnesium fires for the same reason. Magnesium reacts so strongly with oxygen that the carbon dioxide will decompose, giving the fire additional oxygen and making it burn more intensely.

In extreme cases, magnesium will even burn in a nitrogen atmosphere, forming magnesium nitride.

Halon cannot be used because magnesium reacts violently with the chlorine molecules in the gas to form magnesium chloride.

Consequently, special fire-fighting agents are required for fighting magnesium and other flammable metal fires. Because flammable metal fires are considered Class D fires, it is important to verify that portable fire extinguishers provided in accordance with this section are labeled as being effective on such fires. Similarly, any installed fire-extinguishing system must be chosen carefully with the focus on extinguishing agent compatibility with the protected content.

The form of the material involved in the fire will dictate what can be used to extinguish it. The most difficult fire is one involving fines. Normally, a dry extinguishing agent is manually spread over the fire to smother the burning material. Care must be taken, however, to make sure the application does not raise a dust cloud that could cause an explosion.

The long history of magnesium use has resulted in a well-documented fire-fighting strategy for each form of magnesium that could be involved in a fire. The fire code official must verify that the user facility is equipped to fight potential fires and that emergency response personnel are trained in the hazards they may face as well as in the use of the available extinguishers.

Prompt control of magnesium fires requires ready access to fire-extinguishing materials and equipment by every operator at every workstation processing the metal. The fire extinguisher access travel distance of 75 feet (22 860 mm) correlates with Section 906. The 30-foot (9144 mm) travel distance to a stockpiled supply of dry extinguishing agent correlates with the travel distance for an extra-hazard occupancy and recognizes the potential need to make repeated trips to the stockpile to bring a sufficient amount of agent to accomplish extinguishment.

**5906.5.8 Collection of chips, turnings and fines.** Chips, turnings and other fine magnesium scrap shall be collected

## FLAMMABLE SOLIDS

from the pans or spaces under machines and from other places where they collect not less than once each working day. Such material shall be placed in a covered, vented steel container and removed to an *approved* location.

❖ This requirement for collection of highly flammable material is really nothing more than good housekeeping. Keeping the working area free of accumulations of fire fuel means that the fuel load for any potential fire is minimized. As indicated in the commentary to Section 5906.4.2, because magnesium chips, turnings and fines are usually wet with coolant from the processing operation, there is a possibility of hydrogen generation. For this reason, fines must be stored in accordance with Section 5906.4 and in approved steel containers with vented lids to prevent hydrogen buildup.

As was discussed in Chapter 3, the three required elements for a fire are fuel, oxygen and an ignition source. If any one of these three is absent, there will be no fire. Depriving a potential fire of its fuel source is one of the primary ways to prevent fires. Following the other requirements in this chapter will also minimize the oxygen supply and prevent fuel from coming in contact with ignition sources.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

CPSC 16 CFR, 1500 44, *Method for Testing Extremely Flammable and Flammable Solids*. Bethesda, MD: Consumer Product Safety Commission, 2001.

*Fire Protection Handbook*, 20th Ed. Quincy, MA: National Fire Protection Association, 2008.

# Chapter 60: Highly Toxic and Toxic Materials

## General Comments

Toxic and highly toxic materials are addressed in the code because of the immediate threat they pose to occupants, others in the vicinity of a building and facility and emergency responders. As with other health hazard materials, the solid state is usually the least hazardous, while the gaseous form is the most hazardous.

Materials are often listed as being toxic or highly toxic on Material Safety Data Sheets (MSDS). These descriptors do not necessarily mean that the materials would be considered toxic or highly toxic according to the specific definitions found in Chapter 2. Those definitions provide specific criteria that will be discussed in more detail. Generally, the requirements for toxic and highly toxic materials are the most regulated health hazards in the code.

This chapter deals with all three states of toxic and highly toxic materials: solids, liquids and gases. As will be discussed, gases will generally require treatment systems and related ventilation systems.

## Purpose

The main purpose of this chapter is, as noted, to protect occupants, emergency responders and those in the immediate area of the building and facility from short-term, acute hazards associated with a release of or general exposure to toxic and highly toxic materials. The code does not address long-term exposure effects. Such issues are addressed by agencies such as the Environmental Protection Agency (EPA) and Occupational Safety and Health Administration (OSHA).

---

## SECTION 6001 GENERAL

**6001.1 Scope.** The storage and use of highly toxic and toxic materials shall comply with this chapter. *Compressed gases* shall also comply with Chapter 53.

### Exceptions:

1. Display and storage in Group M and storage in Group S occupancies complying with Section 5003.11.
2. Conditions involving pesticides or agricultural products as follows:
  - 2.1. Application and release of pesticide, agricultural products and materials intended for use in weed abatement, erosion control, soil amendment or similar applications when applied in accordance with the manufacturer's instruction and label directions.
  - 2.2. Transportation of pesticides in compliance with the Federal Hazardous Materials Transportation Act and regulations thereunder.
  - 2.3. Storage in *dwellings* or private garages of pesticides registered by the U.S. Environmental Protection Agency to be utilized in and around the home, garden, pool, spa and patio.

❖ This section states that highly toxic materials must be stored and used in accordance with this chapter. Additionally, it notes that gases are subject to the requirements in Chapter 53, which focuses on the

hazards associated with the fact that the material is a compressed gas.

There are various exceptions to this chapter. Exception 1 is related to the increased amounts allowed for storage and display in Group M and S occupancies. These increased amounts apply only to solids and liquids. For this exception to apply, all requirements found in Section 5003.11 are applicable.

Exception 2 is specific to pesticides or other agriculture-related products. Essentially, only storage in a building or facility would be regulated. The application, release or transportation of such materials would be exempt because federal standards would preempt a local jurisdiction from enforcement. In terms of application and release, regulations are specific to activities such as weed control, erosion control and soil amendment. Additionally, pesticides approved for use around homes, gardens, pools, spas and patios can be stored without regulation in private garages and within dwellings.

**6001.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an opera-

tional permit, Section 105.6.21 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

**SECTION 6002  
DEFINITIONS**

**6002.1 Definitions.** The following terms are defined in Chapter 2:

**CONTAINMENT SYSTEM.**

**CONTAINMENT VESSEL.**

**EXCESS FLOW VALVE.**

**HIGHLY TOXIC.**

**OZONE-GAS GENERATOR.**

**PHYSIOLOGICAL WARNING THRESHOLD LEVEL.**

**REDUCED FLOW VALVE.**

**TOXIC.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

**SECTION 6003**

**HIGHLY TOXIC AND TOXIC SOLIDS AND LIQUIDS**

**6003.1 Indoor storage and use.** The indoor storage and use of highly toxic and toxic materials shall comply with Sections 6003.1.1 through 6003.1.5.3.

❖ As noted in the “General Comments” section, liquids and solids are dealt with in one section and gases are dealt with in another. Generally, gases pose a greater hazard because they are more difficult to contain and can have a much more immediate effect. This section contains requirements for indoor storage and use. Outdoor storage and use are discussed in Section 6003.2.

**6003.1.1 Quantities not exceeding the maximum allowable quantity per control area.** The indoor storage or use of highly toxic and toxic solids or liquids in amounts not exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(2) shall be in accordance with Sections 5001, 5003 and 6001.

❖ This section sends the code user to the appropriate sections when the maximum allowable quantities per control area (MAQs) have not been exceeded. As with other materials, when the MAQs have not been exceeded, the requirements are less restrictive. The

code user must comply with Section 6001 as well as Sections 5001 and 5003, which are the general requirements for hazardous materials related to permits, material classification and management plans, hazard identification and other basic requirements. Section 6003 would not apply.

**6003.1.2 Quantities exceeding the maximum allowable quantity per control area.** The indoor storage or use of highly toxic and toxic solids or liquids in amounts exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(2) shall be in accordance with Section 6001, Sections 6003.1.3 through 6003.1.5.3 and Chapter 50.

❖ When the MAQs have been exceeded, the requirements in Sections 6001 and 6003 and all of Chapter 50 are applicable.

**6003.1.3 Treatment system—highly toxic liquids.** Exhaust scrubbers or other systems for processing vapors of highly toxic liquids shall be provided where a spill or accidental release of such liquids can be expected to release highly toxic vapors at *normal temperature and pressure*. Treatment systems and other processing systems shall be installed in accordance with the *International Mechanical Code*.

❖ This requirement is specific to highly toxic liquids and would require a treatment system to collect and process any vapors that might escape if a spill should occur at “normal temperature and pressure.” In other words, if at normal temperature and pressure conditions vapors would not be highly toxic, a treatment system would not be required. The focus of this section is on the inhalation hazards associated with highly toxic materials. A material may be considered highly toxic by skin contact or ingestion, but not create an inhalation hazard because of the low volatility of the liquid.

**6003.1.4 Indoor storage.** Indoor storage of highly toxic and toxic solids and liquids shall comply with Sections 6003.1.4.1 and 6003.1.4.2.

❖ This section is specific to indoor storage and focuses on floor surfaces and separation requirements.

**6003.1.4.1 Floors.** In addition to the requirements set forth in Section 5004.12, floors of storage areas where highly toxic and toxic liquids are stored shall be of liquid-tight construction.

❖ This requirement increases the likelihood that if a highly toxic or toxic liquid comes in contact with the floor of the storage area, it will not soak in and be difficult to remove. If concrete is not properly treated, spills could seep into the floor and give off vapors over time. The use of liquid-tight floors is one of the methods mentioned in Section 5004 for drainage control and secondary containment. The requirements of this section would apply in any case.

The reference to Section 5004.12 requires the floor to be noncombustible except for the surfacing; therefore, the method used to make the floor liquid tight does not need to be noncombustible. The same requirement is stated in Section 5004.2.1.

**6003.1.4.2 Separation—highly toxic solids and liquids.** In addition to the requirements set forth in Section 5003.9.8, highly toxic solids and liquids in storage shall be located in *approved* hazardous material storage cabinets or isolated from other hazardous material storage by construction in accordance with the *International Building Code*.

❖ In order to reduce the possibility of releasing hazardous fumes and vapors due to a fire involving highly toxic liquids and solids, adequate separation from other hazardous materials is required. The intent of this section is to separate flammable, explosive or other highly reactive materials from all highly toxic solids and liquids. A 1-hour fire barrier, constructed in accordance with Section 707 of the *International Building Code*® (IBC®), a 1-hour horizontal assembly constructed in accordance with IBC Section 711 or both, or an approved hazardous material storage cabinet reduces the potential for involvement of highly toxic materials in a fire involving other hazardous materials. This section would not allow a physical separation or a fire barrier that extended above and to the sides of the material, as would be possible with other hazardous materials. Note that these requirements are in addition to the code's requirements for separation of incompatible materials. See the commentary to Section 5003.9.8 for further information on that topic.

**6003.1.5 Indoor use.** Indoor use of highly toxic and toxic solids and liquids shall comply with Sections 6003.1.5.1 through 6003.1.5.3.

❖ Use is more hazardous than storage because the materials are more susceptible to release. The focus of this particular section is on the transfer of highly toxic liquids and requirements for exhaust ventilation systems where highly toxic and toxic materials are being used.

**6003.1.5.1 Liquid transfer.** Highly toxic and toxic liquids shall be transferred in accordance with Section 5005.1.10.

❖ This section refers the code user back to Section 5005.1.10 for requirements on the transfer of liquids with a hazard ranking of 3 or 4. These liquids can be transferred using several different methods, including safety cans, closed piping, approved pump arrangements, an approved engineered liquid transfer system or, under certain conditions, by gravity. It should be noted that Section 5005.1.10 prohibits highly toxic liquids from being transferred where gravity feed is involved regardless of the safeguards. There are exceptions for small amounts of liquids [1.3 gallons (5 L) for a hazard ranking of 4 and 5.3 gallons (20 L) for a hazard ranking of 3]. Section 5005.1.10 is also referenced in Section 6003.2.6 for outdoor liquid transfer.

**6003.1.5.2 Exhaust ventilation for open systems.** Mechanical exhaust ventilation shall be provided for highly toxic and

toxic liquids used in *open systems* in accordance with Section 5005.2.1.1.

**Exception:** Liquids that do not generate highly toxic or toxic fumes, mists or vapors.

❖ This section requires any open use of highly toxic or toxic liquids to be properly ventilated and refers to Section 5005.2.1.1. That section contains the general ventilation requirements for open systems using gases, liquids or solids with a hazard ranking of 3 or 4. Essentially, it requires that vapors be captured at the point of generation.

The exceptions to both Sections 5005.2.1.1 and 6003.1.5.2 state that liquids that do not produce hazardous vapors, mists or fumes need not comply with these ventilation requirements. Much of this will depend on the volatility of the liquid, the degree of hazard of the liquid and how it is used.

**6003.1.5.3 Exhaust ventilation for closed systems.** Mechanical exhaust ventilation shall be provided for highly toxic and toxic liquids used in *closed systems* in accordance with Section 5005.2.2.1.

**Exception:** Liquids that do not generate highly toxic or toxic fumes, mists or vapors.

❖ Section 5005.2.2.2 requires ventilation in accordance with Section 5005.1.1 if the closed system is designed to be opened during normal operations. Section 5005.1.1 is for open systems using materials with a hazard ranking of 3 or 4. The same exception is stated in Section 6003.1.5.2, which exempts liquids that do not produce highly toxic or toxic fumes, vapors or mists (see commentary, Section 6003.1.5.2).

**6003.2 Outdoor storage and use.** Outdoor storage and use of highly toxic and toxic materials shall comply with Sections 6003.2.1 through 6003.2.6.

❖ Outdoor storage and use is generally less hazardous than indoor storage and use because the vapors can disperse more easily to the atmosphere, posing less of a hazard to occupants and those in the vicinity of the building. Because the materials are located outside, however, there are other exposure concerns, such as weather and location of storage and use.

**6003.2.1 Quantities not exceeding the maximum allowable quantity per control area.** The outdoor storage or use of highly toxic and toxic solids or liquids in amounts not exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(4) shall be in accordance with Sections 5001, 5003 and 6001.

❖ As with indoor storage and use, when the MAQs have not been exceeded, the only requirements are those found in Section 6001 and the general requirements of Chapter 50. These requirements address issues such as permits, hazardous materials plans, pipe connections (especially with health-hazard rank-

ing materials of 3 or 4), facility closures and hazard identification and signage.

**6003.2.2 Quantities exceeding the maximum allowable quantity per control area.** The outdoor storage or use of highly toxic and toxic solids or liquids in amounts exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(4) shall be in accordance with Sections 6001 and 6003.2 and Chapter 50.

❖ When the MAQs have been exceeded for the outdoor control areas, the requirements become more extensive. More specifically, compliance with Section 6003.2 is required in addition to Section 6001 and Chapter 50, as applicable.

**6003.2.3 General outdoor requirements.** The general requirements applicable to the outdoor storage of highly toxic or toxic solids and liquids shall be in accordance with Sections 6003.2.3.1 and 6003.2.3.2.

❖ This section sets general requirements for the location and the need for treatment systems to collect vapors from highly toxic liquids.

**6003.2.3.1 Location.** Outdoor storage or use of highly toxic or toxic solids and liquids shall not be located within 20 feet (6096 mm) of *lot lines*, public streets, public alleys, *public ways*, *exit discharges* or *exterior wall* openings. A 2-hour *fire barrier* without openings or penetrations extending not less than 30 inches (762 mm) above and to the sides of the storage is allowed in lieu of such distance. The wall shall either be an independent structure, or the exterior wall of the building adjacent to the storage area.

❖ This section requires that toxic and highly toxic solids and liquids be at least 20 feet (6096 mm) from possible exposure hazards, such as an exit discharge. The concern with highly toxic and toxic materials is the health hazards for building occupants, emergency responders and others in the immediate area.

An alternative to the 20-foot (6096 mm) distance is offered in this section. Essentially, it would allow the use of a 2-hour fire barrier constructed in accordance with IBC Section 707 and without openings, that extends 30 inches (763 mm) above and to the sides of the storage. The wall can be either freestanding or a wall of the building that fits the requirements as a 2-hour fire barrier without openings. Generally, this wall and the distance requirements are for the protection of the toxic and highly toxic liquids and solids from fire exposures that could lead to the release of materials. Additionally, both methods allowed in this section result in a separation (by either distance or construction) from people to reduce the likelihood of contact with hazards.

**6003.2.3.2 Treatment system—highly toxic liquids.** Exhaust scrubbers or other systems for processing vapors of

highly toxic liquid shall be provided where a spill or accidental release of such liquids can be expected to release highly toxic vapors at *normal temperature and pressure (NTP)*. Treatment systems and other processing systems shall be installed in accordance with the *International Mechanical Code*.

❖ This section is the same as Section 6003.1.3 for indoor storage and the use of highly toxic liquids (see commentary, Section 6003.1.3).

**6003.2.4 Outdoor storage piles.** Outdoor storage piles of highly toxic and toxic solids and liquids shall be separated into piles not larger than 2,500 cubic feet (71 m<sup>3</sup>). Aisle widths between piles shall be not less than one-half the height of the pile or 10 feet (3048 mm), whichever is greater.

❖ The requirement in this section seeks to reduce the hazard level of a release of highly toxic and toxic liquids and solids by reducing the amount allowed in a single pile. Additionally, minimum separations between piles are required. These separations serve both as a fire barrier and as access for emergency responders. If the piles become too large, they become difficult to manage if a release should happen or a fire should occur.

**6003.2.5 Weather protection for highly toxic liquids and solids—outdoor storage or use.** Where overhead weather protection is provided for outdoor storage or use of highly toxic liquids or solids, and the weather protection is attached to a building, the storage or use area shall either be equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1, or storage or use vessels shall be fire resistive. Weather protection shall be provided in accordance with Section 5004.13 for storage and Section 5005.3.9 for use.

❖ This section is specific to outdoor storage or use of highly toxic liquids and solids when they are located in an area with weather protection attached to a building. The storage or use must be either sprinklered or placed within fire-resistive containers. Because the storage or use area is next to the building, the concern for a fire and the potential release of liquids and solids is greater. This poses a hazard to both building occupants and emergency responders. Section 5004.13 contains the general requirements for weather-protected storage and references the weather protection provisions of IBC Section 414.6.1.

**6003.2.6 Outdoor liquid transfer.** Highly toxic and toxic liquids shall be transferred in accordance with Section 5005.1.10.

❖ This section refers to Section 5005.1.10 for the general requirements for liquid transfer. This is the same reference used in Section 6003.1.5.1 for indoor liquid transfer (see commentary, Section 6003.1.5.1).

## SECTION 6004

## HIGHLY TOXIC AND TOXIC COMPRESSED GASES

**6004.1 General.** The storage and use of highly toxic and toxic *compressed gases* shall comply with this section.

❖ This section requires all highly toxic and toxic gases to comply with the following subsections.

**6004.1.1 Special limitations for indoor storage and use by occupancy.** The indoor storage and use of highly toxic and toxic *compressed gases* in certain occupancies shall be subject to the limitations contained in Sections 6004.1.1.1 through 6004.1.1.3.

❖ This section places additional limitations on the storage and use of toxic and highly toxic gases in several occupancy types and uses. These are further restrictions on the MAQs given in Chapter 50.

**6004.1.1.1 Group A, E, I or U occupancies.** Toxic and highly toxic *compressed gases* shall not be stored or used within Group A, E, I or U occupancies.

**Exception:** Cylinders not exceeding 20 cubic feet (0.566 m<sup>3</sup>) at *normal temperature and pressure (NTP)* are allowed within gas cabinets or fume hoods.

❖ This section prohibits having any large quantities of highly toxic and toxic gases in these occupancies. With the exception of Group U, these are occupancies that have typically high occupant densities or a vulnerable population. The prohibition for Group U occupancies is likely related to the potential lack of supervision and the types of materials that are likely to be stored along with such gases.

The exception to this section allows small amounts of gases if they are stored or used within gas cabinets or fume hoods. The allowance for small cylinders results from the small potential for release when they are stored in a cabinet or used within a fume hood and the probability that the volume of the release would be low.

**6004.1.1.2 Group R occupancies.** Toxic and highly toxic *compressed gases* shall not be stored or used in Group R occupancies.

❖ This section prohibits the storage and use of highly toxic and toxic gases in all Group R occupancies without exception. Group R occupancies cover a wide variety of dwelling-type occupancies, such as one- and two-family dwellings, apartment buildings, hotels, motels, etc. The hazards posed by the storage and use of toxic or highly toxic gases would be much higher than would reasonably be anticipated by the occupants.

**6004.1.1.3 Offices, retail sales and classrooms.** Toxic and highly toxic *compressed gases* shall not be stored or used in

offices, retail sales or classroom portions of Group B, F, M or S occupancies.

**Exception:** In classrooms of Group B occupancies, cylinders with a capacity not exceeding 20 cubic feet (0.566 m<sup>3</sup>) at *NTP* are allowed in gas cabinets or fume hoods.

❖ This section does not completely prohibit the storage and use of highly toxic liquids in these particular occupancies, but instead focuses on certain portions of occupancies. In particular, this section addresses the offices, retail sales areas and classrooms of Group B, F, M or S occupancies. A normal storage area with no public access, therefore, could be used to store highly toxic or toxic gases, but the office incidental to that storage facility could not.

The exception allows small cylinders in classrooms in Group B occupancies when they are used within gas cabinets or fume hoods. This acknowledges special needs at university laboratories and similar facilities.

**6004.1.2 Gas cabinets.** Gas cabinets containing highly toxic or toxic *compressed gases* shall comply with Section 5003.8.6 and the following requirements:

1. The average ventilation velocity at the face of gas cabinet access ports or windows shall be not less than 200 feet per minute (1.02 m/s) with not less than 150 feet per minute (0.76 m/s) at any point of the access port or window.
2. Gas cabinets shall be connected to an exhaust system.
3. Gas cabinets shall not be used as the sole means of exhaust for any room or area.
4. The maximum number of cylinders located in a single gas cabinet shall not exceed three, except that cabinets containing cylinders not exceeding 1 pound (0.454 kg) net contents are allowed to contain up to 100 cylinders.
5. Gas cabinets required by Section 6004.2 or 6004.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.

❖ This section sets additional requirements for gas cabinets used specifically for highly toxic and toxic gases. Section 5003.8.6 contains the general requirements for all gas cabinets. More specifically, that section sets out construction specifications, requires negative pressure for ventilation and restricts the number of cylinders to three. Section 6004.1.2 is more restrictive, requiring an air velocity of at least 200 feet per minute (1.02 m/s) at the face of the cabinet as well as a connection to an exhaust system and an area ventilation system in addition to the ventilation system in the gas cabinet. A sprinkler system is also required.

## HIGHLY TOXIC AND TOXIC MATERIALS

Section 6004.2.2.7 would require the exhaust to be connected to a treatment system. Item 4 in Section 6004.1.2 does allow up to 100 small cylinders [under 1 pound (0.454 kg) each] instead of the restriction of three larger cylinders. This allowance recognizes the reduced potential for a large release and increases flexibility to meet the needs of the facilities such as laboratories.

**6004.1.3 Exhausted enclosures.** Exhausted enclosures containing highly toxic or toxic *compressed gases* shall comply with Section 5003.8.5 and the following requirements:

1. The average ventilation velocity at the face of the enclosure shall be not less than 200 feet per minute (1.02 m/s) with not less than 150 feet per minute (0.76 m/s).
  2. Exhausted enclosures shall be connected to an exhaust system.
  3. Exhausted enclosures shall not be used as the sole means of exhaust for any room or area.
  4. Exhausted enclosures required by Section 6004.2 or 6004.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.
- ❖ This section, like Section 6004.1.2, requires compliance with the general exhausted enclosure requirements in Section 5003.8.5. Section 5003.8.5, like Section 5003.8.6 for gas cabinets, contains basic construction specifications and requires that the enclosure be at a negative pressure. Additionally, there is a requirement in Section 5003.8.5.3 that a fire-extinguishing system be installed when the materials stored or used in the enclosure are flammable.
- Section 6004.1.3 additionally requires an air velocity of at least 200 feet per minute (1.02 m/s) at the face of the enclosure and that the enclosure be connected to an exhaust system that is not the sole source of ventilation for that area. In addition, this section requires a sprinkler system in the enclosure. This is independent of whether the material is considered flammable.

**6004.2 Indoor storage and use.** The indoor storage and use of highly toxic or toxic *compressed gases* shall be in accordance with Sections 6004.2.1 through 6004.2.2.10.4.

❖ This section is specific to the indoor storage and use of toxic and highly toxic gases. When Section 6004.2 applies, it focuses on the location of cylinders and the removal of unwanted releases of gases. Treatment systems are required to process any gases collected when ventilating results in the release of toxic and highly toxic gases.

**6004.2.1 Applicability.** The applicability of regulations governing the indoor storage and use of highly toxic and toxic

*compressed gases* shall be as set forth in Sections 6004.2.1.1 through 6004.2.1.3.

❖ This section clarifies which requirements apply based on the amount of material in storage or in use.

**6004.2.1.1 Quantities not exceeding the maximum allowable quantity per control area.** The indoor storage or use of highly toxic and toxic gases in amounts not exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(2) shall be in accordance with Sections 5001, 5003, 6001 and 6004.1.

❖ When the MAQs have not been exceeded, only the more general requirements would apply. These include restrictions on the storage and use in certain occupancies, piping connection requirements based on the level of health hazards, permits and other similar requirements. Tables 5003.1.1(2) and 5003.1.1(4) would require putting highly toxic gases in a gas cabinet or exhausted enclosure regardless of the amount of gases stored or used. These gas cabinets and exhausted enclosures need to be in accordance only with the basic requirements of Chapter 50 and do not need to be connected to a treatment system.

**6004.2.1.2 Quantities exceeding the maximum allowable quantity per control area.** The indoor storage or use of highly toxic and toxic gases in amounts exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(2) shall be in accordance with Sections 6001, 6004.1, 6004.2 and Chapter 50.

❖ If the MAQs have been exceeded, the requirements become much more extensive. This requires compliance with all applicable sections of Chapter 50 and also Section 6004.2, which has requirements for treatment systems and gas detection systems.

**6004.2.1.3 Ozone gas generators.** The indoor use of ozone gas-generating equipment shall be in accordance with Section 6005.

❖ This section is a specific reference to Section 6005, which deals with the process of ozone generation. The operation is unique and, therefore, has unique requirements. The requirements in Section 6005 apply when the ozone-generating capacity exceeds 0.5 pound (0.227 kg) in a 24-hour period.

**6004.2.2 General indoor requirements.** The general requirements applicable to the indoor storage and use of highly toxic and toxic *compressed gases* shall be in accordance with Sections 6004.2.2.1 through 6004.2.2.10.4.

❖ The requirements in this section are for both storage and use of toxic and highly toxic gases when the MAQs have been exceeded.

**6004.2.2.1 Cylinder and tank location.** Cylinders shall be located within gas cabinets, exhausted enclosures or gas

rooms. Portable and stationary tanks shall be located within gas rooms or exhausted enclosures.

❖ Toxic and highly toxic gases pose a high threat to occupants and emergency responders if released to the atmosphere; therefore, this section places restrictions on where cylinders and tanks can be located. More specifically, cylinders must be in a gas cabinet or within gas rooms or exhausted enclosures. Tanks, both portable and stationary, must be either in a gas room or an exhausted enclosure. Gas cabinets are not an option because of the size of portable and stationary tanks. Gas cabinets, exhausted enclosures and gas rooms have specific requirements in Sections 6004.1.2, 6004.1.3 and 6004.2.2.6, respectively, in addition to the general requirements in Chapter 50.

**6004.2.2.2 Ventilated areas.** The room or area in which gas cabinets or exhausted enclosures are located shall be provided with exhaust ventilation. Gas cabinets or exhausted enclosures shall not be used as the sole means of exhaust for any room or area.

❖ This section requires that gas cabinets and exhausted enclosures not be the only ventilation provided when toxic or highly toxic gases are stored or used. The room or area must have additional ventilation. The exhaust ventilation for the room need not be processed through a treatment system.

**6004.2.2.3 Leaking cylinders and tanks.** One or more gas cabinets or exhausted enclosures shall be provided to handle leaking cylinders, containers or tanks.

**Exceptions:**

1. Where cylinders, containers or tanks are located within gas cabinets or exhausted enclosures.
2. Where *approved* containment vessels or containment systems are provided in accordance with all of the following:
  - 2.1. Containment vessels or containment systems shall be capable of fully containing or terminating a release.
  - 2.2. Trained personnel shall be available at an *approved* location.
  - 2.3. Containment vessels or containment systems shall be capable of being transported to the leaking cylinder, container or tank.

❖ Section 6004.2.2.1 requires the use of gas cabinets, exhausted enclosures or gas rooms for the storage of cylinders and tanks. This section takes the requirements one step further and requires that one or more additional gas cabinets or exhausted enclosures be provided and ready to receive leaking cylinders or tanks. Exception 1 is for cylinders and tanks that are already contained within gas cabinets or exhausted enclosures.

Exception 2 allows the use of containment vessels and containment systems in place of a gas cabinet or exhausted enclosure to address the release of gases

based on three conditions: the vessel or system must be sufficiently sized to contain the potential release; a trained person must be available; and the containment vessel or system must be transportable to the leaking cylinder or tank.

**6004.2.2.3.1 Location.** Gas cabinets and exhausted enclosures shall be located in gas rooms and connected to an exhaust system.

❖ When gas cabinets and exhausted enclosures are used with leaking tanks, they must be contained in gas rooms. Containment vessels and systems would not have to be located in a gas room.

**6004.2.2.4 Local exhaust for portable tanks.** A means of local exhaust shall be provided to capture leaks from portable tanks. The local exhaust shall consist of portable ducts or collection systems designed to be applied to the site of a leak in a valve or fitting on the tank. The local exhaust system shall be located in a gas room. Exhaust shall be directed to a treatment system in accordance with Section 6004.2.2.7.

❖ This section requires portable tanks located in gas rooms to have an additional local exhaust mechanism. More specifically, Section 6004.2.2.1 requires locating portable tanks in a gas room or exhausted enclosure as a minimum. Since exhausted enclosures would be considered local, an additional local exhaust system would not be required. Only when the sole exhaust mechanism is a gas room would a local exhaust be required. The exhaust from the gas room and the local exhaust system must be processed through a treatment system in accordance with Section 6004.2.2.7. The focus of a local exhaust system should be on the valves or valve fittings where a leak is more likely.

**6004.2.2.5 Piping and controls—stationary tanks.** In addition to the requirements of Section 5003.2.2, piping and controls on stationary tanks shall comply with the following requirements:

1. Pressure relief devices shall be vented to a treatment system designed in accordance with Section 6004.2.2.7.

**Exception:** Pressure relief devices on outdoor tanks provided exclusively for relieving pressure due to fire exposure are not required to be vented to a treatment system provided that:

1. The material in the tank is not flammable.
  2. The tank is not located in a diked area with other tanks containing combustible materials.
  3. The tank is located not less than 30 feet (9144 mm) from combustible materials or structures or is shielded by a *fire barrier* complying with Section 6004.3.2.1.1.
2. Filling or dispensing connections shall be provided with a means of local exhaust. Such exhaust shall be designed to capture fumes and vapors. The exhaust shall be directed to a treatment system in accordance with Section 6004.2.2.7.

## HIGHLY TOXIC AND TOXIC MATERIALS

3. Stationary tanks shall be provided with a means of excess flow control on all tank inlet or outlet connections.

### Exceptions:

1. Inlet connections designed to prevent backflow.
  2. Pressure relief devices.
- ❖ This section is in addition to Section 5003.2.2, which addresses piping, tubing, valves and fittings in general for all hazardous materials. This section focuses on exhaust ventilation for potential leaks and releases associated with piping, filling and dispensing connections on stationary tanks. Section 5003.2.2 contains general requirements covering issues such as compatibility, shutoff valves, backflow prevention and leak detection. This section is specific to stationary tanks because they are more permanent and piping and other controls are more likely on stationary tanks versus portable tanks and cylinders.

The specific requirements found in this section are as follows:

1. If a pressure relief valve is used, the release must be vented directly to a treatment system. There is an exception that pertains to outdoor tanks with pressure valves specifically for pressure relief in a fire. There are several conditions for the exception that address exposure hazards, such as neighboring tanks or combustible hazards. Also, the material in the tank itself cannot be flammable. Although this exception for outdoor tanks is found in the indoor storage and use requirements, Section 6004.3 for outdoor storage and use has a specific requirement in Section 6004.3.2.3 that refers back to this section for piping and controls for outdoor stationary tanks.
2. This item requires a local exhaust system connected to a treatment system for filling and dispensing connections.
3. Excess flow control is required at every tank inlet and outlet to reduce the size of the release and to avoid dangerous reactions and overpressures in other areas of a process designed for a particular flow rate and pressure. There are two exceptions that relate to devices serving a specific purpose, which include an inlet connection designed to address backflow or a pressure relief valve. A pressure relief valve is specifically designed to allow excessive flow beyond the design pressures of the tank to avoid overpressures in the tank.

**6004.2.2.6 Gas rooms.** Gas rooms shall comply with Section 5003.8.4 and both of the following requirements:

1. The exhaust ventilation from gas rooms shall be directed to an exhaust system.

2. Gas rooms shall be equipped with an *approved automatic sprinkler system*. Alternative fire-extinguishing systems shall not be used.

- ❖ The requirements in Chapter 50 address construction and basic ventilation. General gas room requirements are found in Section 5003.8.3. More specifically, Section 5003.8.3 requires an automatic sprinkler system, separation as required in the IBC and maintaining negative pressure in the room. This section takes the requirements one step further and requires that exhaust ventilation be directed to an exhaust system. Section 6004.2.2.7 also requires directing this exhaust system to a treatment system. The second criterion is a restriction that does not allow any alternative fire-extinguishing systems in place of an automatic sprinkler system.

**6004.2.2.7 Treatment systems.** The exhaust ventilation from gas cabinets, exhausted enclosures and gas rooms, and local exhaust systems required in Sections 6004.2.2.4 and 6004.2.2.5 shall be directed to a treatment system. The treatment system shall be utilized to handle the accidental release of gas and to process exhaust ventilation. The treatment system shall be designed in accordance with Sections 6004.2.2.7.1 through 6004.2.2.7.5 and Section 510 of the *International Mechanical Code*.

### Exceptions:

1. Highly toxic and toxic gases—storage. A treatment system is not required for cylinders, containers and tanks in storage where all of the following controls are provided:
  - 1.1. Valve outlets are equipped with gas-tight outlet plugs or caps.
  - 1.2. Handwheel-operated valves have handles secured to prevent movement.
  - 1.3. *Approved* containment vessels or containment systems are provided in accordance with Section 6004.2.2.3.
2. Toxic gases—use. Treatment systems are not required for toxic gases supplied by cylinders or portable tanks not exceeding 1,700 pounds (772 kg) water capacity where the following are provided:
  - 2.1. A *listed* or *approved* gas detection system with a sensing interval not exceeding 5 minutes.
  - 2.2. A *listed* or *approved* automatic-closing fail-safe valve located immediately adjacent to cylinder valves. The fail-safe valve shall close when gas is detected at the permissible exposure limit (PEL) by a gas detection system monitoring the exhaust system at the point of discharge from the gas cabinet, exhausted enclosure, vent-ilated enclosure or gas room. The gas detection system shall comply with Section 6004.2.2.10.

- ❖ Treatment systems are required for all exhaust ventilation and accidental releases of toxic and highly toxic

gases. A treatment system essentially treats the exhaust through methods such as diluting, absorbing, burning and other various methods, which are discussed in Section 6004.2.2.7.1. Generally, Section 6004.2.2.7 and related subsections contain the design criteria for such systems.

There are two overall exceptions where treatment systems would not be required. They are broken into storage and use, respectively. Treatment systems can be very costly and the exceptions give credit to situations where the hazard is low and the benefit of a costly treatment system cannot be justified.

Exception 1 deals with cylinders, containers and tanks in storage. A treatment system would not be required if all three criteria are met. The criteria include caps or plugs on any valves to provide a level of redundancy in case of an accidental release; hand-wheel-operated valves that are secured in place; and the installation of containment vessels or containment systems.

Exception 2 is for toxic gases supplied by cylinders limited to a size of 1,700 pounds (772 kg) water capacity. The 1,700-pound (772 kg) limit was derived as follows: A ton container typically holds about 1,600 pounds (726 kg) of water, and a filling density of approximately 125 percent of the water capacity is allowed for chlorine [ $1,600 \times 1.25 = 2,000$  pounds (908 kg)]. The resulting weight of product in a filled container is one ton for chlorine. The maximum capacity of 1,700 pounds versus 1,600 pounds (772 kg versus 726 kg) is intended to accommodate manufacturing variations that occur from one container to the next, but this does not affect the ultimate gas capacity of a filled container, which is limited to 2,000 pounds (908 kg) regardless of the variation in water capacity. To avoid the use of a treatment system, a gas detection system must also be accompanied by a fail-safe valve adjacent to the cylinder valve. The fail-safe valve must operate when gas is detected at the point of discharge of the location of the cylinder (see commentary to the Section 202 definition of "Fail-safe"). Section 6004.2.2.1 requires cylinders to be located in a gas cabinet, an exhausted enclosure or a gas room.

**6004.2.2.7.1 Design.** Treatment systems shall be capable of diluting, adsorbing, absorbing, containing, neutralizing, burning or otherwise processing the contents of the largest single vessel of compressed gas. Where a total containment system is used, the system shall be designed to handle the maximum anticipated pressure of release to the system when it reaches equilibrium.

- ❖ This section states that a treatment system must process the exhaust ventilation or an accidental release. Various methods are listed but the section is written to allow exploration of other methods. Additionally, this section sets important capacity criteria for the treatment system, which would require it to either be capable of processing the largest vessel or handle the maximum pressure of release at equilibrium when a total containment system is used.

**6004.2.2.7.2 Performance.** Treatment systems shall be designed to reduce the maximum allowable discharge concentrations of the gas to one-half immediate by dangerous to life and health (IDLH) at the point of discharge to the atmosphere. Where more than one gas is emitted to the treatment system, the treatment system shall be designed to handle the worst-case release based on the release rate, the quantity and the IDLH for all *compressed gases* stored or used.

- ❖ Now that the method and the capacity have been established in Section 6004.2.2.7.1, the actual treatment capabilities are described in this section. More specifically, this section describes how well the gases need to be treated. Once treated, the output from the treatment system must not exceed one-half of the immediately dangerous to life and health (IDLH) concentration. If the treatment system is used for a variety of different stored gases that have various levels of toxicity, the treatment system must be able to accommodate the worst-case situation. As an example, the least-toxic gas may have the largest release potential, but the treatment system does not have to work as hard to reduce the IDLH; therefore, both the level of hazard and the amount of the gas must be addressed.

**6004.2.2.7.3 Sizing.** Treatment systems shall be sized to process the maximum worst-case release of gas based on the maximum flow rate of release from the largest vessel utilized. The entire contents of the largest *compressed gas* vessel shall be considered.

- ❖ This section re-emphasizes that the treatment system must be capable of treating the largest single vessel. In addition, this section requires that the maximum flow rates be considered; therefore, it is not simply the capacity of the largest single vessel but also how fast that gas is released. Treatment systems need to account for only a single failure of a vessel, but at the highest flow rate.

**6004.2.2.7.4 Stationary tanks.** Stationary tanks shall be labeled with the maximum rate of release for the *compressed gas* contained based on valves or fittings that are inserted directly into the tank. Where multiple valves or fittings are provided, the maximum flow rate of release for valves or fittings with the highest flow rate shall be indicated. Where liquefied *compressed gases* are in contact with valves or fittings, the liquid flow rate shall be utilized for computation purposes. Flow rates indicated on the label shall be converted to cubic feet per minute (cfm/min) ( $m^3/s$ ) of gas at *normal temperature and pressure (NTP)*.

- ❖ The potential release rates of all valves directly connected to the tank that have the potential for a release of gases must be properly labeled. In addition, the valves that have the highest potential release rates need to be specifically identified. This is especially important when there are multiple valves.

Another requirement of this section is for situations in which the valve is located where it is interacting with the liquid form of the compressed gas. Such interaction will alter the release rate; therefore, the

## HIGHLY TOXIC AND TOXIC MATERIALS

liquid rate of release must be used. When a gas is in liquid form it is denser than the gas form. If released, the liquid vaporizes, expanding into a much larger volume of gas. Finally, to more readily assess the amount of gas that can be released into the room or area, the tank liquid flow rate must be shown on the label as the equivalent gas volume in cubic feet per minute at normal temperature and pressure (NTP). In other words, the flow rate is not as important as the gas volume it will produce when released into the room or area. NTP provides a comparable base value.

**6004.2.2.7.5 Portable tanks and cylinders.** The maximum flow rate of release for portable tanks and cylinders shall be calculated based on the total release from the cylinder or tank within the time specified in Table 6004.2.2.7.5. Where portable tanks or cylinders are equipped with *approved* excess flow or reduced flow valves, the worst-case release shall be determined by the maximum achievable flow from the valve as determined by the valve manufacturer or *compressed gas* supplier. Reduced flow and excess flow valves shall be permanently marked by the valve manufacturer to indicate the maximum design flow rate. Such markings shall indicate the flow rate for air under *normal temperature and pressure*.

❖ Given that flow rates of different portable tanks and cylinders tend to vary because of their portability, this information would be difficult to track; therefore, this section simply requires that the maximum flow rate be determined based on the capacity of the tank and the time prescribed in Table 6004.2.2.7.5. For example, say a portable tank had a capacity (at NTP) of 1,000 cubic feet (28 m<sup>3</sup>) and was not under liquefied conditions. The maximum rate of release based on the criteria given in Table 6004.2.2.7.5 would be as follows:

$$\begin{aligned} 1,000 \text{ cubic feet}/40 \text{ minutes} &= \\ 25 \text{ cubic feet per minute at NTP} \end{aligned}$$

In some cases, portable tanks and cylinders may be equipped with valves that either alter the rate of flow or will stop in the case of flow over the designed rate. In those cases, credit is given to the actual amount of gas released at NTP in determining the maximum flow rate. Valves that are used in this manner must be properly labeled to note the specific flow rate at NTP or function.

**TABLE 6004.2.2.7.5  
RATE OF RELEASE FOR CYLINDERS AND PORTABLE TANKS**

VESSEL TYPE	NONLIQUEFIED (minutes)	LIQUEFIED (minutes)
Containers	5	30
Portable tanks	40	240

**6004.2.2.8 Emergency power.** Emergency power shall be provided for the following systems in accordance with Section 604:

1. Exhaust ventilation system.
2. Treatment system.
3. Gas detection system.

4. Smoke detection system.
5. Temperature control system.
6. Fire alarm system.
7. Emergency alarm system.

❖ Because of the immediate health hazard posed by the release of toxic or highly toxic gases, emergency, rather than standby, power is required. The major difference between them is that standby power activates within 60 seconds whereas emergency power activates within 10 seconds. This section provides a specific list of systems that would require emergency power. The most critical is likely the treatment system.

**6004.2.2.8.1 Fail-safe engineered systems.** Emergency power shall not be required for mechanical exhaust ventilation, treatment systems and temperature control systems where *approved* fail-safe engineered systems are installed.

❖ This section permits the use of an engineered system designed to fail in the appropriate design mode without human intervention in place of an emergency power system. The exception is intended to permit alternative systems that are not subject to power interruptions.

**6004.2.2.9 Automatic fire detection system—highly toxic compressed gases.** An *approved* automatic fire detection system shall be installed in rooms or areas where highly toxic *compressed gases* are stored or used. Activation of the detection system shall sound a local alarm. The fire detection system shall comply with Section 907.

❖ This section requires a fire detection system in rooms or areas where highly toxic gases are stored or used. The intent is that a fire in the area could lead to the release of the highly toxic gases. Fires can heat gases stored and cause expansion, leading to overpressures and releases; therefore, warning of a fire is critical to avoiding such releases. The alarm system needs to provide a local alarm at the building, but the detection is required only in the room or area where the highly toxic gas is stored.

**6004.2.2.10 Gas detection system.** A gas detection system shall be provided to detect the presence of gas at or below the PEL or ceiling limit of the gas for which detection is provided. The system shall be capable of monitoring the discharge from the treatment system at or below one-half the IDLH limit.

**Exception:** A gas detection system is not required for toxic gases when the physiological warning threshold level for the gas is at a level below the accepted PEL for the gas.

❖ This section requires a system to detect the presence of gas in a large enough concentration to exceed the permissible exposure limit (PEL). The system must also be designed to be capable of detecting whether one-half the IDLH has been exceeded at the discharge from the treatment system. This is to ensure that the treatment system is working to capacity or to

indicate that there may be other problems, such as a release larger than the treatment system has been designed to handle. It is important to stress the terminology of “capable,” which would not require monitoring but would require an installation that would enable such monitoring if desired. In many cases, monitoring is done intermittently with portable monitors. Such monitoring may become necessary as a result of environmental restrictions, which are beyond the scope of the code.

There is an exception to the requirement of a gas detection system where the odor of the gas or its physical effects are noticeable far before the PEL is reached. Those indicators should be sufficient to notify people to leave the area.

**6004.2.2.10.1 Gas detection system components.** Gas detection system control units shall be *listed* and *labeled* in accordance with UL 864 or UL 2017, or approved. Gas detectors shall be *listed* and *labeled* in accordance with UL 2075 for use with the gases and vapors being detected, or *approved*.

❖ This section requires gas detection equipment to be listed in accordance with UL 2075 for use with the different gases it will detect. Under UL 2075, a set of flammable gases and concentrations in parts per million (PPM) is developed for each detector or sensor and the manufacturer is required to provide information as to what gases and concentrations the device is designed to detect. Tests under the standard then verify the performance of each detector or sensor for each gas it is designed to detect. The gases that the equipment will detect may be shown in the manufacturer’s instructions rather than on the product. This section is intended to ensure that gas detection system control components are listed in accordance with nationally recognized safety standards. These standards include a comprehensive set of construction and performance requirements that are used to evaluate and list gas detection system control units and gas detectors. This section also provides the fire code official with the ability to approve gas detection system components that may not be listed and labeled.

**6004.2.2.10.2 Alarms.** The gas detection system shall initiate a local alarm and transmit a signal to a constantly attended control station when a short-term hazard condition is detected. The alarm shall be both visual and audible and shall provide warning both inside and outside the area where gas is detected. The audible alarm shall be distinct from all other alarms.

**Exception:** Signal transmission to a constantly attended control station is not required where not more than one cylinder of highly toxic or toxic gas is stored.

❖ Once the gas is detected at the levels noted in Section 6004.2.2.10, a local alarm must be initiated and a signal at a constantly attended control station (such as a security room or fire command center) must be

transmitted. The alarm is intended to alert those both inside the particular area of detection and in the immediate vicinity. This is to prevent any gases that escape from causing harm to those outside the area of release.

The notification to the control station provides information to those who must take a role in emergency response, whereas the local alarm is a warning for those in the vicinity of the release.

A signal need not be sent to the control station if the amount of gas stored or used is a maximum of one cylinder. In that case, a local alarm is sufficient to notify people of the immediate hazard.

**6004.2.2.10.3 Shut off of gas supply.** The gas-detection system shall automatically close the shutoff valve at the source on gas supply piping and tubing related to the system being monitored for whichever gas is detected.

**Exception:** Automatic shutdown is not required for reactors utilized for the production of highly toxic or toxic *compressed gases* where such reactors are:

1. Operated at pressures less than 15 pounds per square inch gauge (psig) (103.4 kPa).
2. Constantly attended.
3. Provided with readily accessible emergency shutoff valves.

❖ The gas detection system also initiates the shutdown of gases at the source for gas supply piping and tubing, making this requirement more applicable to the use of the gas than to storage. The exception applies only to equipment used to make toxic or highly toxic gases, and only when all three of the stated conditions are met. This exception recognizes that pressure is a critical element in how much and how fast a gas is released. A low operating pressure normally means a smaller, more easily controlled release. Having an operator monitoring the equipment at all times is considered an adequate safeguard when shutoff valves are easy to reach in case of an emergency. Under these circumstances, notification by an alarm system and a signal to a constantly attended control station is sufficient to deal with the particular hazard. Automatic shutoff would probably be overly restrictive.

**6004.2.2.10.4 Valve closure.** Automatic closure of shutoff valves shall be in accordance with the following:

1. Where the gas-detection sampling point initiating the gas detection system alarm is within a gas cabinet or exhausted enclosure, the shutoff valve in the gas cabinet or exhausted enclosure for the specific gas detected shall automatically close.
2. Where the gas-detection sampling point initiating the gas detection system alarm is within a gas room and *compressed gas* containers are not in gas cabinets or exhausted enclosures, the shutoff valves on all gas lines for the specific gas detected shall automatically close.

3. Where the gas-detection sampling point initiating the gas detection system alarm is within a piping distribution manifold enclosure, the shutoff valve for the compressed container of specific gas detected supplying the manifold shall automatically close.

**Exception:** Where the gas-detection sampling point initiating the gas-detection system alarm is at a use location or within a gas valve enclosure of a branch line downstream of a piping distribution manifold, the shutoff valve in the gas valve enclosure for the branch line located in the piping distribution manifold enclosure shall automatically close.

- ❖ This section describes three common situations in which gas lines need to automatically close when gas is detected. If the gas is detected within a gas cabinet or exhausted enclosure, only the gas line related to the gas cylinder or container within the cabinet or enclosure must be shut down. If the gas is detected within a gas room, all gas lines containing that particular gas must be shut down because it is difficult to determine where the leak originates when the storage and use are in a larger area. The next criterion is related to situations where the gas sampling occurs within a piping manifold enclosure. Gas sampling in such locations is much more localized and the code requires shutting down only the cylinder supplying the manifold.

The exception is for situations where the gas is clearly being released downstream from the piping distribution manifold enclosure. The problem is with the piping or perhaps at a point of use and can be isolated by simply shutting off that particular branch line from the piping distribution manifold enclosure. This would be allowed only if the gas detection system was sampling at the location of use or within a gas valve enclosure downstream from the distribution piping. Otherwise, it would be difficult to determine where the leak originated and the supply at the cylinder or tank would have to be shut down.

**6004.3 Outdoor storage and use.** The outdoor storage and use of highly toxic and toxic *compressed gases* shall be in accordance with Sections 6004.3.1 through 6004.3.4.

- ❖ Outdoor storage and use is generally less hazardous than indoor storage and use because the toxic and highly toxic gases, if released, are more easily diluted and, thus, the hazard to the people in the surrounding area is reduced. When gases are released outdoors, however, it is more difficult to control where the released gases will go and what or who is being exposed to the hazards; therefore, this section contains restrictions on locations and distance to exposures. This section refers back to many of the requirements found in Section 6004.2, such as for piping and controls for stationary tanks and gas detection.

**6004.3.1 Applicability.** The applicability of regulations governing the outdoor storage and use of highly toxic and toxic

*compressed gases* shall be as set forth in Sections 6004.3.1.1 through 6004.3.1.3.

- ❖ This section defines which requirements of the code apply based on the amount of gases stored and used.

**6004.3.1.1 Quantities not exceeding the maximum allowable quantity per control area.** The outdoor storage or use of highly toxic and toxic gases in amounts not exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(4) shall be in accordance with Sections 5001, 5003 and 6001.

- ❖ This section states that when the MAQs have not been exceeded, the general requirements found in Sections 5001 and 5003 would apply, as appropriate. Section 6001, primarily Section 6001.2, would also apply; therefore, the requirements would be fairly limited for amounts under the MAQs.

**6004.3.1.2 Quantities exceeding the maximum allowable quantity per control area.** The outdoor storage or use of highly toxic and toxic gases in amounts exceeding the *maximum allowable quantity per control area* set forth in Table 5003.1.1(4) shall be in accordance with Sections 6001 and 6004.3 and Chapter 50.

- ❖ When the MAQs have been exceeded, the requirements become more restrictive. All of Chapter 50 would apply, as appropriate to the outdoor storage and use of gases, and Section 6004.3 would apply in its entirety.

**6004.3.1.3 Ozone gas generators.** The outdoor use of ozone gas-generating equipment shall be in accordance with Section 6005.

- ❖ Section 6605 contains the bulk of the requirements for outdoor use of ozone gas-generating equipment (see commentary, Section 6605).

**6004.3.2 General outdoor requirements.** The general requirements applicable to the outdoor storage and use of highly toxic and toxic *compressed gases* shall be in accordance with Sections 6004.3.2.1 through 6004.3.2.4.

- ❖ This section contains the bulk of the requirements for outdoor storage and the use of highly toxic and toxic gases. In several places, the text refers back to various sections in Section 6004.2 to avoid repetitive wording when the same requirements apply to both indoor and outdoor storage and use. The sections that are unique to outdoor storage and use concern location and exposures.

**6004.3.2.1 Location.** Outdoor storage or use of highly toxic or toxic *compressed gases* shall be located in accordance with Sections 6004.3.2.1.1 through 6004.3.2.1.3.

**Exception:** *Compressed gases* located in gas cabinets complying with Sections 5003.8.6 and 6004.1.2 and located 5 feet (1524 mm) or more from buildings and 25 feet (7620 mm) or more from an *exit discharge*.

- ❖ As noted, highly toxic and toxic gases used and stored outdoors are more difficult to contain because

an accidental release could disperse in various directions based on the configuration of the storage, the properties of the gases stored and used and climatic conditions. Additionally, there is less control of exposure hazards, which may affect the storage and use of such gases. The following subsections address distance to exposures, openings in exposed buildings and hazards associated with air intakes into buildings.

There is an exception when cylinders are contained in a gas cabinet that complies with both the general requirements of Chapter 50 and the specific requirements of Section 6004.1.2 for use of highly toxic and toxic gases. In addition, the cabinet must be sufficiently separated from buildings and the exit discharge.

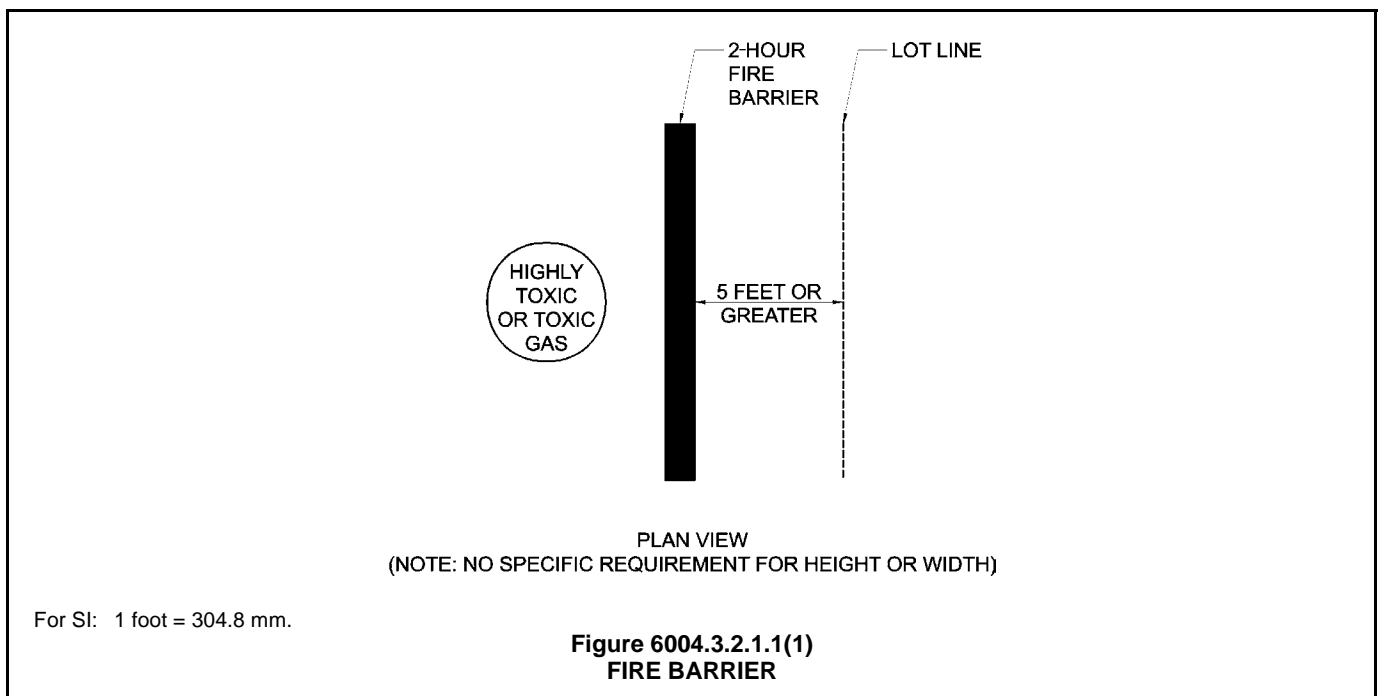

**6004.3.2.1.1 Distance limitation to exposures.** Outdoor storage or use of highly toxic or toxic *compressed gases* shall not be located within 75 feet (22 860 mm) of a *lot line*, public street, public alley, *public way*, *exit discharge* or building not associated with the manufacture or distribution of such gases, unless all of the following conditions are met:

1. Storage is shielded by a 2-hour *fire barrier* that interrupts the line of sight between the storage and the exposure.
2. The 2-hour *fire barrier* shall be located not less than 5 feet (1524 mm) from any exposure.
3. The 2-hour *fire barrier* shall not have more than two sides at approximately 90-degree (1.57 rad) directions, or three sides with connecting angles of approximately 135 degrees (2.36 rad).

❖ A minimum distance of 75 feet (22 860 mm) is required to exposures such as an exit discharge, lot line or public way. The distance to exposures is in

terms of buildings not associated with the manufacture or distribution of highly toxic and toxic gases because buildings associated with those activities would not have separation requirements. It would be impractical for such facilities to be laid out with this kind of separation, and the level of hazard is known and accepted at these facilities. An alternative to the 75-foot (22 860 mm) separation is allowed when certain conditions are met. A 2-hour fire barrier constructed in accordance with IBC Section 707 can be substituted when the conditions stated in this section are met [see Commentary Figure 6004.3.2.1.1(1)]. The code criteria do not set a limit on the height or width of the barrier as long as it interrupts the line of sight between the storage and the exposure, although areas located above and to the sides of the barrier will likely have more restrictive limitations on openings (see commentary, Section 6004.3.2.1.2). Limitations are placed on barriers in terms of the number of walls creating the separation based on the angle of the walls to one another. These are shown in Commentary Figure 6004.3.2.1.1(2). Generally, the limitations are related to the fact that when more than one wall is used there is the potential that some of the natural ventilation of the outdoor storage location would be lost. For instance, allowing three walls at 90 degrees (1.57 rad) versus two walls practically encloses the storage. The allowance of three walls at 135-degree (2.36 rad) angles still results in a level of openness that allows the benefits of natural ventilation.

**6004.3.2.1.2 Openings in exposed buildings.** Where the storage or use area is located closer than 75 feet (22 860 mm) to a building not associated with the manufacture or distribution of highly toxic or toxic *compressed gases*, openings into a building other than for piping are not allowed above the

## HIGHLY TOXIC AND TOXIC MATERIALS

height of the top of the 2-hour *fire barrier* or within 50 feet (15 240 mm) horizontally from the storage area whether or not shielded by a *fire barrier*.

- ❖ When a fire barrier is used in place of the 75-foot (22 860 mm) separation, there are further limitations on openings. Openings other than pipe penetrations are allowed only when the exposure is 50 feet (15 240 mm) or more from the barrier, and then only below the height of the barrier. Piping penetrations are allowed because they are small enough to be considered an insignificant hazard (see Commentary Figure 6004.3.2.1.2).

The primary intent of this section is to protect the highly toxic and toxic gases from a release caused by a fire in the building. Openings such as windows increase the likelihood of a fire heating up a cylinder or tank and causing overpressures that could result in a release. A solid wall decreases the possibility of a fire penetrating or the radiation from the fire from contacting the storage area. Also, openings are a potential method for highly toxic and toxic gases to enter a building. A fire barrier will not stop gases from traveling upward if they are lighter than air.

**6004.3.2.1.3 Air intakes.** The storage or use area shall not be located within 75 feet (22 860 mm) of air intakes.

- ❖ This section addresses the threat of a release of toxic or highly toxic gases getting into a building's heating, ventilating and air-conditioning (HVAC) system. The 75-foot (22 860 mm) separation is consistent with the distances previously laid out. The important distinction with this section is that exposure of the building's exterior is not a concern. Instead, the concern is for the health risks of a gas released into the building's HVAC system.

This section does not differentiate between a building associated with the storage and manufacture of highly toxic and toxic gases and one that is not. The risk to building occupants and emergency responders and the potential hazards of such gases entering a facility's main air source would be the same in either case. Also, gases entering other openings do not have the same potential for circulation around the building as those entering an air intake with the specific purpose of circulation.

**6004.3.2.2 Leaking cylinders and tanks.** The requirements of Section 6004.2.2.3 shall apply to outdoor cylinders and tanks. Gas cabinets and exhausted enclosures shall be located within or immediately adjacent to outdoor storage or use areas.

❖ This section refers back to Section 6004.2.2.3 for requirements for handling leaking cylinders and tanks. Essentially, a gas cabinet or exhausted enclosure is required to contain leaking cylinders and tanks. Section 6004.2.2.3.1 requires that gas cabinets and exhausted enclosures used with leaking cylinders and tanks be located in a gas room. Although this section refers back to these requirements, the code was not intended to require a gas room in outdoor storage and use areas. If a gas room with either a gas cabinet or exhausted enclosure is available nearby, it can be used, but to require an outdoor storage and use area to go indoors would be impractical. Regardless, gas rooms, gas cabinets and exhausted enclosures would have to be connected to an exhaust system that would then be connected to a treatment system. The major difference between the indoor requirements and the outdoor requirements is that cylinders, portable tanks and stationary tanks stored outside of buildings need not be placed in gas cabinets, exhausted enclosures or gas rooms except when they are leaking.

A containment vessel or containment system could also be used as long as several criteria are met (see definitions for “Containment vessel” and “Containment system” in Section 202 and the commentary to Section 6004.2.2.3).

**6004.3.2.3 Local exhaust for portable tanks.** Local exhaust for outdoor portable tanks shall be provided in accordance with the requirements set forth in Section 6004.2.2.4.

❖ This section refers to Section 6004.2.2.4, which would require local exhaust systems for portable tanks to address areas on a tank where leaks are likely to occur. These systems need to be flexible to address the types of tanks likely to be stored or used. Although Section 6004.2.2.4 would require the exhaust system to be located in a gas room, the intent of this section would warrant the elimination of a gas room where the exhaust system is in or immediately adjacent to the outdoor storage area. Again, the intent is not to require outdoor storage to be placed indoors in a gas room. Outdoor storage has slightly different concerns, such as exposure hazards (see commentary, Section 6004.2.2.4).

**6004.3.2.4 Piping and controls-stationary tanks.** Piping and controls for outdoor stationary tanks shall be in accordance with the requirements set forth in Section 6004.2.2.5.

## HIGHLY TOXIC AND TOXIC MATERIALS

❖ This section refers to Section 6004.2.2.5 for requirements. The exception to Section 6004.2.2.5, Item 1 is specific to outdoor tanks. This exception allows for the elimination of a treatment system to collect a release from a pressure relief device that is specifically installed for overpressure caused by fire. To take advantage of this exception, several criteria must be met. These criteria address the reduction of possible fire hazards by ensuring both that the gas stored is not flammable and the exposures to other fire hazards are reduced. This exception recognizes that gases are more readily dispersed outside, which reduces the need for a treatment system to process a release (see commentary, Section 6004.2.2.5).

**6004.3.3 Outdoor storage weather protection for portable tanks and cylinders.** Weather protection in accordance with Section 5004.13 shall be provided for portable tanks and cylinders located outdoors and not within gas cabinets or exhausted enclosures. The storage area shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1.

**Exception:** An *automatic sprinkler system* is not required when:

1. All materials under the weather protection structure, including hazardous materials and the containers in which they are stored, are non-combustible.
  2. The weather protection structure is located not less than 30 feet (9144 mm) from combustible materials or structures or is separated from such materials or structures using a *fire barrier* complying with Section 6004.3.2.1.1.
- ❖ Cylinders and portable tanks that are used strictly for the outdoor storage of highly toxic and toxic gases must be placed in gas cabinets and exhausted enclosures only if they are leaking. Otherwise, outdoor storage simply requires protection from the elements. Sprinklers are required unless every material under the weather protection is noncombustible and the weather protection structure is properly separated either by distance or by construction from combustible exposures such as other storage or buildings. The exception refers back to the exposure requirements in Section 6004.3.2.1.1 for construction requirements. Protecting materials from the elements reduces the likelihood of the tanks and cylinders being damaged and potential release through corrosion. Additionally, the sprinklers protect the storage from a large release if a fire were to occur, causing overpressures in tanks and cylinders and ultimately releases of gases. This protection is especially important because these particular gases are not being processed through a treatment system should a release occur.

**6004.3.4 Outdoor use of cylinders, containers and portable tanks.** Cylinders, containers and portable tanks in out-

door use shall be located in gas cabinets or exhausted enclosures and shall comply with Sections 6004.3.4.1 through 6004.3.4.3.

❖ Because use is more likely than storage to lead to a release of gas, the cylinders, containers or portable tanks that supply the gases need to be located in a gas cabinet or exhausted enclosure and be equipped with a treatment system, emergency power and a gas detection system in accordance with Sections 6004.3.4.1 through 6004.3.4.3.

**6004.3.4.1 Treatment systems.** The treatment system requirements set forth in Section 6004.2.2.7 shall apply to highly toxic or toxic gases located outdoors.

❖ This section refers to the design criteria for treatment systems in Section 6004.2. As noted in Section 6004.2.2.7, a treatment system is required for exhaust ventilation coming from gas cabinets, exhausted enclosures, gas rooms and local exhaust systems. There are exceptions in Section 6004.2.2.7 for both storage and use. The storage exception focuses on securing valve outlets and using containment vessels and systems.

The use exception requires gas detection and fail-safe valve operation. Note that the exception for use is specific only to toxic gases.

For outdoor areas there are only a few occasions where a gas cabinet, exhausted enclosure, gas room or local exhaust would be required. Again, this is related to the fact that gases stored and used outdoors can be more easily dispersed if a release should occur, generally posing a lower hazard to those in the area. The requirements generally are based on the location of the gases. Treatment systems would come into play only for gas cabinets, exhausted enclosures and gas rooms associated with leaking cylinders or tanks and local exhaust for portable containers.

**6004.3.4.2 Emergency power.** The requirements for emergency power set forth in Section 6004.2.2.8 shall apply to highly toxic or toxic gases located outdoors.

❖ See the commentary to Section 6004.2.2.8.

**6004.3.4.3 Gas detection system.** The gas detection system requirements set forth in Section 6004.2.2.10 shall apply to highly toxic or toxic gases located outdoors.

❖ Because this section pertains to outdoor storage and use of highly toxic and toxic gases, the requirement for gas detection systems is less restrictive than it is for indoor storage and use. Essentially, detection systems would be required for small enclosures, such as gas cabinets and exhausted enclosures, and for local enclosures, such as piping manifold enclosures. Otherwise, gas detection is fairly ineffective in the outdoors. The detailed requirements for gas detection are found in Section 6004.2.2.10.

**SECTION 6005  
OZONE GAS GENERATORS**

**6005.1 Scope.** Ozone gas generators having a maximum ozone-generating capacity of 0.5 pound (0.23 kg) or more over a 24-hour period shall be in accordance with Sections 6005.2 through 6005.6.

**Exceptions:**

1. Ozone-generating equipment used in Group R-3 occupancies.
2. Ozone-generating equipment where used in Group H-5 occupancies where in compliance with Chapters 27 and 50 and the other provisions in this chapter for highly toxic gases.

❖ This section differs from most of the rest of this chapter because it deals with the generation (i.e., creation) of a highly toxic gas and not simply its storage or use. The requirements center on the design, location, piping integrity and methods of ozone generator shut-down.

Ozone is a molecule composed of three atoms of oxygen. Two atoms of oxygen form the basic oxygen molecule, which is the oxygen we breathe. The third oxygen atom can detach from the ozone molecule and reattach to molecules of other substances, thereby altering their chemical composition. Generally, this ability to reattach is the reason ozone is generated and used as a method of purification. The primary uses are for the purification of water and air. The two uses are very different in their applications and the success of the air purification is a controversial one because it appears to be ineffective unless

the ozone is present in the atmosphere at concentrations that would be harmful to people. Ozone is actually considered a pollutant when in the atmosphere we breathe.

The ability of ozone to react with organic materials is why it is used in purification. It is this same ability that causes harm to humans. The following table is taken from documentation from the EPA regarding the health effects, risk factors and health standards of various federal agencies.

Because of the nature of fire codes, the main goal of the requirements in this section is to avoid a situation where building occupants and emergency responders are exposed to unsafe levels of ozone on a more immediate basis, which is slightly different than the objectives of the federal agencies listed in Commentary Figure 6005.1.

These requirements apply only to generators that produce 0.5 pound (0.23 kg) or more over a 24-hour period. These tend to be the larger commercial and industrial application generators.

Exception 1 for ozone generators that are found in one- and two-family dwellings (Group R-3) is based on the assumption that these generators would not produce the quantity noted in this section. This exception avoids impractical enforcement.

Exception 2 clarifies that the general conditions in Section 6005.1 do not apply to ozone-generating equipment used in Group H-5 occupancies. Ozone in a Group H-5 occupancy is a hazardous production material (HPM) gas specifically regulated as a highly toxic, oxidizing HPM gas in Chapters 27, 50 and 60.

HEALTH EFFECTS	RISK FACTORS	HEALTH STANDARDS*
<p><b>Potential risk of experiencing:</b> Decreases in lung function Aggravation of asthma Throat irritation and cough Chest pain and shortness of breath Inflammation of lung tissue Higher susceptibility to respiratory infection</p>	<p><b>Factors expected to increase risk and severity of health effects are:</b> Increase in ozone concentration in air Greater duration of exposure for some health effects Activities that raise the breathing rate (e.g., exercise) Certain pre-existing lung diseases (e.g., asthma)</p>	<p><b>Food and Drug Administration (FDA)</b> requires ozone output of indoor medical devices to be no more than 0.05 ppm.</p> <p><b>Occupational Safety and Health Administration (OSHA)</b> requires that worker exposure be limited to an average concentration of no more than 0.10 ppm for a maximum of 8 hours.</p> <p><b>National Institute of Occupational Safety and Health (NIOSH)</b> recommends an upper limit of 0.10 ppm, not to be exceeded at any time.</p> <p><b>Environmental Protection Agency (EPA)</b>'s National Ambient Air Quality Standard for Ozone is a maximum of 8-hour average outdoor concentration of 0.08 ppm.</p>
<p>(*ppm = parts per million)</p>		
<p align="center"><b>Figure 6005.1 FEDERAL AGENCY OZONE STANDARDS</b></p>		

## HIGHLY TOXIC AND TOXIC MATERIALS

**6005.2 Design.** Ozone gas generators shall be designed, fabricated and tested in accordance with NEMA 250.

- ❖ Ozone is generated by applying an electrical current to at least one ozone-generating plate that then charges oxygen in the incoming air and produces ozone; therefore, the generator must comply with NEMA 250 for design, fabrication and testing.

**6005.3 Location.** Ozone generators shall be located in *approved* cabinets or ozone generator rooms in accordance with Section 6005.3.1 or 6005.3.2.

**Exception:** An ozone gas generator within an *approved* pressure vessel where located outside of buildings.

- ❖ Because of the potential health hazards related to the generation of ozone, this section states limitations on the location of generating equipment. Ozone generators must be either in an approved cabinet or in an ozone gas generator room. Details of each are discussed in the subsections that follow.

The exception for ozone gas generators located outside of buildings is applicable only if the generators are contained in an approved pressure vessel. Generally, as with storage and use of gases outdoors, the gas is more likely to be dispersed to the atmosphere without harming people in the surrounding area.

**6005.3.1 Cabinets.** Ozone cabinets shall be constructed of *approved* materials and compatible with ozone. Cabinets shall display an *approved* sign stating: OZONE GAS GENERATOR—HIGHLY TOXIC—OXIDIZER.

Cabinets shall be braced for seismic activity in accordance with the *International Building Code*.

Cabinets shall be mechanically ventilated in accordance with the *International Mechanical Code* with not less than six air changes per hour.

The average velocity of ventilation at makeup air openings with cabinet doors closed shall be not less than 200 feet per minute (1.02 m/s).

- ❖ This section lists criteria for the design and construction of cabinets intended for the ozone gas generators. This includes labeling, ventilation and seismic bracing requirements. For ventilation, it both refers to the *International Mechanical Code*® (IMC®) for requirements and states the following criteria:

- Six air changes per hour.
- Average velocity of 200 feet per minute (1.02 m/s) across the opening of the cabinet.

These criteria result in a negative pressure cabinet with appropriate intake air sizing.

**6005.3.2 Ozone gas generator rooms.** Ozone gas generator rooms shall be mechanically ventilated in accordance with the *International Mechanical Code* with not less than six air changes per hour. Ozone gas generator rooms shall be

equipped with a continuous gas detection system that will shut off the generator and sound a local alarm when concentrations above the permissible exposure limit occur.

Ozone gas generator rooms shall not be normally occupied, and such rooms shall be kept free of combustibles and hazardous material storage. Room access doors shall display an *approved* sign stating: OZONE GAS GENERATOR—HIGHLY TOXIC—OXIDIZER.

- ❖ For larger generators and particular processes, an ozone gas generator room may be more practical than cabinets. This section gives the criteria for design and construction for these rooms. The key construction element is the ventilation requirement of six air changes per hour, which is the same requirement as for cabinets. A gas detection system is also required that will activate a local alarm when the permissible exposure limit has been reached. This limit appears to be 10 parts per million (ppm) in accordance with the information provided by the EPA.

Because ozone is also an oxidizer, combustibles would not be allowed within the room to reduce the potential for an intense fire. In addition, because of the health effects, the rooms are not intended to be normally occupied. These two limitations essentially necessitate a mechanical room-type arrangement. The labeling of the generator room is essential to emergency responders and also to those unfamiliar with the facility.

**6005.4 Piping, valves and fittings.** Piping, valves, fittings and related components used to convey ozone shall be in accordance with Sections 6005.4.1 through 6005.4.3.

- ❖ The requirements found in this section are intended to reduce the weak links in the system that can be found with improper piping connections or fittings.

**6005.4.1 Piping.** Piping shall be welded stainless steel piping or tubing.

**Exceptions:**

1. Double-walled piping.
2. Piping, valves, fittings and related components located in exhausted enclosures.

- ❖ A welded connection is required for piping because it is more reliable than a friction connection or a threaded connection. Additionally, this section requires the piping to be stainless steel to reduce the likelihood of corrosion to which other piping may be susceptible.

There are two exceptions to the welded connection and stainless steel requirement: double wall piping or where all portions of the piping, valves and fittings are located in an exhausted enclosure. Both of these methods reduce the likelihood that a failure in the piping, valves or fittings would result in a release of highly toxic ozone to the atmosphere.

**6005.4.2 Materials.** Materials shall be compatible with ozone and shall be rated for the design operating pressures.

- ❖ It is important that valves or fittings used are compatible with ozone. Section 6005.4.1 requires the piping to be stainless steel unless one of the two exceptions applies. Regardless, the materials used need to be compatible. Essentially, the intent is to avoid leaks or major failures resulting from corrosion.

Also, this section discusses the need for piping to withstand the pressures that are expected, because that could be another potential mode of failure.

**6005.4.3 Identification.** Piping shall be identified with the following: OZONE GAS—HIGHLY TOXIC—OXIDIZER.

- ❖ To alert occupants and emergency responders to the potential dangers of ozone, the piping carrying the ozone must be labeled to list the hazards of this highly toxic and oxidizing gas.

**6005.5 Automatic shutdown.** Ozone gas generators shall be designed to shut down automatically under the following conditions:

1. When the dissolved ozone concentration in the water being treated is above saturation when measured at the point where the water is exposed to the atmosphere.
2. When the process using generated ozone is shut down.
3. When the gas detection system detects ozone.
4. Failure of the ventilation system for the cabinet or ozone-generator room.
5. Failure of the gas detection system.

- ❖ There are several conditions where the ozone generator needs to shut down automatically. These include when dissolved ozone in water being treated in a water purification system is above saturation, when the ozone being generated is not placed directly into use, as in the case of water purification, when ozone is detected or the ventilation and gas detection systems fail. This adds to the levels of redundancies available to enhance personnel safety.

**6005.6 Manual shutdown.** Manual shutdown controls shall be provided at the generator and, where in a room, within 10 feet (3048 mm) of the main *exit* or *exit access* door.

- ❖ A manual shutdown control on the ozone generator is a backup to the automated shutdown system that uses sensors to detect leaks, sound alarms and shut down the system. Because an ozone generator located in a room would almost always be a large-capacity machine, the manual shutdown controls are needed near the main access door to minimize the possibility that any significant quantity of escaping ozone would reach building occupants. Having the controls near the door also minimizes the chance that the person who shuts down the generator in an emergency would be exposed to harmful amounts of ozone. With smaller generators that would more likely be located in a ventilated cabinet or exhausted enclosure, there is no requirement for manual shutdown controls other than those on the generator itself.

## Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 61: Liquefied Petroleum Gases

## General Comments

The use and popularity of liquefied petroleum gas (LP-gas) for domestic purposes varies depending on location. In the United States, propane is the most widely used LP-gas, with butane a distant runner-up. Rural communities, especially those located in cooler climates, tend to use propane as a principal fuel source for domestic cooking, clothes drying, water heating and space heating. This practice tends to be less common in urban and suburban communities served by public utility companies supplying piped natural gas. On the other hand, LP-gas is widely used by industries as a motor fuel for industrial lift trucks; aerosol charging; welding and cutting; auxiliary heating and lighting and, in the agricultural community, as a fuel for drying crops, operating pumps and heating livestock shelters.

Propane is well known as a camping fuel for cooking, lighting, heating and refrigerating. LP-gas also remains a popular standby fuel supply for auxiliary generators. Additionally, utility companies use propane as a substitute for natural gas as a “peak shaving” alternative when supplies run low or prices are high; in this application, propane is usually mixed with air to achieve the same energy content per cubic foot as natural gas.

Propane is widely used as an alternative motor vehi-

cle fuel, and its characteristic as a clean-burning fuel has resulted in the addition of propane dispensers to service stations throughout the country.

Another use for propane, although less popular because it is flammable, is as the working fluid in a refrigeration cycle. In some applications, it is a suitable alternative to R-22 and other chlorofluorocarbon (CFC)-rich refrigerants.

Future uses for LP-gas, and propane in particular, may arise out of an intense interest in independent electrical power generation units, such as fuel cell and microturbine generators. Propane is a leading candidate for these units because of its portability and moderate storage pressures. Additionally, ongoing research on absorption refrigeration cycles may lead to greater interest in propane-powered air conditioners.

## Purpose

Chapter 61 includes requirements for handling, storing and using LP-gas, principally propane, to reduce the possibility of damage to containers, accidental releases of LP-gas and exposure of flammable concentrations of LP-gas to ignition sources.

## SECTION 6101 GENERAL

**6101.1 Scope.** Storage, handling and transportation of liquefied petroleum gas (LP-gas) and the installation of LP-gas equipment pertinent to systems for such uses shall comply with this chapter and NFPA 58. Properties of LP-gases shall be determined in accordance with Appendix B of NFPA 58.

❖ Some of the principal characteristics of LP-gases are shown in Commentary Figure 6101.1(1). They include the limits of flammability, the specific gravity of the gas vapor at 60°F (16°C) and the ignition temperatures of the flammable mixtures.

It is important to recognize that LP-gases exist in both liquid and vapor states at ambient temperatures. When stored in a pressure vessel, the liquid and vapor states of LP-gases will be in equilibrium until the system is called upon to deliver vapor to the appliance it is serving. When this happens, the pressure in the container drops and the liquid begins to boil to produce more vapor and once again reach equilibrium. As vapor is produced through the boiling process, the liquid in the container begins to refrigerate

itself and the entire system cools down. Commentary Figure 6101.1(2) shows the vapor pressure of propane at various temperatures.

LP-gases are heavier than air, and although public perception holds that they will sink to the lowest level of a space, these gases disperse according to the laws of physics just as other gases do. It is not safe to assume that all LP-gases, such as propane, immediately sink to the floor and “pool” there. LP-gases can and will, under ambient conditions, disperse to all parts of a room or space.

LP-gases, such as propane, must be odorized with a warning agent that is detectable at a minimum concentration of one-fifth the lower limit of flammability. The most frequently used odorant for propane is ethyl mercaptan, which is usually added at a pipeline terminal or other supply point before the gas is shipped to a retail bulk storage facility.

LP-gas containers pose the danger of a boiling-liquid expanding-vapor explosion (BLEVE) if they are exposed to a fire. Prolonged flame impingement above the liquid-gas interface, where the heat-absorbing properties of the liquid cannot protect the

container shell from thermal stress, may generate catastrophic failures, expelling tank contents in a fire-ball and propelling container fragments from the site of the accident.

Such violent container failures are extremely dangerous and were much more common in the past, before safety improvements in railcars and cargo transport trucks were introduced. Recently, the propane industry, through the National Propane Gas Association and the Propane Education and Research Council, has developed a program for training emergency response personnel to respond effectively and knowledgeably to threatening incidents involving the transportation, storage or use of propane. The curriculum was made available free of charge to every fire department in the United States.

The requirements of this chapter are intended to address hazards associated with the storage, handling and use of LP-gas. NFPA 58 is supplemented by NFPA 59, which specifically addresses the use of LP-gas at utility gas plants.

The U.S. Department of Transportation (DOT) classifies LP-gas as a hazardous material, and the transportation of LP-gases "in commerce" is regulated by Title 49 of the Code of Federal Regulations. The term

"in commerce" is defined to be transportation by a commercial entity. In other words, transportation of a propane grill cylinder in the passenger compartment of a car is not regulated by the DOT but is by NFPA 58.

**6101.2 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

Distributors shall not fill an LP-gas container for which a permit is required unless a permit for installation has been issued for that location by the *fire code official*.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.28 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

GAS	IGNITION TEMPERATURE (°F)	LOWER FLAMMABLE LIMITATIONS <sup>a</sup>	UPPER FLAMMABLE LIMITATIONS <sup>a</sup>	SPECIFIC GRAVITY OF VAPOR @ 60°F
Butane	550	1.9	8.5	2.0
1-Butene	725	1.6	10.0	1.9
2-Butene (cis)	617	1.7	9.0	1.9
2-Butene (trans)	615	1.8	9.7	1.9
Propane	920	2.1	9.5	1.5
Propylene	851	2.0	11.1	1.5

For SI: °C = [(°F) - 32]/1.8.

a. Lower and upper flammable limitations are percentages of gas in gas-air mixtures. Specific gravity describes the relative weight of a unit of gas compared to air (air = 1.0).

**Source:** NFPA 325M, *Properties of Flammable Solids, Liquids and Gases* (1991).

**Figure 6101.1(1)**  
**PROPERTIES OF COMMON LP-GASES**

TEMP (°F)	PRESS. (psig)	TEMP (°F)	PRESS. (psig)	TEMP (°F)	PRESS. (psig)	TEMP (°F)	PRESS. (psig)
130	257	70	109	20	40	-20	10
120	225	65	100	10	31	-25	8
110	197	60	92	0	23	-30	5
100	172	50	77	-5	20	-35	3
90	149	40	63	-10	16	-40	1
80	128	30	51	-15	13	-44	0

For SI: °C = [(°F) - 32]/1.8.

**Figure 6101.1(2)**  
**VAPOR PRESSURES OF PROPANE**

An operational permit for installations using or storing LP-gas is required except when the installation is a container of 500-gallon (1893 L) water capacity or less and serving a Group R-3 occupancy. In addition, Section 105.7.8 requires that a construction permit be obtained for any installation of or modification to an LP-gas system.

The last sentence of this section is addressing stationary installations of LP-gas and states that for those installations requiring a permit, the container must not be filled unless that permit has been issued.

**6101.3 Construction documents.** Where a single LP-gas container is more than 2,000 gallons (7570 L) in water capacity or the aggregate water capacity of LP-gas containers is more than 4,000 gallons (15 140 L), the installer shall submit *construction documents* for such installation.

❖ This section applies to those installations for which a construction permit is required, namely when a new system is being installed or an existing system is being modified. When container size exceeds the thresholds specified, applicants must submit plans indicating compliance with requirements before approval can be authorized. Plans should be clear, concise, legible, prepared on standard-sized paper and include the following:

- Location and legal identification (address and lot or parcel number) of the lot or site.
- Legal boundaries of the site, including reference to source or survey.
- Location of significant buildings on the lot or site and adjacent lots or sites.
- Location of nearest public roadways and site access.
- Location of all underground and overhead utilities.
- North arrow.
- Topographical features.
- Proposed container location with respect to buildings, building openings, lot lines, public roadways and underground or overhead utilities.
- Container dimensions and capacity.
- Container compliance markings (e.g., ASME, DOT, API).
- Details of container foundation and supports.
- Section through container showing supports and anchors and, if an underground tank, backfill and corrosion protection.
- Arrangement of valves and piping.
- Specifications for containers, valves, piping, tank mounts and pads and other related equipment and appliances.
- Means for protecting valves from tampering.
- Name, address and telephone number of property owner.

- Name, address and telephone number of installer and servicing contractor.

## SECTION 6102 DEFINITIONS

**6102.1 Definitions.** The following terms are defined in Chapter 2:

**LIQUEFIED PETROLEUM GAS (LP-gas).**

**LP-GAS CONTAINER.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 6103 INSTALLATION OF EQUIPMENT

**6103.1 General.** LP-gas equipment shall be installed in accordance with the *International Fuel Gas Code* and NFPA 58, except as otherwise provided in this chapter.

❖ The *International Fuel Gas Code*<sup>®</sup> (IFGC<sup>®</sup>) addresses the installation of equipment downstream from the final pressure regulator in the system, which typically is the second-stage regulator. The IFGC would, therefore, regulate LP-gas piping typically installed indoors, as well as appliance installations.

The remainder of Chapter 61 is devoted primarily to energy-consuming installations at which fuel-burning appliances are installed. NFPA 58 should be referred to for propane bulk plant installations; refrigerated storage installations; marine shipping and receiving installations and equipment-specific requirements such as for installing vaporizers and dispensers. The more detailed provisions in NFPA 58 should be reviewed by the fire code official before approving any LP-gas installation.

**6103.2 Use of LP-gas containers in buildings.** The use of LP-gas containers in buildings shall be in accordance with Sections 6103.2.1 and 6103.2.2.

❖ In general, storing and using LP-gas inside buildings is limited to relatively small quantities. There are some exceptions, such as the use of LP-gas for temporary heating in buildings under construction.

LP-gas containers are either fabricated to the requirements of the American Society of Mechanical Engineers (ASME) *Boiler and Pressure Vessel Code* (BPVC) or the DOT rules contained in Title 49 of the Code of Federal Regulations.

**6103.2.1 Portable containers.** Portable LP-gas containers, as defined in NFPA 58, shall not be used in buildings except as

specified in NFPA 58 and Sections 6103.2.1.1 through 6103.2.1.7.

❖ Portable containers are typically DOT cylinders, which are used in the vertical position. This is not always the case though; some recreational vehicles use DOT cylinders in a horizontal position (see Commentary Figure 6103.2.1).

One of the most common violations involving LP-gas is the storage or use of it inside buildings, particularly residential structures. This is a long-standing requirement that relates to the potential for releasing propane within a building.

In the past, any propane cylinder would release propane simply by opening the service valve; however, advances have been made in the technologies used in the propane industry. Since 1995, propane cylinders shipped with new outdoor cooking equipment (grills, smokers, etc.) must be fitted with valves that will not release propane even if the valve handle is opened, unless a positive, leak-tight connection is made between the cylinder and the cooking equipment. This technology, as well as two others that would stop the flow of gas under fire conditions or if there were a hose line break, are required by ANSI Z21.58.

**6103.2.1.1 Use in basement, pit or similar location.** LP-gas containers shall not be used in a basement, pit or similar location where heavier-than-air gas might collect. LP-gas containers shall not be used in an above-grade underfloor space or basement unless such location is provided with an *approved* means of ventilation.

**Exception:** Use with self-contained torch assemblies in accordance with Section 6103.2.1.6.

❖ Because propane has a specific gravity of 1.52 at 60°F (16°C) (which means it is 1.52 times heavier than air at that temperature), it has been assumed to automatically sink to the ground when it is released to the atmosphere. Even though the laws of physics have proven this concept to be untrue, concerns persist about the ability for propane to disperse in locations where air circulation is restricted. Any ventilation

system design should take into account the expected temperatures at the location and an expected leak rate from the piping system.

Only LP-gas containers are prohibited from being used in basements, pits and similar locations. Hard-piped systems in which the container remains outside the building can serve systems installed in basements, pits and similar locations. The hazard associated with containers in buildings relates to the fact that the pressure in the container is dependent on the temperature of the propane within it and can exceed 100 pounds per square inch gauge (psig) at 70°F (21°C), whereas the pressure in the building piping of a propane service is usually 0.5 psig (3 kPa).

In the past, the model codes prohibited the use of any propane system in spaces below grade. The U.S. Consumer Product Safety Commission (CPSC) staff concluded, however, that the rate of incidents occurring in propane systems used in basements and underground locations is no different than that occurring in above-ground locations.

The exception to this requirement acknowledges the use of self-contained torch assemblies, which are limited to about 1 pound (0.454 kg) (2.5 pounds water) of propane per container.

**6103.2.1.2 Construction and temporary heating.** Portable LP-gas containers are allowed to be used in buildings or areas of buildings undergoing construction or for temporary heating as set forth in Sections 6.19.4, 6.19.5 and 6.19.8 of NFPA 58.

❖ The referenced sections in NFPA 58 address the use of temporary heating in buildings undergoing construction or renovations, or industrial buildings under certain conditions.

**6103.2.1.3 Group F occupancies.** In Group F occupancies, portable LP-gas containers are allowed to be used to supply quantities necessary for processing, research or experimentation. Where manifolded, the aggregate water capacity of such containers shall not exceed 735 pounds (334 kg) per manifold. Where multiple manifolds of such containers are present in the same room, each manifold shall be separated from

For SI: 1 pound = 0.454 kg.

**Figure 6103.2.1**  
**TYPICAL DOT CYLINDERS**

other manifolds by a distance of not less than 20 feet (6096 mm).

❖ The use of manifolds to connect containers increases the overall capacity of the system by increasing its vaporization capacity. The vaporization rate is directly related to the total surface area of the containers. Using manifolds, however, also increases the number of connections made on a system, and, because the connections in a piping system under pressure are where leaks are likely to originate, the total volume of propane in manifolded systems is limited to that shown. The amount of propane in pounds can be calculated from the water capacity in pounds by multiplying by 0.42. In this instance, the amount of propane permitted is about 310 pounds (141 kg).

**6103.2.1.4 Group E and I occupancies.** In Group E and I occupancies, portable LP-gas containers are allowed to be used for research and experimentation. Such containers shall not be used in classrooms. Such containers shall not exceed a 50-pound (23 kg) water capacity in occupancies used for educational purposes and shall not exceed a 12-pound (5 kg) water capacity in occupancies used for institutional purposes. Where more than one such container is present in the same room, each container shall be separated from other containers by a distance of not less than 20 feet (6096 mm).

❖ Further restrictions on the use of propane in educational (schools) and institutional occupancies reflect the likelihood that the occupants of those spaces will be limited in their ability to respond to an emergency.

The minimum distance of 20 feet (6096 mm) is intended to provide a factor of safety so that if one installation becomes a source of an ignited jet plume, any other similar installations would not be directly exposed to the plume.

**6103.2.1.5 Demonstration uses.** Portable LP-gas containers are allowed to be used temporarily for demonstrations and public exhibitions. Such containers shall not exceed a water capacity of 12 pounds (5 kg). Where more than one such container is present in the same room, each container shall be separated from other containers by a distance of not less than 20 feet (6096 mm).

❖ This section restricts the size of LP-gas containers used for demonstrations to roughly 5 pounds (2.3 kg) of propane capacity. There is no restriction on the number of containers, however; only a limitation that they be separated by at least 20 feet (6096 mm) for the same reason as specified in the previous section.

**6103.2.1.6 Use with self-contained torch assemblies.** Portable LP-gas containers are allowed to be used to supply approved self-contained torch assemblies or similar appliances. Such containers shall not exceed a water capacity of 2½ pounds (1 kg).

❖ A common example of the use described in this section is jewelry making using portable LP-gas containers to supply approved self-contained torch assemblies when such containers do not exceed a

2½-pound (1.13 kg) water capacity. This section, which correlates with Section 6.20.9.3 of NFPA 58, is not contingent on the type of operation or whether it is permanent or temporary. Thus, this section allows jewelry manufacturers to use portable LP-gas containers in accordance with the requirements set forth in NFPA 58. NFPA 58 also requires that these LP-gas containers comply with UL 147A, *Nonrefillable (Disposable Type Fuel Gas Cylinder Assemblies)*.

**6103.2.1.7 Use for food preparation.** Where approved, listed LP-gas commercial food service appliances are allowed to be used for food-preparation within restaurants and in attended commercial food-catering operations in accordance with the *International Fuel Gas Code*, the *International Mechanical Code* and NFPA 58.

❖ Although not stated explicitly, this section intends to permit the use of LP-gas containers in buildings with commercial food service cooking appliances. The code requires that those appliances be approved. Typically, this type of appliance will be labeled in accordance with one of the ANSI Z83 series standards for commercial gas cooking equipment.

**6103.2.2 Industrial vehicles and floor maintenance machines.** LP-gas containers on industrial vehicles and floor maintenance machines shall comply with Sections 11.13 and 11.14 of NFPA 58.

❖ This section simply refers to the correct section reference in NFPA 58 for containers serving engines mounted on industrial vehicles and floor maintenance machines.

**6103.3 Location of equipment and piping.** Equipment and piping shall not be installed in locations where such equipment and piping is prohibited by the *International Fuel Gas Code*.

❖ With respect to LP-gas systems, the IFGC addresses equipment and piping downstream of the second-stage regulator, which would typically include all piping and appliances within the building.

## SECTION 6104 LOCATION OF LP-GAS CONTAINERS

**6104.1 General.** The storage and handling of LP-gas and the installation and maintenance of related equipment shall comply with NFPA 58 and be subject to the approval of the *fire code official*, except as provided in this chapter.

❖ This section reinforces the need to review NFPA 58 for detailed provisions before any installation of LP-gas is approved.

**6104.2 Maximum capacity within established limits.** Within the limits established by law restricting the storage of liquefied petroleum gas for the protection of heavily populated or congested areas, the aggregate capacity of any one installation shall not exceed a water capacity of 2,000 gallons

(7570 L) (see Section 3 of the Sample Legislation for Adoption of the *International Fire Code* on page xxi).

**Exception:** In particular installations, this capacity limit shall be determined by the *fire code official*, after consideration of special features such as topographical conditions, nature of occupancy, and proximity to buildings, capacity of proposed LP-gas containers, degree of fire protection to be provided and capabilities of the local fire department.

- ❖ This section originated in NFPA 58 and is intended to establish a limit on ordinary above-ground containers in densely populated areas. The requirement establishes a level of acceptable risk to the general public; however, the scientific basis for the 2,000-gallon (908 kg) limitation is not clear.

The question is often asked, “What is the definition of heavily populated or congested areas?” Heavily populated and congested areas are those areas that are determined by the fire code official to pose a risk of substantial loss from a fire involving large containers of LP-gas and are designated in the jurisdiction’s adopting ordinance. Such areas could be likened to the areas designated as “fire districts” in Appendix D of the IBC. This section refers to “the limits established by law” to cross reference those provisions in the ordinance adopting the code. The model adopting ordinance on page xxi of the *International Fire Code*® (IFC®) includes Section 3 to correlate with this section in defining these limits.

The exception recognizes that consideration of the specific features of the installation, such as fire protection systems, mounding or burying of containers or the capabilities of the local fire-fighting service, should be taken into account before establishing any limit on the system’s capacity.

**6104.3 Container location.** LP-gas containers shall be located with respect to buildings, *public ways* and *lot lines* of adjoining property that can be built upon, in accordance with Table 6104.3.

- ❖ This paragraph references Table 6104.3, which contains the requirements for siting LP-gas containers on a piece of property.

Separating and protecting containers from each other and from buildings and heat-producing appliances are the principal means for preventing container failures and accidental ignitions. Separation serves at least two purposes. Outside a building, separating tanks from structures allows escaping gas to disperse or dilute before it can enter a building or come in contact with an ignition source. Similarly, the container is protected to an extent from a hazardous exposure if escaping gas is ignited, and the tank is protected if the building becomes involved in a fire.

Separating containers from each other or from other groups of containers minimizes the scale of an accident if a tank or group of containers becomes involved in a fire. Though the separation distances do

not result in absolute protection from fire exposures and leaks, they do provide a measure of access for establishing fire-fighting positions to protect tanks and exposures.

**TABLE 6104.3.** See page 61-7.

- ❖ This table has its origins in NFPA 58 and has existed for many years. This establishes reasonable distances that can be used to determine separation requirements between an LP-gas container installation and buildings, lot lines and public ways, as well as between multiple containers installed at the same site. The important factors to consider when establishing suitable distances include the container capacity and whether it is installed above ground, mounded or below ground. See Commentary Figure 6104.3(1) for a graphic depiction of the requirements.

As one would expect, the required distances are reduced for containers that are mounded or installed underground because of the reduced exposure of the container to external sources of heat. Although not defined in the code, the difference between a mounded container and one installed underground is that a mounded container is an ASME container labeled for underground installation but installed above the minimum depth required for underground service. NFPA 58 contains specific provisions for mounding tanks.

Note a to Table 6104.3 defines the endpoint for measuring the separation distance for underground containers as being the relief device, which will release propane to the atmosphere only under abnormal conditions, and the filling connection and liquid-level gauge, both of which release propane during a normal filling operation.

Note b contains a requirement for building overhangs in which the overhang is less than 50 feet (15 240 mm) above the relief device discharge outlet. This dimension represents what is considered a safe distance to prevent the accumulation of LP-gas should the relief device discharge [see Commentary Figure 6104.3(2)].

Note c requires that clearances be provided to allow installation and maintenance, if necessary, for underground tanks, which must be done using a backhoe or some other large piece of equipment.

Note d anticipates an increase in the hazard of those installations made up of at least four containers because of the greater number of joints and connections needed as well as perhaps a greater risk of involvement of the storage system in a building fire.

Note e addresses installing smaller containers and focuses on requirements for locating relief devices and other appurtenances an acceptable distance from potential sources of ignition.

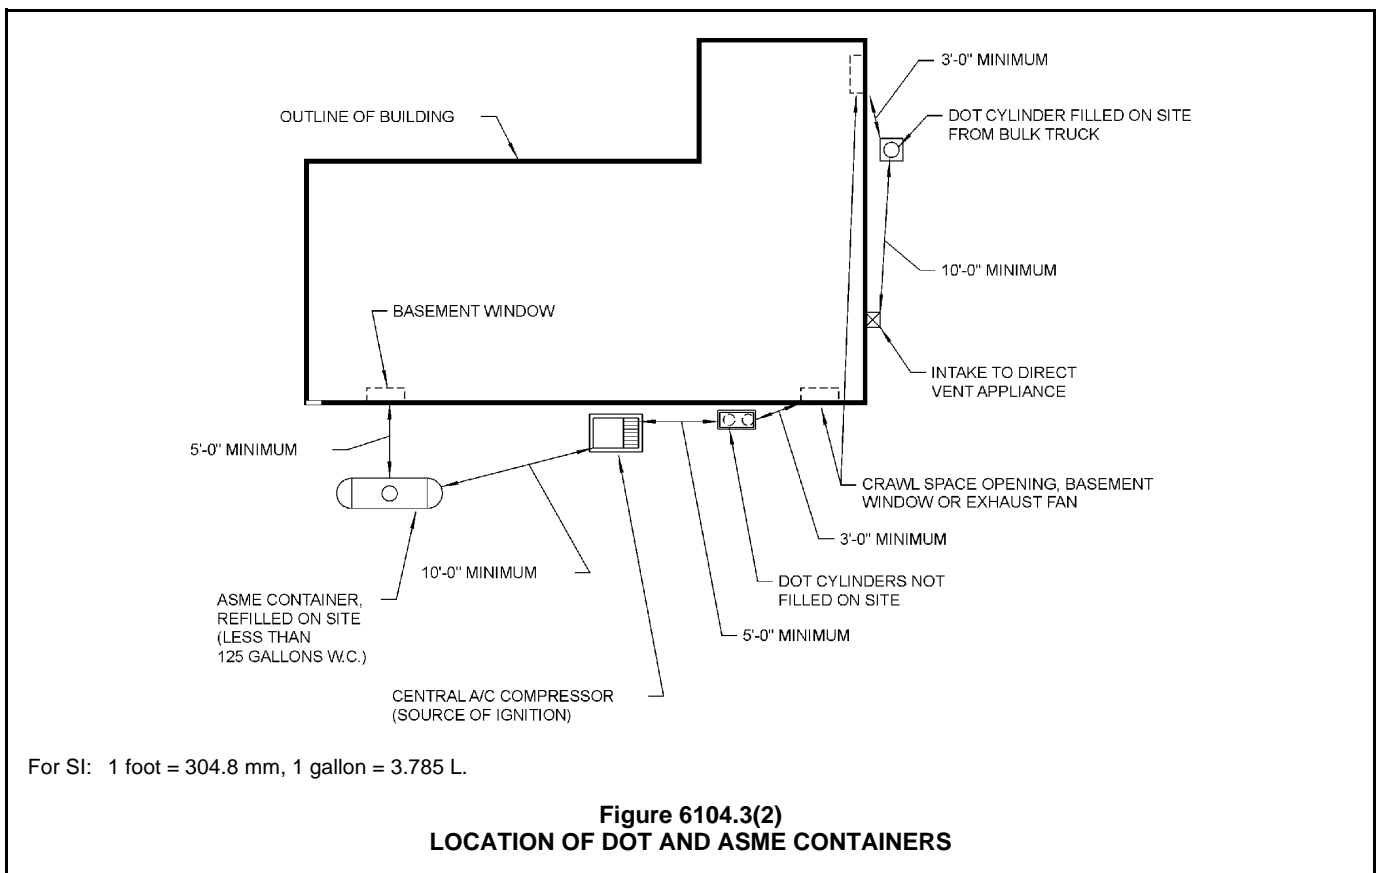

Note f permits a reduction in the required distances for a 1,200-gallon (4,542 L) water capacity container, which is typically the maximum size for a container that would be used for any residential service.

**TABLE 6104.3  
LOCATION OF LP-GAS CONTAINERS**

LP-GAS CONTAINER CAPACITY (water gallons)	MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS AND BUILDINGS, PUBLIC WAYS OR LOT LINES OF ADJOINING PROPERTY THAT CAN BE BUILT UPON		MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS <sup>b, c</sup> (feet)
	Mounded or underground LP-gas containers <sup>a</sup> (feet)	Above-ground LP-gas containers <sup>b</sup> (feet)	
Less than 125 <sup>c, d</sup>	10	5 <sup>e</sup>	None
125 to 250	10	10	None
251 to 500	10	10	3
501 to 2,000	10	25 <sup>e, f</sup>	3
2,001 to 30,000	50	50	5
30,001 to 70,000	50	75	(0.25 of sum of diameters of adjacent LP-gas containers)
70,001 to 90,000	50	100	
90,001 to 120,000	50	125	

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

- a. Minimum distance for underground LP-gas containers shall be measured from the pressure relief device and the filling or liquid-level gauge vent connection at the container, except that all parts of an underground LP-gas container shall be not less than 10 feet from a building or lot line of adjoining property that can be built upon.
- b. For other than installations in which the overhanging structure is 50 feet or more above the relief-valve discharge outlet. In applying the distance between buildings and ASME LP-gas containers with a water capacity of 125 gallons or more, not less than 50 percent of this horizontal distance shall also apply to all portions of the building that project more than 5 feet from the building wall and that are higher than the relief valve discharge outlet. This horizontal distance shall be measured from a point determined by projecting the outside edge of such overhanging structure vertically downward to grade or other level upon which the LP-gas container is installed. Distances to the building wall shall be not less than those prescribed in this table.
- c. Where underground multicontainer installations are composed of individual LP-gas containers having a water capacity of 125 gallons or more, such containers shall be installed so as to provide access at their ends or sides to facilitate working with cranes or hoists.
- d. At a consumer site, if the aggregate water capacity of a multicontainer installation, comprised of individual LP-gas containers having a water capacity of less than 125 gallons, is 500 gallons or more, the minimum distance shall comply with the appropriate portion of Table 6104.3, applying the aggregate capacity rather than the capacity per LP-gas container. If more than one such installation is made, each installation shall be separated from other installations by not less than 25 feet. Minimum distances between LP-gas containers need not be applied.
- e. The following shall apply to above-ground containers installed alongside buildings:
  1. LP-gas containers of less than a 125-gallon water capacity are allowed next to the building they serve where in compliance with Items 2, 3 and 4.
  2. Department of Transportation (DOTn) specification LP-gas containers shall be located and installed so that the discharge from the container pressure relief device is not less than 3 feet horizontally from building openings below the level of such discharge and shall not be beneath buildings unless the space is well ventilated to the outside and is not enclosed for more than 50 percent of its perimeter. The discharge from LP-gas container pressure relief devices shall be located not less than 5 feet from exterior sources of ignition, openings into direct-vent (sealed combustion system) appliances or mechanical ventilation air intakes.
  3. ASME LP-gas containers of less than a 125-gallon water capacity shall be located and installed such that the discharge from pressure relief devices shall not terminate in or beneath buildings and shall be located not less than 5 feet horizontally from building openings below the level of such discharge and not less than 5 feet from exterior sources of ignition, openings into direct vent (sealed combustion system) appliances, or mechanical ventilation air intakes.
  4. The filling connection and the vent from liquid-level gauges on either DOTn or ASME LP-gas containers filled at the point of installation shall be not less than 10 feet from exterior sources of ignition, openings into direct vent (sealed combustion system) appliances or mechanical ventilation air intakes.
- f. This distance is allowed to be reduced to not less than 10 feet for a single LP-gas container of 1,200-gallon water capacity or less, provided such container is not less than 25 feet from other LP-gas containers of more than 125-gallon water capacity.

**6104.3.1 Installation on roof prohibited.** LP-gas containers used in stationary installations shall not be located on the roofs of buildings.

❖ Installation of stationary containers on the roof of buildings is permitted by NFPA 58; however, based on this section, stationary LP-gas containers are not allowed on the roof of any building. This prohibition takes precedence over the NFPA 58 requirements because of Section 102.7 of the code. Note that the use of the word “stationary” is intended to make it clear that this section should not be misinterpreted to include containers used for temporary applications such as applying roofing materials or brazing operations. A stationary LP-gas installation is defined in Chapter 3 of NFPA 58 as “An installation of LP-gas containers, piping and equipment for indefinite use at a particular location; an installation is not normally expected to change in status, condition, or location.” A stationary installation is assembled from approved DOT cylinders or ASME-compliant containers, piping and equipment such as pressure regulators that remain on the site for an indefinite time period. Section 105.7.12 requires a construction permit for any LP-gas system. Temporary operations require an operational permit in accordance with Section 105.6.28 and possibly other operational permits, depending on the specific operation being conducted. For example, LP-gas is commonly used by contractors for soldering water or refrigerant piping systems. Many roof covering systems are applied using LP-gas-fueled torch systems, which constitute hot work and must comply with the requirements in Chapter 35 (see Commentary Figure 6104.3.1). Torch-applied roofing systems also need to comply with the requirements of Section 3317 for hot work. When LP-gas

**Figure 6104.3.1  
TORCH-APPLIED ROOFING APPARATUS**

cylinders are required on a building roof or inside a building for temporary maintenance or construction reasons, their on-site transportation and use should comply with the requirements of Section 6.20 of NFPA 58 for cylinders, equipment, piping and appliances in buildings, building roofs and exterior balconies.

**6104.3.2 Special hazards.** LP-gas containers shall be located with respect to special hazards including, but not limited to, above-ground flammable or *combustible liquid* tanks, oxygen or gaseous hydrogen containers, flooding or electric power lines as specified in Section 6.4.5 of NFPA 58.

❖ Additional requirements may apply when siting an LP-gas container. Other products stored in the vicinity may present specific hazards that must be addressed. Flood hazard areas are defined in Section 202 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>).

**6104.4 Multiple LP-gas container installations.** Multiple LP-gas container installations with a total water storage capacity of more than 180,000 gallons (681 300 L) [150,000-gallon (567 750 L) LP-gas capacity] shall be subdivided into groups containing not more than 180,000 gallons (681 300 L) in each group. Such groups shall be separated by a distance of not less than 50 feet (15 240 mm), unless the containers are protected in accordance with one of the following:

1. Mounded in an *approved* manner.
2. Protected with *approved* insulation on areas that are subject to impingement of ignited gas from pipelines or other leakage.
3. Protected by fire walls of *approved* construction.
4. Protected by an *approved* system for application of water as specified in Table 6.4.2 of NFPA 58.
5. Protected by other *approved* means.

Where one of these forms of protection is provided, the separation shall be not less than 25 feet (7620 mm) between LP-gas container groups.

❖ These separation requirements are intended to minimize the exposure of adjacent containers following ignition of a release and to establish access for fire fighting. When used, insulation must be capable of preventing container temperatures from exceeding 800°F (427°C) for at least 50 minutes. Annex H of NFPA 58 details the performance test for LP-gas tank insulation systems.

## SECTION 6105 PROHIBITED USE OF LP-GAS

**6105.1 Nonapproved equipment.** LP-gas shall not be used for the purpose of operating devices or equipment unless such device or equipment is *approved* for use with LP-gas.

❖ Appliances and equipment must be approved for use with LP-gas. For example, appliances should be listed for use with LP-gas; hoses used to serve LP-gas installations should be listed and labeled for that use.

**6105.2 Release to the atmosphere.** LP-gas shall not be released to the atmosphere, except in accordance with Section 7.3 of NFPA 58.

❖ The release of LP-gas to the atmosphere is not recommended, but sometimes cannot be avoided. Prior to the 2015 edition, the code permitted LP-gas to be released to the atmosphere only while the container is being filled, through the fixed maximum liquid level gauge. One such common instance is when filling a container at a residence. The delivery person must rely on the fixed liquid-level gauge to determine when the maximum amount of LP-gas has been reached. This gauge has a very small circular orifice that is connected to a tube that extends into the container to a level consistent with the height of the liquid when the container would be 80-percent full. When the liquid level in the container being filled reaches the bottom of the tube opening, a small amount of liquid escapes from the gauge to the atmosphere, causing it to vaporize. The vaporizing gas cools the surrounding air to the point that the moisture in the air condenses and forms a white cloud. When the delivery person observes this cloud, the filling operation is stopped.

Another instance in which the release of gas to the atmosphere is unavoidable is when the filling hose is disconnected from the container fill valve. The liquid remaining in the hose is released to the atmosphere and vaporizes.

There are many other situations that require the release of LP-gas under controlled conditions. Section 7.3 of NFPA 58 recognizes additional circumstances that necessitate the release of gas to the atmosphere, including the release of gas when the filling hose is disconnected from the filler valve on the container; the release of gas necessary to make cylinders and other containers safe prior to being serviced; and the release of gas that may be necessary in order to properly purge a container of air to make it safe for filling. These are a few of the common occurrences in the propane industry that necessitate the release of LP-gas to the atmosphere.

## SECTION 6106 DISPENSING AND OVERFILLING

**6106.1 Attendants.** Dispensing of LP-gas shall be performed by a qualified attendant.

❖ This section requires that any person transferring LP-gas must be qualified, which means that person must be trained. A number of training materials are available, most notably the *Certified Employees Training Program* published by the National Propane Gas Association (NPGA).

**6106.2 Overfilling.** LP-gas containers shall not be filled or maintained with LP-gas in excess of either the volume determined using the fixed liquid-level gauge installed in accordance with the manufacturer's specifications and in accordance with Section 5.7.5 of NFPA 58 or the weight

determined by the required percentage of the water capacity marked on the container. Portable LP-gas containers shall not be refilled unless equipped with an overfilling prevention device (OPD) where required by Section 5.7.3 of NFPA 58.

❖ Overfilling a container can result in a catastrophic release of LP-gas because of the relatively high coefficient of expansion of liquid LP-gas. Depending on how much a container has been overfilled, a temperature difference of just a few degrees can result in the container becoming "liquid full," which increases the pressure in the container dramatically and leads to the pressure relief device opening, releasing LP-gas to the atmosphere.

Detailed requirements for filling containers are given in NFPA 58. As stated there, the maximum amount of LP-gas permitted in a container may vary between containers filled by weight or by volume because the density of liquid LP-gas varies greatly with different temperatures.

Since 2002, NFPA 58 has not permitted the filling of cylinders for vapor service in the 4- to 40-pound (1.8 kg and 18 kg) range unless the cylinder is equipped with an overfill prevention device (OPD). An OPD is a float-operated mechanism that is designed to act as a backup to the normal filling procedures (using either a scale or the fixed liquid-level gauge) and will automatically close the filler valve when the liquid in the container reaches 80 percent of the container volume. The OPD cannot be seen, but new containers having this safety device are identifiable by the three lobes on the handwheel on the valve (see Commentary Figure 6106.2). Accordingly, all cylinders in a cylinder exchange program must be

equipped with or retrofitted with an OPD. Prior to the introduction of OPDs, overfilled cylinders may have initially held their charge, but later leaked when cylinder pressure increased due to high ambient temperature exposures. This safeguard against overfilling portable containers is found in referenced Section 5.7.3 of NFPA 58.

This section requires the use of a manufacturer-installed liquid level gauge to fill a container. The liquid level gauge is generally an integral part of the service valve which is used to turn the tank on and off. Service valves have rubber or plastic o-rings that can start to leak over time. It is common practice in the industry to field repair and replace valves and gauges on both ASME tanks and DOTn cylinders, as needed. When a service valve becomes faulty, a new valve is installed with a liquid level gauge tube of exactly the same length. In addition, OPD systems on DOT cylinders may also require periodic replacement. The propane industry has procedures and training to successfully perform these replacements and repair.

This section also acknowledges that the service and repair of propane containers in the field does take place and NFPA 58 Section 5.7.5 covers the requirements for proper installation and the use of liquid level gauges.

**6106.3 Dispensing locations.** The point of transfer of LP-gas from one LP-gas container to another shall be separated from exposures as specified in NFPA 58.

- ❖ Because the release of LP-gas to the atmosphere in small quantities may be unavoidable when filling a container, all possible sources of ignition in the vicinity of the point of transfer must be accounted for. NFPA 58 includes detailed requirements for establishing clearances from those sources of ignition.

### SECTION 6107 SAFETY PRECAUTIONS AND DEVICES

**6107.1 Safety devices.** Safety devices on LP-gas containers, equipment and systems shall not be tampered with or made ineffective.

- ❖ The safety devices found on all propane containers include the service valve, the filler valve (part of the service valve on some containers) and the pressure relief device. In addition, small cylinders with a propane capacity between 4 and 40 pounds (1.8 and 18 kg) now may have a separate device called an OPD attached to the service valve inside the container. See the commentary to Section 6106.2 for further discussion of OPDs.

**6107.2 Smoking and other sources of ignition.** “No Smoking” signs complying with Section 310 shall be posted where required by the *fire code official*. Smoking within 25 feet

(7620 mm) of a point of transfer, while filling operations are in progress at LP-gas containers or vehicles, shall be prohibited.

Control of other sources of ignition shall comply with Chapter 3 of this code and Section 6.22 of NFPA 58.

- ❖ Because of the nature of the filling operation, it may be inevitable that some quantity of gas will be released to the atmosphere; therefore, strict observance of the requirement for prohibiting sources of ignition within the limits prescribed here is essential.

**6107.3 Clearance to combustibles.** Weeds, grass, brush, trash and other combustible materials shall be kept not less than 10 feet (3048 mm) from LP-gas tanks or containers.

- ❖ The concern addressed here is the potential threat to a container of LP-gas from the ignition of nearby combustible material. It has been common practice to exempt from this requirement landscaping materials, such as grass and shrubs, that are regularly maintained.

**6107.4 Protecting containers from vehicles.** Where exposed to vehicular damage due to proximity to alleys, driveways or parking areas, LP-gas containers, regulators and piping shall be protected in accordance with NFPA 58.

- ❖ Because NFPA 58 is specific to LP-gas and contains requirements for vehicle impact protection as well as annex guidance on how to accomplish such protection, it makes sense for this section to reference NFPA 58 for this topic to avoid conflicts between the code and the referenced standard.

### SECTION 6108 FIRE PROTECTION

**6108.1 General.** Fire protection shall be provided for installations having LP-gas storage containers with a water capacity of more than 4,000 gallons (15 140 L), as required by Section 6.25 of NFPA 58.

- ❖ This section refers to NFPA 58 for the criteria to establish where fire protection should be installed at any location where the aggregate water capacity of LP-gas containers exceeds 4,000 gallons (15 140 L). The objective is to provide protection to those containers that are exposed to the threat of fire. NFPA 58 should be referred to for exceptions to this requirement.

**6108.2 Portable fire extinguishers.** Portable fire extinguishers complying with Section 906 shall be provided as specified in NFPA 58.

- ❖ Refer to NFPA 58 to determine where fire extinguishers must be provided.

**SECTION 6109**  
**STORAGE OF PORTABLE LP-GAS**  
**CONTAINERS AWAITING USE OR RESALE**

**6109.1 General.** Storage of portable LP-gas containers of 1,000 pounds (454 kg) or less, whether filled, partially filled or empty, at consumer sites or distribution points, and for resale by dealers or resellers shall comply with Sections 6109.2 through 6109.15.1.

**Exceptions:**

1. LP-gas containers that have not previously been in LP-gas service.
  2. LP-gas containers at distribution plants.
  3. LP-gas containers at consumer sites or distribution points, which are connected for use.
- ❖ This section is intended to apply to DOT cylinders, which are distinguishable from ASME containers by their vertical orientation (ASME containers are usually horizontally oriented) and markings on the collar (see Commentary Figure 6103.2.1).
- The container size threshold of 1,000 pounds (454 kg) is the water capacity of the container; therefore, the maximum propane capacity would be 420 pounds (191 kg).
- Exception 1 applies to containers that are brand new and have never contained LP-gas. Such containers would not be subject to this chapter but, rather, would be treated as any other mercantile product. Exceptions 2 and 3 include those containers already in use and those at LP-gas distribution plants, at which employees are trained in the hazards of LP-gas and whose everyday job functions include the handling of the containers.

**6109.2 Exposure hazards.** LP-gas containers in storage shall be located in a manner that minimizes exposure to excessive temperature rise, physical damage or tampering.

- ❖ Because of the relatively high coefficient of expansion for liquid LP-gas, precautions must be taken to prevent overheating of containers that could lead to releases of LP-gas to the atmosphere.

**6109.3 Position.** LP-gas containers in storage having individual water capacity greater than 2½ pounds (1 kg) [nominal 1-pound (0.454 kg) LP-gas capacity] shall be positioned with the pressure relief valve in direct communication with the vapor space of the container.

- ❖ Liquid propane released to the atmosphere through the relief valve will expand to 270 times its original volume after it vaporizes, whereas propane vapor will expand much less. To avoid the release of liquid propane, it is important to keep the pressure relief device in contact with the vapor space. Most cylinders are designed to be oriented vertically, so the relief device is at the top of the cylinder; however, some cylinders used in the recreational vehicle industry are designed for horizontal orientation only, and must be kept in that position for the relief valve to be in contact with the vapor space. Some cylinders are designed for use in either the horizontal or vertical orientation.

**6109.4 Separation from means of egress.** LP-gas containers stored in buildings in accordance with Sections 6109.9 and 6109.11 shall not be located near *exit access* doors, *exits*, *stairways* or in areas normally used, or intended to be used, as a *means of egress*.

- ❖ This section states that LP-gas containers may not be stored where they would block a means of egress in a building. The required means of egress widths and capacities must not be infringed upon by either LP-gas containers or the cabinets in which they may be stored.

**6109.5 Quantity.** Empty LP-gas containers that have been in LP-gas service shall be considered as full containers for the purpose of determining the maximum quantities of LP-gas allowed in Sections 6109.9 and 6109.11.

- ❖ Because the actual quantity of LP-gas in a container cannot always be determined, every container stored at a location must be treated as a full container.

**6109.6 Storage on roofs.** LP-gas containers that are not connected for use shall not be stored on roofs.

- ❖ The roof is a location that is likely to become warmer than atmospheric conditions on a sunny day; therefore, LP-gas containers must not be stored on roofs when they are not connected for use.

**6109.7 Storage in basement, pit or similar location.** LP-gas containers shall not be stored in a basement, pit or similar location where heavier-than-air gas might collect. LP-gas containers shall not be stored in above-grade underfloor spaces or basements unless such location is provided with an *approved* means of ventilation.

**Exception:** Department of Transportation (DOTn) specification cylinders with a maximum water capacity of 2½ pounds (1 kg) for use in completely self-contained hand torches and similar applications. The quantity of LP-gas shall not exceed 20 pounds (9 kg).

- ❖ Because propane has a specific gravity of 1.52 at 60°F (16°C) (which means it is 1.52 times heavier than air at that temperature), it has been assumed to automatically sink to the ground when it is released to the atmosphere. Even though the laws of physics have proven this concept to be untrue, concerns persist about propane dispersing in locations where air circulation is restricted. Any proposed ventilation system should take into account the expected temperatures at the location.

The exception to this section would permit very small, disposable cylinders to be stored in these locations.

**6109.8 Protection of valves on LP-gas containers in storage.** LP-gas container valves shall be protected by screw-on-type caps or collars that shall be securely in place on all containers stored regardless of whether they are full, partially full or empty. Container outlet valves shall be closed or plugged.

- ❖ Valve assemblies must be protected from physical impact. Cylinders having propane capacities up to 60 pounds (27 kg) will usually have collars that extend above the height of the valves. Larger cylinders will

have screw-on caps or domes that serve the same function.

#### 6109.9 Storage within buildings accessible to the public.

Department of Transportation (DOTn) specification cylinders with maximum water capacity of 2½ pounds (1 kg) used in completely self-contained hand torches and similar applications are allowed to be stored or displayed in a building accessible to the public. The quantity of LP-gas shall not exceed 200 pounds (91 kg) except as provided in Section 6109.11.

❖ This section recognizes that retail stores require inventory that is accessible to the public where hand-held torch assemblies are sold. The smaller cylinders in this section are also used as “starters” for charcoal grills and as fuel for insecticidal foggers and camp lanterns. The phrase “accessible to the public” describes circumstances where public exposure to a fire or explosion would be a concern. Where public access to a building is available, such as in Group M occupancies, a fire or explosion involving LP-gas could place nonemployees at risk. By limiting quantities and container sizes in such publicly accessible facilities, the code minimizes this risk.

**6109.10 Storage within buildings not accessible to the public.** The maximum quantity allowed in one storage location in buildings not accessible to the public, such as industrial buildings, shall not exceed a water capacity of 735 pounds (334 kg) [nominal 300 pounds (136 kg) of LP-gas]. Where additional storage locations are required on the same floor within the same building, they shall be separated by not less than 300 feet (91 440 mm). Storage beyond these limitations shall comply with Section 6109.11.

❖ This section is applicable to industrial or storage facilities where LP-gas-powered forklift trucks are frequently operated and maintained by trained personnel. The requirement permits up to 300 pounds (136 kg) of propane to be stored at a single location. Forklift cylinders, which typically have a 33-pound (15 kg) propane capacity, can be stored in small quantities for convenient exchange during a working shift. Where larger quantities of cylinders are needed by the building operations, to reduce the excess storage exposure to a single-fire incident, the excess quantity must be physically separated by space. Where such spatial separation cannot be achieved, the more restrictive provisions of Section 6109.11 must be applied to provide the needed level of safety.

The reference to Section 6109.11 applies where more than 300 pounds (136 kg) must be stored at a location without the required 300-foot (91 440 mm) separation distance.

The phrase “not accessible to the public” describes circumstances where public exposure to a fire or explosion would be a relatively minor concern. Where public access to a building is not available, such as in Group F or S occupancies, a fire or explosion involving LP-gas would not place nonemployees at risk.

**6109.10.1 Quantities on equipment and vehicles.** LP-gas containers carried as part of service equipment on highway mobile vehicles need not be considered in the total storage capacity in Section 6109.10, provided such vehicles are stored in private garages and do not carry more than three LP-gas containers with a total aggregate LP-gas capacity not exceeding 100 pounds (45.4 kg) per vehicle. LP-gas container valves shall be closed.

❖ This section addresses vehicles carrying LP-gas that is ancillary to service equipment on the vehicle. Typically, LP-gas may be found on fabrication trucks and mechanics’ trucks for use with welding equipment, roofing tar trucks for torches used on roofs and plumbers’ trucks for use with lead melting pots.

**6109.11 Storage within rooms used for gas manufacturing.** Storage within buildings or rooms used for gas manufacturing, gas storage, gas-air mixing and vaporization, and compressors not associated with liquid transfer shall comply with Sections 6109.11.1 and 6109.11.2.

❖ The requirements of this section might typically apply to the storage of LP-gas containers used for standby gas systems in which LP-gas is mixed with air to achieve an energy content similar to that of natural gas, thereby permitting gas appliances and equipment to continue operating without a change in burner controls. These systems are commonly found in larger industrial applications.

**6109.11.1 Quantity limits.** The maximum quantity of LP-gas shall be 10,000 pounds (4540 kg).

❖ Limiting LP-gas to 10,000 pounds (4,540 kg) [roughly 3,000-gallon (11 355 L) water capacity container] is considered to be an acceptable threshold for the safe and efficient operation of standby gas systems.

**6109.11.2 Construction.** The construction of such buildings and rooms shall comply with requirements for Group H occupancies in the *International Building Code*, Chapter 10 of NFPA 58 and both of the following:

1. Adequate vents shall be provided to the outside at both top and bottom, located not less than 5 feet (1524 mm) from building openings.
2. The entire area shall be classified for the purposes of ignition source control in accordance with Section 6.2.2 of NFPA 58.

❖ Section 508 of the *International Building Code*® (IBC®) contains specific requirements to address the separation of mixed occupancies to isolate the hazard of storing up to 10,000 pounds (4540 kg) of LP-gas in a room or a building. In addition to those requirements, Item 1 of this section requires adequate ventilation openings to assist in the dilution of gas should a leak occur. Chapter 10 of NFPA 58 contains information on venting as well as other aspects of the design of rooms of this nature. Item 2 refers to NFPA 58, which contains extensive information on establishing the proper hazard classification that

would govern the requirements for electrical wiring systems and limit ignition sources.

**6109.12 Location of storage outside of buildings.** Storage outside of buildings of LP-gas containers awaiting use, resale or part of a cylinder exchange program shall be located in accordance with Table 6109.12.

❖ This section regulates, by reference to Table 6109.12, the placement of cylinders awaiting use or resale and cylinder exchange cabinets, which are increasingly being used to distribute the 20-pound (9 kg) gas grill cylinders to the public. Exchange cabinets are typically constructed of steel and are ventilated to permit the dispersal of gas should a leak occur.

**TABLE 6109.12.** See below.

❖ This table provides correlation with NFPA 58 and allows all code users to quickly identify minimum required separation distances to all regulated exposures. As in Section 6104, this table is based on the quantity of LP-gas stored (not the size of the container) and is intended to limit the two-way exposure between containers and the built environment.

Regarding Column 5 of the table, prior to the introduction of OPDs, overfilled cylinders may have initially held their charge, but later leaked when cylinder pressure increased due to high ambient temperature exposures, a significant source of concern. Today, cylinder exchange operators report that cylinder leaks due to overfill have declined to almost zero based on the use of OPDs and by the widespread use of new grill cylinder valves that will only allow gas to flow if a cylinder valve is mated to an appliance connection device. These measures prevent fugitive releases due to exposure of overfilled cylinders to high ambient temperatures and due to cylinder valves that have not been completely closed. By using cylinders that mitigate the risk of vapor releases based on improved equipment technologies, cylinder exchange stations are now much safer than they were in the early- to mid-1990s when it was necessary to rely on minimum separation distances to prevent fugitive vapors from entering nearby buildings.

Column 6 of the table considers separation from

the doorway or openings in a single-exit building (see Section 1006.2) based on quantity of gas stored. If a fire occurs inside of a building, the presence of a propane exchange station outside is not an egress or life safety concern. Individuals leaving the building could simply exit past the station. If a fire occurs outside, the fire will have to achieve a size that is adequate to raise the temperature of stored propane to the 150°F (66°C) range before a standard cylinder relief vent would be expected to operate. Given the minimum required 10-foot (3048 mm) separation to combustibles in Column 7, it is reasonable to assume that building occupants would have time to evacuate a single-exit building before an exposure fire caused cylinder venting. Scenarios involving a release of gas from an overfilled cylinder and subsequent migration to an ignition source are no longer regarded as plausible based on the mandatory use of OPDs and the likely use of leak-resistant cylinder valves. With regard to Column 7, it should be noted that this prescriptive separation from combustible materials is not consistent with NFPA 58, which uses a more performance-oriented approach. However, the fire service's desire for a specific minimum distance has been clearly expressed in the past; therefore, the distance was retained in the table.

Column 8 contains a required 20-foot (6096 mm) separation to motor fuel dispensers which completes the reference to Chapter 61 made in Section 2307.4. Motor fuel-dispensing facilities are considered Group M occupancies and frequently include convenience stores in addition to motor fuel-dispensing operations. Column 8 specifies a minimum separation distance between the LP-gas container area and any flammable or combustible liquid-dispensing operation or the outdoor storage of combustible materials to reduce the potential fire hazard exposure.

**6109.13 Protection of containers.** LP-gas containers shall be stored within a suitable enclosure or otherwise protected against tampering. Vehicle impact protection shall be provided as required by Section 6107.4.

**Exception:** Vehicle impact protection shall not be required for protection of LP-gas containers where the

**TABLE 6109.12**  
**SEPARATION FROM EXPOSURES OF LP-GAS CONTAINERS AWAITING USE,**  
**RESALE OR EXCHANGE STORED OUTSIDE OF BUILDINGS**

QUANTITY OF LP-GAS STORED (pounds)	MINIMUM SEPARATION DISTANCE FROM STORED LP-GAS CYLINDERS TO (feet):						
	Nearest important building or group of buildings or line of adjoining property that may be built upon	Line of adjoining property occupied by schools, places of religious worship, hospitals, athletic fields or other points of public gathering; busy thoroughfares; or sidewalks	LP-gas dispensing station	Doorway or opening to a building with two or more means of egress	Doorway or opening to a building with one means of egress	Combustible materials	Motor vehicle fuel dispenser
720 or less	0	0	5	5	10	10	20
721 – 2,500	0	10	10	5	10	10	20
2,501 – 6,000	10	10	10	10	10	10	20
6,001 – 10,000	20	20	20	20	20	10	20
Over 10,000	25	25	25	25	25	10	20

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg.

containers are kept in lockable, ventilated cabinets of metal construction.

- ❖ At public facilities, tampering with LP-gas containers may be a problem. For that reason, locked metal cabinets are used to provide not only tamper protection but also substantial protection from vehicular impact (see Commentary Figure 6109.13). See the commentary to Section 6107.4. The exception reflects the results of impact testing done on a variety of cabinet designs, which found that lockable metal cabinet construction provided equivalent protection.

#### 6109.14 Alternative location and protection of storage.

Where the provisions of Sections 6109.12 and 6109.13 are impractical at construction sites, or at buildings or structures undergoing major renovation or repairs, the storage of containers shall be as required by the *fire code official*.

- ❖ These requirements permit the fire code official to approve storage sites for LP-gas even if compliance with Sections 6109.12 and 6109.13 is not practical. This would especially be the case at construction sites and other transient installations in which LP-gas containers may be moved frequently.

**6109.15 LP-gas cylinder exchange for resale.** In addition to other applicable requirements of this chapter, facilities operating LP-gas cylinder exchange stations that are accessible to the public shall comply with the following requirements.

1. Cylinders shall be secured in a lockable, ventilated metal cabinet or other *approved* enclosure.
2. Cylinders shall be accessible only by authorized personnel or by use of an automated exchange system in accordance with Section 6109.15.1.

3. A sign shall be posted on the entry door of the business operating the cylinder exchange stating “DO NOT BRING LP-GAS CYLINDERS INTO THE BUILDING” or similar *approved* wording.

4. An emergency contact information sign shall be posted within 10 feet (3048 mm) of the cylinder storage cabinet. The content, lettering, size, color and location of the required sign shall be as required by the *fire code official*.

- ❖ Cylinder exchange cabinets, such as the one shown in Commentary Figure 6109.13, for 20-pound (9 kg) LP-gas cylinders have been available to consumers for over 15 years and have a very respectable safety record. Cabinets for exchange of industrial cylinders, such as those found on forklift trucks, are also in use. While a limited number of incidents resulting from impact from vehicles have been reported, none of these events has resulted in loss of life or severe injuries. It is estimated that several million sales transactions occur annually at cylinder exchange stations.

This section addresses all LP-gas cylinder exchange stations, whether they are manual or automatic. Item 1 requires that all cylinder exchange cabinets be designed so the cabinet provides ventilation for the stored cylinders and is equipped with a means of securing cylinders against tampering.

Item 2 limits access to cylinders to authorized personnel or to users of automated cylinder exchange stations. At an automated cylinder exchange station, Item 5 of Section 6109.15.1 requires that when a manual override occurs, it must be performed by an authorized person before returning the station to automatic operation. In the absence of a definition for

Figure 6109.13  
INSTALLATION OF LP-GAS CONTAINERS FOR RETAIL SALE OR EXCHANGE

the term “authorized personnel,” fire code officials could apply the requirements in Section 4.4 of NFPA 58 for qualification of personnel who are involved in the operation of cylinder exchange stations. NFPA 58 requires that they receive documented training in proper cylinder-handling procedures with refresher training at least every 3 years. Training can often be provided by the LP-gas supplier and many suppliers offer programs prepared by the Propane Education and Research Council, which offers a Certified Employee Training Program to its members. In Item 3, an approved sign is required to inform consumers that bringing cylinders inside of a building is prohibited, based on the requirement in Section 6109.9, and Item 4 requires a sign that provides emergency contact information in the event of a leaking cylinder or other emergency involving the exchange station.

**6109.15.1 Automated cylinder exchange stations.** Cylinder exchange stations that include an automated vending system for exchanging cylinders shall comply with the following additional requirements:

1. The vending system shall only permit access to a single cylinder per individual transaction.
  2. Cabinets storing cylinders shall be designed such that cylinders can only be placed inside when they are oriented in the upright position.
  3. Devices operating door releases for access to stored cylinders shall be permitted to be pneumatic, mechanical or electrically powered.
  4. Electrical equipment inside of or within 5 feet (1524 mm) of a cabinet storing cylinders, including but not limited to electronics associated with vending operations, shall comply with the requirements for Class I, Division 2 equipment in accordance with NFPA 70.
  5. A manual override control shall be permitted for use by authorized personnel. On newly installed cylinder exchange stations, the vending system shall not be capable of returning to automatic operation after a manual override until the system has been inspected and reset by authorized personnel.
  6. Inspections shall be conducted by authorized personnel to verify that all cylinders are secured, access doors are closed and the station has no visible damage or obvious defects that necessitate placing the station out of service. The frequency of inspections shall be as specified by the *fire code official*.
- ❖ One of the bigger advancements in LP-gas cylinder exchange programs is the use of automation at the point-of-sale (POS). These improvements have allowed exchange stations to become self-service, meaning that retailers can allow their employees to focus on other interests in the store rather than managing the exchange of LP-gas cylinders. Consumers can now use an electronic banking card at automated exchange stations where they receive a properly

filled and code-compliant cylinder of LP-gas while the supplier receives an empty cylinder in return (see Commentary Figure 6109.13).

This section contains provisions for regulating these automated LP-gas cylinder exchange stations. These requirements increase the likelihood that consumers will properly remove filled cylinders and return empty cylinders. Item 1 requires that the vending system be designed to limit the consumer to one cylinder per transaction. Item 2 requires that the system accommodate cylinders placed only in the upright position. As indicated in Item 3, door-release components inside the exchange cabinet can be powered by pneumatic, mechanical or electrical energy. Where door release components or other equipment in the cabinet are electrically operated, Item 4 requires hazardous location electrical equipment in accordance with Article 500 of NFPA 70 and specifies the boundary [within 5 feet (1524 mm)] of the hazardous location to mitigate the risk of igniting fugitive gas. Normally, flammable gases in storage do not require classified hazardous location electrical equipment, but in the case of these automated LP-gas cylinder exchange stations, the possibility exists for a cylinder valve to not be completely closed on a cylinder that has been returned by a consumer. Some cabinet manufacturers provide a remote POS kiosk that is located more than 5 feet (1524 mm) from the exchange station to accommodate this requirement with ordinary electrical equipment. As with any mechanical or electro-mechanical vending device, failures can and do occur and Item 5 provides a means for authorized personnel to deal with such failures by using a manual override control. Item 6 requires that automated cylinder exchange stations be inspected by authorized personnel (see commentary, Section 6109.15, Item 5) at a frequency specified by the fire code official. Factors to consider in establishing a required inspection frequency could include the servicing/refilling interval for the cabinet.

## SECTION 6110 LP-GAS CONTAINERS NOT IN SERVICE

**6110.1 Temporarily out of service.** LP-gas containers whose use has been temporarily discontinued shall comply with all of the following:

1. Be disconnected from appliance piping.
  2. Have LP-gas container outlets, except relief valves, closed or plugged.
  3. Be positioned with the relief valve in direct communication with the LP-gas container vapor space.
- ❖ When a new LP-gas supplier installs a tank at a customer's facility, he or she is responsible for ensuring that the previous supplier's tank is removed from service and safely stored until it can be retrieved.

**6110.2 Permanently out of service.** LP-gas containers to be placed permanently out of service shall be removed from the site.

❖ This provision is an extension of Section 6110.1 and requires that any container placed out of service must be retrieved by its owner.

### SECTION 6111 PARKING AND GARAGING OF LP-GAS TANK VEHICLES

**6111.1 General.** Parking of LP-gas tank vehicles shall comply with Sections 6111.2 and 6111.3.

**Exception:** In cases of accident, breakdown or other emergencies, LP-gas tank vehicles are allowed to be parked and left unattended at any location while the operator is obtaining assistance.

❖ In this context, LP-gas tank vehicles include bulk cargo tank vehicles, either transports (semitruck trailers) or bobtails [usually up to 5,000-gallon (18 925 L) water capacity]. The exception to this section recognizes the possibility of a mechanical breakdown of a vehicle while in service.

**6111.2 Unattended parking.** The unattended parking of LP-gas tank vehicle shall be in accordance with Sections 6111.2.1 and 6111.2.2.

❖ Unattended parking may be defined as the parking of a cargo tank vehicle used to transport LP-gas where either the driver or other responsible person is not able to respond to situations involving the vehicle that may occur.

**6111.2.1 Near residential, educational and institutional occupancies and other high-risk areas.** LP-gas tank vehicles shall not be left unattended at any time on residential streets or within 500 feet (152 m) of a residential area, apartment or hotel complex, educational facility, hospital or care facility. Tank vehicles shall not be left unattended at any other place that would, in the opinion of the *fire code official*, pose an extreme life hazard.

❖ Because of the hazardous cargo involved, operator control must be maintained over cargo tank vehicles used to transport LP-gas. In other words, LP-gas transports must not be left unattended. This is especially true in areas where high occupancy levels exist and the possibility of tampering with the vehicle increases.

**6111.2.2 Durations exceeding 1 hour.** LP-gas tank vehicles parked at any one point for longer than 1 hour shall be located as follows:

1. Off public streets, highways, public avenues or public alleys.
2. Inside of a bulk plant.

3. At other *approved* locations not less than 50 feet (15 240 mm) from buildings other than those *approved* for the storage or servicing of such vehicles.

❖ When a vehicle will be parked for more than 1 hour, it will probably be unattended and, therefore, special conditions are imposed.

The first condition specifies that the vehicle must not be parked on a public way. The second condition permits the vehicle to be parked in an LP-gas bulk plant, which is a plant with containers used for storing LP-gas, until the gas is delivered to the end user. The third condition permits the fire code official to approve alternative locations for parking LP-gas cargo tank vehicles. The fire code official might base approval on the proximity to occupied buildings and spaces as well as the potential for tampering with the vehicle.

**6111.3 Garaging.** Garaging of LP-gas tank vehicles shall be as specified in NFPA 58. Vehicles with LP-gas fuel systems are allowed to be stored or serviced in garages as specified in Section 11.16 of NFPA 58.

❖ This section applies not only to cargo tank vehicles used to transport and deliver LP-gas, but also to motor vehicles fueled by LP-gas. NFPA 58 contains extensive provisions for garaging these vehicles. Section 6.24.9 of NFPA 58 contains parking, service and repair requirements for vehicles equipped with an LP-gas system not used for propulsion, such as a recreational vehicle with an on-board LP-gas cooking system.

# Chapter 62: Organic Peroxides

## General Comments

This chapter addresses the hazards associated with the storage, handling and use of organic peroxides. These chemicals possess the characteristics of flammable or combustible liquids and are also strong oxidizers. Class V organic peroxides pose little fire hazard; therefore, these materials are not regulated by specific storage or use requirements. Some organic peroxides are unstable and become increasingly reactive with age or heating.

Organic peroxides pose the dual hazard of being both oxidizers and flammable or explosive compounds. This unusual combination of properties requires special storage and handling precautions to prevent uncontrolled release, contamination, hazardous chemical reactions, fires or explosions. In addition to these properties, organic peroxides are unusually sensitive to temperature. Heat, whether by fire exposure or environmental, is a major factor in the decomposition of peroxide compounds. Some organic peroxides will decompose uneventfully when subject to a gradual temperature increase but may explode if they undergo the thermal shock of a rapid, uncontrolled temperature rise.

J.S. Townsend (1993) notes that some organic peroxides are just as dangerous when they become too cold as when they are too hot. For example, acetyl peroxide becomes unstable above 122°F (50°C)—its self-accelerating decomposition temperature (SADT). When cooled below 17°F (-8.3°F), acetyl peroxide forms crystals that are shock sensitive. Consequently, special precautions must be taken to transport and store acetyl peroxide between 32°F (0°C) and 90°F (32°C).

Organic peroxides are commonly used in the plastics industry to initiate polymerization. Although the requirements of this chapter pertain to industrial applications in which significant quantities of organic peroxides are stored or used, smaller quantities of organic peroxides still pose a significant hazard. These materials, therefore, must be stored and used in accordance with the applicable provisions of this chapter and Chapter 50.

## Purpose

The provisions of this chapter are intended to manage the fire and oxidation hazards of organic peroxides by preventing their uncontrolled release.

---

## SECTION 6201 GENERAL

**6201.1 Scope.** The storage and use of organic peroxides shall be in accordance with this chapter and Chapter 50.

Unclassified detonable organic peroxides that are capable of *detonation* in their normal shipping containers under conditions of fire exposure shall be stored in accordance with Chapter 56.

❖ The specific requirements for the storage, handling and use of organic peroxides in this chapter are intended to complement the general hazardous materials requirements of Chapter 50. Because of the hazards to people and property, organic peroxides capable of being detonated in their usual shipping containers or packages under fire conditions must be stored in accordance with the provisions of Chapter 56 for explosives. Examples of unclassified detonable (UD) materials are organic peroxides classified as Type A by DOTn 49 CFR; 173.128(b)(1) and materials classified as explosives by DOTn 49 CFR; 173, Subpart C. DOTn Type A organic peroxides have an SADT of 122°F (50°C) or less.

**6201.2 Permits.** Permits shall be required for organic peroxides as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

## SECTION 6202 DEFINITION

**6202.1 Definition.** The following term is defined in Chapter 2:

### ORGANIC PEROXIDE.

Class I.

Class II.

**Class III.**

**Class IV.**

**Class V.**

**Unclassified detonable.**

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated term used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 6203 GENERAL REQUIREMENTS

**6203.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of organic peroxides in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003, 6201 and 6203.

- ❖ The provisions of this section complement the requirements of Chapter 50 in structures occupied for the storage, handling or use of organic peroxides. The regulations contained in Sections 6203.1.1 through 6203.1.1.4 assume that the quantity of organic peroxides in a given building is limited to the maximum allowable quantities (MAQs) per control area as established in Section 5003.1; thus, the building is not classified in Occupancy Group H. The general requirements of Sections 5001 and 5003 are fully applicable to the storage and use of organic peroxides, in addition to the provisions of this chapter.

**6203.1.1 Special limitations for indoor storage and use by occupancy.** The indoor storage and use of organic peroxides shall be in accordance with Sections 6203.1.1.1 through 6203.1.1.4.

- ❖ Because certain occupancies may need to have organic peroxides on hand, Sections 6203.1.1.1 through 6203.1.1.4 provide regulations specific to occupancy group classifications and that recognize the relative hazards of both the occupancy and the organic peroxide.

**6203.1.1.1 Group A, E, I or U occupancies.** In Group A, E, I or U occupancies, any amount of unclassified detonable and Class I organic peroxides shall be stored in accordance with the following:

1. Unclassified detonable and Class I organic peroxides shall be stored in hazardous materials storage cabinets complying with Section 5003.8.7.
  2. The hazardous materials storage cabinets shall not contain other storage.
- ❖ Because of their respective explosive or higher deflagration hazard characteristics, even the smallest quantity of UD or Class I organic peroxides present in

Group A, E, I or U occupancies must be stored in an approved hazardous materials storage cabinet constructed and placarded in accordance with Section 5003.8.7 to reduce the exposure of the materials to hazards from the surrounding environment.

In accordance with Note g in Table 5003.1.1(1), storage of UD organic peroxide in any amount is allowed only in buildings equipped throughout with an approved automatic sprinkler system, in accordance with Section 903.3.1. Also, based on Note e in Table 5003.1.1(1), where an approved storage cabinet is used, the MAQ that can be kept in the occupancies can be doubled.

To reduce the likelihood of contamination of the organic peroxide materials or damage to their packaging, Item 2 prohibits the storage of other materials in the approved organic peroxide storage cabinet.

In accordance with Section 6201.1, storage of UD organic peroxides must also comply with the applicable provisions of Chapter 56 for explosives.

**6203.1.1.2 Group R occupancies.** Unclassified detonable and Class I organic peroxides shall not be stored or used within Group R occupancies.

- ❖ Because of their explosive or higher deflagration hazard characteristics, UD and Class I organic peroxide cannot be stored in any residential occupancy within the scope of the code's regulations. Storage would result in an increased danger to the occupants, as well as exposure of the peroxides to the otherwise unregulated environment.

**6203.1.1.3 Group B, F, M or S occupancies.** Unclassified detonable and Class I organic peroxides shall not be stored or used in offices, or retail sales areas of Group B, F, M or S occupancies.

- ❖ Because of their explosive or higher deflagration hazard characteristics, UD and Class I organic peroxide cannot be stored in occupancies in Group B, F, M or S. Storage would result in an increased danger to the occupants, as well as exposure of the peroxides to the higher relative fire loads typically encountered in these occupancies.

**6203.1.1.4 Classrooms.** In classrooms in Group B, F or M occupancies, any amount of unclassified detonable and Class I organic peroxides shall be stored in accordance with the following.

1. Unclassified detonable and Class 1 organic peroxides shall be stored in hazardous materials storage cabinets complying with Section 5003.8.7.
2. The hazardous materials storage cabinets shall not contain other storage.

- ❖ It is the intent of this section to allow for the occasional use of limited amounts of organic peroxides in certain scientific, experimental or demonstration settings; however, this section does not allow storage of any quantity of these materials for any length of time.

The fire code official may limit the amount of organic peroxides brought into a structure for these uses. The quantity actually needed for the experiment should determine the amount allowed into a structure.

Because of their explosive or higher deflagration hazard characteristics, even the smallest quantity of UD or Class I organic peroxides must be stored in an approved hazardous materials storage cabinet constructed and placarded in accordance with Section 5003.8.7 to reduce the exposure of the materials to hazards from the surrounding environment.

In accordance with Note g in Table 5003.1.1(1), storage of UD organic peroxide in any amount is allowed only in buildings equipped throughout with an approved automatic sprinkler system, in accordance with Section 903.3.1. Also, based on Note g in Table 5003.1.1(1), where an approved storage cabinet is used, the MAQ that could be kept in these occupancies can be doubled.

To reduce the likelihood of contaminating organic peroxide materials or damaging their packaging, Item 2 prohibits the storage of other materials in the approved organic peroxide storage cabinet.

Note that in accordance with Section 6201.1, storage of UD organic peroxides must also comply with the applicable provisions of Chapter 56 for explosives.

**6203.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of organic peroxides in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

- ❖ The provisions of this section complement the requirements of Chapter 50 in structures occupied for the storage, handling or use of organic peroxides. The regulations in this section assume that the quantity of organic peroxides in a given building is in excess of the MAQ as established in Section 5003.1 and, therefore, that the building is classified in Occupancy Group H. The requirements of Chapter 50 apply to the storage and use of organic peroxides in addition to the provisions of this chapter.

## SECTION 6204 STORAGE

**6204.1 Indoor storage.** Indoor storage of organic peroxides in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

Indoor storage of unclassified detonable organic peroxides that are capable of *detonation* in their normal shipping containers under conditions of fire exposure shall be stored in accordance with Chapter 56.

- ❖ This section regulates the indoor storage of organic peroxides when in excess of the MAQ in buildings or portions of buildings classified in Occupancy Group

H. The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of organic peroxides inside of structures must comply with Sections 6204.1.1 through 6204.1.11 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

Because of the explosion hazard, UD organic peroxides must be stored in accordance with the provisions of this section and Chapter 56 for explosives.

**6204.1.1 Detached storage.** Storage of organic peroxides shall be in detached buildings where required by Section 5003.8.2.

- ❖ Detached structures designed and constructed for the sole purpose of organic peroxide storage provide the best protection for people and property from fire and explosions. Detached storage structures should be constructed of noncombustible materials to prevent them from becoming involved in an outside fire that may endanger their contents or a fire stemming from ignited contents in storage.

Section 5003.8.2 and Table 5003.8.2 require detached storage when the indoor storage quantities are more than 2 tons (4 metric tons) of Class I, more than 25 tons (50 metric tons) of Class II and more than 50 tons (100 metric tons) of Class III organic peroxides. See the commentary to Section 5003.8.2 and Table 5003.8.2 for further discussion of detached storage requirements. Commentary Figure 6204.1.1 shows a cross-sectional diagram of a typical detached storage building.

**6204.1.2 Distance from detached buildings to exposures.**

In addition to the requirements of the *International Building Code*, detached storage buildings for Class I, II, III, IV and V organic peroxides shall be located in accordance with Table 6204.1.2. Detached buildings containing quantities of unclassified detonable organic peroxides in excess of those set forth in Table 5003.8.2 shall be located in accordance with Table 5604.5.2(1).

- ❖ The *International Building Code*® (IBC®) prescribes minimum fire-resistance ratings for exterior walls of buildings based on clearances from adjacent structures and lot lines. The separation distances prescribed by this section are minimums notwithstanding the inherent fire-resistance ratings of the exterior wall assemblies. These clearances are intended to reduce the hazard to nearby structures and people in the event of a fire or explosion in a detached storage structure used for the storage of organic peroxides.

**TABLE 6204.1.2.** See page 62-4.

- ❖ The separation distances specified in the table are intended to reduce the effects of radiant heat exposure in the event of a fire in an adjacent storage structure. Separation distances for UD organic peroxides must conform to the requirements of Table 5604.5.2(2).

**ORGANIC PEROXIDES**

**6204.1.3 Liquid-tight floor.** In addition to the requirements of Section 5004.12, floors of storage areas shall be of liquid-tight construction.

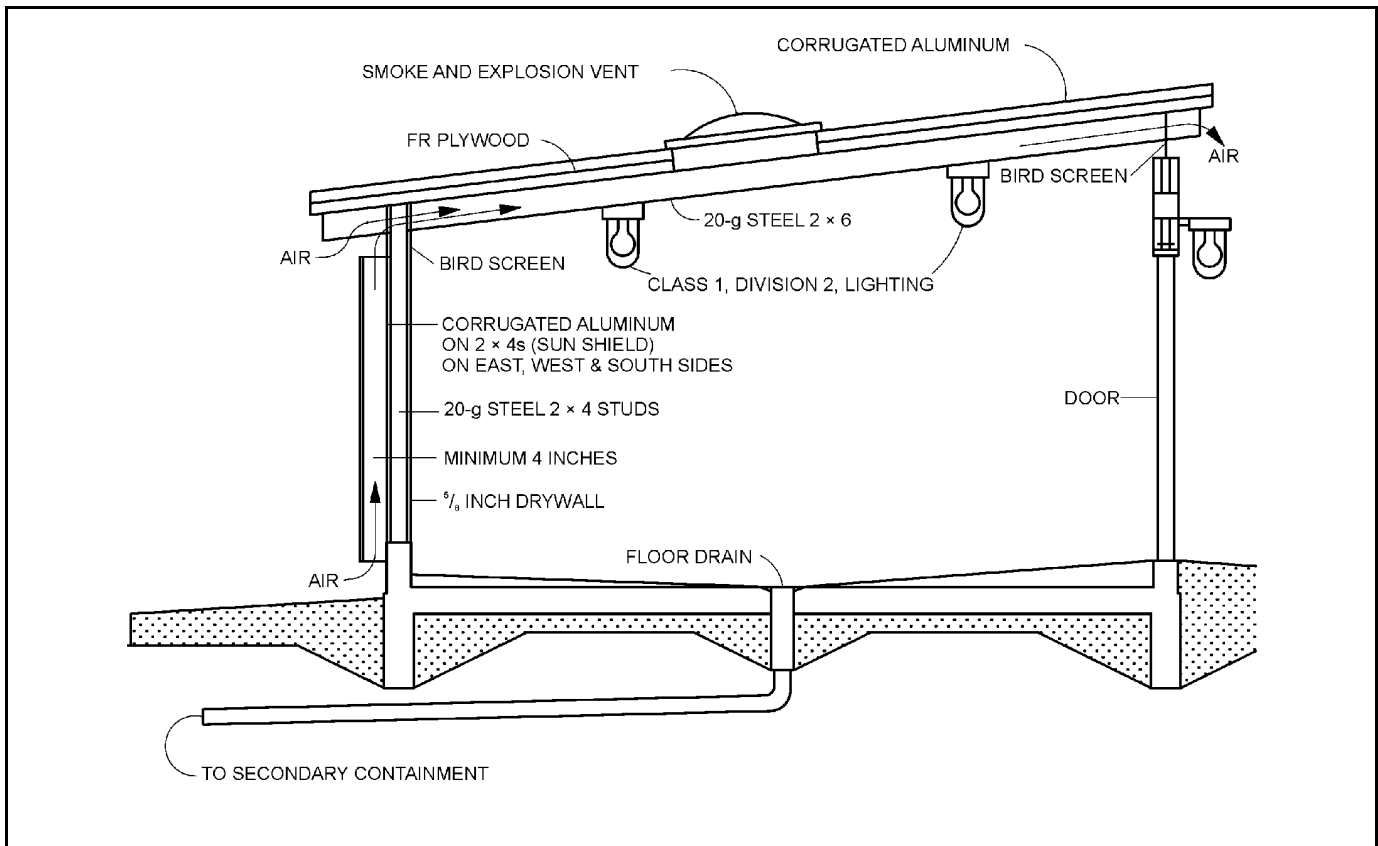

❖ In addition to the requirement of Section 5004.12 that floors be constructed of noncombustible materials, liquid-tight floors are required so as to prevent the passage of liquids to adjacent spaces.

**6204.1.4 Electrical wiring and equipment.** In addition to the requirements of Section 5003.9.4, electrical wiring and equipment in storage areas for Class I or II organic peroxides

shall comply with the requirements for electrical Class I, Division 2 locations.

❖ Because of the danger of ignition by arcs or sparks in the event of an accidental spill or leak, electrical equipment and devices in storage areas for organic peroxides must be classified for use in Class I, Division 2 hazardous locations as described in NFPA 70.

**6204.1.5 Smoke detection.** An *approved* supervised smoke detection system in accordance with Section 907 shall be provided in rooms or areas where Class I, II or III organic perox-

**Figure 6204.1.1**

**ORGANIC PEROXIDES—DISTANCE TO EXPOSURES FROM DETACHED STORAGE BUILDINGS OR OUTDOOR STORAGE AREAS**

ORGANIC PEROXIDE CLASS	MAXIMUM STORAGE QUANTITY (POUNDS) AT MINIMUM SEPARATION DISTANCE					
	Distance to buildings, lot lines, public streets, public alleys, public ways or means of egress			Distance between individual detached storage buildings or individual outdoor storage areas		
	50 feet	100 feet	150 feet	20 feet	75 feet	100 feet
I	2,000	20,000	175,000	2,000	20,000	175,000
II	100,000	200,000	No Limit	100,000 <sup>a</sup>	No Limit	No Limit
III	200,000	No Limit	No Limit	200,000 <sup>a</sup>	No Limit	No Limit
IV	No Limit	No Limit	No Limit	No Limit	No Limit	No Limit
V	No Limit	No Limit	No Limit	No Limit	No Limit	No Limit

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg.

a. Where the amount of organic peroxide stored exceeds this amount, the minimum separation shall be 50 feet.

ides are stored. Activation of the smoke detection system shall sound a local alarm.

**Exception:** A smoke detection system shall not be required in detached storage buildings equipped throughout with an *approved* automatic fire-extinguishing system complying with Chapter 9.

- ❖ An automatic fire detection system with central, remote or proprietary station supervision and a local alarm signal is required to provide early warning of fire to building occupants and fire suppression personnel. Detectors and installation methods in organic peroxide storage areas should be selected for compatibility with the materials stored. Fire alarm equipment and installation methods must comply with Section 907. Materials that give off strong vapors may interfere with fire detection system components or trigger nuisance alarm signals. The required local alarm is intended to alert the occupants in the immediate vicinity of the storage area to a potential hazardous condition. The local alarm is not intended to be part of an evacuation alarm system for the entire structure.

The exception indicates that automatic fire detection is not required in detached storage buildings when an automatic fire suppression system is provided. Automatic sprinklers or other approved fire suppression systems reduce the danger to people and property from fire by detecting the fire, sounding an alarm, transmitting the alarm to the fire department and containing or suppressing the fire. Sprinkler systems in detached storage buildings must be supervised by a connection to a central station, a remote supervising station or a proprietary supervising station, or, when approved by the fire code official, connected to a system that produces an audible and visual signal monitored at a constantly attended on-site location. See the commentary to Section 903.4 for further discussion of sprinkler system supervision and Section 904.3.5 for further discussion of alternative automatic fire-extinguishing system supervision.

**6204.1.6 Maximum quantities.** Maximum allowable quantities per building in a mixed occupancy building shall not

exceed the amounts set forth in Table 5003.8.2. Maximum allowable quantities per building in a detached storage building shall not exceed the amounts specified in Table 6204.1.2.

- ❖ This section establishes the maximum allowable indoor storage quantities of organic peroxide on a per-building basis, as opposed to a per-control area basis, and regulates both mixed occupancy buildings and detached organic peroxide storage buildings.

**6204.1.7 Storage arrangement.** Storage arrangements for organic peroxides shall be in accordance with Table 6204.1.7 and shall comply with all of the following:

1. Containers and packages in storage areas shall be closed.
2. Bulk storage shall not be in piles or bins.
3. A minimum 2-foot (610 mm) clear space shall be maintained between storage and uninsulated metal walls.
4. Fifty-five-gallon (208 L) drums shall not be stored more than one drum high.

- ❖ These provisions detail storage requirements related to the hazards of release or ignition of liquids and vapors of organic peroxide stored in structures. Some of the factors that are considered are as follows:

1. Open containers or packages may permit the release of flammable or oxidizing materials or vapors.
2. Containers in bulk piles or bins may be susceptible to physical damage from stacking or product movement, which could damage the container and lead to an uncontrolled release of product.
3. The required separation distance is intended to minimize the effects of radiant heat exposures to stored materials in the event of a fire outside the structure.
4. The stacking of drums may result in a container being damaged during product movement if a drum is dropped or tipped over.

**TABLE 6204.1.7.** See below.

- ❖ See the commentary to Section 6204.2.4.

**TABLE 6204.1.7  
STORAGE OF ORGANIC PEROXIDES**

ORGANIC PEROXIDE CLASS	PILE CONFIGURATION				MAXIMUM QUANTITY PER BUILDING
	Maximum width (feet)	Maximum height (feet)	Minimum distance to next pile (feet)	Minimum distance to walls (feet)	
I	6	8	4 <sup>a</sup>	4 <sup>b</sup>	Note c
II	10	8	4 <sup>a</sup>	4 <sup>b</sup>	Note c
III	10	8	4 <sup>a</sup>	4 <sup>b</sup>	Note c
IV	16	10	3 <sup>a, d</sup>	4 <sup>b</sup>	No Requirement
V	No Requirement	No Requirement	No Requirement	No Requirement	No Requirement

For SI: 1 foot = 304.8 mm.

- a. Not less than one main aisle with a minimum width of 8 feet shall divide the storage area.
- b. Distance to noncombustible walls is allowed to be reduced to 2 feet.
- c. See Table 6204.1.2 for maximum quantities.
- d. The distance shall be not less than one-half the pile height.

**6204.1.8 Location in building.** The storage of Class I or II organic peroxides shall be on the ground floor. Class III organic peroxides shall not be stored in basements.

❖ Class I and II organic peroxides may not be stored above or below the ground floor because of concerns for fire-fighter access. Because of their lower relative hazard, Class III organic peroxides may be stored on floors above grade; however, they may not be stored on floors below grade because of the difficulty of manual fire suppression operations in below-grade areas.

**6204.1.9 Contamination.** Organic peroxides shall be stored in their original DOTn shipping containers. Organic peroxides shall be stored in a manner to prevent contamination.

❖ Organic peroxides must be kept in original U.S. Department of Transportation (DOT)-approved shipping containers to facilitate identification and to minimize the possibility of accidental spills or ignition. The stability of organic peroxides can be markedly reduced through contamination by various materials, such as strong acids or alkalis, sulfur-based compounds or reducing agents of any type. Storage practices must prevent contamination and the hazards associated with it.

**6204.1.10 Explosion control.** Indoor storage rooms, areas and buildings containing unclassified detonable and Class I organic peroxides shall be provided with explosion control in accordance with Section 911.

❖ Because of the possibility of a deflagration or detonation in the event of ignition of Class I organic peroxides, explosion relief venting must be provided to protect the storage building or structure from collapse. Explosion venting must conform to the requirements in Section 911.

**6204.1.11 Standby power.** Standby power shall be provided in accordance with Section 604 for the following systems used to protect Class I and unclassified detonable organic peroxide:

1. Exhaust ventilation system.
2. Treatment system.
3. Gas detection system.
4. Smoke detection system.
5. Temperature control system.
6. Fire alarm system.
7. Emergency alarm system.

❖ A standby power system complying with Section 604 is required as a backup power supply for the systems listed in this section. These systems may also be connected to an approved emergency power system instead of a separate standby power system (see commentary, Section 604).

**6204.1.11.1 Fail-safe engineered systems.** Standby power shall not be required for mechanical exhaust ventilation,

treatment systems and temperature control systems where *approved* fail-safe engineered systems are installed.

❖ This section recognizes the use of an engineered system designed to always fail in the appropriate design mode without human intervention rather than an emergency power system. The exception is intended to permit alternative systems that are not subject to power interruptions.

**6204.2 Outdoor storage.** Outdoor storage of organic peroxides in amounts exceeding the *maximum allowable quantities per control area* indicated in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

❖ This section regulates the outdoor storage of organic peroxides when in excess of the MAQ per outdoor control area established by Table 5003.1.1(3). The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of organic peroxides in outdoor control areas must comply with Sections 6204.2.1 through 6204.2.5 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

**6204.2.1 Distance from storage to exposures.** Outdoor storage areas for organic peroxides shall be located in accordance with Table 6204.1.2.

❖ The IBC prescribes minimum fire-resistance ratings for exterior walls of buildings based on clearances from adjacent structures and lot lines. The separation distances prescribed by this section are minimums notwithstanding the inherent fire-resistance ratings of the exterior wall assemblies. These clearances are intended to reduce the hazard to nearby structures and people in the event of a fire or explosion in a detached storage structure or outdoor area used for the storage of organic peroxides.

**6204.2.2 Electrical wiring and equipment.** In addition to the requirements of Section 5003.9.4, electrical wiring and equipment in outdoor storage areas containing unclassified detonable, Class I or II organic peroxides shall comply with the requirements for electrical Class I, Division 2 locations.

❖ Because of the danger of ignition by arcs or sparks in the event of an accidental spill or leak, electrical equipment and devices in outdoor organic peroxide storage areas must be classified for use in Class I, Division 2 hazardous locations as described in NFPA 70.

**6204.2.3 Maximum quantities.** Maximum quantities of organic peroxides in outdoor storage shall be in accordance with Table 6204.1.2.

❖ Outdoor storage of organic peroxides must comply with the requirements specified in Table 6204.1.2, which establishes the minimum separation distances required between the outdoor storage area and exposures, including other outdoor storage areas, and the MAQ of organic peroxides being stored.

**6204.2.4 Storage arrangement.** Storage arrangements shall be in accordance with Table 6204.1.7.

- ❖ Similar to Section 6204.1.7 for indoor storage, this section references the provisions of Table 6204.1.7 for organic peroxide storage arrangements. Pile limitations specified in the table are based on the relative hazard of the material when involved in fire. These limits apply to Class I, II, III and IV organic peroxides in combustible and noncombustible containers and packages.

**6204.2.5 Separation.** In addition to the requirements of Section 5003.9.8, outdoor storage areas for organic peroxides in amounts exceeding those specified in Table 5003.8.2 shall be located a minimum distance of 50 feet (15 240 mm) from other hazardous material storage.

- ❖ The required minimum 50-foot (15 240 mm) separation distance from other hazardous materials storage is intended to reduce the hazard of dangerous chemical reactions with other incompatible materials in the event of a spill, fire or explosion.

## SECTION 6205 USE

**6205.1 General.** The use of organic peroxides in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5005 and this chapter.

- ❖ This section applies to indoor and outdoor dispensing, use and handling of organic peroxides when the amounts being dispensed, used or handled are in excess of the MAQ per indoor or outdoor control area indicated in Table 5003.1.1(1) or 5003.1.1(3), respectively. The administrative, general, use, dispensing and handling provisions of Chapter 50 are applicable, in addition to the requirements of this chapter.

Once the MAQ of organic peroxide per control area has been exceeded, indoor areas where materials are being dispensed, used or handled must be located in a building or portion of a building complying with the IBC for a Group H occupancy because of the increased hazards associated with quantity.

Although no occupancy group is assigned to them, outside organic peroxide use areas require an increased level of regulation when quantities exceed the MAQs per outdoor control area. The MAQs per control area listed in Tables 5003.1.1(1) and 5003.1.1(3) have been divided into closed-use and open-use systems. Corresponding MAQs recognize that an open-use condition is generally more hazardous than a closed-use condition because the organic peroxide is more directly exposed to the surrounding environment and can become more readily involved in an incident than if it is totally confined. The MAQs for use are based on the aggregate quantity in both use and storage, not exceeding the exempt amount listed for storage.

## Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

Bulletin 19A, *Suggested Relative Hazard Classification of Organic Peroxides*. Washington, DC: Society of the Plastics Industry, 1975.

# Chapter 63: Oxidizers, Oxidizing Gases and Oxidizing Cryogenic Fluids

## General Comments

Solid, liquid and gaseous oxidizers and oxidizing cryogenic fluids are common industrial chemicals. These compounds are often used because of their reactive properties. Common oxidizers include bromates, chlorates, chlorites, dichromates, hypochlorites, nitrates, nitrites, permanganates, inorganic peroxides and inorganic superoxides. Oxidizing cryogenic fluids include liquid oxygen, which is regulated by this chapter in addition to Chapter 55.

Requirements for the storage and use of liquid oxygen for respiratory care in Group I-1, I-4 and R occupancies are now specified in Chapter 63. Section 6306 was developed in response to changes in technology that improve in-home care of patients with respiratory ailments. This section now allows patients to utilize a liquid oxygen ambulatory care container and to be able to refill the container from a liquid oxygen home care container in a home setting.

Although oxidizers themselves do not burn, they pose unique fire hazards because of their ability to support combustion by breaking down and giving off oxygen. The hazard classification system for these materials described in the definition of "Oxidizer" in Section 6302.1 reflects the varying reactivity of oxidizers when they come in contact with combustible materials. The classification system originated in NFPA 430, upon which the provisions of this chapter are based but that is not referenced by the code except for sprinkler design criteria in Section 6304.1.4.

Cryogenic oxygen regulated by this chapter is also known as liquid oxygen (LOX). Oxygen is converted to LOX because it is less bulky and costly to handle when compared to an equivalent volume of compressed oxygen stored in high-pressure cylinders. LOX is defined in Section 6302.1 as an oxidizing gas in the cryogenic state and has a boiling point temperature of  $-297.3^{\circ}\text{F}$  ( $-165^{\circ}\text{C}$ ). LOX, as with other cryogenic fluids, presents a number of hazards.

Because of the extremely low boiling points of cryogenic fluids, containers for cryogenic fluids, piping and pressure relief and control devices must be constructed of materials that are resistant to these temperatures.

Materials like carbon steel and all plastics are not acceptable for cryogenic fluid service.

Cryogenic fluids are gases that have been condensed into a fluid and have extremely large expansion ratios. LOX has a liquid-to-gas expansion ratio [measured from its boiling point temperature to normal temperature and pressure (NTP)] of one to 960. Because of the large expansion ratio, the design of the containers must include a means of pressure relief anywhere in the piping system where LOX can be trapped, such as a pipe located between two valves that are closed.

The physical hazard as an oxidizer remains when oxygen is converted to LOX. As a result, a small release of liquid may produce a sufficient volume of oxygen to create an oxygen-enriched atmosphere. An atmosphere containing 23 percent or more by volume of oxygen is considered to be oxygen enriched. LOX and its cold vapors are capable of causing severe burns to human tissues.

The oxidizer hazard classifications defined in this chapter do not correspond to those given in NFPA 704. The NFPA 704 system indicates whether a given material will support combustion by using the "OXY" symbol in the lower quadrant of the placard. No numerical hazard value is assigned to a material's oxidizing ability in the NFPA 704 system.

When the specific hazard classification of a material is not known, the fire code official must use judgment in approving the assignment of materials to specific hazard classes. The best source of guidance is the information supplied by the Material Safety Data Sheets (MSDS) (see commentary, Section 407).

## Purpose

Chapter 63 addresses the hazards associated with oxidizing materials and establishes criteria for their safe storage and protection in indoor and outdoor storage facilities, minimizing the potential for uncontrolled releases and contact with fuel sources. The chapter also provides reasonable safeguards for the storage and use of medical oxygen in home health care settings.

**SECTION 6301  
GENERAL**

**6301.1 Scope.** The storage and use of oxidizing materials shall be in accordance with this chapter and Chapter 50. Oxidizing gases shall also comply with Chapter 53. Oxidizing *cryogenic fluids* shall also comply with Chapter 55.

**Exceptions:**

1. Display and storage in Group M and storage in Group S occupancies complying with Section 5003.11.
  2. Bulk oxygen systems at industrial and institutional consumer sites shall be in accordance with NFPA 55.
  3. Liquid oxygen stored or used in home health care in Group I-1, I-4 and R occupancies in accordance with Section 6306.
- ❖ This chapter is based in part on former NFPA 430 (now Chapter 15 of NFPA 400), addressing the hazards presented by the storage and use of oxidizers. In addition to the requirements of this chapter, oxidizing compressed gases are subject to Chapter 53 and oxidizing cryogenic fluids to Chapter 55.

Exception 1 states that this chapter does not apply to oxidizers where stored and displayed in Group M occupancies or where stored in Group S occupancies. Instead, they are governed by Section 5003.11 for those occupancy groups. In that section, Class 4 oxidizers are prohibited in Group M mercantile occupancies because of their detonable hazard potential. Quantities of all other oxidizer classes are limited on a per-control-area basis to limit exposure to people and property (see commentary, Section 5003.11). This exception would permit an increase above the maximum allowable quantities per control area (MAQs) indicated in Table 5003.1.1(1) for oxidizers while still maintaining a mercantile or storage occupancy group classification.

Exception 2 makes it clear that bulk oxygen systems, as defined in Section 6302.1, are not within the scope of this chapter but are required to comply with the provisions of NFPA 55.

It is not realistic to apply the MAQ/control area concept set forth in Chapter 50 to the widespread use and distribution of liquid oxygen in home health care settings. Exception 3 clarifies that LOX stored and used for home health care in the indicated occupancies in accordance with Section 6306 is not required to also comply with Chapter 50 or 55 provisions. The concept in Section 6306 is to limit not only the individual container size but also the total number of containers allowed in an individual dwelling unit. Trying to further regulate the quantity in a building is not considered by either industry or the fire service to be a reasonable or enforceable regulatory approach. A

similar statement in Section 5301.1 sends the user to this chapter for regulation of oxidizing gases (including oxygen), which will get the user to Section 6306, as well.

**6301.2 Permits.** Permits shall be required as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.21 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

**SECTION 6302  
DEFINITIONS**

**6302.1 Definitions.** The following terms are defined in Chapter 2:

**BULK OXYGEN SYSTEM.**

**LIQUID OXYGEN AMBULATORY CONTAINER.**

**LIQUID OXYGEN HOME CARE CONTAINER.**

**OXIDIZER.**

**Class 4.**

**Class 3.**

**Class 2.**

**Class 1.**

**OXIDIZING CRYOGENIC FLUID.**

**OXIDIZING GAS.**

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

**SECTION 6303  
GENERAL REQUIREMENTS**

**6303.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of oxidizing materials in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be

in accordance with Sections 5001, 5003, 6301 and 6303. Oxidizing gases shall also comply with Chapter 53.

❖ The provisions of this section complement the requirements of Chapter 50 in structures used for the storage, handling or use of oxidizing materials. Unless otherwise indicated in a particular section, the regulations contained in Sections 6303.1.1 through 6303.1.3 assume that the quantity of oxidizers in a given building is limited to the MAQs established in Section 5003.1; thus, the building is not classified in Occupancy Group H. The general requirements of Sections 5001 and 5003 are fully applicable to the storage and use of organic peroxides in addition to the provisions of this chapter. In the event that the oxidizer being stored is a gas, it will also be subject to Chapter 53.

**6303.1.1 Special limitations for indoor storage and use by occupancy.** The indoor storage and use of oxidizing materials shall be in accordance with Sections 6303.1.1.1 through 6303.1.1.3.

❖ Because certain occupancies may need to have oxidizing materials on hand, Sections 6303.1.1.1 through 6303.1.1.3 provide regulations that are specific to occupancy group classifications and recognize the relative hazards of both the occupancy and the oxidizing material.

**6303.1.1.1 Class 4 liquid and solid oxidizers.** The storage and use of Class 4 liquid and solid oxidizers shall comply with Sections 6303.1.1.1.1 through 6303.1.1.1.4.

❖ Because of their explosive or higher deflagration hazard characteristics, Class 4 liquid and solid oxidizers warrant special consideration and limitations when stored or used in certain occupancies, as indicated in Sections 6303.1.1.1.1 through 6303.1.1.1.4.

**6303.1.1.1.1 Group A, E, I or U occupancies.** In Group A, E, I or U occupancies, any amount of Class 4 liquid and solid oxidizers shall be stored in accordance with the following:

1. Class 4 liquid and solid oxidizers shall be stored in hazardous materials storage cabinets complying with Section 5003.8.7.
2. The hazardous materials storage cabinets shall not contain other storage.

❖ Because of their explosive or higher deflagration hazard characteristics, even the smallest quantity of Class 4 liquid and solid oxidizers present in Group A, E, I or U occupancies must be stored in an approved hazardous materials storage cabinet constructed and placarded in accordance with Section 5003.8.6 to reduce the exposure of the materials to hazards from the surrounding environment.

It should also be noted that Note g to Table 5003.1.1(1) limits storage of Class 4 liquid and solid oxidizers in any amount to buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Also, based on Note e to Table 5003.1.1(1), if an approved storage cabinet is used, the MAQ that could be kept

in occupancies equipped with sprinklers can be doubled.

**6303.1.1.1.2 Group R occupancies.** Class 4 liquid and solid oxidizers shall not be stored or used within Group R occupancies.

❖ Because Class 4 liquid and solid oxidizers are a great explosive hazard, they cannot be stored in any residential occupancy within the scope of the code's regulations because of the increased danger to the occupants and the otherwise unregulated environment to which the materials could be exposed.

**6303.1.1.1.3 Offices and retail sales areas.** Class 4 liquid and solid oxidizers shall not be stored or used in offices or retail sales areas of Group B, F, M or S occupancies.

❖ Because Class 4 liquid and solid oxidizers are a great explosive hazard, they cannot be stored in offices or retail sales areas of occupancies in Group B, F, M or S because of the increased danger to the occupants and the higher relative fire loads typically encountered in these occupancies.

**6303.1.1.1.4 Classrooms.** In classrooms of Group B, F or M occupancies, any amount of Class 4 liquid and solid oxidizers shall be stored in accordance with the following:

1. Class 4 liquid and solid oxidizers shall be stored in hazardous materials storage cabinets complying with Section 5003.8.7.
2. Hazardous materials storage cabinets shall not contain other storage.

❖ This section allows the occasional use of limited amounts of Class 4 liquid and solid oxidizers in certain scientific, experimental or demonstration settings; however, storage of any quantity of these materials for any length of time is not allowed. The fire code official may limit the amount of Class 4 liquid and solid oxidizers brought into a structure for these uses. The quantity actually needed for the experiment should determine the amount allowed into a structure.

Because of their explosive hazard characteristics, even the smallest quantity of Class 4 liquid and solid oxidizers must be stored in an approved hazardous materials storage cabinet, constructed and placarded in accordance with Section 5003.8.6, to reduce the exposure of the materials to hazards from the surrounding environment. Based on Note e to Table 5003.1.1(1), where an approved storage cabinet is used, the MAQ that could be kept in such occupancies can be doubled.

Note g to Table 5003.1.1(1) allows storage of Class 4 liquid and solid oxidizers in any amount only in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

To reduce the likelihood of contamination of the Class 4 oxidizer materials or damage to their packaging, Item 2 prohibits the storage of other materials in the approved storage cabinet.

**6303.1.1.2 Class 3 liquid and solid oxidizers.** Not more than 200 pounds (91 kg) of solid or 20 gallons (76 L) of liquid Class 3 oxidizer is allowed in storage and use where such materials are necessary for maintenance purposes or operation of equipment. The oxidizers shall be stored in *approved* containers and in an *approved* manner.

❖ The higher amounts of Class 3 liquid and solid oxidizers permitted by this section in storage and use are in recognition of their common use for building maintenance purposes or equipment operation. Proper storage practices and safeguards must still be observed.

**6303.1.1.3 Oxidizing gases.** Except for cylinders of nonliquefied *compressed gases* not exceeding a capacity of 250 cubic feet (7 m<sup>3</sup>) or liquefied *compressed gases* not exceeding a capacity of 46 pounds (21 kg) each used for maintenance purposes, patient care or operation of equipment, oxidizing gases shall not be stored or used in Group A, E, I or R occupancies or in offices in Group B occupancies.

The aggregate quantities of gases used for maintenance purposes and operation of equipment shall not exceed the *maximum allowable quantity per control area* listed in Table 5003.1.1(1).

Medical gas systems and medical gas supply cylinders shall also be in accordance with Section 5306.

❖ In Occupancy Groups A, E, I or R, or offices in Group B occupancies, up to the MAQ of oxidizing gases per control area established in Table 5003.1.1(1) are allowed for maintenance and critical functions, such as patient care and maintenance of equipment.

To limit the amount of gas that could be released in any given incident, no individual cylinder may exceed a capacity of 250 cubic feet (7 m<sup>3</sup>) for nonliquefied compressed gases or 46 pounds (21 kg) for liquefied compressed gases. Consistent with Section 6301.1, the provisions of Chapter 53 are also applicable to oxidizer gases, in addition to the provisions of this section.

The quantity limitation to office spaces in Group B occupancies allows small laboratories, doctor or dental spaces, or other nonoffice uses classified as Group B to store and use quantities up to the MAQs of flammable or oxidizing gases.

**6303.1.2 Emergency shutoff.** *Compressed gas* systems conveying oxidizing gases shall be provided with *approved* manual or automatic emergency shutoff valves that can be activated at each point of use and at each source.

❖ In order to maintain control over the flow of oxidizer gases under emergency conditions, each supply source and point of use of oxidizer compressed gas must have an approved emergency shutoff valve. These valves must be excess flow control valves to

regulate the rate of flow of hazardous materials in the piping system, fail-safe valves or other approved types that will operate automatically, or there must be a manual means of operation to give the fire department or other responsible persons the ability to stop the flow of hazardous materials in an emergency. The valves must be readily accessible and comply with Section 5003.2.2.1. Also see the commentary to the definitions of “Emergency shutoff valve,” “Emergency shutoff valve, manual” and “Emergency shutoff valve, automatic” in Section 202.

**6303.1.2.1 Shutoff at source.** A manual or automatic fail-safe emergency shutoff valve shall be installed on supply piping at the cylinder or bulk source. Manual or automatic cylinder valves are allowed to be used as the required emergency shutoff valve where the source of supply is limited to unmanifolded cylinder sources.

❖ Where the source of the gas is limited to “cylinder sources” that are not manifolded, the shutoff valve can be the cylinder valve itself. If cylinders are manifolded or if the source is other than cylinders, an independent shutoff valve is required to be installed on the piping system.

**6303.1.2.2 Shutoff at point of use.** A manual or automatic emergency shutoff valve shall be installed on the supply piping at the point of use or at a point where the equipment using the gas is connected to the supply system.

❖ Emergency shutoff valves at the point of use are to be installed on the supply piping either at the use point or where equipment is connected. Either manual or automatic valves are allowed to be used. For example, it is common in some installations to have gas piped to a room for use with portable or fixed equipment. Emergency shutoff valves are typically provided at the point where the piping first enters the room. Equipment may not be connected to the valve; however, the valve represents the point of connection for use. When equipment is connected to the supply system, a valve that isolates the equipment is required. It may or may not be the same valve as that used at the point of penetration. Either valve is allowed to be manual or automatic, and either valve serves as an emergency shutoff valve.

**6303.1.3 Ignition source control.** Ignition sources in areas containing oxidizing gases shall be controlled in accordance with Section 5003.7.

❖ Given the fact that oxidizers enhance or accelerate the combustion process, ignition sources, such as smoking and open flames, must be strictly controlled in oxidizer storage or use areas in accordance with the provisions of Section 5003.7 to reduce the likelihood of a fire involving the stored material.

**6303.2 Class 1 oxidizer storage configuration.** The storage configuration of Class I liquid and solid oxidizers shall be as set forth in Table 6303.2.

❖ See the commentary to Table 6303.2.

**TABLE 6303.2  
STORAGE OF CLASS 1 OXIDIZER LIQUIDS AND SOLIDS**

STORAGE CONFIGURATION	LIMITS (feet)
Piles	
Maximum width	24
Maximum height	20
Maximum distance to aisle	12
Minimum distance to next pile <sup>a</sup>	4
Minimum distance to walls <sup>b</sup>	2
Maximum quantity per pile	200 tons
Maximum quantity per building	No Limit

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg, 1 ton = 0.907185 metric ton.

a. The minimum aisle width shall be equal to the pile height, but not less than 4 feet and not greater than 8 feet.

b. There shall be no minimum distance from the pile to a wall for amounts less than 9,000 pounds.

❖ Class 1 oxidizers are the least susceptible to spontaneous reactions at elevated temperatures (such as from exposure fires). The limitations of Table 6303.2 apply to Class 1 oxidizers in containers and packages. Combustible containers such as fiber drums, cardboard or plastic boxes, paper or plastic bags and plastic bottles or jugs are common packaging materials for oxidizers. Expanded polystyrene foam and other plastic and cellulosic combustible materials are also commonly used as packing materials. Noncombustible containers, such as glass jugs and bottles, are common containers but are usually shipped in combustible packing materials and boxes to prevent damage. Occasionally, some materials may be shipped or stored in metal drums. Whenever possible, materials should be kept in original shipping containers to prevent spillage or contamination.

**SECTION 6304  
STORAGE**

**6304.1 Indoor storage.** Indoor storage of oxidizing materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) shall be in accordance with Sections 5001, 5003 and 5004 and this chapter.

❖ This section regulates the indoor storage of oxidizing materials when quantities are in excess of the MAQ and classified in Occupancy Group H. The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of oxidizing materials inside structures must comply with Sections 6304.1.1 through 6304.2.4 to

prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

**6304.1.1 Explosion control.** Indoor storage rooms, areas and buildings containing Class 4 liquid or solid oxidizers shall be provided with explosion control in accordance with Section 911.

❖ Because of the possibility of a deflagration or detonation in the event of ignition of oxidizers, explosion relief venting meeting the requirements of Section 911 must be installed to protect the storage building or structure from collapse.

**6304.1.2 Automatic sprinkler system.** The *automatic sprinkler system* for oxidizer storage shall be designed in accordance with NFPA 400.

❖ This section, as with all of Section 6304.1, is applicable to oxidizer storage buildings or portions of buildings classified in Occupancy Group H. Section 903.2.5.1 generally requires that sprinklers be installed throughout the Group H occupancy in accordance with Section 903.3.1.1. Because of the unique fire protection challenges presented by the storage of liquid and solid oxidizers, this section mandates that the sprinkler design for oxidizer storage be in accordance with NFPA 400, which includes special sprinkler design densities based on the class of oxidizer being protected and the manner of storage. These requirements are also duplicated in NFPA 13.

Note that only the sprinkler design criteria contained in NFPA 400 may be used because the rest of the standard is not included in the reference and, therefore, would not be applicable. See the commentary to Section 102.7 for further discussion of the limitations on the use of referenced standards.

**6304.1.3 Liquid-tight floor.** In addition to Section 5004.12, floors of storage areas for liquid and solid oxidizers shall be of liquid-tight construction.

❖ Floors and sills of rooms or areas used to contain hazardous material spills must be liquid tight to prevent the flow of liquids to adjoining areas (see commentary, Section 5004.2). The floor surface should be compatible with the oxidizer materials to be retained and must be noncombustible, as required by Section 5004.12.

**6304.1.4 Smoke detection.** An *approved* supervised smoke detection system in accordance with Section 907 shall be installed in liquid and solid oxidizer storage areas. Activation of the smoke detection system shall sound a local alarm.

**Exception:** Detached storage buildings protected by an *approved* automatic fire-extinguishing system.

❖ An automatic fire detection system with central, remote or proprietary station supervision and a local alarm signal is required for early warning of fire to building occupants and fire suppression personnel.

Detectors and installation methods in oxidizer storage areas must be selected for compatibility with the materials stored. Fire alarm equipment and installation methods must comply with Section 907. Materials that emit strong vapors may interfere with fire detection system components or trigger nuisance alarm signals. The required local alarm is intended to alert the occupants in the immediate vicinity of the storage area to a potentially hazardous condition. The alarm is not intended to be part of an evacuation alarm system for the entire structure.

The exception indicates that automatic fire detection is not required in detached storage buildings where there is an automatic fire suppression system. Automatic sprinklers or approved alternative fire-extinguishing systems reduce the danger to people and property from fire by detecting the fire, sounding an alarm, transmitting the alarm to the fire department and suppressing the fire.

Fire-extinguishing systems in detached storage buildings must be supervised by connection to a central station, a remote supervising station or a proprietary supervising station or, when approved by the fire code official, connected to a system that produces an audible and visual signal monitored at a constantly attended on-site location. See the commentary to Section 903.4 for further discussion of sprinkler system supervision, and Section 904.3.5 for further discussion of alternative automatic fire-extinguishing system supervision.

**6304.1.5 Storage conditions.** The maximum quantity of oxidizers per building in storage buildings shall not exceed those quantities set forth in Tables 6304.1.5(1) through 6304.1.5(3).

The storage configuration for liquid and solid oxidizers shall be as set forth in Table 6303.2 and Tables 6304.1.5(1) through 6304.1.5(3).

Class 2 oxidizers shall not be stored in *basements* except where such storage is in stationary tanks.

Class 3 and 4 oxidizers in amounts exceeding the *maximum allowable quantity per control area* set forth in Section 5003.1 shall be stored on the ground floor only.

❖ This section covers storage requirements related to the hazards of oxidizers stored in storage structures. MAQs of oxidizers and their arrangement in the building must comply with Tables 6304.1.5(1) through (3).

Because of the moderate hazard of Class 2 oxidizers, they can be stored in basements, but only when contained in approved stationary tanks that comply with the applicable provisions of Section 5003.2.

Because of their greater relative hazard, storage of Class 3 and 4 oxidizers in excess of the MAQs above or below the ground floor is prohibited. The greater hazard results in more problems associated with manual fire suppression operations in below-grade areas. Ground-floor storage also facilitates fire-fighter access to the storage area.

**TABLE 6304.1.5(1)**  
**STORAGE OF CLASS 2 OXIDIZER LIQUIDS AND SOLIDS**

STORAGE CONFIGURATION	LIMITS		
	Control area storage	Group H occupancy storage	Detached storage
Piles			
Maximum width	16 feet	25 feet	25 feet
Maximum height	Note a	Note a	Note a
Maximum distance to aisle	8 feet	12 feet	12 feet
Minimum distance to next pile	Note b	Note b	Note b
Minimum distance to walls	2 feet	2 feet <sup>c</sup>	2 feet <sup>c</sup>
Maximum quantity per pile	MAQ	100 tons	100 tons
Maximum quantity per building	MAQ	2000 tons	No Limit

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg, 1 ton = 0.907185 metric ton.

- a. Maximum storage height in nonsprinklered buildings is limited to 6 feet. In sprinklered buildings see NFPA 400 for storage heights based on ceiling sprinkler protection.
- b. The minimum aisle width shall be equal to the pile height, but not less than 4 feet and not greater than 8 feet.
- c. For protection level and detached storage under 4,500 pounds, there shall be no minimum separation distance between the pile and any wall.

❖ Table 6304.1.5(1) applies equally to Class 3 oxidizers in combustible and noncombustible containers and packages in control areas, Group H storage rooms and detached storage structures. Aisle widths that are equal to the pile height, as stated in Note b, reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel.

**TABLE 6304.1.5(2)**  
**STORAGE OF CLASS 3 OXIDIZER LIQUIDS AND SOLIDS**

STORAGE CONFIGURATION	LIMITS		
	Control area storage	Group H occupancy storage	Detached storage
Piles			
Maximum width	12 feet	16 feet	20 feet
Maximum height	Note a	Note a	Note a
Maximum distance to aisle	8 feet	10 feet	10 feet
Minimum distance to next pile	Note b	Note b	Note b
Minimum distance to walls	4 feet	4 feet <sup>c</sup>	4 feet <sup>c</sup>
Maximum quantity per pile	NA	30 tons	100 tons
Maximum quantity per building	MAQ	1200 tons	No Limit

For SI: 1 foot = 304.8 mm, 1 pound = 0.454 kg, 1 ton = 0.907185 metric ton.

- a. Maximum storage height in nonsprinklered buildings is limited to 6 feet. In sprinklered buildings see NFPA 400 for storage heights based on ceiling sprinkler protection.
- b. The minimum aisle width shall be equal to the pile height, but not less than 4 feet and not greater than 8 feet.
- c. For protection level and detached storage under 2,300 pounds, there shall be no minimum separation distance between the pile and any wall.

❖ Table 6304.1.5(2) applies equally to Class 3 oxidizers in combustible and noncombustible containers and

packages in control areas, Group H storage rooms and detached storage structures. Aisle widths that are equal to the pile height, as stated in Note b, reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel.

**TABLE 6304.1.5(3)**  
**STORAGE OF CLASS 4 OXIDIZER LIQUIDS AND SOLIDS**

STORAGE CONFIGURATION	LIMITS (feet)
Piles	
Maximum length	10
Maximum width	4
Maximum height	8
Minimum distance to next pile	8
Maximum quantity per building	No Limit

For SI: 1 foot = 304.8 mm.

❖ Table 6304.1.5(3) applies to the storage of Class 4 oxidizers in quantities greater than the exempt amounts specified in Table 5003.1.1(1). Aisle widths that are equal to the pile height, as required in the table, reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel.

**6304.1.6 Separation of Class 4 oxidizers from other materials.** In addition to the requirements in Section 5003.9.8, Class 4 oxidizer liquids and solids shall be separated from other hazardous materials by not less than a 1-hour *fire barrier* or stored in hazardous materials storage cabinets.

❖ Above all else, oxidizers must be kept away from flammable and combustible liquids and explosive materials. Other chemicals may also react violently with some oxidizers and some oxidizers will react with other oxidizers. For example, triazinetriones (chlorinated isocyanurates) are incompatible with hypochlorites. Materials should be checked for compatibility before storage arrangements are approved. See the MSDS for each product for guidance on compatibility.

Class 4 oxidizers must be stored in separate hazardous materials storage cabinets or in rooms separated from other storage areas by 1-hour fire-resistance-rated construction.

**6304.1.7 Contamination.** Liquid and solid oxidizers shall not be stored on or against combustible surfaces. Liquid and solid oxidizers shall be stored in a manner to prevent contamination.

❖ Combustible surfaces may be ignited in the event of a spill or uncontrolled release of oxidizing material, including its vapors. Protective floor and wall coverings should be checked for compatibility with the oxidizing materials even if the underlying material is

compatible. Noncombustible materials, such as unprotected ferrous metals, may corrode or react violently in the presence of certain oxidizing materials. For example, concentrated hydrogen peroxide (greater than 52-percent solution) may produce a violent decomposition reaction in contact with iron, copper, chromium, brass, bronze, lead, silver and manganese. The corrosive effects of many oxidizers may also damage concrete surfaces.

**6304.1.8 Detached storage.** Storage of liquid and solid oxidizers shall be in detached buildings where required by Section 5003.8.2.

❖ Section 5003.8.2 and Table 5003.8.2 require detached storage for Class 4 oxidizer solids and liquids when the MAQ is exceeded. See the commentary to Section 5003.8.2 and Table 5003.8.2.

**6304.1.8.1 Separation distance.** Detached storage buildings for Class 4 oxidizer liquids and solids shall be located not less than 50 feet (15 240 mm) from other hazardous materials storage.

❖ When the MAQ is exceeded for Class 4 oxidizer liquids and solids, the occupancy group is Group H-1, the same as for explosives. The minimum separation distance specified is intended to reduce the effects of radiant heat or physical damage exposure in the event of a fire or explosion in a detached storage building.

**6304.2 Outdoor storage.** Outdoor storage of oxidizing materials in amounts exceeding the *maximum allowable quantities per control area* set forth in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5004 and this chapter. Oxidizing gases shall also comply with Chapter 53.

❖ This section regulates the outdoor storage of oxidizing materials when in excess of the MAQ established by Table 5003.1.1(3). The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of oxidizing materials in outdoor control areas must comply with Sections 6304.2.1 through 6304.2.4 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion. In addition to the requirements of this chapter, oxidizing compressed gases are subject to the requirements of Chapter 53.

**6304.2.1 Distance from storage to exposures for oxidizing gases.** Outdoor storage areas for oxidizing gases shall be located in accordance with Table 6304.2.2.

❖ Table 6304.2.1 contains separation distances for outdoor storage of oxidizing gases that are intended to minimize radiant heat transfer and fire spread between exposures.

**TABLE 6304.2.1.** See page 63-8.

❖ Table 6304.2.1 establishes spatial separation (or alternative) safeguards required for the outside storage of oxidizing compressed gases when in excess of the outside storage MAQ shown in Table 5003.1.1(3).

The required separation distance is intended to minimize radiant heat transfer between exposures. Separation distances provide a measure of protection against the possibility of fire spread in the event of a fire involving the stored material or an incident involving another exposure, such as a building on the same or an adjacent lot, or a vehicle in the public right-of-way. IBC Section 414.6 contains additional protection requirements for outside storage conditions in areas that are provided with an overhead roof structure or canopy to protect the materials from the weather.

Note a allows encroachment on property lines, public streets, public ways, etc., through the use of a protective 2-hour fire barrier (constructed as required by IBC Section 707, which acts as a shield between the storage and the exposure. The note recognizes that a 2-hour fire-barrier wall provides an equivalent means of achieving the objective of spatial separation. Where a separation assembly is used instead of a physical separation distance, the wall must extend vertically beyond the roof or wall opening of the larger structure on each side (top and sides) to prevent a fire from lapping over or extending around the wall and must be arranged to prevent hazardous accumulation of gas.

**6304.2.1.1 Oxidizing cryogenic fluids.** Outdoor storage areas for oxidizing *cryogenic fluids* shall be located in accordance with Chapter 55.

❖ This section indicates that outdoor storage areas for oxidizing cryogenic fluids are subject to the outdoor storage requirements found in Section 5504.3.

**6304.2.2 Storage configuration for liquid and solid oxidizers.** Storage configuration for liquid and solid oxidizers shall be in accordance with Table 6303.2 and Tables 6304.1.5(1) through 6304.1.5(3).

❖ The outside storage arrangements for liquid and solid oxidizers are the same as for inside storage arrangements contained in Section 6304.1.8 and its referenced tables (see commentary, Section 6304.1.8).

**6304.2.3 Storage configuration for oxidizing gases.** Storage configuration for oxidizing gases shall be in accordance with Table 6304.2.2.

❖ To minimize radiant heat transfer and fire spread between exposures, Table 6304.2.2 contains separa-

tion distances for the outdoor storage of oxidizer gases when in excess of the outside storage MAQ shown in Table 5001.1.1(3).

**SECTION 6305  
USE**

**6305.1 Scope.** The use of oxidizers in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5005 and this chapter. Oxidizing gases shall also comply with Chapter 53.

❖ This section applies to all indoor and outdoor dispensing, use and handling of oxidizers when these amounts are in excess of the MAQ per indoor or outdoor control area indicated in Table 5003.1.1(1) or 5003.1.1(3), respectively. The administrative, general use, handling and dispensing provisions of Chapter 50 are applicable in addition to the requirements of this chapter.

Once the MAQs of oxidizers per control area have been exceeded, indoor areas where materials are being dispensed, used or handled must be located in a building or portion of a building complying with the IBC for a Group H occupancy as a result of the increased hazards associated with quantity.

Although no occupancy group is assigned to them, outside oxidizer use areas must have an increased level of regulation when quantities exceed the MAQs per outdoor control area listed in Table 5003.1.1(3). Corresponding MAQs recognize that an open-use condition is generally more hazardous than a closed-use condition because the oxidizer is more directly exposed to the surrounding environment and can become more readily involved in an incident than if totally confined. The MAQs for use are based on the aggregate quantity in both use and storage being within the MAQs listed for storage.

**SECTION 6306  
LIQUID OXYGEN IN HOME HEALTH CARE**

**6306.1 General.** The storage and use of liquid oxygen (LOX) in home health care in Group I-1, I-4 and R occupancies shall

**TABLE 6304.2.1  
OXIDIZER GASES—DISTANCE FROM STORAGE TO EXPOSURES<sup>a</sup>**

QUANTITY OF GAS STORED (cubic feet at NTP)	DISTANCE TO A BUILDING NOT ASSOCIATED WITH THE MANUFACTURE OR DISTRIBUTION OF OXIDIZING GASES OR PUBLIC WAY OR LOT LINE THAT CAN BE BUILT UPON (feet)	DISTANCE BETWEEN STORAGE AREAS (feet)
0 – 50,000	5	5
50,001 – 100,000	10	10
100,001 or greater	15	10

For SI: 1 foot = 304.8 mm, 1 cubic foot = 0.02832 m<sup>3</sup>.

a. The minimum required distances shall not apply where fire barriers without openings or penetrations having a minimum fire-resistance rating of 2 hours interrupt the line of sight between the storage and the exposure. The configuration of the fire barrier shall be designed to allow natural ventilation to prevent the accumulation of hazardous gas concentrations.

comply with Sections 6306.2 through 6306.6, or shall be stored and used accordance with Chapter 50.

❖ As the population ages, the use of LOX in home health care settings is expected to increase. Section 6306 was developed in response to changes in technology that improve the care of patients with respiratory ailments in their own homes allowing them to utilize a LOX ambulatory care container and to be able to refill it from a LOX home care container. Section 6306 will enhance public safety by establishing minimum requirements for LOX storage and use in the occupancies where the material is most frequently encountered. In addition, Section 6306 requires that the suppliers provide a reasonable level of information regarding safeguards to be supplied by the users, and fills a void in the code that has been characterized by a growing concern and “need to know” expressed by the code enforcement community. There may be certain circumstances that make compliance with the provisions of Section 6306 impractical or impossible, in which case, the provisions of Chapters 50 and 55 of the code would be applicable.

**6306.2 Information and instructions to be provided.** The seller of liquid oxygen shall provide the user with information in written form that includes, but is not limited to, the following:

1. Manufacturer’s instructions and labeling for safe storage and use of the containers.
2. Locating containers away from ignition sources, *exits*, electrical hazards and high-temperature devices in accordance with Section 6306.3.3.
3. Restraint of containers to prevent falling in accordance with Section 6306.3.4.
4. Requirements for handling containers in accordance with Section 6306.3.5.
5. Safeguards for refilling containers in accordance with Section 6306.3.6.
6. Signage requirements in accordance with Section 6306.6.

❖ This section requires that the LOX purveyor provide the customer with written, basic instructions on the safe storage, use, handling and refilling of LOX containers.

**6306.3 Liquid oxygen home care containers.** Containers of liquid oxygen in home health care shall be in accordance with Sections 6306.3.1 through 6306.3.6.

❖ This section introduces the requirements applicable to home health care LOX containers. See the commentary to the Chapter 2 definitions of “Liquid oxygen home care container” and “Liquid oxygen ambulatory container.”

**6306.3.1 Maximum individual container capacity.** Liquid oxygen home care containers shall not exceed an individual

capacity of 15.8 gallons (60 L) in Group I-1, I-4 and R occupancies. Liquid oxygen ambulatory containers are allowed in Group I-1, I-4 and R occupancies. Containers of liquid oxygen in home health care shall also be stored, used and filled in accordance with Section 6306 and Sections 5503.1 and 5503.2.

❖ The sizes of LOX ambulatory and health care containers in Group I-1, I-4 and R occupancies are limited to 0.396 gallons (0.75 L) and 15.8 gallons (60 L), respectively, as established in the definitions in Section 6302.1 and by this section. It is necessary to establish container size limits because there has been a trend to increase the size of the containers delivered to the user, in some cases, simply in order to avoid more frequent deliveries. If it is necessary to have individual containers larger than the limits established here, then the MAQ and control area concept set forth in Chapter 50 will apply. The general requirements of Chapter 55 for containers and their pressure relief devices are also applicable to these containers.

**6306.3.2 Manufacturer’s instructions and labeling.** Containers shall be stored, used and operated in accordance with the manufacturer’s instructions and labeling.

❖ Compliance with the LOX container manufacturer’s storage, use and operating instructions is a fundamental requirement consistent with all *International Codes*® and those instructions are considered an enforceable extension of the code. Federal, state, county or municipal laws might supercede part of or be applied in addition to the requirements in the instructions.

**6306.3.3 Locating containers.** Containers shall not be located in areas where any of the following conditions exist:

1. They can be overturned due to operation of a door.
2. They are in the direct path of egress.
3. They are subject to falling objects.
4. They can become part of an electrical circuit.
5. Open flames and high-temperature devices can cause a hazard.

❖ The requirements in this section ensure that LOX home care and ambulatory containers are not located in areas where they can be damaged, near sources of ignition or in the direct path of egress. Home care and ambulatory containers must be located so that they are protected from being overturned resulting from the impact of a door or from falling objects, such as a bookshelf. Containers are not allowed to be located in the direct path of a means of egress to avoid damage to containers or injury to occupants egressing the area. Containers also must be located so they cannot become part of an electrical circuit or near open flames or high-temperature devices.

**6306.3.4 Restraining containers.** Liquid oxygen home care containers shall be restrained while in storage or use to prevent falling caused by contact, vibration or seismic activity. Containers shall be restrained by one of the following methods:

1. Restraining containers to a fixed object with one or more restraints.
  2. Restraining containers within a framework, stand or assembly designed to secure the container.
  3. Restraining containers by locating a container against two points of contact such as the walls of a corner of a room or a wall and a secure furnishing or object such as a desk.
- ❖ To avoid physical damage to the containers and to protect the user from injury due to falling containers, LOX home care containers are required to be restrained. This section specifies three approved methods of restraint to prevent a home care container from being overturned due to mechanical impact or a seismic event.

**6306.3.5 Container handling.** Containers shall be handled by use of a cart or hand truck designed for such use.

**Exceptions:**

1. Liquid oxygen home care containers equipped with a roller base.
  2. Liquid oxygen ambulatory containers are allowed to be hand carried.
- ❖ This section requires that if containers are moved, to avoid damage due to dropping or upset, they must be transported using a cart or hand truck suitable for the purpose. Because the level of stability and efficiency in container moving is provided by roller bases that are made for the container, Exception 1 exempts LOX home care containers equipped with rollers or caster wheels in their bases. Exception 2 recognizes that some ambulatory containers are made for portability and are hand carried.

**6306.3.6 Filling of containers.** The filling of containers shall be in accordance with Sections 6306.3.6.1 through 6306.3.6.3.

❖ This section introduces the following requirements applicable to the filling of home health care LOX containers.

**6306.3.6.1 Filling location.** Liquid oxygen home care containers and ambulatory containers shall be filled outdoors.

**Exception:** Liquid oxygen ambulatory containers are allowed to be filled indoors where the supply container is specifically designed for filling such containers and written instructions are provided by the container manufacturer.

❖ A requirement for filling LOX home care and ambulatory containers outdoors is specified in this section. The exception allows ambulatory LOX containers to be filled indoors, provided the supply container is designed for the filling of such containers by the

patient or other individuals and written instructions for the proper filling of these containers are provided by the home care container manufacturer.

**6306.3.6.2 Incompatible surfaces.** A drip pan compatible with liquid oxygen shall be provided under home care container fill and vent connections during the filling process in order to protect against liquid oxygen spillage from coming into contact with combustible surfaces, including asphalt.

❖ This section requires the use of a LOX-compatible drip pan located beneath the container to prevent any spilled LOX from contacting surfaces whose combustibility would be greatly enhanced by contact with the LOX. Asphalt surfaces are especially problematic because LOX that contacts asphalt can act as a contact explosive, resulting in a low-pressure explosion.

**6306.3.6.3 Open flames and high-temperature devices.** The use of open flames and high-temperature devices shall be in accordance with Section 5003.7.2.

❖ During LOX container filling operations, open flame sources and high-temperature devices must be separated from home care and ambulatory containers in accordance with Section 5003.7.2 (see commentary, Section 5003.7.2).

**6306.4 Maximum aggregate quantity.** The maximum aggregate quantity of liquid oxygen allowed in storage and in use in each *dwelling unit* shall be 31.6 gallons (120 L).

**Exceptions:**

1. The maximum aggregate quantity of liquid oxygen allowed in Group I-4 occupancies shall be limited by the maximum allowable quantity set forth in Table 5003.1.1(1).
  2. Where individual sleeping rooms are separated from the remainder of the *dwelling unit* by *fire barriers* constructed in accordance with Section 707 of the *International Building Code*, and *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both, having a minimum *fire-resistance rating* of 1 hour, the maximum aggregate quantity per *dwelling unit* shall be increased to allow not more than 31.6 gallons (120 L) of liquid oxygen per sleeping room.
- ❖ This section establishes a maximum aggregate amount of 31.6 gallons (120 L) inside of each dwelling unit. This allows for one container to be in use and an additional cylinder in storage.
- Exception 1 further requires that the total amount of LOX stored indoors in Group I-4 occupancies not exceed the MAQ for cryogenic oxidizing liquids specified in Table 5003.1.1(1). That table establishes an MAQ for LOX of 45 gallons (170.3 L) in a one-story, Group I-4 occupancy constructed as a single control area and allows the quantity to be increased by 100 percent if the building is protected throughout by an approved automatic sprinkler system complying with NFPA 13. Additional amounts of LOX are permitted if it is stored in approved hazardous materials storage cabinets or if a Group I-4 occupancy is constructed

with additional control areas. Keep in mind that even though these occupancies may be equipped with automatic sprinklers, the ability to increase the MAQ by 100 percent in Table 5003.1.1(1) is only applicable when the sprinkler system is designed in accordance with NFPA 13. Designs in accordance with NFPA 13D or 13R would not qualify for an increase.

Exception 2 permits a maximum of 31.6 gallons (120 L) of LOX in an individual sleeping room when the room is separated from the remainder of the dwelling unit by 1-hour fire-resistance-rated fire barriers and horizontal assemblies constructed in accordance with the requirements in IBC Chapter 7.

**6306.5 Smoking prohibited.** Smoking shall be prohibited in rooms or areas where liquid oxygen is in use.

❖ Smoking is a significant ignition source and LOX is a hazardous material that can enhance the burning rate of combustible materials. Smoking is therefore prohibited in all areas where LOX is in use (also see commentary, Sections 310 and 6306.6.1).

**6306.6 Signs.** Warning signs for occupancies using home health care liquid oxygen shall be in accordance with Sections 6306.6.1 and 6306.6.2.

❖ This section introduces the requirements for warning signs applicable to home health care LOX storage, use or transfer.

**6306.6.1 No smoking sign.** A sign stating “OXYGEN—NO SMOKING” shall be posted in each room or area where liquid oxygen containers are stored, used or filled.

❖ Since smoking is prohibited by Section 6306.5, it is reasonable to provide appropriate warning signs in each room where LOX is stored, used or transferred stating that smoking is banned (see Section 310 for additional requirements for these signs).

**6306.6.2 Premises signage.** Where required by the *fire code official*, each *dwelling unit* or *sleeping unit* shall have an *approved* sign indicating that the unit contains liquid oxygen home care containers.

❖ When the fire code official deems it necessary, this section authorizes him or her to require a sign for each sleeping or dwelling unit to identify the presence of LOX to fire fighters. During the development of Section 6306, concern was expressed that there could be privacy and personal safety issues in placing such signage in public spaces. Accordingly, this section should be applied judiciously and sparingly, and only when absolutely essential to fire-fighter safety.

**6306.7 Fire department notification.** Where required by the *fire code official*, the liquid oxygen seller shall notify the fire department of the locations of liquid oxygen home care containers.

❖ This section requires the seller of the LOX to notify the fire code official of the locations where LOX is being used for home health care. Note that this section is only applicable when it is required by the fire

code official. Some jurisdictions may not want this information due to the potentially large volume of information involved or the lack of resources to process it.

# Chapter 64: Pyrophoric Materials

## General Comments

Because of their capacity to ignite spontaneously at low temperatures, pyrophoric materials pose unusual deflagration and detonation hazards to building occupants and fire-fighting personnel. Advance knowledge of the materials present in the building through the issuance of permits and the submittal of Material Safety Data Sheets (MSDS), as noted in Section 407, are essential for effective preplanning by the fire department. The ability to fight fires involving pyrophoric materials may be somewhat limited since many pyrophoric materials are also highly reactive with water. Interior fire fighting may not be an option unless adequate alternative extinguishing agents are available.

Some flammable liquids may also be considered pyrophoric liquids. Diethylzinc, for example, is considered a pyrophoric liquid in accordance with NFPA 49 (found in the NFPA *Fire Protection Guide to Hazardous Materials*), but has a U.S. Department of Transportation (DOT) classification as a flammable liquid. Since this material is known to ignite spontaneously when exposed to air, the multiple hazards of being both pyrophoric and flammable must be addressed.

Alkali metals, such as sodium, potassium and lithium, are examples of pyrophoric solids. Most of these reactive metals are not found free in nature, but are combined with other elements. Sodium, for example, burns violently and ignites spontaneously when exposed to moist air. Sodium that comes in contact with water may be accompanied by hydrogen explosions.

Diborane and phosphine are pyrophoric gases that must comply with the provisions of this chapter as well as those of Chapter 53.

The proper classification of materials as pyrophoric is essential to providing adequate means of hazard mitigation. Pyrophoric materials, as indicated earlier, may also pose multiple hazards similar to flammable liquids, flammable solids and water-reactive materials.

In previous editions of the code, there were extensive regulations in Section 6406 for silane gas tetrahydride ( $\text{SiH}_4$ ); CAS No. 7803-62-5], a common but dangerous pyrophoric gas that is also classified as unstable (reactive)(see commentary, Chapter 66). Due to the development of a standard for its storage and handling, this chapter now regulates silane by reference to the applicable Compressed Gas Association (CGA) standard, G-13. Silane gas or mixtures of silane gas are commonly found in the semiconductor and photovoltaic cell manufacturing processes and allied industries. Silane gas is distributed at 100-percent concentration or it can be distributed as a mixture with other gases, such as various concentrations of silane mixed with nitrogen or hydro-

gen. This chapter only addresses silane gas or mixtures of silane gas that behave as a pyrophoric and flammable gas.

Silane is classified as a pyrophoric material and a Class 1 Unstable (reactive) compressed gas. It can autoignite or spontaneously ignite when it is exposed to air without any source of ignition. Silane has a lower flammable limit of 1.37 percent by volume in air. It begins to exhibit pyrophoric characteristics at about 4.5 percent volume in air. Silane is a unique hazardous material in that it is also metastable, meaning that it can have delayed ignition. This metastable characteristic is dangerous because it allows a volume of gas to accumulate inside of a building. In such cases, a deflagration can occur, which can cause structural damage to buildings, injure or kill individuals located close to the release, and complicate the emergency response due to its potential energy. It is for this reason that Section 911.1 and Table 911.1 require deflagration venting when the amount of silane stored inside of buildings exceeds its maximum allowable quantity.

Because of silane's importance in the manufacturing of semiconductors and photovoltaic products and its increased use, manufacturers of silane in conjunction with its users have performed extensive testing of this hazardous material. These tests, along with incident experiences and peer-reviewed scientific data, resulted in the development of the 2006 edition of ANSI/CGA Standard G-13, *Storage and Handling of Silane and Silane Mixtures*.

Excluding the introduction, scope, definitions and references, CGA G-13 is divided into 14 sections. These sections address the following:

- Physical and chemical properties of silane.
- Requirements for its proper indoor and outdoor storage.
- Configuration of the piping, valves and fitting.
- Packaging of silane, gas and flame detection systems.
- Fire protection.
- Ventilation.
  - Purge gas systems.
  - Electrical installation requirements.
  - Supervisory controls of mechanical ventilation, gas monitoring and flame detection systems.

The standard also contains four informational appendices that address protective equipment required for personnel working on silane systems, the compressibility of silane, minimum separation distances from silane

storage to certain thermal flux (e.g., radiant energy) exposures and blast overpressure.

The requirements for outdoor storage are based on a series of silane release tests and the development of a mathematic model that were sponsored by the CGA. During these tests silane was released from DOT tube trailers, International Standards Organization (ISO) module packs (which are another form of bulk compressed packaging), and containers with a volume of more than 16 cubic feet (450 L). The testing results were used in the development of requirements for separation distances of cylinders and large bulk sources of silane.

For cylinders with a volume of less than 16 cubic feet (450 L), CGA G-13 requires the outdoor separation distance to be established based on the volume of silane gas in each nest of compressed gas cylinders (see Chapter 2 for the definition of "Nesting"). The separation distances are intended to limit the thermal flux of the radiation produced by a silane jet fire and are limited based on the volume of each cylinder in each nest and if the cylinder is constructed of steel, fiber overwrapped aluminum or aluminum.

For bulk storage containers including silane tube trailers, ISO modules and containers greater than 450 liters (16 cubic feet) in volume, the CGA standard establishes minimum separation distances to protect exposures from the energy of a 0.5 psig (3.44 kPa) blast overpressure. Blast overpressure is the pressure above the ambient pressure that is manifested in the shock wave of a deflagration or a detonation. The threshold of 0.5 psig (3.44 kPa) value was chosen as the acceptable level of blast overpressure for both buildings and occu-

pants because a frame structure can normally withstand that level of external force with no serious structural damage, and it is unlikely that human beings inside the building would normally suffer any serious injury.

The separation distances from the exposures are based on the stored pressure within the bulk containers or cylinders and the diameter of the pressure relief device. CGA G-13 limits the maximum pressure in the bulk containers or cylinders to 1,600 psig (11 032 kPa) and requires minimum separation distances from a bulk silane source and exposures.

CGA G-13 also contains extensive requirements for the indoor storage and use of silane. It is important to note that some of the requirements of CGA G-13 exceed the requirements of former Section 4106, which was deleted in the 2012 edition of the code.

### Purpose

This chapter regulates the hazards associated with pyrophoric materials, which are capable of spontaneously igniting in the air at or below a temperature of 130°F (54°C). Many pyrophoric materials also pose severe flammability or reactivity hazards. This chapter addresses only the hazards associated with pyrophoric materials. Other materials that pose multiple hazards must conform to the requirements of the code with respect to all hazards (see Section 5001.1). Strict compliance with the provisions of this chapter, along with proper housekeeping and storage arrangements, can reduce the exposure hazards associated with the involvement of pyrophoric materials in a fire or other emergency.

## SECTION 6401 GENERAL

**6401.1 Scope.** The storage and use of pyrophoric materials shall be in accordance with this chapter. *Compressed gases* shall also comply with Chapter 53.

❖ This chapter details specific requirements for the storage of pyrophoric materials. The requirements of this chapter are intended to complement the general requirements for hazardous materials in Chapter 50. Pyrophoric gases are also regulated by Chapter 53. The classification of pyrophoric materials is based on the definition indicated in Section 202, which is derived from DOL 29 CFR; Part 1910.1200.

**6401.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is

issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit, Section 105.6.21 for discussion of specific quantity-based operational permits for the materials regulated in this chapter and Section 105.7 for a general discussion of activities requiring a construction permit.

The permit process also notifies the fire department of the need for prefire planning for hazardous property.

## SECTION 6402 DEFINITION

**6402.1 Definition.** The following term is defined in Chapter 2:

### PYROPHORIC.

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper

application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

## SECTION 6403 GENERAL REQUIREMENTS

**6403.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of pyrophoric materials in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003, 6401 and 6403.

❖ The provisions of this section complement the requirements of Chapter 50 for structures occupied for the storage, handling or use of pyrophoric materials. The general requirements of Sections 5001 and 5003, in addition to the provisions of this chapter, are fully applicable to the storage and use of organic peroxides.

**6403.1.1 Emergency shutoff.** *Compressed gas* systems conveying pyrophoric gases shall be provided with *approved* manual or automatic emergency shutoff valves that can be activated at each point of use and at each source.

❖ To provide control over the flow of pyrophoric gases under emergency conditions, each supply source as well as each point of use of pyrophoric compressed gas must be equipped with an approved emergency shutoff valve. These are excess flow control valves that regulate the rate of flow of hazardous materials in the piping system, fail-safe valves or other approved types that will operate automatically or manually to give the fire department or other responsible persons the ability to stop the flow of hazardous material in an emergency. The valves must be readily accessible and comply with Section 5003.2.2.1. See also the commentary to the definitions of “Emergency shutoff valve,” “Emergency shutoff valve, manual” and “Emergency shutoff valve, automatic” in Section 202.

**6403.1.1.1 Shutoff at source.** An automatic emergency shutoff valve shall be installed on supply piping at the cylinder or bulk source. The shutoff valve shall be operated by a remotely located manually activated shutdown control located not less than 15 feet (4572 mm) from the source of supply. Manual or automatic cylinder valves are allowed to be used as the required emergency shutoff valve where the source of supply is limited to unmanifolded cylinder sources.

❖ This section requires that an automatic emergency shutoff valve be provided on pyrophoric compressed gas systems activated by a remotely located, manually activated control. A minimum distance of 15 feet (4572 mm) has been specified to provide reasonable separation distance between the control and the source as a means to protect persons using the con-

trol from radiant heat in a fire event. When the source of supply is limited to unmanifolded cylinders, the cylinder valve is allowed to be either manual or automatic.

**6403.1.1.2 Shutoff at point of use.** A manual or automatic emergency shutoff valve shall be installed on the supply piping at the point of use or at a point where the equipment using the gas is connected to the supply system.

❖ Emergency shutoff valves at the point of use are to be installed on the supply piping either at the use point or where equipment is connected. Either manual or automatic valves are allowed to be used. For example, it is common in some installations to have gas piped to a room for use with portable or fixed equipment. Emergency shutoff valves are typically provided at the point where the piping first enters the room. Equipment may not be connected to the valve; however, the valve represents the point of connection for use. When equipment is connected to the supply system, a valve that isolates the equipment is required. It may or may not be the same valve as that used at the point of penetration. Either valve is allowed to be manual or automatic, and either valve serves as an emergency shutoff valve.

**6403.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of pyrophoric materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

❖ This section complements the requirements of Chapter 50 for structures used for the storage, handling or use of pyrophoric materials. The regulations contained in this section assume that the quantity of pyrophoric materials in a given building is in excess of the maximum allowable quantities per control area (MAQ) as established in Section 5003.1, thus classifying the building as a Group H occupancy. The requirements of Chapter 50 apply to the storage and use of pyrophoric materials, in addition to the provisions of this chapter.

## SECTION 6404 STORAGE

**6404.1 Indoor storage.** Indoor storage of pyrophoric materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1), shall be in accordance with Sections 5001, 5003 and 5004 and this chapter.

The storage of silane gas, and gas mixtures with a silane concentration of 1.37 percent or more by volume, shall be in accordance with CGA G-13.

❖ This section regulates the indoor storage of pyrophoric materials when they exceed the MAQ in buildings or portions of buildings classified as a Group H occupancy. The general and storage provisions of Chapter 50 are applicable, in addition to the require-

ments of this section. Storage of pyrophoric materials inside of structures must comply with Sections 6404.1.1 through 6404.1.4 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion. Section 6405.3 covers silane gas use. See the commentary introduction to this chapter for a detailed discussion of silane.

**6404.1.1 Liquid-tight floor.** In addition to the requirements of Section 5004.12, floors of storage areas containing pyrophoric liquids shall be of liquid-tight construction.

❖ Floors and sills of rooms or areas used to contain hazardous material spills must be liquid tight to prevent the flow of liquids to adjoining areas (see commentary, Section 5004.2). The floor surface should be compatible with the pyrophoric materials to be retained and must be noncombustible, as required by Section 5004.12.

**6404.1.2 Pyrophoric solids and liquids.** Storage of pyrophoric solids and liquids shall be limited to a maximum area of 100 square feet (9.3 m<sup>2</sup>) per pile. Storage shall not exceed 5 feet (1524 mm) in height. Individual containers shall not be stacked.

Aisles between storage piles shall be not less than 10 feet (3048 mm) in width.

Individual tanks or containers shall not exceed 500 gallons (1893 L) in capacity.

❖ Inside storage restrictions, including pile height, container arrangement and aisle width, are intended to reduce the potential involvement of multiple piles, reduce the exposure hazard to occupants and facilitate fire department access to the storage areas. Inside storage of pyrophoric liquids in tanks or containers is limited to an individual capacity of 500 gallons (1893 L) to reduce the exposure hazard in the event of a single container failure. Prohibiting the stacking of individual containers reduces the likelihood of container failure from stacking stresses. Wide aisles reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel. While not specifically mentioned in this section, inside storage must also be protected as required by Chapter 50, which includes provisions for incompatible material storage, security, signage, control of ignition sources and submittal of a storage plan.

**6404.1.3 Pyrophoric gases.** Storage of pyrophoric gases shall be in detached buildings where required by Section 5003.8.2.

❖ This section is an important cross reference to Section 5004.14 and Table 5004.14. The table requires that storage of more than 2,000 cubic feet (57 m<sup>3</sup>) of pyrophoric gas must be in a detached building complying with Section 5004.14.

Detached structures designed and constructed for the sole purpose of pyrophoric material storage provide the best protection for people and property from fire and explosion. Detached storage structures should be constructed of noncombustible materials to prevent them from becoming involved in an outside fire that may endanger their contents or a fire stemming from ignited contents in storage (see the commentary to Section 5004.14 and Table 5004.14 for further discussion of detached storage requirements).

**6404.1.4 Separation from incompatible materials.** In addition to the requirements of Section 5003.9.8, indoor storage of pyrophoric materials shall be isolated from incompatible hazardous materials by 1-hour *fire barriers* with openings protected in accordance with the *International Building Code*.

**Exception:** Storage in *approved* hazardous materials storage cabinets constructed in accordance with Section 5003.8.7.

❖ This section is intended to separate all incompatible, flammable, explosive or other highly reactive materials from the inside storage areas of pyrophoric materials. A 1-hour fire barrier assembly or, as allowed by the exception, an approved hazardous materials storage cabinet can reduce the potential involvement of pyrophoric materials in a fire involving other incompatible hazardous materials. Note that the provisions of Section 6404.1.4 are to be applied in addition to the requirements of Section 5003.9.8.

**6404.2 Outdoor storage.** Outdoor storage of pyrophoric materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003 and 5004, and this chapter.

The storage of silane gas, and gas mixtures with a silane concentration of 1.37 percent or more by volume, shall be in accordance with CGA G-13.

❖ Sections 6404.2.1 and 6404.2.2 are applicable for the outdoor storage of pyrophoric materials in excess of the MAQ listed in Table 5003.1.1(3). The provisions of this section, in addition to the provisions of Sections 5001, 5003 and 5004, are applicable to outdoor areas used for the storage of pyrophoric materials because of the severity of the hazards posed by these materials. Regardless of quantity, silane gas and certain silane gas mixtures must also comply with the provisions of CGA G-13. See the commentary introduction to this chapter for a detailed discussion of silane.

**6404.2.1 Distance from storage to exposures.** The separation of pyrophoric solids, liquids and gases from buildings, *lot lines*, public streets, public alleys, *public ways* or *means of egress* shall be in accordance with the following:

1. Solids and liquids. Two times the separation required by Chapter 57 for Class IB flammable liquids.

2. Gases. The location and maximum amount of pyrophoric gas per storage area shall be in accordance with Table 6404.2.1.

- ❖ To minimize radiant heat transfer and fire spread between stored pyrophoric solid and liquid materials and the listed exposures, the values shown for Class IB flammable liquids in Table 5704.4.2 are applied and then doubled. Similarly, Table 6404.2.1 is referenced for the outdoor storage of pyrophoric gases.

**TABLE 6404.2.1.** See below.

- ❖ Table 6404.2.1 establishes the spatial separation distance (or alternative safeguards) required for the outside storage of pyrophoric compressed gases when in excess of the outside storage MAQ shown in Table 5003.1.1(3).

The required separation distance is intended to minimize radiant heat transfer between storage and exposures. Separation distances provide a measure of protection against the possibility of fire spread in the event of a fire involving either the stored material or another exposure, such as a building on the same or an adjacent lot or a vehicle in the public right-of-way. Section 414.6 of the *International Building Code*® (IBC)® contains additional protection requirements for outside storage in areas that have an overhead roof structure or canopy to protect the materials from the weather.

Note a recognizes that a 2-hour fire barrier wall (constructed in accordance with IBC Section 707), provides an equivalent means of achieving the objectives of spatial separation. Where a separation assembly is used instead of the tabular separation distance, the wall must be arranged to prevent a hazardous accumulation of gas.

**6404.2.2 Weather protection.** Where overhead construction is provided for sheltering outdoor storage areas of pyrophoric materials, the storage areas shall be provided with *approved* automatic fire-extinguishing system protection.

- ❖ The general requirements for construction of weather protection roofs over outdoor storage areas are contained in Section 5004.13 of the code and IBC Section 414.6; however, due to the hazards of pyrophoric

materials, this section is a specific provision applicable to pyrophoric materials that requires roofed-over outdoor storage areas to be sprinklered.

**SECTION 6405  
USE**

**6405.1 General.** The use of pyrophoric materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5005 and this chapter.

- ❖ This section applies to all indoor and outdoor dispensing, use and handling of pyrophoric material when the amounts being dispensed, used or handled are in excess of the MAQs per indoor or outdoor control area as indicated in Table 5003.1.1(1) or 5003.1.1(3), respectively. The administrative, general use, handling and dispensing provisions of Chapter 50 are applicable, in addition to the requirements of this chapter.

Once the MAQ of pyrophoric material has been exceeded, indoor areas where materials are being dispensed, used or handled must be located in a building or portion of a building complying with the IBC for a Group H occupancy because of the increased hazards associated with quantity.

Although no occupancy group is assigned to them, outside pyrophoric material use areas require an increased level of regulation when quantities exceed the MAQs per outdoor control area listed in Table 5003.1.1(3). Corresponding MAQs recognize that an open-use condition is generally more hazardous than a closed-use condition because the pyrophoric material is more directly exposed to the surrounding environment and can become more readily involved in an incident than if it is totally confined. The maximum allowable quantities per control area for use are based on the aggregate quantity in both use and storage not exceeding the maximum allowable quantities per control area listed for storage.

**6405.2 Weather protection.** Where overhead construction is provided for sheltering of outdoor use areas of pyrophoric

**TABLE 6404.2.1  
PYROPHORIC GASES—DISTANCE FROM STORAGE TO EXPOSURES<sup>a</sup>**

MAXIMUM AMOUNT PER STORAGE AREA (cubic feet)	MINIMUM DISTANCE BETWEEN STORAGE AREAS (feet)	MINIMUM DISTANCE TO LOT LINES OF PROPERTY THAT CAN BE BUILT UPON (feet)	MINIMUM DISTANCE TO PUBLIC STREETS, PUBLIC ALLEYS OR PUBLIC WAYS (feet)	MINIMUM DISTANCE TO BUILDINGS ON THE SAME PROPERTY		
				Nonrated construction or openings within 25 feet	Two-hour construction and no openings within 25 feet	Four-hour construction and no openings within 25 feet
250	5	25	5	5	0	0
2,500	10	50	10	10	5	0
7,500	20	100	20	20	10	0

For SI: 1 foot = 304.8 mm, 1 cubic foot = 0.02832 m<sup>3</sup>.

- a. The minimum required distances shall be reduced to 5 feet when protective structures having a minimum fire resistance of 2 hours interrupt the line of sight between the container and the exposure. The protective structure shall be at least 5 feet from the exposure. The configuration of the protective structure shall allow natural ventilation to prevent the accumulation of hazardous gas concentrations.

## PYROPHORIC MATERIALS

materials, the use areas shall be provided with *approved* automatic fire-extinguishing system protection.

❖ The general requirements for the construction of weather protection roofs over outdoor use areas are contained in Section 5005.3.9 of the code and IBC Section 414.6; however, due to the hazards of pyrophoric materials, this section is a specific provision applicable to pyrophoric materials that requires roofed-over outdoor use areas to be sprinklered.

**6405.3 Silane gas.** The use of silane gas, and gas mixtures with a silane concentration of 1.37 percent or more by volume, shall be in accordance with CGA G-13.

❖ Regardless of quantity, the use of silane gas and certain silane gas mixtures must comply with the provisions of CGA G-13. See the commentary introduction to this chapter for a discussion of silane.

### Bibliography

The following resource material was used in the preparation of the commentary for this chapter of the code:

*Fire Protection Guide to Hazardous Materials*, 13th ed.  
Quincy, MA: National Fire Protection Association,  
2001.

# Chapter 65: Pyroxylin (Cellulose Nitrate) Plastics

## General Comments

Pyroxylin (cellulose nitrate) plastic is formulated from a combination of cellulose, nitric acid and sulfuric acid. The resulting compound, also known as pyroxylin or nitrocellulose, is an unstable and extremely combustible plastic. Once exposed to elevated temperatures, pyroxylin (cellulose nitrate) plastic is subject to spontaneous ignition. The products of combustion of pyroxylin (cellulose nitrate) plastic are extremely toxic because nitrogen oxides are produced at the elevated temperatures reached when this material burns rapidly.

Pyroxylin (cellulose nitrate) plastic, also called “gun cotton,” was discovered to be a powerful explosive and replaced common gunpowder as the explosive charge in the ammunition for rifles and artillery in World War I. Other early uses included being a replacement material for elephant tusk ivory in billiard balls (which had a tendency to explode on a hard break), as casino dice and as the laminating adhesive in early forms of automotive safety glass. It has also been used as a film base for photographic film, as well as to encase documents, book leaves, etc.; however, its flammability and the fact that it causes severe deterioration of the materials it supposedly protects has prevented its widespread use in preservation work.

Many of these products are no longer manufactured from pyroxylin (cellulose nitrate) plastic. Although it has been replaced in many applications by safer plastics, it is still used in many industrial applications such as shoe heels, housewares and lacquers.

Raw pyroxylin (cellulose nitrate) plastic is usually shipped in drums and covered with water or another solvent, usually alcohol.

Water-wet pyroxylin plastic presents the least hazard, while alcohol-wet and other types of solvent-wet pyroxy-

lin plastic possess hazards similar to those of the solvent involved. Because nitrocellulose becomes increasingly unstable as temperatures increase and may ignite easily from frictional heat, drums must never be pushed, rolled or dragged across the floor. Pyroxylin (cellulose nitrate) plastic is especially susceptible to ignition, burns vigorously once ignited (at a rate approximately 15 times that of a comparable mass of paper), produces toxic nitrogen oxides and will burn in the absence of oxygen.

## Purpose

This chapter addresses the significant hazards associated with pyroxylin (cellulose nitrate) plastics, which are the most dangerous and unstable of all plastic compounds. The chemically bound oxygen in their structure permits them to burn vigorously in the absence of atmospheric oxygen. Although these compounds produce approximately the same amount of energy when they burn as paper, pyroxylin (cellulose nitrate) plastics burn at a rate 15 times greater than comparable common combustibles. When burning, these materials release highly flammable and toxic combustion byproducts. Consequently, pyroxylin (cellulose nitrate) plastic fires are very difficult to control and must be virtually flooded to extinguish them. Even storage cabinets, which may be used only for temporary (e.g., overnight) storage of pyroxylin (cellulose nitrate) plastic films, must be sprinklered. Strict compliance with the provisions of this chapter, along with proper housekeeping and storage arrangements, help to reduce the hazards associated with pyroxylin (cellulose nitrate) plastics in a fire or other emergencies.

---

## SECTION 6501 GENERAL

**6501.1 Scope.** This chapter shall apply to the storage and handling of plastic substances, materials or compounds with cellulose nitrate as a base, by whatever name known, in the form of blocks, sheets, tubes or fabricated shapes.

Cellulose nitrate motion picture film shall comply with the requirements of Section 306.

❖ This section establishes that any raw materials or finished products containing any amount of pyroxylin

(cellulose nitrate) plastic are subject to the regulations of this chapter. This is true even if the materials are called something other than pyroxylin (cellulose nitrate) plastic, such as xyloidin, collodion, photocotton, pyrocollodion, guncotton or smokeless powder. Compliance with the applicable provisions of Section 407 and Chapter 50, which include, but are not limited to, Material Safety Data Sheets (MSDS) submittal, hazard identification signs and labeling provisions, is also required. Pyroxylin (cellulose nitrate) plastic in the form of motion picture film is regulated by Section 306, as noted in this section.

**6501.2 Permits.** Permits shall be required as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit; Section 105.6.39 for discussion of specific operational permits for the storage, handling or use of pyroxylin plastics; and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

## SECTION 6502 DEFINITIONS

**6502.1 Terms defined in Chapter 2.** Words and terms used in this chapter and defined in Chapter 2 shall have the meanings ascribed to them as defined therein.

- ❖ This section directs the code user to Chapter 2 of the code for the proper application of the terms used in this chapter. These terms may be defined in Chapter 2 of the code or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or may retain their ordinary (dictionary) meaning (see also commentary, Sections 201.1 through 201.4).

## SECTION 6503 GENERAL REQUIREMENTS

**6503.1 Displays.** Cellulose nitrate (pyroxylin) plastic articles are allowed to be placed on tables not more than 3 feet (914 mm) wide and 10 feet (3048 mm) long. Tables shall be spaced at least 3 feet (914 mm) apart. Where articles are displayed on counters, they shall be arranged in a like manner.

- ❖ Because of pyroxylin (cellulose nitrate) plastic's hazardous instability and easily ignitable composition, its exposure to the ambient environment in public venues must be strictly controlled to minimize the amount of material exposed to potential ignition sources and the number of persons exposed to its hazards, should it be ignited. This section places strict limits on the size of an individual display surface and requires that multiple display surfaces be separated from one another by minimum 3-foot (914 mm) aisles to not only limit the number of tables involved in a single incident but also to provide free egress circulation in the event of an emergency.

**6503.2 Space under tables.** Spaces underneath tables shall be kept free from storage of any kind and accumulation of paper, refuse and other combustible material.

- ❖ The importance of good housekeeping in reducing the exposure of pyroxylin (cellulose nitrate) plastic display objects to fire exposure cannot be overstated.

Prohibiting the storage or accumulation of any combustible material beneath tables on which pyroxylin (cellulose nitrate) plastic display objects are arrayed will reduce the display's exposure to fire in the event such stored materials were to be ignited.

**6503.3 Location.** Sales or display tables shall be so located that in the event of a fire at the table, the table will not interfere with free *means of egress* from the room in not less than one direction.

- ❖ Display tables placed in corridors or aisles may unduly expose egressing persons to rapidly burning pyroxylin (cellulose nitrate) plastic objects, reduce required egress capacity or require substantial effort to remove the tables or negotiate the reduced egress path quickly. Anything that slows egress may also impede access, particularly to fire fighters who may be called to rescue occupants or fight the fire.

**6503.4 Lighting.** Lighting shall not be located directly above cellulose nitrate (pyroxylin) plastic material, unless provided with a suitable guard to prevent heated particles from falling.

- ❖ Because it is pyroxylin (cellulose nitrate) plastic's nature to rapidly deteriorate and ignite when exposed to heat, the hazard posed by light fixtures located over display tables must be reduced in an approved manner. Ideally, the display tables should be located where hot particles from a broken light bulb cannot fall on the pyroxylin (cellulose nitrate) plastic materials. When that is not possible, fixtures must be enclosed to prevent debris from a broken bulb from falling out of the fixture.

## SECTION 6504 STORAGE AND HANDLING

**6504.1 Raw material.** Raw cellulose nitrate (pyroxylin) plastic material in a Group F building shall be stored and handled in accordance with Sections 6504.1.1 through 6504.1.7.

- ❖ Raw pyroxylin (cellulose nitrate) plastic materials present increased hazards when they are involved in manufacturing processes. To reduce those increased hazards, the provisions of Sections 6504.1.1 through 6504.1.7 are applicable to buildings used for the fabrication of items containing pyroxylin (cellulose nitrate) plastic.

**6504.1.1 Storage of incoming material.** Where raw material in excess of 25 pounds (11 kg) is received in a building or *fire area*, an *approved* vented cabinet or *approved* vented vault equipped with an *approved automatic sprinkler system* shall be provided for the storage of material.

- ❖ The amount of heat liberated by pyroxylin (cellulose nitrate) plastic when burning and the speed with which it burns make conventional extinguishment virtually impossible. This, coupled with the poisonous combustion gases, produce conditions that require material confinement and rapid fire suppression. This section requires that quantities of pyroxylin (cellulose nitrate) plastic in excess of 25 pounds (11 kg) be con-

finished to an approved storage cabinet complying with Section 5003.8.7 or an approved vault constructed in accordance with the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>). While typical pyroxylin (cellulose nitrate) plastic storage cabinets are limited to a 30-cubic-foot (0.8 m<sup>3</sup>) volume, typical pyroxylin (cellulose nitrate) plastic vault construction has a fire-resistance rating of 4 hours because of the violent nature of the stored material. Cabinets and vaults must be vented to the outdoors to relieve the pressure buildup resulting from the rapid decomposition of the stored material and equipped with automatic sprinklers designed in accordance with Section 903.3.1.1.

**6504.1.2 Capacity limitations.** Cabinets in any one workroom shall not contain more than 1,000 pounds (454 kg) of raw material. Each cabinet shall not contain more than 500 pounds (227 kg). Each compartment shall not contain more than 250 pounds (114 kg).

❖ To provide a reasonable quantity of material to work with in the manufacturing process while minimizing the quantity of pyroxylin (cellulose nitrate) plastic exposed to a single fire, this section limits the aggregate and per-cabinet and cabinet compartment quantities.

**6504.1.3 Storage of additional material.** Raw material in excess of that allowed by Section 6504.1.2 shall be kept in vented vaults not exceeding 1,500-cubic-foot capacity (43 m<sup>3</sup>) of total vault space, and with *approved* construction, venting and sprinkler protection.

❖ Quantities of pyroxylin (cellulose nitrate) plastic in excess of the 1,000 pounds (454 kg) allowed by Section 6504.1.2 to be readily accessible in cabinets in work spaces must be stored in approved sprinklered and vented vaults no larger than 1,500 cubic feet each in volume [approximately 10 feet by 15 feet by 10 feet (3048 mm by 4572 mm by 3048 mm) high] to limit the amount of material involved in a fire.

**6504.1.4 Heat sources.** Cellulose nitrate (pyroxylin) plastic shall not be stored within 2 feet (610 mm) of heat-producing appliances, steam pipes, radiators or chimneys.

❖ Because pyroxylin (cellulose nitrate) plastic rapidly decomposes and will spontaneously burst into flame when in contact with heated objects in the presence of sufficient oxygen, it is extremely important to reduce the hazard by keeping stored materials well away from the common sources of heat noted in this section. Storing pyroxylin (cellulose nitrate) plastic in an unheated room would be an ideal strategy for this hazard.

**6504.1.5 Accumulation of material.** In factories manufacturing articles of cellulose nitrate (pyroxylin) plastics, *approved* sprinklered and vented cabinets, vaults or storage rooms shall be provided to prevent the accumulation in workrooms of raw stock in process or finished articles.

❖ This section reinforces the provisions of Sections 6504.1.1, 6504.1.2 and 6504.1.3 and intends to limit the amount of raw pyroxylin (cellulose nitrate) plastic

stock or finished product exposed to the hazards of manufacturing operations by mandating that all pyroxylin (cellulose nitrate) plastic materials, whether raw stock or finished product, be stored in sprinklered, vented vaults or cabinets.

**6504.1.6 Operators.** In workrooms of cellulose nitrate (pyroxylin) plastic factories, operators shall not be stationed closer together than 3 feet (914 mm), and the amount of material per operator shall not exceed one shift's supply and shall be limited to the capacity of three tote boxes, including material awaiting removal or use.

❖ To isolate the manufacturing hazard of labor (i.e., the hazards involved in the manipulation of materials in the manufacturing, packing or shipping of finished products), as well as the in-process quantity of pyroxylin (cellulose nitrate) plastic (either raw or finished product), this section requires that workstations in the factory have a clearance from one another of no less than 3 feet (914 mm). Depending on the specific articles being manufactured, the quantity of pyroxylin raw material or finished product allowed at any workstation may vary but cannot exceed the amount needed for a single work shift or three tote boxes, whichever is the greater amount. The term "tote box," although not defined in the code, describes portable containers used to transport raw pyroxylin (cellulose nitrate) plastic or finished pyroxylin (cellulose nitrate) plastic products between a central storage vault and a workstation.

**6504.1.7 Waste material.** Waste cellulose nitrate (pyroxylin) plastic materials such as shavings, chips, turnings, sawdust, edgings and trimmings shall be kept under water in metal receptacles until removed from the premises.

❖ The manufacturing process may involve shaving, scraping, sanding or cutting of pyroxylin (cellulose nitrate) plastic, all of which produce finely divided scrap material that presents much more surface area susceptible to the hazards of ignition than the larger, more dense work pieces from which they came. To reduce the measurable increase in the hazard, this section requires extraordinary collection and storage safeguards for such scrap material in water-filled metal containers. These containers should be removed from the work area at the end of each shift for disposal.

**6504.2 Fire protection.** The manufacture or storage of articles of cellulose nitrate (pyroxylin) plastic in quantities exceeding 100 pounds (45 kg) shall be located in a building or portion thereof equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ Because pyroxylin (cellulose nitrate) plastics pose unusual and substantial fire risks, burn at a rate 15 times greater than comparable common combustibles and, when burning, release highly flammable and toxic combustion byproducts, fires involving these materials are very difficult to control. This section mirrors the provisions of Section 1103.5.1 and

## PYROXYLIN (CELLULOSE NITRATE) PLASTICS

specifies a sprinkler threshold quantity of 100 pounds (45 kg); however, the need for additional fire protection should be considered for pyroxylin (cellulose nitrate) plastics in any amount.

**6504.3 Sources of ignition.** Sources of ignition shall not be located in rooms in which cellulose nitrate (pyroxylin) plastic in excess of 25 pounds (11 kg) is handled or stored.

❖ Consistent with the hazards presented by pyroxylin (cellulose nitrate) plastic, this section prohibits the presence of recognized ignition sources in storage and manufacturing areas where more than 25 pounds (11 kg) of material are present to minimize the amount of material exposed.

**6504.4 Heating.** Rooms in which cellulose nitrate (pyroxylin) plastic is handled or stored shall be heated by low-pressure steam or hot water radiators.

❖ This section reinforces the provisions of Sections 6504.1.4 and 6504.3 by mandating indirect heat only by either low-pressure steam or hot water in rooms where pyroxylin (cellulose nitrate) plastic is stored or processed. In this way, the hazards of open-flame, fuel-fired heat sources do not exist and cannot expose the pyroxylin (cellulose nitrate) plastic to ignition.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 66: Unstable (Reactive) Materials

## General Comments

This chapter regulates the storage of unstable (reactive) materials. Unstable (reactive) materials may react spontaneously with themselves, other chemicals or when exposed to light, heat, cold, moisture, air or physical shock. These materials may burn, explode, polymerize or decompose to form toxic materials. Unstable (reactive) materials are used in a variety of industrial applications, including food processing and the manufacture of plastics, textiles, fireworks, explosives, rocket propellants, special fuel systems and dyes. These hazardous materials may also be found in the preparation of certain medicines or fumigants. They pose unusual and substantial risks to the general public, fire fighters and emergency response personnel under a variety of conditions.

Advance knowledge of the materials being stored in structures through the permit process and the submittal of Material Safety Data Sheets (MSDS), in accordance with Section 407, is essential for adequate control of the hazard and for prefire planning by the fire department. This is especially important for unstable (reactive) liquid and solid materials because of their unpredictable and violent nature.

During a mishap, a variety of hazards can be created by these materials, including explosions, violent decomposition, toxic products of combustion, toxic vapors, corrosion injuries, poisoning or violent polymerization.

Spills or leaks of unstable materials may be handled by absorbing them with inert materials and then removal

or, in cases of larger spills, flushing with large volumes of water if no additional hazard will be created.

Fires in structures or vehicles storing or carrying unstable chemicals should be approached with extreme caution to avoid injury from an explosion, such as a tank boiling liquid expanding vapor explosion (BLEVE). Unless and until specific and reliable information on the stored materials is available to fire command personnel, the scene should be treated as though the incident involves explosives, and personnel and apparatus should be kept well away.

## Purpose

This chapter addresses the hazards of unstable (reactive) liquid and solid materials, as well as unstable (reactive) compressed gas materials. In addition to their unstable reactivity, these materials may pose other hazards, such as toxicity, corrosivity, explosivity, flammability or oxidizing potential. This chapter, however, is intended to address those materials whose primary hazard is unstable reactivity. Materials that pose multiple hazards must conform to the requirements of the code with respect to all hazards (see commentary, Section 5001.1). Strict compliance with the provisions of this chapter, along with proper housekeeping and storage arrangements, help to reduce the exposure hazards associated with unstable (reactive) materials in a fire or other emergency.

---

## SECTION 6601 GENERAL

**6601.1 Scope.** The storage and use of unstable (reactive) materials shall be in accordance with this chapter. *Compressed gases* shall also comply with Chapter 53.

### Exceptions:

1. Display and storage in Group M and storage in Group S occupancies complying with Section 5003.11.
  2. Detonable unstable (reactive) materials shall be stored in accordance with Chapter 56.
- ❖ This chapter details specific requirements for the storage of unstable (reactive) materials. The requirements of this chapter are intended to complement the hazardous materials general storage requirements of

Chapter 50. Hazardous gases are also regulated by Chapter 53. The chemicals classified as unstable (reactive) are based on the definition in Section 6602.1, which is derived from NFPA 704.

Exception 1 makes it clear that this chapter does not apply to unstable (reactive) materials stored and displayed in Group M occupancies or stored in Group S occupancies; Section 5003.11 covers those occupancy groups. Also in that section, Class 4 unstable (reactive) materials are prohibited in Group M (mercantile) occupancies because of their detonable hazard potential. Quantities of all other classes are limited on a per-control area basis to limit exposure to people and property (see commentary, Section 5003.11). This exception would permit an increase above the maximum allowable quantity per control area (MAQ) indicated in Table 5003.1.1(1) for unsta-

## UNSTABLE (REACTIVE) MATERIALS

ble (reactive) materials while still maintaining a mercantile or storage occupancy group classification.

Exception 2 recognizes the violent, explosive nature of detonable unstable (reactive) materials and directs that they be stored in accordance with the requirements for explosives and blasting agents in Chapter 56 to provide the safeguards commensurate with their hazards.

**6601.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit; Section 105.6.21 for discussion of specific quantity-based operational permits for the materials regulated in this chapter; and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

### SECTION 6602 DEFINITION

**6602.1 Definition.** The following term is defined in Chapter 2:

#### UNSTABLE (REACTIVE) MATERIAL.

- Class 4.
- Class 3.
- Class 2.
- Class 1.

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated term used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

### SECTION 6603 GENERAL REQUIREMENTS

**6603.1 Quantities not exceeding the maximum allowable quantity per control area.** Quantities of unstable (reactive) materials not exceeding the *maximum allowable quantity per control area* shall be in accordance with Sections 6603.1.1 through 6603.1.2.5.

❖ The regulations contained in Sections 6603.1.1 through 6603.1.2.5 assume that the quantity of unstable (reactive) materials in a given building is limited to the MAQs as established in Section 5003.1; thus, the building is not classified in Occupancy Group H.

**6603.1.1 General.** The storage and use of unstable (reactive) materials in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003, 6601 and 6603.

❖ This section complements the requirements of Chapter 50 in structures occupied for the storage, handling or use of unstable (reactive) materials. Unless otherwise indicated in a particular section, the regulations contained in Sections 6603.1.2 through 6603.1.2.5 assume that the quantity of unstable (reactive) materials in a given building is limited to the MAQs as established in Section 5003.1. The general requirements of Sections 5001 and 5003 are fully applicable to the storage and use of unstable (reactive) materials, in addition to the provisions of this chapter.

**6603.1.2 Limitations for indoor storage and use by occupancy.** The indoor storage of unstable (reactive) materials shall be in accordance with Sections 6603.1.2.1 through 6603.1.2.5.

❖ Because unstable (reactive) materials may be needed in certain occupancies, Sections 6603.1.2.1 through 6603.1.2.5 provide regulations that are specific to occupancy group classifications and that recognize the relative hazards of both the occupancy and the unstable (reactive) materials.

**6603.1.2.1 Group A, E, I or U occupancies.** In Group A, E, I or U occupancies, any amount of Class 3 and 4 unstable (reactive) materials shall be stored in accordance with the following:

1. Class 3 and 4 unstable (reactive) materials shall be stored in hazardous material storage cabinets complying with Section 5003.8.7.
2. The hazardous material storage cabinets shall not contain other storage.

❖ Because of their explosive or higher deflagration hazard characteristics, even the smallest quantity of Class 3 and 4 unstable (reactive) materials present in Group A, E, I or U occupancies must be stored in an approved hazardous material storage cabinet constructed and placarded in accordance with Section 5003.8.6 to reduce the exposure of the materials to hazards from the surrounding environment.

In accordance with Table 5003.1.1(1), Note g, storage of Class 4 unstable (reactive) materials in any amount is allowed only in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Also, based on Table 5003.1.1(1), Note e, where an approved storage cabinet is used, the MAQ of unstable (reactive) materials that could be kept in those occupancies can be doubled.

To reduce the likelihood of contamination of the organic peroxide materials or damage to their packaging, Item 2 prohibits the storage of other materials in the approved unstable (reactive) materials storage cabinet.

**6603.1.2.2 Group R occupancies.** Class 3 and 4 unstable (reactive) materials shall not be stored or used within Group R occupancies.

❖ Because of their respective explosive or higher deflagration hazard characteristics, Class 3 and 4 unstable (reactive) materials storage in any residential occupancy within the scope of the code's regulations is prohibited because of the increased danger to the occupants and the otherwise unregulated environment to which those materials could be exposed.

**6603.1.2.3 Group M occupancies.** Class 4 unstable (reactive) materials shall not be stored or used in retail sales portions of Group M occupancies.

❖ Because of their explosive hazard characteristics, Class 4 unstable (reactive) materials storage in occupancies in Group M is prohibited because of the increased danger to the occupants and the higher relative fire loads typically encountered in these occupancies to which the materials could be exposed.

**6603.1.2.4 Offices.** Class 3 and 4 unstable (reactive) materials shall not be stored or used in offices of Group B, F, M or S occupancies.

❖ Because of their explosive hazard characteristics, Class 3 and 4 unstable (reactive) materials storage in office areas of occupancies in Group B, F, M or S is prohibited because of the increased danger to the occupants and the higher relative fire loads typically encountered in these occupancies.

**6603.1.2.5 Classrooms.** In classrooms in Group B, F or M occupancies, any amount of Class 3 and 4 unstable (reactive) materials shall be stored in accordance with the following:

1. Class 3 and 4 unstable (reactive) materials shall be stored in hazardous material storage cabinets complying with Section 5003.8.7.
2. The hazardous material storage cabinets shall not contain other storage.

❖ This section is intended to allow for the occasional use of limited amounts of Class 3 and 4 unstable (reactive) materials in certain scientific, experimental or demonstration settings; however, it is not the intent to allow storage of any quantity of these materials for any length of time. The fire code official may limit the amount of unstable (reactive) materials brought into a structure for these uses. The quantity actually needed for the experiment or demonstration should determine the amount allowed into a structure.

Because of its respective explosive or higher deflagration hazard characteristics, even the smallest quantity of Class 3 or 4 unstable (reactive) materials must be stored in an approved hazardous material storage cabinet constructed and placarded in accordance with Section 5003.8.6 to reduce the exposure of the materials to hazards from the surrounding environment.

In accordance with Table 5003.1.1(1), Note g, stor-

age of Class 4 unstable (reactive) materials in any amount is allowed only in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Also, based on Table 5003.1.1(1), Note e, where an approved storage cabinet is used, the MAQ that could be kept in such occupancies can be doubled. To reduce the likelihood of contamination of the unstable (reactive) materials or damage to their packaging, Item 2 prohibits the storage of other materials in the approved unstable (reactive) material storage cabinet.

**6603.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of unstable (reactive) materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

❖ This section complements the requirements of Chapter 50 in structures occupied for the storage, handling or use of unstable (reactive) materials. The regulations contained in this section assume that the quantity of unstable (reactive) material in a given building or portion of a building is in excess of the MAQs as established in Section 5003.1; thus, the building or portion of the building is classified in Occupancy Group H. The requirements of Chapter 50 apply to the storage and use of unstable (reactive) material, in addition to the provisions of this chapter.

## SECTION 6604 STORAGE

**6604.1 Indoor storage.** Indoor storage of unstable (reactive) materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

In addition, Class 3 and 4 unstable (reactive) detonable materials shall be stored in accordance with the *International Building Code* requirements for *explosives*.

❖ This section regulates the indoor storage of unstable (reactive) materials when in excess of the MAQ in buildings or portions of buildings classified in Occupancy Group H. The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of unstable (reactive) materials inside structures must comply with Sections 6604.1.1 through 6604.1.5 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

Because of the explosion hazard, Class 3 and 4 detonable unstable (reactive) materials must be stored as required by this section, Chapter 56 and the *International Building Code*® (IBC®) requirements for explosives.

## UNSTABLE (REACTIVE) MATERIALS

**6604.1.1 Detached storage.** Storage of unstable (reactive) materials shall be in detached buildings when required in Section 5003.8.2.

❖ Detached structures designed and constructed for the sole purpose of unstable (reactive) materials storage are the best protection for people and property from fire and explosion. Detached storage structures should be constructed of noncombustible materials to prevent them from becoming involved in either an outside fire that may endanger their contents or an indoor fire due to the structure's contents igniting.

Section 5003.8.2 and Table 5003.8.2 require detached storage when the indoor storage quantities are more than 1 ton (908 kg) of Class 3 unstable (reactive) solid or liquid materials, more than 25 tons (22 700 kg) of Class 2 unstable (reactive) solid or liquid material, more than 2,000 cubic feet (57 m<sup>3</sup>) of Class 3 gaseous unstable (reactive) material or more than 10,000 cubic feet (283 m<sup>3</sup>) of Class 2 unstable (reactive) gaseous material. See the commentaries to Section 5003.8.2 and Table 5003.8.2 for further discussion of detached storage requirements.

**6604.1.2 Explosion control.** Indoor storage rooms, areas and buildings containing Class 3 or 4 unstable (reactive) materials shall be provided with explosion control in accordance with Section 911.

❖ Because of the possibility of a deflagration or detonation in the event of ignition of Class 3 or 4 unstable (reactive) materials, explosion relief venting must be installed to protect the storage building or structure from collapse. Explosion venting must conform to the requirements of Section 911.

**6604.1.3 Liquid-tight floor.** In addition to Section 5004.12, floors of storage areas for liquids and solids shall be of liquid-tight construction.

❖ Floors and sills of rooms or areas used to contain hazardous material spills must be liquid tight to prevent the flow of liquids to adjoining areas (see commentary, Section 5004.2). The floor surface should be compatible with the unstable (reactive) materials to be retained and must be noncombustible, as required by Section 5004.12.

**6604.1.4 Storage configuration.** Unstable (reactive) materials stored in quantities greater than 500 cubic feet (14 m<sup>3</sup>) shall be separated into piles, each not larger than 500 cubic feet (14 m<sup>3</sup>). Aisle width shall not be less than the height of the piles or 4 feet (1219 mm), whichever is greater.

**Exception:** Materials stored in tanks.

❖ These provisions detail storage requirements related to the hazards of release or ignition of unstable (reactive) materials stored in structures and are intended to reduce the amount of material exposed in a single incident by managing pile sizes and their separation. Aisle widths that are equal to the pile height or are 4 feet (3048 mm), whichever is greater, reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of

a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel.

Although not specifically mentioned in this section, inside storage must also be protected in accordance with Chapter 50, which includes provisions for incompatible material storage, security, signage, control of ignition sources and submittal of a storage plan.

**6604.1.5 Location in building.** Unstable (reactive) materials shall not be stored in *basements*.

❖ Storage of unstable (reactive) material below the ground floor is prohibited to facilitate fire-fighter access and also because of the inherent difficulty associated with manual fire suppression operations in below-grade areas.

**6604.2 Outdoor storage.** Outdoor storage of unstable (reactive) materials in amounts exceeding the *maximum allowable quantities per control area* indicated in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

❖ This section regulates the outdoor storage of unstable (reactive) materials when in excess of the MAQ established by Table 5003.1.1(3). The general and storage provisions of Chapter 50 are applicable in addition to the requirements of this section. Storage of unstable (reactive) materials in outdoor control areas must comply with Sections 6604.2.1 and 6604.2.2 to prevent uncontrolled release or exposure to conditions that could result in a fire or explosion.

**6604.2.1 Distance from storage to exposures Class 4 and 3 (detonable) materials.** Outdoor storage of Class 4 or 3 (detonable) unstable (reactive) material shall be in accordance with Table 5604.5.2(2). The number of pounds of material listed in the table shall be the net weight of the material present. Alternatively, the number of pounds of material shall be based on a trinitrotoluene (TNT) equivalent weight.

❖ The distance requirements are divided into three subsections to address the different natures of unstable (reactive) materials. As previously drafted, suitable locations for Class 4 and 3 (detonable) unstable reactive materials had not been addressed. The tabular distances listed in Table 5604.5.2(2) provided by the Institute of Makers of Explosives have been developed based on pounds of trinitrotoluene (TNT) or a TNT weight. A TNT equivalent weight is comparable to the net explosive weight as used by the table (also see the commentary to the definition of “Net explosive weight” in Section 202).

**6604.2.2 Distance from storage to exposures Class 3 (deflagratable) materials.** Outdoor storage of deflagratable Class 3 unstable (reactive) materials shall be in accordance with Table 5604.5.2(3). The number of pounds of material listed shall be the net weight of the material present.

❖ This section addresses Class 3 (deflagrating) unstable (reactive) materials and relies on Table 5604.5.2(3) for the quantity-distance regulations. Note that the use of TNT equivalent weights are not

applied but, rather, the net weight of stored material is used.

**6604.2.3 Distance from storage to exposures Class 2 and 1 materials.** Outdoor storage of Class 2 or 1 unstable (reactive) materials shall not be located within 20 feet (6096 mm) of buildings not associated with the manufacture or distribution of such materials, *lot lines*, public streets, public alleys, *public ways* or *means of egress*. The minimum required distance shall not apply when *fire barriers* without openings or penetrations having a minimum fire-resistance rating of 2 hours interrupt the line of sight between the storage and the exposure. The *fire barrier* shall either be an independent structure or the exterior wall of the building adjacent to the storage area.

❖ This section addresses Class 2 unstable (reactive) materials. The provisions of this section from the previous edition have been retained with a modification that exempts buildings associated with the manufacture or distribution of Class 2 and 1 materials. The exemption is similar to that provided for the manufacture and distribution of toxic or highly toxic compressed gases found in Section 6004.3.2.1.2 or for oxidizing gases found in Table 6304.2.2. The exemption has been broadened to include solids, liquids and gases based on the fact that manufacturing buildings processing these materials typically stage or store materials inside and immediately outside of the building where processing is conducted, while materials that have explosive effects are (or should be) located at distances comparable to those used for explosive materials. Line of sight protection is used in lieu of a 30-inch (762 mm) requirement for the protection from radiant flux.

**6604.2.4 Storage configuration.** Piles of unstable (reactive) materials shall not exceed 1,000 cubic feet (28 m<sup>3</sup>).

❖ The size of storage piles of unstable (reactive) materials is regulated by this section based on the hazards of the unstable (reactive) materials being stored. To limit the amount of material involved in a single fire, unstable (reactive) materials are limited to piles no larger than 10 feet by 10 feet by 10 feet (3048 mm by 3048 mm) high.

**6604.2.5 Aisle widths.** Aisle widths between piles shall not be less than one-half the height of the pile or 10 feet (3048 mm), whichever is greater.

❖ Minimum 10-foot-wide (3048 mm) aisles provide access to the storage area for emergency personnel and reduce the likelihood of a “domino” effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel should a pile topple over.

## SECTION 6605 USE

**6605.1 General.** The use of unstable (reactive) materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3) shall

be in accordance with Sections 5001, 5003, 5005 and this chapter.

❖ This section applies to all indoor and outdoor dispensing, use and handling of unstable (reactive) materials when the amounts being dispensed, used or handled are in excess of the MAQs per indoor or outdoor control area indicated in Table 5003.1.1(1) or 5003.1.1(3), respectively. The administrative general, use, handling and dispensing provisions of Chapter 50 are applicable, in addition to the requirements of this chapter.

Once the MAQ of unstable (reactive) materials has been exceeded, indoor areas where materials are being dispensed, used or handled must be located in a building or portion of a building complying with the IBC for a Group H occupancy because of the increased hazards associated with quantity. Although no occupancy group is assigned to them, outside unstable (reactive) materials use areas must be regulated more closely when quantities exceed the MAQs per outdoor control area.

The MAQs listed in Table 5003.1.1(1) or 5003.1.1(3) have been divided into closed-use and open-use systems. Corresponding MAQs recognize that an open-use system is generally more hazardous than a closed-use system because the unstable (reactive) materials are more directly exposed to the surrounding environment and can become more readily involved in an incident than if they are totally confined. The MAQs for use are based on the aggregate quantity in both use and storage not exceeding the MAQ listed for storage.

### Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

NFPA 704-12, *Identification of the Fire Hazards of Materials for Emergency Response*. Quincy, MA: National Fire Protection Association, 2011.

*Police and Fire Interest Bulletin No 7, Unstable (Reactive) Chemicals*. New York: American Insurance Association, 1973.

# Chapter 67: Water-Reactive Solids and Liquids

## General Comments

Water-reactive materials are used in a variety of industrial applications for the processing of other materials, such as descaling (salt) baths in the metal processing industry, dehydrating agents in sulfonation processes (the addition of fuming sulfuric acid to a product being treated) and a variety of other complex chemical industrial processes. They also may be found in the manufacture of a variety of consumer products, such as soaps and detergents, rodenticides, fertilizers, silicone rubber and pharmaceutical products.

Advance knowledge of the materials stored in structures through permits and the submittal of Material Safety Data Sheets (MSDS) are essential for effective prefire planning by the fire department. This is especially important in prefire planning for water-reactive materials, because the presence of these materials severely limits the fire department's ability to use water as the primary fire suppression tool.

Water-reactive materials may react to water in a variety of ways, including explosion, violent splattering, production of toxic gases, rapid decomposition with the evolution of large volumes of heat that may ignite nearby combustibles or any combination of these reactions. Alternative fire suppression protocols must be developed well in advance of an incident and the requisite alternative suppression medium obtained, rather than having to go searching for it at the time of an emergency. Depending on the specific water-reactive material involved in an incident, the alternative extinguishing media could include dry graphite, soda ash, sodium chloride, dry sand or specialized dry powder agents,

such as Lith-X or Met-L-X, both manufactured by the Ansul Fire Protection Company.

If a manageable spill occurs without a fire, the material can be confined by a dam of dry sand and then covered with an absorbent material, such as vermiculite, dolomite or more dry sand. Once absorbed, the material must be moved outside with care for disposal. Water-reactive materials that are spilled outdoors are sometimes best handled by allowing them to react and hastening that process by applying water. Large volumes of water are required for this procedure and they must be applied from a safe distance by personnel wearing full protective clothing and breathing apparatus. This method will not only accelerate the reaction, but also disperse and dilute the fumes generated.

## Purpose

This chapter addresses the hazards associated with water-reactive materials that are solid or liquid at normal temperatures and pressures. In addition to their water reactivity, these materials may pose a wide range of other hazards, such as toxicity, flammability, corrosiveness or oxidizing potential. This chapter addresses only those materials whose primary hazard is water reactivity. Materials that pose multiple hazards must conform to the requirements of the code with respect to all hazards (see commentary, Section 5001.1). Strict compliance with the requirements of this chapter, along with proper housekeeping and storage arrangements, helps to reduce the exposure hazards associated with water-reactive materials in a fire or other emergency.

---

## SECTION 6701 GENERAL

**6701.1 Scope.** The storage and use of water-reactive solids and liquids shall be in accordance with this chapter.

### Exceptions:

1. Display and storage in Group M and storage in Group S occupancies complying with Section 5003.11.
  2. Detonable water-reactive solids and liquids shall be stored in accordance with Chapter 56.
- ❖ This chapter contains specific requirements for the storage of water-reactive materials. The requirements of this chapter are intended to complement the

hazardous materials general storage requirements of Chapter 50. Classification of solids and liquids as being water reactive is based on their relative degree of hazard as described in the definition in Section 6502.

Exception 1 makes it clear that this chapter does not apply to water-reactive materials stored and displayed in Group M occupancies or stored in Group S occupancies, and defers to the requirements of Section 5003.11 for those occupancy groups. In that section, quantities are limited on a per-control-area basis to limit exposure to people and property (see commentary, Section 5003.11). This exception would permit an increase above the maximum allowable quantities per control area (MAQ) indicated in Table

5003.1.1(1) for water-reactive materials while still maintaining a mercantile or storage occupancy group classification.

Exception 2 recognizes the violent, explosive nature of detonable water-reactive materials and directs that they be stored in accordance with the requirements for explosives and blasting agents (see Chapter 56) to provide the safeguards commensurate with their hazards.

**6701.2 Permits.** Permits shall be required as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit; Section 105.6.21 for a discussion of specific quantity-based operational permits for the materials regulated in this chapter; and Section 105.7 for a general discussion of activities requiring a construction permit. The permit process also notifies the fire department of the need for prefire planning for hazardous property.

### SECTION 6702 DEFINITION

**6702.1 Definition.** The following term is defined in Chapter 2:

#### WATER-REACTIVE MATERIAL.

- Class 3.
- Class 2.
- Class 1.

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201.1 through 201.4).

### SECTION 6703 GENERAL REQUIREMENTS

**6703.1 Quantities not exceeding the maximum allowable quantity per control area.** The storage and use of water-reactive solids and liquids in amounts not exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Sections 5001, 5003, 6701 and 6703.

- ❖ This section complements the requirements of Chapter 50 in structures occupied for the storage, handling or use of water-reactive materials limited to the MAQs as established in Section 5003.1. The general

requirements of Sections 5001 and 5003 are fully applicable to the storage and use of water-reactive materials, in addition to the requirements of this chapter.

**6703.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of water-reactive solids and liquids in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.

- ❖ This section complements the requirements of Chapter 50 in structures occupied for the storage, handling or use of water-reactive materials. The regulations contained in this section assume that the quantity of water-reactive materials in a given building is in excess of the MAQs as established in Section 5003.1; thus, the building is classified in Occupancy Group H. The requirements of Chapter 50 apply to the storage and use of water-reactive material, in addition to the requirements of this chapter.

### SECTION 6704 STORAGE

**6704.1 Indoor storage.** Indoor storage of water-reactive solids and liquids in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1), shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

- ❖ This section regulates the indoor storage of water-reactive materials when in excess of the MAQ in buildings or portions of buildings classified in Occupancy Group H. The general and storage requirements of Chapter 50 are applicable in addition to the requirements of this section. Storage of water-reactive materials inside structures must comply with Sections 6701.1 through 6704.1.7 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

**6704.1.1 Detached storage.** Storage of water-reactive solids and liquids shall be in detached buildings where required by Section 5003.8.2.

- ❖ This section regulates the indoor storage of water-reactive materials when in excess of the MAQ in buildings or portions of buildings classified in Occupancy Group H. The general and storage requirements of Chapter 50 are applicable in addition to the requirements of this section. Storage of water-reactive materials inside structures must comply with Sections 6701.1 through 6704.1.7 to prevent uncontrolled release or exposure to conditions that may result in a fire or explosion.

**6704.1.2 Liquid-tight floor.** In addition to the provisions of Section 5004.12, floors in storage areas for water-reactive solids and liquids shall be of liquid-tight construction.

- ❖ Floors and sills of rooms or areas used to contain hazardous material spills must be liquid tight to pre-

vent the flow of liquids to adjoining areas (see commentary, Section 5004.2). The floor surface should be compatible with the water-reactive materials to be retained and must be noncombustible, as required by Section 5004.12.

**6704.1.3 Waterproof room.** Rooms or areas used for the storage of water-reactive solids and liquids shall be constructed in a manner which resists the penetration of water through the use of waterproof materials. Piping carrying water for other than *approved automatic sprinkler systems* shall not be within such rooms or areas.

❖ The design and construction of rooms used for storing water-reactive materials must prevent water from coming into contact with the stored materials. The building materials should be noncombustible so they do not contribute fuel to a fire or reaction and should be designed to resist the passage of flowing water.

A major safeguard is planning the design of the room and locating it to minimize water hazards. For example, in a two-story building it would not be appropriate to put a water-reactive materials storage room directly below a locker room with showers or a bathroom located on the second floor.

Similarly, the enclosure walls of a storage room should not contain plumbing piping. Though water piping may not be run into or through storage rooms, the code recognizes that automatic sprinkler systems are a more regulated type of water piping system and have a low leakage and failure rate when properly installed and maintained.

**6704.1.4 Water-tight containers.** Where Class 3 water-reactive solids and liquids are stored in areas equipped with an *automatic sprinkler system*, the materials shall be stored in closed water-tight containers.

❖ In the event of a sprinkler discharge in response to a fire, the application of water should not aggravate the fire by causing a violent exothermic reaction with the water-reactive materials in storage that might not otherwise become involved. To reduce this hazard and to complement the provisions of Section 6704.1.4, water-reactive materials must be stored in water-tight containers of 60 gallons (227 L) or less than capacity that comply with Section 5003.2 (see the commentary to the Section 202 definition of "Container").

**6704.1.5 Storage configuration.** Water-reactive solids and liquids stored in quantities greater than 500 cubic feet (14 m<sup>3</sup>) shall be separated into piles, each not larger than 500 cubic feet (14 m<sup>3</sup>). Aisle widths between piles shall not be less than the height of the pile or 4 feet (1219 mm), whichever is greater.

**Exception:** Water-reactive solids and liquids stored in tanks.

Class 2 water-reactive solids and liquids shall not be stored in *basements* unless such materials are stored in closed water-tight containers or tanks.

Class 3 water-reactive solids and liquids shall not be stored in *basements*.

Class 2 or 3 water-reactive solids and liquids shall not be stored with flammable liquids.

❖ This section details storage requirements related to the hazards of release or ignition of water-reactive materials stored in structures and is intended to reduce the amount of material exposed in a single incident by managing pile sizes and their separation. Water-reactive materials are limited to piles no larger than 500 cubic feet (14 m<sup>3</sup>) in volume [approximately 8 feet by 8 feet by 8 feet high (2438 mm by 2438 mm by 2438 mm)]. Aisle widths that are equal to the pile height or 4 feet (1219 mm), whichever is greater, reduce the fire exposure hazard between piles and, in the event of a fire-related collapse of a pile, reduce the likelihood of a "domino" effect that could not only increase fire intensity but also completely block access to pile areas by fire suppression personnel. Although not specifically mentioned in this section, inside storage must also comply with Chapter 50, which includes provisions for incompatible material storage, security, signage, control of ignition sources and submittal of a storage plan.

The exception exempts tank storage from the requirements of this section; however, the tanks must conform to the requirements of Section 5003.2.

Because Class 2 oxidizers are potentially explosive, they may be stored in basements only when contained in approved stationary tanks or containers that comply with the applicable requirements of Section 5003.2 and this section.

Because Class 3 water-reactive materials are violently reactive, they may not be stored in a basement because of the limited access for fire suppression operations, the potential for increased damage to the structure and exposure of the occupants to danger.

Class 2 and 3 water-reactive materials may not be stored in the same room or area as flammable liquids because of their violent reactivity and their incompatibility. See the commentary to Section 5003.9.8 for a discussion of precautions to be taken with incompatible materials.

**6704.1.6 Explosion control.** Indoor storage rooms, areas and buildings containing Class 2 or 3 water-reactive solids and liquids shall be provided with explosion control in accordance with Section 911.

❖ The violently reactive nature of Class 2 and 3 water-reactive materials can seriously damage or destroy a storage room or structure. To prevent damage or destruction in storage rooms or structures where Class 2 or 3 water-reactive materials are stored, an explosion control system must be installed as required in Section 911.

**6704.2 Outdoor storage.** Outdoor storage of water-reactive solids and liquids in quantities exceeding the *maximum*

allowable quantity per control area indicated in Table 5003.1.1(3) shall be in accordance with Sections 5001, 5003, 5004 and this chapter.

❖ This section regulates the outdoor storage of water-reactive material when in excess of the MAQ established by Table 5003.1.1(3). The general and storage provisions of Chapter 50 are applicable, in addition to the requirements of this section.

**6704.2.1 General.** Outdoor storage of water-reactive solids and liquids shall be within tanks or closed water-tight containers and shall be in accordance with Sections 6704.2.2 through 6704.2.5.

❖ Similar to Sections 6704.1.3 and 6704.1.5, which require waterproof rooms and water-tight containers for the storage of water-reactive materials, this section carries the protection of the material one step further by requiring that water-reactive materials stored outdoors be in closed, water-tight containers or tanks to reduce the likelihood that rain or snow will come into contact with them. Storage of water-reactive material in outdoor control areas must comply with Sections 6704.2.1 through 6704.2.5 to prevent uncontrolled release or exposure to conditions that could result in a fire or explosion.

**6704.2.2 Class 3 distance to exposures.** Outdoor storage of Class 3 water-reactive solids and liquids shall not be within 75 feet (22 860 mm) of buildings, *lot lines*, public streets, public alleys, *public ways* or *means of egress*.

❖ The required separation distances are based on the class of water-reactive material and are intended to reduce the hazard of radiant heat transfer to nearby structures, public streets or alleys or egress elements from buildings. The distances also protect the property in question from heat exposure from incidents on or off the property.

**6704.2.3 Class 2 distance to exposures.** Outdoor storage of Class 2 water-reactive solids and liquids shall not be within 20 feet (6096 mm) of buildings, *lot lines*, public streets, public alleys, *public ways* or *means of egress*. A 2-hour fire barrier without openings or penetrations, and extending not less than 30 inches (762 mm) above and to the sides of the storage area, is allowed in lieu of such distance. The wall shall either be an independent structure, or the exterior wall of the building adjacent to the storage area.

❖ The required separation distances in this section are based on the less violently reactive Class 1 and 2 water-reactive materials and are intended to reduce the hazard of radiant heat transfer to nearby structures, public streets or alleys or egress elements from buildings. The distances also protect the property in question from heat exposure from incidents on or off the property.

This section also recognizes that, for these less violently reactive water-reactive materials, a minimum separation distance of 20 feet (6096 mm) provides adequate protection and that a solid, 2-hour fire bar-

rier, constructed in accordance with Section 707 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), is an equivalent way to meet the objectives of spatial separation. Where a separation assembly is installed instead of having the separation distance, the wall must extend vertically beyond the roof or wall of the larger structure on each side (top and sides) to prevent a fire from lapping over or extending around the wall.

**6704.2.4 Storage conditions.** Class 3 water-reactive solids and liquids shall be limited to piles not greater than 500 cubic feet (14 m<sup>3</sup>).

Class 2 water-reactive solids and liquids shall be limited to piles not greater than 1,000 cubic feet (28 m<sup>3</sup>).

Aisle widths between piles shall not be less than one-half the height of the pile or 10 feet (3048 mm), whichever is greater.

❖ The size of storage piles of water-reactive materials is regulated by this section based on the hazards of the water-reactive materials being stored. To limit the amount of material involved in a single fire, water-reactive materials are limited to piles no larger than approximately 8 feet by 8 feet by 8 feet high (2438 mm by 2438 mm by 2438 mm) for Class 3 or 10 feet by 10 feet by 10 feet high (3048 mm by 3048 mm by 3048 mm) for Class 2 materials. The required aisle width ensures access to the storage area for emergency personnel and reduces the likelihood of a “domino” effect that could not only increase fire intensity, but also completely block access to pile areas by fire suppression personnel should a pile topple over.

**6704.2.5 Containment.** Secondary containment shall be provided in accordance with the provisions of Section 5004.2.2.

❖ To prevent the flow of water-reactive liquids to adjoining rooms or spaces, secondary containment complying with Section 5004.2.2 is required by this section. The design of drainage and secondary containment systems must take into consideration automatic sprinkler design discharge flow rates and fire suppression hand line [typically 1½- or 1¾-inch (38 or 44 mm) hose] flows.

Note that secondary containment requirements do not provide for control of the flammable, irritating or toxic vapors given off by reacted materials, and care must be taken to minimize exposure to hazardous vapors.

Runoff from spills or manual fire suppression activities may result in environmental contamination if not properly controlled (see commentary, Section 5004.2).

## SECTION 6705 USE

**6705.1 General.** The use of water-reactive solids and liquids in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) or 5003.1.1(3)

shall be in accordance with Sections 5001, 5003, 5005 and this chapter.

- ❖ This section applies to all indoor and outdoor dispensing, use and handling operations of water-reactive materials when the amounts being dispensed, used or handled are in excess of the MAQs in accordance with indoor or outdoor areas indicated in Table 5003.1.1(1) or 5003.1.1(3), respectively. The administrative, general use, handling and dispensing provisions of Chapter 50 are applicable, in addition to the requirements of this chapter.

Once the MAQ per control area of water-reactive materials has been exceeded, indoor areas where materials are being dispensed, used or handled must be located in a building or portion of a building complying with the IBC for a Group H occupancy because of the increased hazards associated with quantity. Although no occupancy group is assigned to them, outside water-reactive materials use areas must be regulated more heavily when quantities exceed the MAQs.

The MAQs listed in Table 5003.1.1(1) or 5003.1.1(3) have been divided into closed-use and open-use systems. Corresponding MAQs recognize that an open-use system is generally more hazardous than a closed-use system because the water-reactive materials are more directly exposed to the surrounding environment and can become more readily involved in an incident than if they are totally confined. The MAQs for use are based on the aggregate quantity in both use and storage not exceeding the MAQ listed for storage.

### Bibliography

## Part VI—Referenced Standards

# Chapter 80: Referenced Standards

### General Comments

Not every document related to fire safety system design, installation and construction is qualified to be a referenced standard. The International Code Council® (ICC®) has adopted a criterion that referenced standards in the *International Codes*® and standards intended for adoption into the *International Codes* must meet to qualify as a referenced standard. The policy is as follows:

**Referenced Standards:** In order for a standard to be considered for reference or to continue to be referenced by the codes, a standard shall meet the following criteria:

#### Code References:

1. The standard and the manner in which it is to be utilized shall be specifically referenced in the code text.
2. The need for the standard to be referenced shall be established.

#### Standard Content:

1. A standard or portions of a standard intended to be enforced shall be written in mandatory language.
2. The standard shall be appropriate for the subject covered.
3. All terms shall be defined when they deviate from an ordinarily accepted meaning or a dictionary definition.
4. The scope or application of a standard shall be clearly described.
5. The standard shall not have the effect of requiring proprietary materials.
6. The standard shall not prescribe a proprietary agency for quality control or testing.
7. The test standard shall describe, in detail, preparation of the test sample, sample selection or both.
8. The test standard shall prescribe the reporting format for the test results. The format shall identify the key performance criteria of the element(s) tested.
9. The measure of performance for which the test is conducted shall be clearly defined in either the test standard or in code text.

10. The standard shall not state that its provisions shall govern whenever the referenced standard is in conflict with the requirements of the referencing code.
11. The preface to the standard shall announce that the standard is promulgated according to a consensus procedure.

#### Standard Promulgation:

1. The standard shall be completed and readily available prior to final action consideration. In order for a new standard to be considered for reference by the code, two copies of such a standard shall be submitted in at least a consensus draft form.
2. The standard shall be developed and maintained through a consensus process, such as ASTM or ANSI.

Once a standard is incorporated into the code through the code development process, it becomes an enforceable part of the code, subject to the limitations of the text reference in accordance with Section 102.7. When the code is adopted by a jurisdiction, the referenced portion (only the referenced portion) of the standard is also part of that jurisdiction's adopted code. It is for this reason that the criteria were developed.

Compliance with this policy means that documents or portions of documents incorporated into the code by reference are, among others, developed through the use of a consensus process, written in mandatory language and do not mandate the use of proprietary materials or agencies. The requirement that a standard be developed through a consensus process is vital, because it means that the standard will be representative of the most current body of available knowledge on the subject as determined by a broad range of interested or affected parties without dominance by any single interest group. A true consensus process has many attributes, including, but not limited to:

- An open process that has formal (published) procedures allowing for the consideration of all viewpoints.
- A definitive review period that allows for the standard to be updated or revised.
- A process of notification to all interested parties.
- An appeals process.

**REFERENCED STANDARDS**

Many available documents related to fire safety system design, installation and construction, though useful, are not “standards” and are not appropriate for reference in the code. Often, these documents are developed or written with the intention of being used for regulatory purposes and are unsuitable for use as a regulation because of extensive use of recommendations, advisory comments and nonmandatory terms. Typical examples of such documents include installation instructions, guidelines and practices.

The ICC standards policy results in regulations that are clear, concise and enforceable; thus the requirement that standards be written in mandatory language. This requirement is not intended to mean that a standard cannot contain informational or explanatory material that will aid the user of the standard in its application. When it is the desire of the standard’s promulgating agency for such material to be included, however, the information must appear in a nonmandatory location, such as an annex or appendix, and be clearly identified as not being part of the standard.

Overall, standards referenced by the code must be authoritative, relevant, up to date and, most important, reasonable and enforceable. Standards that comply with ICC’s standards policy fulfill these expectations.

**Purpose**

As a performance-based code, the *International Fire Code*® (IFC®) contains numerous references to documents that are used to regulate materials and methods of construction. The references to these documents within the code text consist of the promulgating agency’s acronym and its publication designation (for example, ASME A17.1), as well as a further indication that the document being referenced is the one that is listed in Chapter 80. Chapter 80 contains all of the information that is necessary to identify the specific referenced document. Included is the following information

on a document’s promulgating agency (see Commentary Figure 80):

- The promulgating agency (the agency’s title).
- The promulgating agency’s acronym.
- The promulgating agency’s address.

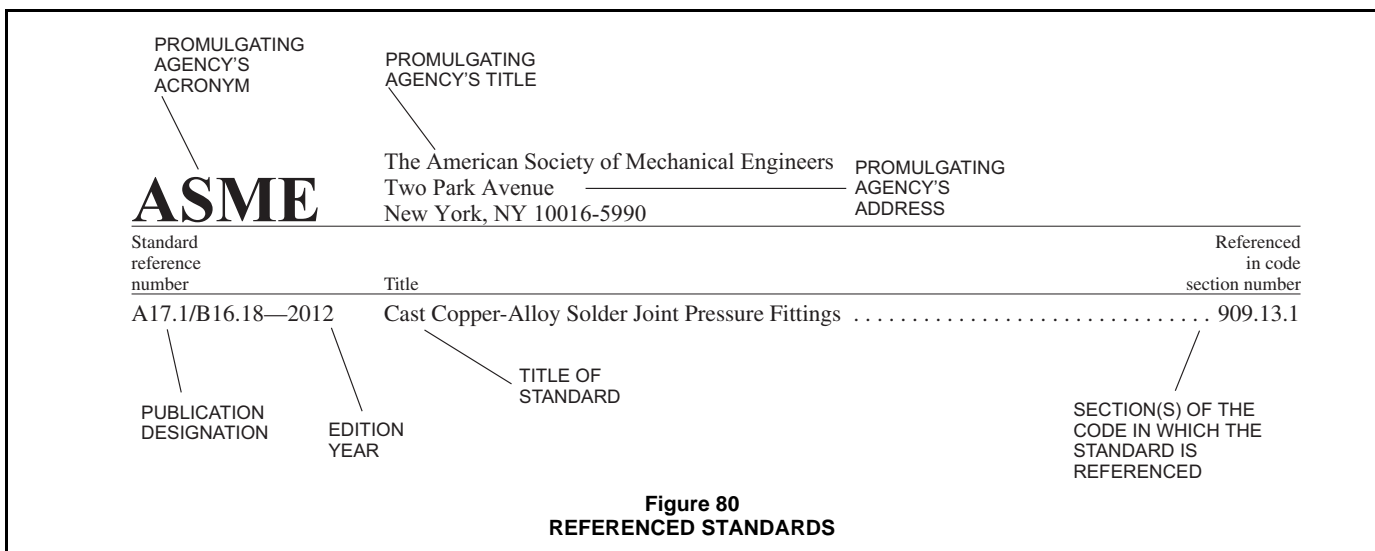

For example, a reference to an ASME standard within the code indicates that the document is promulgated by the American Society of Mechanical Engineers (ASME), which is located in New York City. Chapter 80 lists the standards’ agencies alphabetically for ease of identification.

Chapter 80 also includes the following information on the referenced document itself (see Commentary Figure 80):

- The document’s publication designation.
- The document’s edition year.
- The document’s title.
- Any addenda or revisions to the document known at the time of the code’s publication.
- Every section of the code in which the document is referenced.

For example, a reference to ASME B16.18 indicates that this document can be found in Chapter 80 under the heading ASME. The specific standards designation is B16.18. For convenience, these designations are listed in alphanumeric order. Chapter 80 identifies that: ASME 16.18 is titled *Cast Copper-Alloy Solder Joint Pressure Fittings*, the applicable edition (its year of publication) is 2001, and it is referenced in one specifically identified section of the code.

Using the system established for the family of *International Codes*, the specific edition of a specific standard is clearly identified and the requirements necessary for compliance can be readily determined. The basis for code compliance is, therefore, established and available on an equal basis to the fire code official, builder, designer and owner.

**Figure 80  
REFERENCED STANDARDS**

This chapter lists the standards that are referenced in various sections of this document. The standards are listed herein by the promulgating agency of the standard, the standard identification, the effective date and title, and the section or sections of this document that reference the standard. The application of the referenced standards shall be as specified in Section 102.7.

## Part VII—Appendices

# Appendix A: Board of Appeals

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

### General Comments

When adopted, this appendix provides jurisdictions with detailed appeals board member qualifications and administrative procedures to supplement the basic requirements found in Section 108 of the code.

### Purpose

This appendix contains optional criteria for administrative procedures of the board of appeals and board member qualifications. A jurisdiction that wants to make this appendix a mandatory part of the code needs to specifically list this appendix in its adoption ordinance (see page xxi of the code for a sample ordinance for adoption).

---

### SECTION A101 GENERAL

**A101.1 Scope.** A board of appeals shall be established within the jurisdiction for the purpose of hearing applications for modification of the requirements of the *International Fire Code* pursuant to the provisions of Section 108 of the *International Fire Code*. The board shall be established and operated in accordance with this section, and shall be authorized to hear evidence from appellants and the *fire code official* pertaining to the application and intent of this code for the purpose of issuing orders pursuant to these provisions.

❖ Section 108 establishes a board of appeals, provides a framework for the composition of the board, defines the limits of the board's authority and requires that the board adopt a set of rules of procedure for its operation. This appendix describes a model board of appeals that the jurisdiction may adopt and gives both a recommended board membership and a recommended operating procedure for the conduct of the board. The jurisdiction must adopt this appendix as part of its fire code before the board and its operations, as described in the appendix, can be authorized.

**A101.2 Membership.** The membership of the board shall consist of five voting members having the qualifications established by this section. Members shall be nominated by the *fire code official* or the chief administrative officer of the jurisdiction, subject to confirmation by a majority vote of the governing body. Members shall serve without remuneration or compensation, and shall be removed from office prior to the end of their appointed terms only for cause.

❖ This section details the method of appointment and the general administrative policy pertaining to the

board. The five subsections, Sections A101.2.1 through A101.2.5, list the recommended makeup of the board and the qualifications each member should have to serve on the board.

It is important that the decisions of the appeals board be based purely on the technical merits involved in an appeal and that only technical people rule on technical matters, with due regard for state-of-the-art fire protection and construction technology. The board should not be expected to engage in policy or political deliberations. Members of the appeals board are expected to have experience in matters of fire safety and building construction technology as prescribed in Sections A101.2.1 through A101.2.5.

The board of appeals is to consist of five members recommended by the fire code official and appointed by the chief administrative officer of the jurisdiction—typically, the mayor or city manager. To enhance the integrity of the board and its deliberations and preclude any accusations of partiality on the part of a board member, the members are to serve strictly as volunteers in the community interest, without salary, stipend or any other form of compensation.

**A101.2.1 Design professional.** One member shall be a practicing design professional registered in the practice of engineering or architecture in the state in which the board is established.

❖ The architectural or engineering design professional serves on the board to give a balanced perspective to board deliberations. His or her role should be to evaluate the general design features of the appeal to determine whether they satisfy the intent of the code.

**A101.2.2 Fire protection engineering professional.** One member shall be a qualified engineer, technologist, technician or safety professional trained in fire protection engineering, fire science or fire technology. Qualified representatives in this category shall include fire protection contractors and certified technicians engaged in *fire protection system* design.

- ❖ This board member is expected to evaluate appeals to determine whether they represent good, logical solutions to fire safety questions that satisfy code requirements and are consistent with current fire protection engineering principles. Note that this position does not specifically require professional registration in the state but may be filled by any technical person qualified in fire protection technology, including experienced fire protection system installation contractors and system designers.

**A101.2.3 Industrial safety professional.** One member shall be a registered industrial or chemical engineer, certified hygienist, certified safety professional, certified hazardous materials manager or comparably qualified specialist experienced in chemical process safety or industrial safety.

- ❖ The key words in this section are “chemical process safety” or “industrial safety.” This board member should contribute specialized knowledge of this field to board deliberations. His or her concerns should be more with industrial processes and inventories than with design or safety features, although his or her knowledge of the processes and the materials involved in them should bear on both. Note that this position also does not necessarily require professional registration in the state but may be filled by any technical person qualified in matters of chemical or industrial safety. This member’s input would be especially valuable in appeals involving the application and enforcement of the hazardous material provisions of the code.

**A101.2.4 General contractor.** One member shall be a contractor regularly engaged in the construction, *alteration*, maintenance, repair or remodeling of buildings or building services and systems regulated by the code.

- ❖ The experienced general contractor adds to the board’s expertise in determining the practicality of an appeal. This member many times may be a counterbalance to the opinion of the design professional. That is, the design may satisfy the definition of good engineering practice but not be practical or economical to construct or be compatible with an existing structure in the case of building modifications or additions.

**A101.2.5 General industry or business representative.** One member shall be a representative of business or industry not represented by a member from one of the other categories of board members described above.

- ❖ This board member, as stated in the code text, is expected to represent a point of view not represented by the other four board members. This member could, for example, be nominated by the jurisdiction’s

Chamber of Commerce or Industrial Development Board.

**A101.3 Terms of office.** Members shall be appointed for terms of 4 years. No member shall be reappointed to serve more than two consecutive full terms.

- ❖ Limiting terms of service serves two purposes. First, it ensures a turnover of membership so that professionals not currently on the board will have an opportunity to serve. Second, it tells the prospective board nominee that there is a definite term of service being committed to. In larger jurisdictions where the board may be very busy, these principles can also help reduce the potential for the so-called “burnout” syndrome among board members.

**A101.3.1 Initial appointments.** Of the members first appointed, two shall be appointed for a term of 1 year, two for a term of 2 years, one for a term of 3 years.

- ❖ The staggered terms for initial appointees ensures that no more than two board members will come up for reappointment or replacement in any one year unless one or more members resigns for personal reasons or is replaced for cause. This method of staggered appointment also allows for a smooth transition of board of appeals members, providing continuity of board action over the years.

**A101.3.2 Vacancies.** Vacancies shall be filled for an unexpired term in the manner in which original appointments are required to be made. Members appointed to fill a vacancy in an unexpired term shall be eligible for reappointment to two full terms.

- ❖ This section authorizes filling vacancies on the board outside of regular term expirations and sets the limits on terms of service for the new appointee. Vacancies are filled in the same manner as outlined in Section A101.2, with persons possessing qualifications equivalent to those of the board member being replaced.

**A101.3.3 Removal from office.** Members shall be removed from office prior to the end of their terms only for cause. Continued absence of any member from regular meetings of the board shall, at the discretion of the applicable governing body, render any such member liable to immediate removal from office.

- ❖ No board member can be removed from office without cause. Although there may be many reasons for removing a serving board member, the only one identified here is chronic failure to perform board duties by attending scheduled regular meetings. This does not mean absence is the only reason for removal.

**A101.4 Quorum.** Three members of the board shall constitute a quorum. In varying the application of any provisions of this code or in modifying an order of the *fire code official*, affirmative votes of the majority present, but not less than three, shall be required.

- ❖ This section clearly defines a quorum and also states that no matter how many members are present at the meeting, at least three affirmative votes are required

for passage of a proposal for code variance or modification.

**A101.5 Secretary of board.** The *fire code official* shall act as secretary of the board and shall keep a detailed record of all its proceedings, which shall set forth the reasons for its decisions, the vote of each member, the absence of a member and any failure of a member to vote.

❖ This section establishes the fire code official as the board secretary and defines the secretary's duties. Because the deliberations and actions of a board of appeals are considered legal proceedings, the secretary is required to record the proceedings in substantial detail. These details may be needed for any future review of the board's decision or for documentation in executing the procedures established by this appendix.

**A101.6 Legal counsel.** The jurisdiction shall furnish legal counsel to the board to provide members with general legal advice concerning matters before them for consideration. Members shall be represented by legal counsel at the jurisdiction's expense in all matters arising from service within the scope of their duties.

❖ This section requires the jurisdiction to appoint legal counsel to give the board opinions on the legality of proposed variances and also to represent board members at the jurisdiction's expense should a legal action result from their decisions within the scope of their duties. This legal representation for board members would not be considered remuneration or compensation to the board member, which is prohibited by Section A101.2.

**A101.7 Meetings.** The board shall meet at regular intervals, to be determined by the chairman. In any event, the board shall meet within 10 days after notice of appeal has been received.

❖ This section establishes ground rules for when meetings are to be held and gives the chairperson of the board the responsibility for making sure meetings are held to give timely response to appellants. In order that an appellant's request be heard in a timely manner, the board must meet within 10 days of the filing of an appeal. In large jurisdictions, where there are likely to be more appeals, the board will often set a regular schedule of meeting dates, such as monthly, and the 10-day rule would not apply.

**A101.8 Conflict of interest.** Members with a material or financial interest in a matter before the board shall declare such interest and refrain from participating in discussions, deliberations and voting on such matters.

❖ This section defines conflict of interest for board members and states their expected behavior. All members must recuse themselves from any appeal proceeding in which they have a personal, professional or financial interest.

**A101.9 Decisions.** Every decision shall be promptly filed in writing in the office of the *fire code official* and shall be open to public inspection. A certified copy shall be sent by mail or

otherwise to the appellant, and a copy shall be kept publicly posted in the office of the *fire code official* for 2 weeks after filing.

❖ This section establishes guidelines for posting decisions and notifying appellants. Once an appeal is concluded and a board has taken action, the board secretary must prepare one or more certified copies of the written report for record and distribution. The report copies must be certified as required by applicable state laws pertaining to such matters, which can often be accomplished by a commissioned notary public. The office of the municipal clerk or the board's legal counsel should be able to provide guidance on the subject. To ensure that the decisions and actions of the board are publicly broadcast, a copy of all decisions must be posted in a publicly accessible location in the office of the fire code official for at least two weeks from the date of the action. The appellant must also be given a certified copy of the decision by personal service or ordinary mail service, although certified mail with a requested return receipt would be advisable.

**A101.10 Procedures.** The board shall be operated in accordance with the Administrative Procedures Act of the state in which it is established or shall establish rules and regulations for its own procedure not inconsistent with the provisions of this code and applicable state law.

❖ This section establishes the responsibility of the board to operate using procedures established by the state or jurisdiction having authority. If those administrative procedures do not exist in a given jurisdiction, the board is to write its own procedures consistent with both the code and existing state law.

Hearings before the board must be open to the public as required by state law. The appellant, the appellant's representative, the building official and any person whose interests are affected must be heard.

# Appendix B: Fire-Flow Requirements for Buildings

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

The availability of water is essential for fire-fighting operations. The amount of water required to fight a fire depends on many things, including the type of construction, the location of the fire, the contents of the building, response time and the capabilities of the fire department. Fires will increase in size very quickly from the time of ignition to the arrival of the fire department. Couple these unknowns with the fact that the actual water available varies significantly from one jurisdiction to another and, in many cases, from one location to another in the same jurisdiction, and it is easy to see that determining the necessary water supply is not an exact science. The fire-flow rates given in this appendix are a simplified version of the method previously published by the Insurance Services Office (ISO), *Guide for Determination of Required Fire Flow* (ISO 1972). This particular method took several factors into account that included construction type, size and location of the building. The actual equation used with the ISO guide was as follows:

$$F = 18 C(A)^{0.5}$$

where:

$F$  = Required fire flow (gpm).

$C$  = Coefficient related to the type of construction.

$A$  = Total floor area (including all stories but excluding the basement).

Type of Construction	Coefficient
Wood-frame construction	1.5
For ordinary construction	1.0
Noncombustible construction	0.8
Fire-resistive construction	0.6

This equation came with various increases and decreases that will be discussed throughout this commentary. The simplified version of this method is included here for two reasons. First, the guidelines were difficult to obtain; and second, the methodology was considered overly complex for the degree of accuracy it

gave.

Fire-flow determination is not an exact science. Several methods beyond the one presented by ISO have been available over the years and none is able to provide a correct answer for all situations. Fires grow quickly during their initial stages and the amount of water necessary increases as the fire grows. The larger the fire, the larger the water supply necessary. This is why sprinklers require, comparably, much less water as they can attack the fire at a very early stage. For these reasons, this appendix does not provide a single answer to solve the problem of determining the amount of fire flow required. It is a decision that must involve many factors.

This appendix was developed independent of the sprinkler standards NFPA 13, 13R and 13D. These standards sometimes have requirements for inside and outside hose streams that are independent of the fire-flow requirements.

## Purpose

This appendix provides a tool for jurisdictions to establish a policy for fire-flow requirements. The determination of required fire flow is not an exact science, but having some level of information provides a consistent way of choosing the appropriate fire flow for buildings throughout a jurisdiction.

The primary tool used in this appendix is Table B105.1, which presents fire flows based on construction type and building area. This table is based on the correlation of the ISO method and the construction types used in the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>). Because of the wide variations in water availability and the application of fire flow in different communities, these provisions are presented in this appendix.

The important message sent by this appendix is that some sort of policy should be in place to provide requirements that are consistent within a jurisdiction. Fire-flow requirements have the tendency to be somewhat controversial for the simple reasons that the facilities needed to provide them can be very costly to construct and install and appear to the building owners, in many cases, to yield little benefit.

## SECTION B101 GENERAL

**B101.1 Scope.** The procedure for determining fire-flow requirements for buildings or portions of buildings hereafter constructed shall be in accordance with this appendix. This appendix does not apply to structures other than buildings.

- ❖ This appendix is clearly intended for buildings only and would not be applicable to outside storage areas or similar hazards. Target hazards such as petroleum bulk plants, refineries, lumberyards, junk yards, etc., which present high-challenge fire suppression scenarios, must be specifically evaluated and protected commensurate with the hazards and operational challenges that they present.

The provisions of this appendix were originally drafted based on the ISO *Guide for Determination of Required Fire Flow* (now called the *Guide for Determination of Needed Fire Flow*), which focuses on buildings only and takes into account the construction type and building size as well as exposures from other buildings nearby. This method may not translate very well to other hazards but could be used as a starting point for other types of facilities. Also, the scope of this appendix is intended for new construction rather than existing buildings. Providing fire flow is generally costly, and requiring it for existing buildings would likely be unreasonable.

Note that the appendix applies only if specifically adopted by ordinance by a jurisdiction. See the commentary to Sections 102.5 and 507.1 for a discussion of this appendix's application (if adopted) to buildings constructed under the *International Residential Code*® (IRC®).

## SECTION B102 DEFINITIONS

**B102.1 Definitions.** For the purpose of this appendix, certain terms are defined as follows:

- ❖ Definitions can help in the understanding and application of the code requirements. Having the definitions here puts them close to the subject matter to which they pertain.

**FIRE-FLOW.** The flow rate of a water supply, measured at 20 pounds per square inch (psi) (138 kPa) residual pressure, that is available for fire fighting.

- ❖ A consistent criterion is used to measure the water available for fire fighting. The criterion is that the fire flow available be measured at a residual pressure of 20 pounds per square inch (psi) (138 kPa). Residual pressure is the pressure in the water main measured when the water is flowing, as opposed to static pressure, which is measured when the water is not flowing.

The residual pressure criterion of 20 psi (138 kPa) is used because it is the minimum pressure recommended for fire engine use by water authorities in

order to minimize the possibility of creating a negative pressure in the water main and damaging the water supply system. It also provides a consistent point from which to measure the available flow. Flow will vary based on the pressure for each system. NFPA 291 provides information on fire-flow testing and formulae for calculating test results, including how to calculate the flow available at the 20 psi (138 kPa) residual pressure.

**FIRE-FLOW CALCULATION AREA.** The floor area, in square feet (m<sup>2</sup>), used to determine the required fire flow.

- ❖ This term defines what portion of the building is to be accounted for when applying Table B105.1. This term differs from the IBC definition of "Fire area" in that this definition allows a fire-flow calculation area, for the purposes of defining fire flow, to be divided only by a fire wall with no openings or penetrations. Fire barriers and fire partitions could not be used to create separate fire-flow calculation areas (see commentary, Section B104.2).

## SECTION B103 MODIFICATIONS

**B103.1 Decreases.** The fire chief is authorized to reduce the fire-flow requirements for isolated buildings or a group of buildings in rural areas or small communities where the development of full fire-flow requirements is impractical.

- ❖ The purpose of this section is to recognize that many factors may require adjustments to the numbers in Table B105.1. This particular section generally addresses issues such as proximity to exposures, general location, configuration and practicality.

This section gives the fire code official the authority to make adjustments based on the impracticality of fire-flow requirements in rural areas. The text conveys the message that the requirements found here will not be appropriate for all situations. For example, requiring that a fire main be extended to a house located by itself in the middle of a large open field is impractical. This is especially the case if the fire department has a considerable response time. When a considerable response time exists for buildings, such as one- and two-family dwellings in isolated locations, the effectiveness of fire flow is likely to be low because intervention may not be necessary once the fire department arrives. Although, if this same house is located in an wildland-urban interface area, this may be a different issue. The house may be a complete loss, but the protection of the wildland from the exposure of this fire may be necessary.

This section is intended to provide flexibility to better fit the needs of a specific community. In addition to the example above, the following examples describe instances where requiring the full fire flow given in Table B105.1(2) would be unreasonable:

- A rural area dependent on tanker supplies and on-site water sources.

- A water system for a small town or community provided for domestic consumption with some incidental fire hydrants, but with no serious intent to provide fire protection water.
- A fire department that does not have the equipment to pump the required fire flow.

Section B103.3 discusses alternative approaches for water supplies.

**B103.2 Increases.** The fire chief is authorized to increase the fire-flow requirements where conditions indicate an unusual susceptibility to group fires or conflagrations. An increase shall not be more than twice that required for the building under consideration.

❖ As discussed in Section B103.1, the fire flows provided in this appendix are not appropriate for all situations. This section gives jurisdictions the authority to increase fire flow when necessary. The focus of this section is on densely populated occupancies and on buildings arranged in a way that makes conflagration more likely. These provisions were based on the ISO guide, and this particular section is primarily focusing on proximity to exposures. The ISO guide included specific increases for close proximity buildings and other exposures. This appendix does not include specific increases but does give jurisdictions the authority to make adjustments based on these concerns. Adjustments, however, are not to exceed twice the required fire flow. This section and Section B103.1 together suggest that each jurisdiction have a specific policy that can anticipate various scenarios to enable a consistent approach to those undertaking construction in the jurisdiction.

**B103.3 Areas without water supply systems.** For information regarding water supplies for fire-fighting purposes in rural and suburban areas in which adequate and reliable water supply systems do not exist, the *fire code official* is authorized to utilize NFPA 1142 or the *International Wildland-Urban Interface Code*.

❖ In many cases the infrastructure simply does not exist to provide the large amounts of water required by Table B105.1, but the hazards require that some level of water be available for fire-fighting activities. This section provides an outside resource in the use of either NFPA 1142 or the *International Wildland-Urban Interface Code*® (IWUIC®). NFPA 1142 gives options for areas where adequate and reliable water supplies are not available. It provides minimum requirements for situations where the water is to come from drafting sources, such as a river, canal, stream or pond.

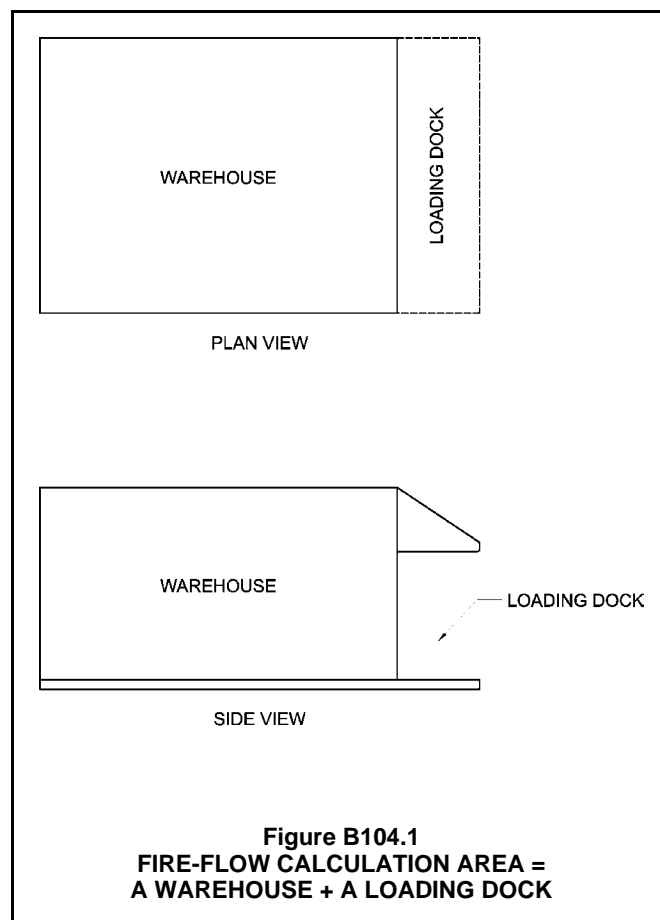

The IWUIC, in Chapter 4, includes alternative approaches to address the lack of water supplies in areas where providing necessary fire flow is typically difficult. Such alternatives include more restrictive construction types and providing defensible spaces to compensate for a reduced water supply. Also, water supply methodologies are presented for both natural and man-made sources.

## SECTION B104 FIRE-FLOW CALCULATION AREA

**B104.1 General.** The fire-flow calculation area shall be the total floor area of all floor levels within the *exterior walls*, and under the horizontal projections of the roof of a building, except as modified in Section B104.3.

❖ This section establishes the area that is to be taken to Tables B105.1(1) and B105.1(2) to determine the minimum fire flow, including how to separate a building into multiple fire-flow calculation areas in order to have lower fire-flow requirements. Fire-flow calculation areas are defined differently here than is the term “Fire area” in the IBC. This difference is described in the commentary for the definition of “Fire-flow calculation area” in Section B102 of this appendix.

The fire-flow calculation area includes all floors and horizontal projections of a building (see Figure B104.1). The area under horizontal projections is important because either combustibles may be located below those areas or the construction itself is combustible. Both situations add to the fire loading of the building. In some cases, horizontal projections can cover a significant area. There are some exceptions for Type IA and IB construction because they are inherently less combustible structures (see commentary, Section B104.3).

**B104.2 Area separation.** Portions of buildings which are separated by *fire walls* without openings, constructed in accordance with the *International Building Code*, are allowed to be considered as separate fire-flow calculation areas.

❖ To reduce the amount of fire flow required, fire walls without openings can be constructed to create separate fire-flow calculation areas. Fire barriers or fire partitions cannot be used to create separate fire-flow calculation areas. It should be noted that IBC Section 706 regulates the construction of fire walls and would generally allow properly protected openings in them (see IBC Section 706.8). However, consistent with Section 102.10 of the code, this section would supercede the IBC fire wall opening provisions since this section is a specific prohibition on any openings in fire walls that are used to reduce the fire-flow calculation area.

**B104.3 Type IA and Type IB construction.** The fire-flow calculation area of buildings constructed of Type IA and Type IB construction shall be the area of the three largest successive floors.

**Exception:** Fire-flow calculation area for open parking garages shall be determined by the area of the largest floor.

❖ Type IA and IB construction are essentially noncombustible and have the tendency to limit fire spread within the buildings more so than other construction types. Therefore, the fire-flow calculation area needs to include only the three largest successive floors. Successive floors are specified because of the logical progression of a fire. The concept of three largest successive floors appears to come from the ISO guide. These guidelines allowed the fire-flow calculation area for fire-resistive construction to only include six successive floors if vertical openings were not protected, and three successive floors if the vertical openings were protected. Taking the three largest floors when they are separated from one another may be overly conservative.

The exception to this section allows open parking garages to count only the largest floor for the fire-flow calculation area. This is probably related to the facts that fires in such facilities tend to be limited to one or two cars and that such facilities have large openings through which the hot gases and smoke from a fire can dissipate quickly, limiting the intensity of the fire.

**SECTION B105**

**FIRE-FLOW REQUIREMENTS FOR BUILDINGS**

**B105.1 One- and two-family dwellings, Group R-3 and R-4 buildings and townhouses.** The minimum fire-flow and flow duration requirements for one- and two-family *dwellings*, Group R-3 and R-4 buildings and townhouses shall be as specified in Tables B105.1(1) and B105.1(2).

❖ This section establishes fire-flow requirements for one- and two-family dwellings, in two distinct categories. The first category is one- and two-family dwellings, Group R3 and R4 buildings and townhouses through reference to Tables B105.1(1) and B105.1(2). Table B105.1(1) essentially addresses two different area ranges and whether automatic sprinkler systems are installed. Where the area is 3,600 square feet or greater, reference is made to Table B105.1(2). It should be noted that automatic sprinkler systems shall comply with either NFPA 13D or IRC Section 2904. Buildings addressed by Section B105.2 allow a larger decrease in fire flow but require an NFPA 13 or NFPA 13R system.

**TABLE B105.1(1).** See below.

❖ This table sets out the requirements for one- and two-family dwellings, Group R3 and R4 buildings and townhouses. The criteria for fire flow is based on two major factors. The first is the area of the building. The table addresses buildings up to 3,600 square feet and greater than 3,600 square feet. The second is whether a sprinkler system is provided. The type of sprinkler system is either that required by NFPA 13D or IRC P2904. The assumption would be that more restrictive systems, such as those required by NFPA13R or 13, would also be permitted.

Essentially, for less than 3,600 square feet, the fire flow is reduced by 50 percent. This is consistent with exceptions present in past editions of the code. Once 3,600 square feet has been reached, compliance with Table B105.1(2) is required. Note that a 50-percent reduction is allowed by Table B105.1(2) for these buildings.

The original ISO guide provided a simplified approach for one- and two-family dwellings. That approach stated that fire flows should be based on a limitation of two stories and a relationship to proximity of exposures. The fire-flow requirements based on

**TABLE B105.1(1)  
REQUIRED FIRE-FLOW FOR ONE- AND TWO-FAMILY DWELLINGS, GROUP R-3 AND R-4 BUILDINGS AND TOWNHOUSES**

FIRE-FLOW CALCULATION AREA (square feet)	AUTOMATIC SPRINKLER SYSTEM (Design Standard)	MINIMUM FIRE-FLOW (gallons per minute)	FLOW DURATION (hours)
0-3,600	No automatic sprinkler system	1,000	1
3,601 and greater	No automatic sprinkler system	Value in Table B105.1(2)	Duration in Table B105.1(2) at the required fire-flow rate
0-3,600	Section 903.3.1.3 of the <i>International Fire Code</i> or Section P2904 of the <i>International Residential Code</i>	500	1/2
3,601 and greater	Section 903.3.1.3 of the <i>International Fire Code</i> or Section P2904 of the <i>International Residential Code</i>	1/2 value in Table B105.1(2)	1

For SI: 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon per minute = 3.785 L/m.

proximity to exposures in the ISO guide were as follows:

EXPOSURE DISTANCE (ft)	FIRE-FLOW REQUIREMENT (gpm)
Over 100	500
31-100	750-1000
11-30	1000-1500
10 or less	1500-2000

For SI: 1 foot = 304.8 mm, 1 gallon per minute = 3.785 L/m.

This appendix uses 1,000 gpm (3785 L/min), which would be equivalent to a 30-foot (9144 mm) distance from exposures. This was taken as an average to provide a reasonable number for a majority of one- and two-family dwellings. Also, as discussed in the beginning of this appendix, based on the amount of variability involved with fighting fires, taking an average and applying it to all one- and two-family dwellings may be the most reasonable approach.

This appendix also does not use the two-story limitation but, rather, uses an area limitation of 3,600 square feet (345 m<sup>2</sup>) for the 1,000-gpm (3785 L/min) requirement. This is a more realistic approach because the ISO guide probably did not anticipate the larger floor area of today's houses and the large number of townhouses.

The table recognizes the efficacy of automatic sprinkler systems in reducing the amount of water needed to suppress fires and allows a reduction in fire flow of 50 percent where sprinklers are installed. This allowance for sprinklers does not amount to a requirement that a sprinkler system be installed. Rather, it allows a design alternative to be utilized in the event that there is insufficient water available to meet the required fire flow for a building established by this appendix. Table B105.2 allows a similar reduction for all other types of buildings.

A review of the original ISO guide reveals that there was no reduction for sprinklers in one- and two-family dwellings. However, in 1972 sprinklers were extremely uncommon within homes, and since that time sprinkler technology has changed dramatically. Section B105.2 contains more discussion on the application of this concept of reductions for sprinklers. Generally, the reduction is intended to encourage installation of an automatic sprinkler system because it is easier to control a fire that is attacked during the incipient stages.

**TABLE B105.1(2).** See page B-6.

❖ Table B105.1(2) establishes the fire-flow and duration requirements based on the fire-flow calculation area, as defined by the definition in this appendix and Section B103, and the construction types defined in the IBC. As the construction type becomes more combustible, the fire-flow requirements increase. Likewise, as the area of the building increases, the fire-flow requirements increase. The last column also specifies a minimum duration of fire flow. The duration of fire flow varies from a minimum of 2 hours to 4

hours. Flow duration may be an issue that each jurisdiction may need to consider when assessing the capabilities of the department, the hazards presented and the availability of water supply (see commentary, Section B105.1).

Applying this table, for example, a 50,000-square-foot (4546 m<sup>2</sup>) Type IV construction building would require a fire flow of 4,000 gpm (15 140 L/min) with a duration of 4 hours. If the building was sprinklered in accordance with NFPA 13, the required fire flow would only be 25 percent or 1,000 gpm (5678 L/min).

This table does not address use and occupancy classifications. A Type IA construction building housing a Group A occupancy would be treated the same as a Type IA construction building housing a Group H or F occupancy. Again, this table was formed based on the approaches presented by the ISO guide, which focus on construction types.

A common question when applying this table is how to deal with a building that incorporates multiple construction types. Such scenarios would be better addressed through a percentage approach. For example, in a building that has two construction types, Types IA and VA, having areas of 25,000 square feet (2323 m<sup>2</sup>) and 10,000 square feet (929 m<sup>2</sup>), respectively, the fire flow would be calculated as follows:

Total building area

25,000 square feet (Type IA) + 10,000 square feet (Type VA) = 35,000 square feet (3252 m<sup>2</sup>)

Fire flow per construction type

Type IA at 35,000 square feet = 2,000 gpm (7370 L/min)  
Type VA at 35,000 square feet = 3,250 gpm (12 112 L/min)

Percentage of building

IA = 25,000/35,000 × 100 = 71.4 percent

VA = 10,000/35,000 × 100 = 28.6 percent

Therefore

0.714 (2,000 gpm) + 0.286 (3,250 gpm) = 2,357.5 = Approximately 2,350 gpm (8894 L/min)

**B105.2 Buildings other than one- and two-family dwellings, Group R-3 and R-4 buildings and townhouses.** The minimum fire-flow and flow duration for buildings other than one- and two-family *dwellings*, Group R-3 and R-4 buildings and townhouses shall be as specified in Tables B105.2 and B105.1(2).

❖ This section refers all buildings that are not one- and two-family dwellings to Tables B105.1(2) and B105.2 for the minimum fire-flow and duration requirements. Table B105.1(2) provides the fire flow and Table B105.2 provides the reductions allowed for having either an NFPA 13 or NFPA 13R automatic sprinkler system. In such buildings, the reduction is 75 percent versus the 50-percent reduction allowed for one- and two-family dwellings in Table B105.1(1).

The tabular fire flows, based on the 1972 ISO

APPENDIX B

guide, are extremely high and it is doubtful that many water supply systems and fire departments can develop them. Also, it should be noted that the current ISO guide on this topic for sprinklered buildings requires providing only the calculated sprinkler demand plus hose stream allowances, calling the continued validity of this appendix into question. The updated ISO publication, *Guide for the Determination of Needed Fire Flows*, as with its predecessor, is a tool for the development of fire insurance ratings and is not intended to be used for legislating an individual sprinklered building's fire flow. That document states, "ISO does not determine a needed fire flow for buildings rated and coded by ISO as protected by an automatic sprinkler system meeting applicable National Fire Protection Association standards."

The allowance for buildings equipped with an automatic sprinkler system is intended to encourage the

use of sprinklers. It does not link to any other portions of the code or the IBC in terms of height and area requirements and limitations. Therefore, it can be used in addition to any trade-offs for sprinklers. Keep in mind that as the area of the building increases so do the fire-flow requirements. Therefore, even though a reduction may be given to a building that has already increased its area based on sprinklers, the overall fire flow will be larger because of this area increase.

The original ISO guide allowed only a 25-percent reduction for sprinklers. As mentioned in Section B105.1, sprinkler technology has changed dramatically since the guidelines were developed in the early 1970s. Also, the ISO guide allowed reduction in fire flow for buildings with light fire loads that this appendix does not.

**TABLE B105.1(2)**  
**REFERENCE TABLE FOR TABLES B105.1(1) AND B105.2**

FIRE-FLOW CALCULATION AREA (square feet)					FIRE-FLOW (gallons per minute) <sup>b</sup>	FLOW DURATION (hours)

—	—	156,701-167,900	113,201-121,300	69,601-74,600	7,250	
—	—	167,901-179,400	121,301-129,600	74,601-79,800	7,500	
—	—	179,401-191,400	129,601-138,300	79,801-85,100	7,750	
—	—	191,401-Greater	138,301-Greater	85,101-Greater	8,000	

For SI: 1 square foot = 0.0929 m<sup>2</sup>, 1 gallon per minute = 3.785 L/m, 1 pound per square inch = 6.895 kPa.

a. Types of construction are based on the *International Building Code*.

b. Measured at 20 psi residual pressure.

**TABLE 105.2.** See below.

❖ This table provides allowances for reduced fire flow based on the installation of an automatic sprinkler system. More specifically, the fire flow obtained from Table B105.1(2) can be reduced to 25 percent where an NFPA 13 or NFPA 13R system is installed. The only major difference in the allowance given for both sprinkler systems is the minimum flow permitted. NFPA 13 systems can have a fire flow as low as 1,000 gpm, whereas an NFPA 13R system will allow a reduction to a minimum of 1,500 gpm. This is related to the relative performance of the type of sprinkler system. More credit was deemed necessary for NFPA 13 systems. Note with the reductions in this table and also Table B105.1(1) for one- and two-family dwellings, Group R3 and R4 Buildings and townhouses that there is no specific approval required by the fire official to apply these reductions. In the past, this approach has led to confusion as to how to differentiate situations where such an allowance was appropriate and where a lesser reduction was necessary.

**B105.3 Water supply for buildings equipped with an automatic sprinkler system.** For buildings equipped with an approved *automatic sprinkler system*, the water supply shall be capable of providing the greater of:

1. The *automatic sprinkler system* demand, including hose stream allowance.
2. The required fire-flow.

❖ This section clarifies that the fire-flow requirements are not in addition to the sprinkler demand. What is required is determining which needs a larger water supply. The greater of the sprinkler demand or the demand developed in accordance with Appendix B will be the required fire flow.

**TABLE B105.2  
REQUIRED FIRE-FLOW FOR BUILDINGS OTHER THAN ONE- AND TWO-FAMILY DWELLINGS, GROUP R-3 AND R-4 BUILDINGS AND TOWNHOUSES**

AUTOMATIC SPRINKLER SYSTEM (Design Standard)	MINIMUM FIRE-FLOW (gallons per minute)	FLOW DURATION (hours)
No automatic sprinkler system	Value in Table B105.1(2)	Duration in Table B105.1(2)
Section 903.3.1.1 of the <i>International Fire Code</i>	25% of the value in Table B105.1(2) <sup>a</sup>	Duration in Table B105.1(2) at the reduced flow rate
Section 903.3.1.2 of the <i>International Fire Code</i>	25% of the value in Table B105.1(2) <sup>b</sup>	Duration in Table B105.1(2) at the reduced flow rate

For SI: 1 gallon per minute = 3.785 L/m.

- a. The reduced fire-flow shall be not less than 1,000 gallons per minute.
- b. The reduced fire-flow shall be not less than 1,500 gallons per minute.

# Appendix C: Fire Hydrant Locations and Distribution

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Fire hydrants are among the primary ways to access water for fighting fires. The location and spacing of hydrants are important to the success of fire-fighting operations. The difficulty with determining the spacing of fire hydrants is that every situation is unique and has unique challenges. Finding one methodology for determining hydrant spacing is difficult. This particular appendix gives one methodology fire departments can work with to set a policy for new buildings and facilities.

This methodology is located in an appendix because, as with fire-flow requirements (Appendix B), many factors affect the need for and location of hydrants. Also, in many jurisdictions, hydrant spacing is prescribed by zoning regulations or by the water authority. This appendix is simply one approach for spacing hydrants that can be used when no other guidelines are given.

## Purpose

Section 507.5.1 requires hydrants to be within 400 feet (122 m) of all portions of new buildings and facilities. If a building or facility cannot meet that criterion, on-site fire hydrants and mains are required. This appendix provides some guidance on the spacing of the on-site hydrants based on the required fire flow. These guidelines could also be used to require hydrants on public streets and roads where no other entity regulates such hydrants.

The general approach is to use fire-flow requirements to determine the number and spacing of hydrants—the higher the fire-flow requirements, the larger the number of hydrants required and the smaller the spacing between hydrants. The spacings given in this appendix are independent of the distance to a building and are simply focused on having the correct number and spacing of hydrants on a fire apparatus access road.

---

## SECTION C101 GENERAL

**C101.1 Scope.** In addition to the requirements of Section 507.5.1 of the *International Fire Code*, fire hydrants shall be provided in accordance with this appendix for the protection of buildings, or portions of buildings, hereafter constructed or moved into the jurisdiction.

❖ This section establishes the applicability of this appendix, where specifically adopted, to only new buildings and portions of buildings constructed or moved into a jurisdiction. Another important aspect of this section is that these requirements are in addition to what is already required in Section 507.5.1. This is similar to the scope of Appendix B. Generally, both fire flow and fire hydrants are fairly expensive and requiring them for an existing building would likely be cost prohibitive. Note also that the provisions in this appendix may not be adequate for structures other than buildings or for outside storage or processing operations. Target hazards such as petroleum bulk plants, refineries, lumberyards, junk yards, etc., which present high-challenge fire suppression scenarios, must be specifically evaluated and protected commensurate with the hazards and operation challenges they present.

A question that often arises is whether the code is intended to regulated fire hydrant systems in residential developments where buildings are constructed under the provisions of the *International Residential Code*® (IRC®). That question is specifically addressed in Section 102.5. See the commentary to that section for further discussion of this topic.

## SECTION C102 NUMBER OF FIRE HYDRANTS

**C102.1 Minimum number of fire hydrants for a building.**

The number of fire hydrants available to a building shall be not less than the minimum specified in Table C102.1.

❖ This section is focused only on the number of hydrants required. Table C102.1 shows a minimum number of hydrants based on the required fire flow. In many cases, a particular fire flow may require only one or two hydrants.

**TABLE C102.1.** See page Appendix C-2.

❖ This table is referenced throughout this appendix for the minimum number of hydrants and spacing limits. These limits are based on the fire flow required for a particular building. In terms of the spacing limitations,

there are two criteria. First is the average distance between hydrants. Second is a maximum distance limitation from any point on a street or accessway to a hydrant. When the number of required fire hydrants increases, the maximum distance does not always correspond to half of the average distance between hydrants. Instead, this distance is larger than half the distance to compensate for the fact that the average spacing between hydrants as the number of hydrants increases may result in spacings larger than those shown in column three. Otherwise, the maximum distance listed in column four would limit the spacing [see Commentary Figure C102.1(1)].

One question that is often asked with these requirements is whether the table—or the entire appendix, for that matter—requires minimum flows per hydrant. This particular appendix does not address minimum flow per hydrant or how the flow is to be subdivided. Fire-flow requirements are addressed in Appendix B.

**Note a**

This note is referenced in the third column for the average spacing between hydrants and restricts the spacing between hydrants on dead-end streets or roads to 100 feet less than the required spacing. This avoids a hydrant being located an impractical distance from hazards. Otherwise, a hydrant could literally be placed at the end of street and provide little benefit to buildings on that street.

**Note b**

The intent of this note is to provide guidance for placing hydrants along boulevards with uncrossable medians and multilane roads that carry a heavy traffic load each day. Such roadways present the fire department with several challenges to rapidly accessing installed fire hydrants. Boulevards with built-up or walled medians can prevent ready access to hydrants if they are on the opposite side of the street from a fire incident. Accordingly, fire hydrants are required to be installed on both sides of the boulevard right-of-way. Arterial streets with high traffic flows are also problematic as accessing hydrants on the opposite side of the street presents risk to fire fighters and apparatus when leading out or manually dragging supply hoses across such busy thoroughfares.

In addition to those dangers, police agencies already faced with the traffic control needs of the fire scene are often opposed to shutting down major streets for prolonged periods of time since doing so can have an adverse “domino effect” on traffic management in other areas of the community. These hydrants are typically intended for use only with highway hazards and may be spaced every 500 feet (152 m) on each side in alternating positions [resulting in a hydrant every 250 feet (76 200 mm)] [see Commentary Figure C102.1(2)]

**TABLE C102.1  
REQUIRED NUMBER AND SPACING OF FIRE HYDRANTS**

FIRE-FLOW REQUIREMENT (gpm)	MINIMUM NUMBER OF HYDRANTS	AVERAGE SPACING BETWEEN HYDRANTS <sup>a, b, c, f, g</sup> (feet)	MAXIMUM DISTANCE FROM ANY POINT ON STREET OR ROAD FRONTAGE TO A HYDRANT <sup>d, f, g</sup>
1,750 or less	1	500	250
2,000-2,250	2	450	225
2,500	3	450	225
3,000	3	400	225
3,500-4,000	4	350	210
4,500-5,000	5	300	180
5,500	6	300	180
6,000	6	250	150
6,500-7,000	7	250	150
7,500 or more	8 or more <sup>c</sup>	200	120

For SI: 1 foot = 304.8 mm, 1 gallon per minute = 3.785 L/m.

- a. Reduce by 100 feet for dead-end streets or roads.
- b. Where streets are provided with median dividers that cannot be crossed by fire fighters pulling hose lines, or where arterial streets are provided with four or more traffic lanes and have a traffic count of more than 30,000 vehicles per day, hydrant spacing shall average 500 feet on each side of the street and be arranged on an alternating basis.
- c. Where new water mains are extended along streets where hydrants are not needed for protection of structures or similar fire problems, fire hydrants shall be provided at spacing not to exceed 1,000 feet to provide for transportation hazards.
- d. Reduce by 50 feet for dead-end streets or roads.
- e. One hydrant for each 1,000 gallons per minute or fraction thereof.
- f. A 50-percent spacing increase shall be permitted where the building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*.
- g. A 25-percent spacing increase shall be permitted where the building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.2 or 903.3.1.3 of the *International Fire Code* or Section P2904 of the *International Residential Code*.

**Note c**

This note requires that new fire mains installed along fire apparatus access roads or streets without structures have hydrants at least every 1,000 feet (305 m) for the protection of hazards such as car fires or other traffic- or transportation-related hazards. This note does not require that water mains specifically be placed along roadways for this purpose; only that when such mains are installed or extended, hydrants must be provided.

**Note d**

This note requires, as does Note a, that the distance to a hydrant be reduced by 50 feet (13 240 mm) on dead-end streets and roads. Again, this avoids a hydrant being unnecessarily far from buildings.

**Note e**

This note applies only to situations where the table requires eight or more hydrants and that hydrants be added for every 1,000 gpm (3785 L/min) or fraction thereof of fire flow required beyond 7,500 gpm (28 387 L/min). This means that one additional hydrant would be required for fire flows up to 8,500 gpm (2028 L/min). No minimum fire flow per hydrant is specified.

**Note f**

This note is consistent with the decreases in fire flow allowed in Appendix b. This note allows a 50-percent increase in spacing between hydrants where buildings are equipped throughout with an NFPA 13 automatic sprinkler system.

**Note g**

Similar to Note f, this note is consistent with the decreases in fire flow allowed in Appendix B. This note allows a 25-percent increase in spacing between hydrants where buildings are equipped throughout with an NFPA 13R or 13D automatic sprinkler system.

**SECTION C103  
FIRE HYDRANT SPACING**

**C103.1 Hydrant spacing.** Fire apparatus access roads and public streets providing required access to buildings in accordance with Section 503 of the *International Fire Code* shall be provided with one or more fire hydrants, as determined by Section C102.1. Where more than one fire hydrant is required, the distance between required fire hydrants shall be in accordance with Sections C103.2 and C103.3.

❖ This section specifies that when fire apparatus access roads are required by Section 503 such roads be provided with hydrants as set forth in Section C102.1. Where more than one hydrant is required, the distance between hydrants is more specifically dealt with in Sections C103.2 and C103.3. If there is a complex of buildings, each with a low required fire flow, the spacing requirements would dictate additional hydrants. A fire flow of 2,000 gpm (7570 L/min) would require only two hydrants with a maximum average spacing of 450 feet (137 160 mm), but because of the size of the complex additional

hydrants may be necessary to achieve proper spacing along the access road (see Commentary Figure C103.1). In this particular case, the number of hydrants, not the spacing, drives the layout.

**C103.2 Average spacing.** The average spacing between fire hydrants shall be in accordance with Table C102.1.

**Exception:** The average spacing shall be permitted to be increased by 10 percent where existing fire hydrants provide all or a portion of the required number of fire hydrants.

❖ This section states that the spacing designated in Table C102.1 is an average. Real-life conditions, however, often result in the need for approximate spacing of hydrants. In some cases, good judgment would dictate deviation from rigid exact spacing so that hydrants could be located where more than one building could access them [see Commentary Figure C103.2].

The exception allows a 10-percent deficiency in average hydrant spacing when using existing hydrants. For example, if the average spacing allowed is 350 feet (106 m), the largest average spacing allowed by this exception would be  $350 \times 1.10 = 385$  feet (117 m). The allowance of longer average spacing for existing hydrants is important in enabling their use with new buildings.

**C103.3 Maximum spacing.** The maximum spacing between fire hydrants shall be in accordance with Table C102.1.

❖ This section requires that no point on a street or access road be beyond the distance to a hydrant shown in the last column of Table C102.1. This distance is not an average but a maximum distance (see Commentary Figure C103.3).

**SECTION C104**

**CONSIDERATION OF EXISTING FIRE HYDRANTS**

**C104.1 Existing fire hydrants.** Existing fire hydrants on public streets are allowed to be considered as available to meet the requirements of Sections C102 and C103. Existing fire hydrants on adjacent properties are allowed to be considered as available to meet the requirements of Sections C102 and C103 provided that a fire apparatus access road extends between properties and that an easement is established to prevent obstruction of such roads.

❖ To meet the number and spacing requirements of this appendix, existing hydrants may be counted as available. In smaller buildings, this could mean that the fire hydrants available may be sufficient to meet the hydrant spacing needs. Hydrants on adjacent property should not be used unless access is always available to the fire department. This may require an easement on the adjacent property.

The following resource material was used in the preparation of the commentary for this appendix of the code.

IRC-15, *International Residential Code*. Washington, DC: International Code Council, 2014.

**Figure C103.1  
HYDRANT SPACING**

# Appendix D: Fire Apparatus Access Roads

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Fire apparatus access is essential to successful fire-fighting and rescue operations. Fire department vehicles vary widely in size and operational needs and must be able to maneuver into position to properly undertake their fire-fighting activities. The needs of each jurisdiction will therefore vary with the equipment used. Needs assessment should also include consideration of mutual-aid companies that may respond from outside the jurisdiction. Access roads must be designed to provide the fire department with the required access to all structures on a site.

## Purpose

This appendix contains more detailed elements for use with the basic access requirements found in Section

503. Section 503 gives some minimum criteria, such as a maximum distance of 150 feet (45 720 mm) and a minimum width of 20 feet (6090 mm), but in many cases Section 503 does not state specific criteria. For example, what specific load should a fire apparatus access road be able to carry and what specific grade is allowed? Section 503 cannot go to this level of detail because needs vary widely from one jurisdiction to another. This appendix, like Appendices B and C, is a tool for jurisdictions seeking guidance in establishing access requirements.

Some of the other requirements found in this appendix address access layouts for multiple-family residential developments and large one- and two-family subdivisions. Also, specific examples for various types of turnarounds for fire department apparatus and parking regulation signage are included.

---

## SECTION D101 GENERAL

**D101.1 Scope.** Fire apparatus access roads shall be in accordance with this appendix and all other applicable requirements of the *International Fire Code*.

- ❖ If this appendix has been adopted by a jurisdiction, this particular section simply states that all fire apparatus access roads must meet the requirements of this appendix and other applicable requirements. More specifically, Section 503 would also apply.

Be aware that essentially all roads leading to a particular building or facility, whether public or private, are fire apparatus access roads. Generally, the requirements of this appendix and Section 503 would be required only for new buildings and facilities. However, in some cases, improvements to existing roads and access ways may be necessary to meet the needs of the fire department.

Note that the appendix applies only if specifically adopted by ordinance by a jurisdiction. See the commentary to Sections 102.5 and 507.1 for a discussion of this appendix's application (if adopted) to buildings constructed under the *International Residential Code*® (IRC®).

## SECTION D102 REQUIRED ACCESS

**D102.1 Access and loading.** Facilities, buildings or portions of buildings hereafter constructed shall be accessible to fire department apparatus by way of an *approved* fire apparatus access road with an asphalt, concrete or other *approved* driving surface capable of supporting the imposed load of fire apparatus weighing at least 75,000 pounds (34 050 kg).

- ❖ This section contains more detailed specifications for the road surface and applied loads. In Section 503, it simply states that the road must be able to withstand the loads and be of "all-weather driving capability." This section states that the surface be of asphalt, concrete or other approved material and be able to withstand a load of 75,000 pounds (34 050 kg).

## SECTION D103 MINIMUM SPECIFICATIONS

**D103.1 Access road width with a hydrant.** Where a fire hydrant is located on a fire apparatus access road, the minimum road width shall be 26 feet (7925 mm), exclusive of shoulders (see Figure D103.1).

- ❖ The access road width of 20 feet (6096 mm) stated in Section 503 does not specifically account for the

presence of the hydrant. This section specifically requires a minimum width of 26 feet (7925 mm) when a hydrant is located along that access roadway (see Figure D103.1). This provides more room for the fire department vehicle to maneuver and connect to the hydrant. In many cases, a full 26-foot (7925 mm) width may not be possible for a majority of the access road and a possible solution is to simply widen the access road for a short distance to accommodate hydrant use. Including adjacent road shoulders in the width measurement could yield substandard and inadequate driving surfaces for apparatus. Accordingly, this section makes it clear that any road shoulders are not to be included in the minimum fire apparatus access road width. Section 503 is generic because available water supplies are not always accessed using hydrants. In some cases, the water comes from a tanker or from an on-site water supply.

**D103.2 Grade.** Fire apparatus access roads shall not exceed 10 percent in grade.

**Exception:** Grades steeper than 10 percent as *approved* by the fire chief.

❖ Section 503 discusses grade in generalities and states that the grade be within the limits established by the fire code official. The criteria are generic because the conditions in different jurisdictions will

vary. For example, some fire department apparatus is able to handle steeper grades than others, and the likelihood of inclement weather, such as snow, will affect the ability of the vehicles to handle the terrain.

This appendix states a numerical criterion of not more than 10 percent, which is fairly conservative for most situations. This number gives something specific for a jurisdiction to cite without having to determine the actual grade. There is an exception to this section that would allow the fire chief to approve a grade greater than 10 percent. This gives the jurisdiction flexibility for specific situations where terrain might call for a steeper grade.

**D103.3 Turning radius.** The minimum turning radius shall be determined by the *fire code official*.

❖ The turning radius is left generic within both Section 503 and this section because of the large variation in the equipment used by fire departments. Each fire department must assess the specific abilities of its vehicles to set a minimum turning radius. The diagrams in Figure D103.1 set the turning radius at 28 feet (8534 mm), which may not be satisfactory for all jurisdictions.

**D103.4 Dead ends.** Dead-end fire apparatus access roads in excess of 150 feet (45 720 mm) shall be provided with width and turnaround provisions in accordance with Table D103.4.

For SI: 1 foot = 304.8 mm.

**FIGURE D103.1**  
**DEAD-END FIRE APPARATUS ACCESS ROAD TURNAROUND**

**TABLE D103.4**  
**REQUIREMENTS FOR DEAD-END**  
**FIRE APPARATUS ACCESS ROADS**

LENGTH (feet)	WIDTH (feet)	TURNAROUNDS REQUIRED
0-150	20	None required
151-500	20	120-foot Hammerhead, 60-foot “Y” or 96-foot diameter cul-de-sac in accordance with Figure D103.1
501-750	26	120-foot Hammerhead, 60-foot “Y” or 96-foot diameter cul-de-sac in accordance with Figure D103.1
Over 750		Special approval required

For SI: 1 foot = 304.8 mm.

❖ Though the widths of the access roadways may be sufficient to move and operate the necessary equipment at a fire scene, they may not be wide enough for the vehicles to turn around. On through streets this is not an issue, but when the road is a dead end and is sufficiently long, some means are necessary to enable fire department vehicles to turn around rather than having to back up over excessive distances. The three major methods used to provide a turn-around area are a cul-de-sac, hammerhead and “Y.” Figure D103.1 shows examples of all three types. Section 503 does not give any specific guidance. Each jurisdiction can choose from a variety of ways to accomplish this.

Dead ends require a fire vehicle turnaround when they exceed 150 feet (45 720 mm). The turnaround is to be located at the end of the roadway or within 150 feet (45 720 mm) of the end of the roadway to limit the backing distance to a maximum of 150 feet (45 720 mm). Backing a large vehicle, such as a tower ladder, over 150 feet (45 720 mm) can be especially challenging, especially in cases where the engineer may have to use a video camera-equipped back-up system due to the vehicle’s length. Refer to the table for more guidance in determining the kind of turning radius required. In any event, the configuration of the roadway and turnaround must be approved by the fire code official.

This table, which is based on the length of a dead end, sets minimum widths and recommends which types of turnarounds should be used. The diagrams in Figure D103.1 show the configurations of these turnarounds.

**D103.5 Fire apparatus access road gates.** Gates securing the fire apparatus access roads shall comply with all of the following criteria:

1. Where a single gate is provided, the gate width shall be not less than 20 feet (6096 mm). Where a fire apparatus road consists of a divided roadway, the gate width shall be not less than 12 feet (3658 mm).
2. Gates shall be of the swinging or sliding type.
3. Construction of gates shall be of materials that allow manual operation by one person.

4. Gate components shall be maintained in an operative condition at all times and replaced or repaired when defective.
5. Electric gates shall be equipped with a means of opening the gate by fire department personnel for emergency access. Emergency opening devices shall be *approved by the fire code official*.
6. Methods of locking shall be submitted for approval by the *fire code official*.
7. Electric gate operators, where provided, shall be *listed* in accordance with UL 325.
8. Gates intended for automatic operation shall be designed, constructed and installed to comply with the requirements of ASTM F 2200.

❖ Gates are sometimes required by the fire code official to limit access to certain hazardous fire areas. They are also often used as a security mechanism for gated communities and complexes. Section 503 discusses the use of gates in more general terms whereas this section provides more specific guidelines. The nine requirements stated here all must be complied with where applicable. They focus on maintaining the required width, ease of use and ability to open in an emergency. The construction and installation of gates and methods for opening the gates, whether by manual means or by a listed electrical mechanism, must comply with the referenced standards and be approved by the fire code official. This ensures that the operating procedures of the fire department are taken into account. See the commentary to Sections 503.5 and 503.6 for further information on gates.

**D103.6 Signs.** Where required by the *fire code official*, fire apparatus access roads shall be marked with permanent NO PARKING—FIRE LANE signs complying with Figure D103.6. Signs shall have a minimum dimension of 12 inches (305 mm) wide by 18 inches (457 mm) high and have red letters on a white reflective background. Signs shall be posted on one or both sides of the fire apparatus road as required by Section D103.6.1 or D103.6.2.

❖ One of the more challenging aspects of access roads is maintaining the necessary width. Parked cars can reduce this width if parking is not prohibited and the prohibition is posted. Section 503.3 addresses this need by giving the fire code official the authority to require marking of fire access roads. This section and Figure D103.6 add wording and dimension specifications for the signs needed to mark areas where parking is prohibited.

**D103.6.1 Roads 20 to 26 feet in width.** Fire lane signs as specified in Section D103.6 shall be posted on both sides of fire apparatus access roads that are 20 to 26 feet wide (6096 to 7925 mm).

❖ This section requires that parking be prohibited on both sides of narrower fire apparatus access roads. Twenty feet (6096 mm) is the appropriate width

needed for two average-size fire trucks to pass one another. If that width is reduced by parking even on one side, it will be potentially difficult for a fire department to undertake emergency operations in that area.

FIGURE D103.6  
FIRE LANE SIGNS

**D103.6.2 Roads more than 26 feet in width.** Fire lane signs as specified in Section D103.6 shall be posted on one side of fire apparatus access roads more than 26 feet wide (7925 mm) and less than 32 feet wide (9754 mm).

- ❖ Because this width is more than sufficient for maneuvering at least two fire department vehicles by one another, parking would be allowed on one side.

**SECTION D104  
COMMERCIAL AND INDUSTRIAL DEVELOPMENTS**

**D104.1 Buildings exceeding three stories or 30 feet in height.** Buildings or facilities exceeding 30 feet (9144 mm) or three stories in height shall have at least two means of fire apparatus access for each structure.

- ❖ This section addresses commercial and industrial buildings that, because of their height, can create a large challenge to a fire department. This section, along with Sections D105, D106 and D107, contains requirements for fire apparatus access roads for specific kinds of buildings or developments. Section 503 gives the fire code official the authority to require more access roads but does not specify when the additional roads are required. The need for additional access roads will depend on so many factors that each situation must be judged individually.

Because of the height of these buildings, various types of vehicles may be needed, and having two or more means of approaching the site may be necessary to manage and manipulate the vehicles.

**D104.2 Buildings exceeding 62,000 square feet in area.** Buildings or facilities having a gross *building area* of more than 62,000 square feet (5760 m<sup>2</sup>) shall be provided with two separate and *approved* fire apparatus access roads.

**Exception:** Projects having a gross *building area* of up to 124,000 square feet (11 520 m<sup>2</sup>) that have a single *approved* fire apparatus access road when all buildings are

equipped throughout with *approved automatic sprinkler systems*.

- ❖ Where buildings are very large in area, two separate fire apparatus access roads are required because a large building may be difficult to access rapidly and, if one of the access roads is blocked, there is a potential for a large fire loss. The exception acknowledges the ability of automatic sprinklers to prevent most fires from growing out of control quickly even when the building area is doubled and there is only a single, approved fire apparatus access road.

**D104.3 Remoteness.** Where two fire apparatus access roads are required, they shall be placed a distance apart equal to not less than one half of the length of the maximum overall diagonal dimension of the lot or area to be served, measured in a straight line between accesses.

- ❖ This concept is similar to the one dealing with the remoteness of exits in Section 1007.1.1. One of the primary reasons for multiple access roads is to ensure that if one access road is blocked or otherwise unavailable, another will allow access to the fire department. Therefore, when more than one access road is required, they need to be separated by enough distance to avoid a situation where both would be blocked or unavailable simply because they are too close to one another.

**SECTION D105  
AERIAL FIRE APPARATUS ACCESS ROADS**

**D105.1 Where required.** Where the vertical distance between the grade plane and the highest roof surface exceeds 30 feet (9144 mm), approved aerial fire apparatus access roads shall be provided. For purposes of this section, the highest roof surface shall be determined by measurement to the eave of a pitched roof, the intersection of the roof to the exterior wall, or the top of parapet walls, whichever is greater.

- ❖ Aerial apparatus access roads are required when the fire department cannot reach the roof or upper stories with ground ladders. The Insurance Services Office (ISO) Fire Suppression Rating Schedule suggests that fire departments carry a 35-foot ground ladder. When setting up a 35-foot ground ladder appropriately, the effective vertical reach of the ladder is approximately 30 feet; hence the 30-foot requirement within this section. Note that the measurement in this section is from grade plane to the edge of the roof where the ladder would be placed. If this measurement is greater than 30 feet, then an aerial apparatus access road would be required. The term eave is the most common term used in the *International Building Code*® (IBC®) when describing the edge of a peaked roof and is thus used herein. See also the commentary to the definition of “Grade plane” in Chapter 2.

**D105.2 Width.** Aerial fire apparatus access roads shall have a minimum unobstructed width of 26 feet (7925 mm), exclu-

sive of shoulders, in the immediate vicinity of the building or portion thereof.

- ❖ This section specifies the minimum road width needed for aerial apparatus. This width allows the aerial apparatus outriggers to be set solidly on the road surface for safe operation of the aerial equipment. Including adjacent road shoulders in the width measurement could yield substandard and inadequate driving or set-up surfaces for aerial apparatus. Accordingly, this section makes it clear that any road shoulders are not to be included in the minimum fire apparatus access road width.

**D105.3 Proximity to building.** At least one of the required access routes meeting this condition shall be located within a minimum of 15 feet (4572 mm) and a maximum of 30 feet (9144 mm) from the building, and shall be positioned parallel to one entire side of the building. The side of the building on which the aerial fire apparatus access road is positioned shall be approved by the *fire code official*.

- ❖ This section requires that the access road be specifically located where aerial equipment will have maximum access to the building. The fire code official, in consultation with the fire chief, must approve the final location of the aerial fire apparatus access road required by this section. Although not stated in this section, fireground operation protocols often place an aerial apparatus/truck company on the front side of the building so that the entire front, which could include emergency escape and rescue openings, can be reached by the ladder or the tower basket. The road that will meet the requirements of this section will often be the public street upon which the building fronts. The distance from the building to the road must be reviewed and approved to match the capabilities of the fire department aerial equipment versus the building's height.

**D105.4 Obstructions.** Overhead utility and power lines shall not be located over the aerial fire apparatus access road or between the aerial fire apparatus road and the building. Other obstructions shall be permitted to be placed with the approval of the *fire code official*.

- ❖ This section establishes requirements for controlling overhead obstructions to aerial fire apparatus positioned on aerial fire apparatus access roads to avoid the possibility of personnel injury and equipment damage, especially from electrical shock. The requirements prohibit overhead obstructions between the aerial fire apparatus access road and the building, but permit the fire code official to allow limited obstructions that do not affect the placement or use of aerial fire apparatus, such as site vegetation or a porte-cochere at the entrance to a building.

## SECTION D106

### MULTIPLE-FAMILY RESIDENTIAL DEVELOPMENTS

**D106.1 Projects having more than 100 dwelling units.** Multiple-family residential projects having more than 100

*dwelling units* shall be equipped throughout with two separate and *approved* fire apparatus access roads.

**Exception:** Projects having up to 200 *dwelling units* may have a single *approved* fire apparatus access road when all buildings, including nonresidential occupancies, are equipped throughout with *approved automatic sprinkler systems* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

- ❖ This section is intended to provide some specific guidance to jurisdictions for dealing with larger apartment complexes. Again, Section 503 suggests that more than one access road is needed when there is a potential for an access road to be unavailable. In a large complex there is a large potential for loss. Lack of access should not become a factor in such a loss.

This section requires at least two separate access roads any time the number of dwelling units exceeds 100. The term "approved" is used because the layout of the complex may require some specific considerations when providing the access roads. For example, having two access roads leading onto a facility that come together before reaching the actual buildings may not satisfy the criterion of remoteness to be effective in an emergency.

The exception would allow a single access road for up to 200 dwelling units if all buildings on the site are fully sprinklered to meet code requirements. This exception acknowledges the effectiveness of sprinklers in slowing the growth of fires; therefore, the risk of having the access road blocked or unusable is more acceptable.

**D106.2 Projects having more than 200 dwelling units.** Multiple-family residential projects having more than 200 *dwelling units* shall be provided with two separate and *approved* fire apparatus access roads regardless of whether they are equipped with an *approved automatic sprinkler system*.

- ❖ Because of the large size of such complexes and the potential for large losses, even where sprinklers are installed as required by Section 903.2.8, two approved access roads must be provided. This section emphasizes that the exception in Section D106.1 is for up to 200 units only.

**D106.3 Remoteness.** Where two fire apparatus access roads are required, they shall be placed a distance apart equal to not less than one-half of the length of the maximum overall diagonal dimension of the property or area to be served, measured in a straight line between accesses.

- ❖ This concept is similar to the one dealing with the remoteness of exits in Section 1007.1.1. One of the primary reasons for multiple access roads is to ensure that if one access road is blocked or otherwise unavailable, another will allow access by the fire department. Therefore, when more than one access road is required, those roads must be separated by enough distance to avoid a situation where both would be blocked or unavailable simply because they are too close to one another.

## SECTION D107 ONE- OR TWO-FAMILY RESIDENTIAL DEVELOPMENTS

**D107.1 One- or two-family dwelling residential developments.** Developments of one- or two-family dwellings where the number of *dwelling units* exceeds 30 shall be provided with two separate and *approved* fire apparatus access roads.

### Exceptions:

1. Where there are more than 30 *dwelling units* on a single public or private fire apparatus access road and all *dwelling units* are equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1, 903.3.1.2 or 903.3.1.3 of the *International Fire Code*, access from two directions shall not be required.
  2. The number of *dwelling units* on a single fire apparatus access road shall not be increased unless fire apparatus access roads will connect with future development, as determined by the *fire code official*.
- ❖ This section requires that one- and two-family dwelling subdivisions with more than 30 dwellings have more than one fire apparatus access road into the development. The second access road is needed in case one access road for any reason becomes unusable

Exception 1 states that when there are more than 30 dwelling units equipped throughout with an approved sprinkler system in accordance with NFPA 13, 13R or 13D, as applicable or approved, a second access road is not required. This recognizes the effectiveness and reliability of properly designed and installed automatic sprinkler systems in mitigating the need to have two access points.

Exception 2 requires approval by the fire code official any time a new house is constructed on an existing access road. Once the maximum number of dwelling units allowed by this section has been reached, no further development may occur unless the fire code official determines that there will be a future road connection that will prevent creation of an excessive dead-end situation with no means for apparatus turn-around. Such determination by the fire code official should consider the phased development of an individual project or adjacent projects. Requiring evidence of legal agreements for specific future development would be prudent, especially in times of economic uncertainty. This gives the fire code official an opportunity to assess whether additional access is required in the interim.

**D107.2 Remoteness.** Where two fire apparatus access roads are required, they shall be placed a distance apart equal to not less than one-half of the length of the maximum overall diagonal dimension of the property or area to be served, measured in a straight line between accesses.

- ❖ This concept is similar to the one dealing with the remoteness of exits in Section 1007.1.1. One of the primary reasons for multiple access roads is to

ensure that if one access road is blocked or otherwise unavailable, another will allow access by the fire department. Therefore, when more than one access road is required, those roads must be separated by enough distance to avoid a situation where both would be blocked or unavailable simply because they are too close to one another.

## SECTION D108 REFERENCED STANDARDS

ASTM	F2200—13	Standard Specification for Automated Vehicular Gate Construction	D103.5
ICC	IFC—15	International Fire Code	D101.1, D107.1
UL	325—02	Door, Drapery, Gate, Louver, and Window Operators and Systems, with Revisions through June 2013	D103.5

### Bibliography

The following resource material was used in the preparation of the commentary for this appendix of the code.

*2015 International Code Interpretations*. Washington, DC: International Code Council, 2015.

# Appendix E: Hazard Categories

*This appendix is for information purposes and is not intended for adoption.*

## General Comments

This appendix contains guidance for designers, engineers, architects, building officials, plans reviewers and inspectors in the classifying of hazardous materials so that proposed designs can be evaluated intelligently and accurately and can be an extremely useful tool for all concerned. A thorough understanding of how Material Safety Data Sheets (MSDS) are created and how to read them makes these hazard evaluations much easier.

## Purpose

The descriptive materials and explanations of hazardous materials and how to report and evaluate them on the MSDS that are contained in this appendix are intended to be instructional as well as informative. A thorough understanding of how to prepare and interpret the MSDS makes the code user's job easier.

---

## SECTION E101 GENERAL

**E101.1 Scope.** This appendix provides information, explanations and examples to illustrate and clarify the hazard categories contained in Chapter 50 of the *International Fire Code*. The hazard categories are based upon the DOL 29 CFR. Where numerical classifications are included, they are in accordance with nationally recognized standards.

This appendix should not be used as the sole means of hazardous materials classification.

❖ Although this appendix contains guidance in classifying hazardous materials, there are several other sources available to the fire code official or building official. The actual MSDS should be the only method used in the final classification of products because of the different characteristics that a blend of products produces. General classification information can come from NFPA 704, Chemical Hazards Response Information System (CHRIS) manuals, MSDS online and other methods.

It is important to remember that many chemicals have multiple hazards associated with them. A chemical may be a toxic poison (Group H-4) and also have a flammable or combustible base (Group H-2 or H-3), which creates additional problems. Section 5001 states, "Where a material has multiple hazards, all hazards shall be addressed." This means that the building must be protected in the above example as a Group H-4 use, as well as a Group H-3 use when the products are in sealed containers and a Group H-2 use if they are open to the air.

## SECTION E102 HAZARD CATEGORIES

**E102.1 Physical hazards.** Materials classified in this section pose a *physical hazard*.

❖ A chemical presents a physical hazard when there is evidence that it is a combustible liquid, compressed gas, cryogenic, explosive, a flammable gas, a flammable liquid, a flammable solid, an organic peroxide, an oxidizer, or a pyrophoric or unstable (reactive) or water-reactive material (see commentary, Section 5001.2.2.1).

**E102.1.1 Explosives and blasting agents.** The current UN/ DOT classification system recognized by international authorities, the Department of Defense and others classifies all *explosives* as Class 1 materials. They are then divided into six separate divisions to indicate their relative hazard. There is not a direct correlation between the designations used by the old DOT system and those used by the current system nor is there correlation with the system (high and low) established by the Bureau of Alcohol, Tobacco, Firearms and Explosives (BATF). Table 5604.3 of the *International Fire Code* provides some guidance with regard to the current categories and their relationship to the old categories. Some items may appear in more than one division, depending on factors such as the degree of confinement or separation, by type of packaging, storage configuration or state of assembly.

In order to determine the level of hazard presented by *explosive materials*, testing to establish quantitatively their *explosive* nature is required. There are numerous test methods that have been used to establish the character of an *explosive material*. Standardized tests, required for finished goods con-

taining *explosives* or *explosive materials* in a packaged form suitable for shipment or storage, have been established by UN/DOT and BATF. However, these tests do not consider key elements that should be examined in a manufacturing situation. In manufacturing operations, the condition and/or the state of a material may vary within the process. The in-process material classification and classification requirements for materials used in the manufacturing process may be different from the classification of the same material where found in finished goods depending on the stage of the process in which the material is found. A classification methodology must be used that recognizes the hazards commensurate with the application to the variable physical conditions as well as potential variations of physical character and type of *explosive* under consideration.

Test methods or guidelines for hazard classification of energetic materials used for in-process operations shall be *approved* by the *fire code official*. Test methods used shall be DOD, BATF, UN/DOT or other *approved* criteria. The results of such testing shall become a portion of the files of the jurisdiction and be included as an independent section of any Hazardous Materials Management Plan (HMMP) required by Section 5605.2.1 of the *International Fire Code*. Also see Section 104.7.2 of the *International Fire Code*.

Examples of materials in various Divisions are as follows:

1. Division 1.1 (High *Explosives*). Consists of *explosives* that have a mass explosion hazard. A mass explosion is one that affects almost the entire pile of material instantaneously. Includes substances that, where tested in accordance with *approved* methods, can be caused to detonate by means of a blasting cap where unconfined or will transition from *deflagration* to a *detonation* where confined or unconfined. Examples: dynamite, TNT, nitroglycerine, C-3, HMX, RDX, encased *explosives*, military ammunition.
2. Division 1.2 (Low *Explosives*). Consists of *explosives* that have a projection hazard, but not a mass explosion hazard. Examples: nondetonating encased *explosives*, military ammunition and the like.
3. Division 1.3 (Low *Explosives*). Consists of *explosives* that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard. The major hazard is radiant heat or violent burning, or both. Can be deflagrated where confined. Examples: smokeless powder, propellant *explosives*, display fireworks.
4. Division 1.4. Consists of *explosives* that pose a minor explosion hazard. The *explosive* effects are largely confined to the package and no projection of fragments of appreciable size or range is expected. An internal fire must not cause virtually instantaneous explosion of almost the entire contents of the package. Examples: squibs (nondetonating igniters), *explosive* actuators, *explosive* trains (low-level detonating cord).
5. Division 1.5 (Blasting Agents). Consists of very insensitive *explosives*. This division comprises substances that have a mass explosion hazard, but are so insensitive that there is very little probability of initiation or of transition from burning to *detonation* under normal conditions of transport. Materials are not cap sensitive; however, they are mass detonating where provided with sufficient input. Examples: oxidizer and liquid fuel slurry mixtures and gels, ammonium nitrate combined with fuel oil.
6. Division 1.6. Consists of extremely insensitive articles that do not have a mass *explosive* hazard. This division comprises articles that contain only extremely insensitive detonating substances and that demonstrate a negligible probability of accidental initiation or propagation. Although this category of materials has been defined, the primary application is currently limited to military uses. Examples: Low vulnerability military weapons.

*Explosives* in each division are assigned a compatibility group letter by the Associate Administrator for Hazardous Materials Safety (DOT) based on criteria specified by DOTn 49 CFR. Compatibility group letters are used to specify the controls for the transportation and storage related to various materials to prevent an increase in hazard that might result if certain types of *explosives* were stored or transported together. Altogether, there are 35 possible classification codes for *explosives*, e.g., 1.1A, 1.3C, 1.4S, etc.

- ❖ It is recognized that the hazard classification of goods packaged for release to the Department of Transportation (DOT) system is likely to be different from that of the same material when found in an unpackaged or bulk form. For example, a finished article as manufactured or packaged and classified as Division 1.4 may contain Division 1.1 or 1.3 material. Although the ingredients may in fact be classified differently when removed from the package or article, the hazard level of the finished device may be classified with a different level of hazard from the ingredients alone. Classification, in part, is based on the protection offered by the final package, the article itself, as well as the configuration or nature of the energetic materials as they exist within the article. Recognizing the fact that the hazard level of an energetic material can vary based on the physical character (size and shape) or configuration (physical arrangement) in which the material is found is key to understanding the nature of *explosives* and proper application of the code.

Scientific methods are needed to appraise the hazards of materials as they appear in the manufacturing process. By granting the fire code official authority to approve test methods, flexibility is provided while at the same time maintaining a reasonable level of control. By recording the technical basis of decision within the Hazardous Materials Management Plan (HMMP), a record of the criteria used to establish the

hazard level is maintained by the applicant. The reference to Section 104.7.2 refers the fire code official back to the administrative section of the code to exercise authority for outside technical assistance in those cases where such assistance is warranted. The terminology used in the examples reflects the current terminology, and examples accurately portray materials that may be encountered. The explanatory language has been drawn in pertinent part from 49 CFR Sections 173.50 and 173.58. Although the DOT has eliminated the Class A, B and C nomenclature, the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) has retained the use of the terms “high explosives” and “low explosives.” These terms are included in parenthesis where appropriate.

By definition, an “Explosive” is a chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G.

The term “explosive” includes any material determined to be within the scope of USC Title 18: Chapter 63 and also includes any material classified as an explosive other than consumer fireworks, 1.4G, by the hazardous materials regulations of DOTn 49 CFR. See the commentary to the definition of “Explosive” in Section 202.

The former classification system used by DOTn (UN/DOTn Class 1 explosives) included the terms “high explosives” and “low explosives.” The following terms further define explosives under the current system used by DOTn for all explosive materials defined as hazard Class 1 materials. Compatibility group letters are used together with the division to specify further limitations on each division noted; for example, the letter “G” identifies the material as a pyrotechnic substance or article containing a pyrotechnic substance and similar materials.

**Division 1.1.** Explosives that are a mass explosion hazard. A mass explosion is one that affects almost the entire load instantaneously.

**Division 1.2.** Explosives that have a projection hazard but not a mass explosion hazard.

**Division 1.3.** Explosives that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard.

**Division 1.4.** Explosives that pose a minor explosion hazard. The explosive effects are largely confined to the package and no projection of fragments of appreciable size or range is to be expected. An external fire must not cause virtually instantaneous explosion of almost the entire contents of the package.

**Division 1.5.** Very insensitive explosives. This division comprises substances that have a mass explosion hazard but are so insensitive that there is very little probability of initiation or of transition from burning to detonation under normal conditions of transport.

**Division 1.6.** Extremely insensitive articles that do not have a mass explosion hazard. This division comprises articles that contain only extremely insensitive detonating substances and which demonstrate a negligible probability of accidental initiation or propagation.

The term “explosive material” means explosives, blasting agents and detonators.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 56.

#### **E102.1.2 Compressed gases.** Examples include:

1. Flammable: acetylene, carbon monoxide, ethane, ethylene, hydrogen, methane. Ammonia will ignite and burn although its flammable range is too narrow for it to fit the definition of “Flammable gas.”

For binary mixtures where the hazardous component is diluted with a nonflammable gas, the mixture shall be categorized in accordance with CGA P-23.

2. Oxidizing: oxygen, ozone, oxides of nitrogen, chlorine and fluorine. Chlorine and fluorine do not contain oxygen but reaction with flammables is similar to that of oxygen.
3. Corrosive: ammonia, hydrogen chloride, fluorine.
4. Highly toxic: arsine, cyanogen, fluorine, germane, hydrogen cyanide, nitric oxide, phosphine, hydrogen selenide, stibine.
5. Toxic: chlorine, hydrogen fluoride, hydrogen sulfide, phosgene, silicon tetrafluoride.
6. Inert (chemically unreactive): argon, helium, krypton, neon, nitrogen, xenon.
7. Pyrophoric: diborane, dichloroborane, phosphine, silane.
8. Unstable (reactive): butadiene (unstabilized), ethylene oxide, vinyl chloride.

#### ❖ Compressed gases by definition are a material, or mixture of materials, that:

1. Is a gas at 68°F (20°C) or less at 14.7 pounds per square inch atmosphere (psia) (101 kPa) of pressure; and
2. Has a boiling point of 68°F (20°C) or less at 14.7 psia (101 kPa), which is either liquefied, nonliquefied or in solution, except those gases that have no other health or physical hazard properties and are not considered to be compressed until the pressure in the packaging exceeds 41 psia (282 kPa) at 68°F (20°C).

The states of a compressed gas are categorized as follows:

1. Nonliquefied compressed gases are gases, other than those in solution, that are in a packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).
2. Liquefied compressed gases are gases that, in a packaging under the charged pressure, are partially liquid at a temperature of 68°F (20°C).
3. Compressed gases in solution are nonliquefied gases that are dissolved in a solvent.
4. Compressed gas mixtures consist of a mixture of two or more compressed gases contained in a packaging, the hazard properties of which are represented by the properties of the mixture as a whole.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004, 5005 and 6004 and Chapters 53, 54, 55 and 58. In addition, flammable gases that are binary mixtures (i.e., compounded or consisting of two things or parts) diluted with a nonflammable gas present special categorization challenges, and therefore must be evaluated in accordance with CGA P-23. This standard provides consistency with industry standards for categorization.

**E102.1.3 Flammable and combustible liquids.** Examples include:

1. Flammable liquids.

Class IA liquids shall include those having *flash points* below 73°F (23°C) and having a *boiling point* at or below 100°F (38°C).

Class IB liquids shall include those having *flash points* below 73°F (23°C) and having a *boiling point* at or above 100°F (38°C).

Class IC liquids shall include those having *flash points* at or above 73°F (23°C) and below 100°F (38°C).

2. Combustible liquids.

Class II liquids shall include those having *flash points* at or above 100°F (38°C) and below 140°F (60°C).

Class IIIA liquids shall include those having *flash points* at or above 140°F (60°C) and below 200°F (93°C).

Class IIIB liquids shall include those liquids having *flash points* at or above 200°F (93°C).

- ❖ Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 57.

**E102.1.4 Flammable solids.** Examples include:

1. Organic solids: camphor, cellulose nitrate, naphthalene.

2. Inorganic solids: decaborane, lithium amide, phosphorous heptasulfide, phosphorous sesquisulfide, potassium sulfide, anhydrous sodium sulfide, sulfur.
3. Combustible metals (except dusts and powders): cesium, magnesium, zirconium.

- ❖ A flammable solid is a solid, other than a blasting agent or explosive, that is capable of causing fire through friction, absorption of moisture, spontaneous chemical change or retained heat from manufacturing or processing; has an ignition temperature below 212°F (100°C); or that burns so vigorously and persistently when ignited as to create a serious hazard. A chemical shall be considered a flammable solid as determined in accordance with the test method of CPSC 16 CFR; Part 1500.44 if it ignites and burns with a self-sustained flame at a rate greater than 0.1 inch (2.5 mm) per second along its major axis.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 59.

**E102.1.5 Combustible dusts and powders.** Finely divided solids that could be dispersed in air as a dust cloud: wood sawdust, plastics, coal, flour, powdered metals (few exceptions).

- ❖ Combustible dusts and combustible fibers are listed separately because they are not subcategories of flammable solids in either the maximum allowable quantity tables in Chapter 50 or in their respective material-specific hazard chapters.

**E102.1.6 Combustible fibers.** See Section 5202.1.

- ❖ See the commentary to Section E102.1.5.

**E102.1.7 Oxidizers.** Examples include:

1. Gases: oxygen, ozone, oxides of nitrogen, fluorine and chlorine (reaction with flammables is similar to that of oxygen).
2. Liquids: bromine, hydrogen peroxide, nitric acid, perchloric acid, sulfuric acid.
3. Solids: chlorates, chromates, chromic acid, iodine, nitrates, nitrites, perchlorates, peroxides.

- ❖ An oxidizer is material that readily yields oxygen or other oxidizing gas, or that readily reacts to promote or initiate combustion of combustible materials. An oxidizing gas is a gas that can support and accelerate combustion of other materials. Examples of other oxidizing gases include bromine, chlorine and fluorine.

**E102.1.7.1 Examples of liquid and solid oxidizers according to hazard.**

Class 4: ammonium perchlorate (particle size greater than 15 microns), ammonium permanganate, guanidine nitrate, hydrogen peroxide solutions more than 91 percent by weight, perchloric acid solutions more than 72.5 percent by weight, potassium superoxide, tetranitromethane.

Class 3: ammonium dichromate, calcium hypochlorite (over 50 percent by weight), chloric acid (10 percent maximum concentration), hydrogen peroxide solutions (greater than 52 percent up to 91 percent), mono-(trichloro)-tetra-(monopotassium di-chloro)-penta-s-triazinetrione, nitric acid, (fuming -more than 86 percent concentration), perchloric acid solutions (60 percent to 72 percent by weight), potassium bromate, potassium chlorate, potassium dichloro-s-triazinetrione (potassium dichloro-isocyanurate), potassium perchlorate (99 percent), potassium permanganate (greater than 97.5 percent), sodium bromate, sodium chlorate, sodium chlorite (over 40 percent by weight) and sodium dichloro-s-triazinetrione anhydrous (sodium dichloro-isocyanurate anhydrous).

Class 2: barium bromate, barium chlorate, barium hypochlorite, barium perchlorate, barium permanganate, 1-bromo-3-chloro-5, 5-dimethylhydantoin, calcium chlorate, calcium chlorite, calcium hypochlorite (50 percent or less by weight), calcium perchlorate, calcium permanganate, calcium peroxide (75 percent), chromium trioxide (chromic acid), copper chlorate, halane (1, 3-di-chloro-5, 5-dimethylhydantoin), hydrogen peroxide (greater than 27.5 percent up to 52 percent), lead perchlorate, lithium chlorate, lithium hypochlorite (more than 39 percent available chlorine), lithium perchlorate, magnesium bromate, magnesium chlorate, magnesium perchlorate, mercurous chlorate, nitric acid (more than 40 percent but less than 86 percent), perchloric acid solutions (more than 50 percent but less than 60 percent), potassium peroxide, potassium superoxide, silver peroxide, sodium chlorite (40 percent or less by weight), sodium perchlorate, sodium perchlorate monohydrate, sodium permanganate, sodium peroxide, sodium persulfate (99 percent), strontium chlorate, strontium perchlorate, thallium chlorate, urea hydrogen peroxide, zinc bromate, zinc chlorate and zinc permanganate.

Class 1: all inorganic nitrates (unless otherwise classified), all inorganic nitrites (unless otherwise classified), ammonium persulfate, barium peroxide, hydrogen peroxide solutions (greater than 8 percent up to 27.5 percent), lead dioxide, lithium hypochlorite (39 percent or less available chlorine), lithium peroxide, magnesium peroxide, manganese dioxide, nitric acid (40 percent concentration or less), perchloric acid solutions (less than 50 percent by weight), potassium dichromate, potassium monopersulfate (45 percent KHSO<sub>5</sub> or 90 percent triple salt), potassium percarbonate, potassium persulfate, sodium carbonate peroxide, sodium dichloro-s-triazinetrione dihydrate, sodium dichromate, sodium perborate (anhydrous), sodium perborate monohydrate, sodium perborate tetra-hydrate, sodium percarbonate, strontium peroxide, trichloro-s-triazinetrione (trichloroisocyanuric acid) and zinc peroxide.

- ❖ **Class 4.** An oxidizer that can undergo an explosive reaction as a result of contamination or exposure to thermal or physical shock. In addition, the oxidizer will enhance the burning rate and can cause spontaneous ignition of combustibles.

**Class 3.** An oxidizer that will cause a severe increase in the burning rate of combustible materials with which it comes in contact or that will undergo vigorous self-sustained decomposition as a result of contamination or exposure to heat.

**Class 2.** An oxidizer that will cause a moderate increase in the burning rate or that causes spontaneous ignition of combustible materials with which it comes in contact.

**Class 1.** An oxidizer whose primary hazard is that it slightly increases the burning rate but that does not cause spontaneous ignition when it comes in contact with combustible materials.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 63.

**E102.1.8 Organic peroxides.** Organic peroxides contain the double oxygen or peroxy (-o-o) group. Some are flammable compounds and subject to explosive decomposition. They are available as:

1. Liquids.
2. Pastes.
3. Solids (usually finely divided powders).

❖ Organic peroxides can pose an explosion hazard (detonation or deflagration) or they can be shock sensitive. They can also decompose into various unstable compounds over an extended period of time.

**E102.1.8.1 Classification of organic peroxides according to hazard.**

Unclassified: Unclassified organic peroxides are capable of *detonation* and are regulated in accordance with Chapter 56 of the *International Fire Code*.

Class I: acetyl cyclohexane sulfonyl 60-65 percent concentration by weight, fulfonyl peroxide, benzoyl peroxide over 98 percent concentration, t-butyl hydroperoxide 90 percent, t-butyl peroxyacetate 75 percent, t-butyl peroxyisopropylcarbonate 92 percent, diisopropyl peroxydicarbonate 100 percent, di-n-propyl peroxydicarbonate 98 percent, and di-n-propyl peroxydicarbonate 85 percent.

Class II: acetyl peroxide 25 percent, t-butyl hydroperoxide 70 percent (with DTBP and t-BuOH diluents), t-butyl peroxybenzoate 98 percent, t-butyl peroxy-2-ethylhexanoate 97 percent, t-butyl peroxyisobutyrate 75 percent, t-butyl peroxyisopropyl-carbonate 75 percent, t-butyl peroxy-pivalate 75 percent, dibenzoyl peroxydicarbonate 85 percent, di-sec-butyl peroxydicarbonate 98 percent, di-sec-butyl peroxydicarbonate 75 percent, 1,1-di-(t-butylperoxy)-3,5,5-trimethylcyclohexane 95 percent, di-(2-ethylhexyl) peroxydicarbonate 97 percent, 2,5-dimethyl-2,5 di (benzoylperoxy) hexane 92 percent, and peroxyacetic acid 43 percent.

Class III: acetyl cyclohexane sulfonal peroxide 29 percent, benzoyl peroxide 78 percent, benzoyl peroxide paste 55 percent, benzoyl peroxide paste 50 percent peroxide/50 percent butylbenzylphthalate diluent, cumene hydroperoxide 86 percent, di-(4-butylcyclohexyl) peroxydicarbonate 98 percent, t-butyl peroxy-2-ethylhexanoate 97 percent, t-butyl peroxyneodecanoate 75 percent, decanoyl peroxide 98.5 percent, di-t-butyl peroxide 99 percent, 1,1-di-(t-butylperoxy)3,5,5-trimethylcyclohexane 75 percent, 2,4-dichlorobenzoyl peroxide 50 percent, di-isopropyl peroxydicarbonate 30 percent, 2,-5-di-methyl-2,5-di-(2-ethylhexanolyperoxy)-hexane 90 percent, 2,5-dimethyl-2,5-di-(t-butylperoxy) hexane 90 percent and methyl ethyl ketone peroxide 9 percent active oxygen diluted in dimethyl phthalate.

Class IV: benzoyl peroxide 70 percent, benzoyl peroxide paste 50 percent peroxide/15 percent water/35 percent butylphthalate diluent, benzoyl peroxide slurry 40 percent, benzoyl peroxide powder 35 percent, t-butyl hydroperoxide 70 percent, (with water diluent), t-butyl peroxy-2-ethylhexanoate 50 percent, decumyl peroxide 98 percent, di-(2-ethylhexal) peroxydicarbonate 40 percent, laurel peroxide 98 percent, p-methane hydroperoxide 52.5 percent, methyl ethyl ketone peroxide 5.5 percent active oxygen and methyl ethyl ketone peroxide 9 percent active oxygen diluted in water and glycols.

Class V: benzoyl peroxide 35 percent, 1,1-di-t-butyl peroxy 3,5,5-trimethylcyclohexane 40 percent, 2,5-di-(t-butyl peroxy) hexane 47 percent and 2,4-pentanedione peroxide 4 percent active oxygen.

- ❖ **Unclassified detonable.** Organic peroxides that are capable of detonation. These peroxides pose an extremely high explosion hazard through rapid explosive decomposition.

**Class I.** Those formulations that are capable of deflagration but not detonation.

**Class II.** Those formulations that burn very rapidly and that pose a moderate reactivity hazard.

**Class III.** Those formulations that burn rapidly and that pose a moderate reactivity hazard.

**Class IV.** Those formulations that burn in the same manner as ordinary combustibles and that pose a minimal reactivity hazard.

**Class V.** Those formulations that burn with less intensity than ordinary combustibles or do not sustain combustion and that pose no reactivity hazard.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 62.

#### **E102.1.9 Pyrophoric materials.** Examples include:

1. Gases: diborane, phosphine, silane.
2. Liquids: diethylaluminum chloride, di-ethylberyllium, diethylphosphine, diethylzinc, dimethylarsine, triethylaluminum etherate, tri-ethylbismuthine, triethylboron, trimethylaluminum, trimethylgallium.

3. Solids: cesium, hafnium, lithium, white or yellow phosphorous, plutonium, potassium, rubidium, sodium, thorium.

- ❖ **Pyrophoric materials** are two or more unmixed, commercially manufactured, prepackaged chemical substances, including oxidizers, flammable liquids or solids or similar substances that are not independently classified as explosives but that, when mixed or combined, form an explosive that is intended for blasting.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 64.

#### **E102.1.10 Unstable (reactive) materials.** Examples include:

Class 4: acetyl peroxide, dibutyl peroxide, dinitrobenzene, ethyl nitrate, peroxyacetic acid and picric acid (dry) trinitrobenzene.

Class 3: hydrogen peroxide (greater than 52 percent), hydroxylamine, nitromethane, paranitroaniline, perchloric acid and tetrafluoroethylene monomer.

Class 2: acrolein, acrylic acid, hydrazine, methacrylic acid, sodium perchlorate, styrene and vinyl acetate.

Class 1: acetic acid, hydrogen peroxide 35 percent to 52 percent, paraldehyde and tetrahydrofuran.

- ❖ An unstable (reactive) material is a material, other than an explosive, that in its pure state or as commercially produced, will vigorously polymerize, decompose, condense or become self-reactive and undergo other violent chemical changes, including explosion, when:

1. Exposed to heat, friction, or shock;
2. In the absence of an inhibitor;
3. In the presence of contaminants; or
4. In contact with incompatible materials.

Unstable (reactive) materials are subdivided as follows:

**Class 4.** Materials that in themselves are readily capable of detonation, explosive decomposition or reaction at normal temperatures and pressures. This class includes materials that are sensitive to mechanical or localized thermal shock at normal temperatures and pressures.

**Class 3.** Materials that in themselves are capable of detonation, explosive decomposition or reaction but that require a strong initiating source or must be heated under confinement before initiation. This class includes materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures.

**Class 2.** Materials that in themselves are normally unstable and readily undergo violent chemical change but do not detonate. This class includes materials that can undergo chemical change with rapid release of energy at normal temperatures

and pressures, and that can undergo violent chemical change at elevated temperatures and pressures.

**Class 1.** Materials that in themselves are normally stable but that can become unstable at elevated temperatures and pressures.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 66.

**E102.1.11 Water-reactive materials.** Examples include:

Class 3: aluminum alkyls such as triethylaluminum, isobutylaluminum and trimethylaluminum; bromine pentafluoride, bromine trifluoride, chlorodiethylaluminum and diethylzinc.

Class 2: calcium carbide, calcium metal, cyanogen bromide, lithium hydride, methylchlorosilane, potassium metal, potassium peroxide, sodium metal, sodium peroxide, sulfuric acid and trichlorosilane.

Class 1: acetic anhydride, sodium hydroxide, sulfur monochloride and titanium tetrachloride.

- ❖ A water-reactive material explodes; violently reacts; produces flammable, toxic or other hazardous gases; or evolves enough heat to cause self-ignition or ignition of nearby combustibles upon exposure to water or moisture. Water-reactive materials are subdivided as follows:

Class 3. Materials that react explosively with water without requiring heat or confinement.

Class 2. Materials that may form potentially explosive mixtures with water.

Class 1. Materials that may react with water with some release of energy, but not violently.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 67.

**E102.1.12 Cryogenic fluids.** The cryogenics listed will exist as *compressed gases* where they are stored at ambient temperatures.

1. Flammable: carbon monoxide, deuterium (heavy hydrogen), ethylene, hydrogen, methane.
2. Oxidizing: fluorine, nitric oxide, oxygen.
3. *Corrosive*: fluorine, nitric oxide.
4. Inert (chemically unreactive): argon, helium, krypton, neon, nitrogen, xenon.
5. Highly toxic: fluorine, nitric oxide.

- ❖ A cryogenic fluid is liquid having a boiling point lower than 150°F (101°C) at 14.7 pounds per square inch atmosphere (psia) (101 kPa).

A flammable cryogenic fluid is cryogenic fluid that is flammable in its vapor state.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 55.

**E102.2 Health hazards.** Materials classified in this section pose a *health hazard*.

- ❖ If a chemical is classified as a health hazard, there is statistically significant evidence that it can cause acute or chronic health effects in exposed persons. The term “health hazard” includes chemicals that are toxic, highly toxic and corrosive.

**E102.2.1 Highly toxic materials.** Examples include:

1. Gases: arsine, cyanogen, diborane, fluorine, germane, hydrogen cyanide, nitric oxide, nitrogen dioxide, ozone, phosphine, hydrogen selenide, stibine.
2. Liquids: acrolein, acrylic acid, 2-chloroethanol (ethylene chlorohydrin), hydrazine, hydrocyanic acid, 2-methylaziridine (propylenimine), 2-methyl-acetonitrile (acetone cyanohydrin), methyl ester isocyanic acid (methyl isocyanate), nicotine, tetranitromethane and tetraethylstannane (tetraethyltin).
3. Solids: (aceto) phenylmercury (phenyl mercuric acetate), 4-aminopyridine, arsenic pentoxide, arsenic trioxide, calcium cyanide, 2-chloroacetophenone, aflatoxin B, decaborane(14), mercury (II) bromide (mercuric bromide), mercury (II) chloride (*corrosive* mercury chloride), pentachlorophenol, methyl parathion, phosphorus (white) and sodium azide.

- ❖ A highly toxic material produces a lethal dose or lethal concentration that falls within any of the following categories:

1. A chemical that has a median lethal dose (LD<sub>50</sub>) of 50 milligrams or less per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
2. A chemical that has a median lethal dose (LD<sub>50</sub>) of 200 milligrams or less per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.
3. A chemical that has a median lethal concentration (LC<sub>50</sub>) in air of 200 parts per million by volume or less of gas or vapor, or 2 milligrams per liter or less of mist, fume or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

Mixtures of these materials with ordinary materials, such as water, might not warrant classification as highly toxic. Although this system is basically simple in application, any hazard evaluation that is required for the precise categorization of this type of material must be performed by experienced, technically competent persons.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 60.

**E102.2.2 Toxic materials.** Examples include:

1. Gases: boron trichloride, boron trifluoride, chlorine, chlorine trifluoride, hydrogen fluoride, hydrogen sulfide, phosgene, silicon tetrafluoride.
2. Liquids: acrylonitrile, allyl alcohol, alpha-chlorotoluene, aniline, 1-chloro-2,3-epoxypropane, chloroformic acid (allyl ester), 3-chloropropene (allyl chloride), o-cresol, crotonaldehyde, dibromomethane, diisopropylamine, diethyl ester sulfuric acid, dimethyl ester sulfuric acid, 2-furaldehyde (furfural), furfural alcohol, phosphorus chloride, phosphoryl chloride (phosphorus oxychloride) and thionyl chloride.
3. Solids: acrylamide, barium chloride, barium (II) nitrate, benzidine, p-benzoquinone, beryllium chloride, cadmium chloride, cadmium oxide, chloroacetic acid, chlorophenylmercury (phenyl mercuric chloride), chromium (VI) oxide (chromic acid, solid), 2,4-dinitrotoluene, hydroquinone, mercury chloride (calomel), mercury (II) sulfate (mercuric sulfate), osmium tetroxide, oxalic acid, phenol, P-phenylenediamine, phenylhydrazine, 4-phenylmorpholine, phosphorus sulfide, potassium fluoride, potassium hydroxide, selenium (IV) disulfide and sodium fluoride.

❖ A toxic chemical falls within any of the following categories:

1. A chemical that has a median lethal dose (LD<sub>50</sub>) of more than 50 milligrams per kilogram, but not more than 500 milligrams per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
2. A chemical that has a median lethal dose (LD<sub>50</sub>) of more than 200 milligrams per kilogram but not more than 1,000 milligrams per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.
3. In air of more than 200 parts per million but not more than 2,000 parts per million by volume of gas or vapor, or more than 2 milligrams per liter but not more than 20 milligrams per liter of mist, fume or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 60.

**E102.2.3 Corrosives.** Examples include:

1. Acids: Examples: chromic, formic, hydrochloric (muriatic) greater than 15 percent, hydrofluoric, nitric

(greater than 6 percent, perchloric, sulfuric (4 percent or more).

2. Bases (alkalis): hydroxides-ammonium (greater than 10 percent), calcium, potassium (greater than 1 percent), sodium (greater than 1 percent); certain carbonates-potassium.
3. Other *corrosives*: bromine, chlorine, fluorine, iodine, ammonia.

**Note:** *Corrosives* that are oxidizers, e.g., nitric acid, chlorine, fluorine; or are *compressed gases*, e.g., ammonia, chlorine, fluorine; or are water-reactive, e.g., concentrated sulfuric acid, sodium hydroxide, are *physical hazards* in addition to being *health hazards*.

- ❖ Corrosive chemicals cause visible destruction of, or irreversible alterations in, living tissue by chemical action at the point of contact. A chemical shall be considered corrosive if, when tested on the intact skin of albino rabbits by the method described in DOTn 49 CFR, Part 173, it destroys or changes irreversibly the structure of the tissue at the point of contact following an exposure period of 4 hours. This term does not refer to action on inanimate surfaces.

Chemicals in this classification must meet the minimum requirements of Sections 5001, 5003, 5004 and 5005, and Chapter 54.

## SECTION E103 EVALUATION OF HAZARDS

**E103.1 Degree of hazard.** The degree of hazard present depends on many variables that should be considered individually and in combination. Some of these variables are as shown in Sections E103.1.1 through E103.1.5.

- ❖ How can the degree of hazard presented by the various chemicals that may be in the structure under design or review be determined? The only way to ensure that the structure is constructed or reviewed to the correct standards is to obtain and review the MSDS on the specific chemicals proposed. Owners can expect their structures to be required to meet a number of federal laws that regulate hazardous materials, including: the Superfund Amendments and Reauthorization Act of 1986 (SARA), the Resource Conservation and Recovery Act of 1976 (RCRA), the Hazardous Materials Transportation Act (HMTA), the Occupational Safety and Health Act (OSHA), the Toxic Substances Control Act (TSCA) and the Clean Air Act and Title III of SARA.

Community building/fire departments must make certain that the properties in their areas meet Title III of SARA, which regulates the packaging, labeling, handling, storage and transportation of hazardous materials. The law requires facilities to furnish information about the quantities and health effects of materials used at the facility and to promptly notify local and state officials whenever a significant release of hazardous materials occurs. Title 42, Chapter 116, Subchapter II, Section 11021 of the

Emergency Planning and Community Right-to-Know Act contains the following requirements for the submittal of MSDS:

Basic requirement

1. Submission of MSDS or list

The owner or operator of any facility which is required to prepare or have available a material safety data sheet for a hazardous chemical under the Occupational Safety and Health Act of 1970 (29 U.S.C. 651 et seq.) and regulations promulgated under that Act shall submit a material safety data sheet for each chemical.

These MSDS are a guide to determining the specific hazards presented to a community. The sections that follow, along with their commentary, should help determine whether the MSDS is complete and correct in identifying the properties and characteristics of the hazardous materials expected in the subject occupancy.

**E103.1.1 Chemical properties of the material.** Chemical properties of the material determine self reactions and reactions that could occur with other materials. Generally, materials within subdivisions of hazard categories will exhibit similar chemical properties. However, materials with similar chemical properties could pose very different hazards. Each individual material should be researched to determine its hazardous properties and then considered in relation to other materials that it might contact and the surrounding environment.

❖ When we think of chemical properties, what should we be looking for in the MSDS in terms of reactivity hazards?

*Hypergolic materials* are those chemicals that will ignite when they come in contact with each other. Rocket propellants and military munitions are the most common uses of this type of material.

*Pyrophoric materials* react and ignite on contact with air. Common storage practices have this type of material stored in inert substances or under pressure in sealed containers to prevent the introduction of air.

*Water-reactive materials* will react on contact with water. It is very important to the emergency personnel that these chemicals be identified and labeled properly. The use of fire hoses and sprinklers with this type of material can be very dangerous for the responding personnel.

*Unstable materials* can violently decompose with little or no outside stimulus. Several of the materials used in the development of plastics can exhibit these traits.

**E103.1.2 Physical properties of the material.** Physical properties, such as whether a material is a solid, liquid or gas at ordinary temperatures and pressures, considered along with chemical properties will determine requirements for containment of the material. Specific gravity (weight of a liquid compared to water) and vapor density (weight of a gas com-

pared to air) are both physical properties that are important in evaluating the hazards of a material.

❖ When we think of physical properties, what should we be looking for in the MSDS?

*Flammable and combustible liquids classifications* are determined by their chemical flash points and boiling points. The only difference between the various classifications of flammable and combustible liquids is the degree difference in these two chemical properties.

*Ignition temperature* is the temperature that the fuel in air must be heated for self-sustained combustion without help from a heat source. This gives the MSDS user a point to determine how the method of storage can change the properties of the chemical.

*Flammability range* is a very important property to understand because it will relate to the amount of ventilation that may be required to satisfy the *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>). If a storage atmosphere is within the flammability range, a dangerous situation exists. In this condition the only element missing to start a fire is an ignition source; thus, an incident could happen at any time. In the reverse, when the storage arrangement is outside the flammability range, a much safer condition exists because the air-to-chemical ratio must be within the range prior to a dangerous incident.

*Specific gravity* is the weight of the item compared to the weight of an equal volume of water. Water is given a specific gravity of 1.00. If the chemical has a specific gravity less than 1.00, the chemical will float on water. For that reason, water would not be an effective extinguishing tool. Also, the chemical will flow with any runoff of fire-fighting water. Diking or another containment method is needed to contain the fire-fighting water and chemicals. If the chemical has a specific gravity greater than 1.00, the chemical will sink in water. It is important to note that most flammable liquids have a specific gravity less than 1.00. Review the MSDS for the specific requirements for the chemicals.

*Vapor density* is similar to specific gravity; however, it is a comparison between the densities of a gas/vapor and air. Again, air is given a density of 1.00. If the chemical has a vapor density less than 1.00, it will rise. In many cases the vapor density being less than 1.00 is a good property because there are far fewer high ignition sources; however, remember that in an incident, the gas/vapor can be spread over a larger area. The spreading can reduce the flammability range enough to greatly lessen the possibility of a fire. If the vapor density is greater than 1.00, the gas/vapor will sink to the lowest point in the storage area. An example of a protection method in the codes for this property is the requirement that gas-fired appliances in garages must be 18 inches (457 mm) above the floor surface. This allows a chemical with a high vapor density to spread across

the floor surface without encountering an ignition source.

*Water solubility* refers to the chemical's ability to mix with water. This information can be used in creating a proper response to an emergency incident.

**E103.1.3 Amount and concentration of the material.** The amount of material present and its concentration must be considered along with physical and chemical properties to determine the magnitude of the hazard. Hydrogen peroxide, for example, is used as an antiseptic and a hair bleach in low concentrations (approximately 8 percent in water solution). Over 8 percent, hydrogen peroxide is classed as an oxidizer and is toxic. Above 90 percent, it is a Class 4 oxidizer "that can undergo an explosive reaction when catalyzed or exposed to heat, shock or friction," a definition that incidentally also places hydrogen peroxide over 90-percent concentration in the unstable (reactive) category. Small amounts at high concentrations could present a greater hazard than large amounts at low concentrations.

❖ Many chemicals exhibit combined chemical traits, one of which is toxicity. The amount of damage that can be inflicted on the environment is based on the toxicity and the threshold limit values, lethal dosage, lethal concentration or emergency exposure limits.

Review the chemicals that will be housed in the structure or used in the process. Look at their chemical, physical and toxicity properties. The method of storage and the amounts of chemical will also play a major role in determining hazards. Chemical and physical characteristics were covered in Sections E103.1.1 and E103.1.2. This section covers the properties of toxicity.

*Threshold limit value*, also known as "time weighted average" (TLV/TWA), is the maximum amount of chemical that the human body can be exposed to for 8 hours a day or 40 hours a week without dangerous effects. This number is important when checking or reviewing the ventilation for a structure. TLV/TWA is normally expressed in parts per million, while others are sometimes expressed as a percentage per billion. This is the number of molecules of chemical per molecules of air. It is important to note that the smaller the ratio, the more toxic the material.

*Lethal dosage* (LD) is the minimum amount of solid or liquid that, when ingested or absorbed through the skin, may be fatal. MSDS provide this information typically as LD<sub>50</sub>. This notation represents the amount of chemical that will kill at least 50 percent of the test subjects when exposed. The amount is expressed in milligrams per kilogram of body weight.

*Lethal concentration* (LC) is the minimum concentration in the gaseous state that, when inhaled, may be fatal. MSDS provide this information typically as LC<sub>50</sub>. This notation is expressed in milligrams per liter.

*Emergency exposure limit* or TLV short-term exposure limit (EEL or TLVSTEL) is the maximum amount of chemical that can be tolerated with no permanent toxic effects.

*Ceiling limit* (TLVC) is the amount of chemical that normally will not cause immediate irritation. This limit should never be reached in normal operation, even for an instant.

**E103.1.3.1 Mixtures.** Gases—toxic and highly toxic gases include those gases that have an LC<sub>50</sub> of 2,000 parts per million (ppm) or less when rats are exposed for a period of 1 hour or less. To maintain consistency with the definitions for these materials, exposure data for periods other than 1 hour must be normalized to 1 hour. To classify mixtures of *compressed gases* that contain one or more toxic or highly toxic components, the LC<sub>50</sub> of the mixture must be determined. Mixtures that contain only two components are binary mixtures. Those that contain more than two components are multicomponent mixtures. Where two or more hazardous substances (components) having an LC<sub>50</sub> below 2,000 ppm are present in a mixture, their combined effect, rather than that of the individual substance components, must be considered. In the absence of information to the contrary, the effects of the hazards present must be considered as additive. Exceptions to the above rule could be made when there is a good reason to believe that the principal effects of the different harmful substances (components) are not additive.

For binary mixtures where the hazardous component is diluted with a nontoxic gas such as an inert gas, the LC<sub>50</sub> of the mixture is estimated by use of the methodology contained in CGA P-20. The hazard zones specified in CGA P-20 are applicable for DOTn purposes and shall not be used for hazard classification.

❖ This information allows evaluation of the methods of calculation submitted by the chemical engineer. It is not designed for the inspector/plans examiner to perform the calculations during inspection or plan review. Mixtures and chemicals should be evaluated by a qualified person such as a chemical engineer, with the information submitted to the inspector/plans examiner. MSDS for the specific mixtures can be submitted in place of separate chemical engineering evaluations. Calculations for toxic gas mixtures are included in the referenced standard CGA P-20 and will bring consistency to the definition of "Toxic gas mixtures." It is easy to determine the proper hazard classification of toxic gas mixtures by using CGA P-20.

**E103.1.4 Actual use, activity or process involving the material.** The definition of handling, storage and use in *closed systems* refers to materials in packages or containers. Dispensing and use in open containers or systems describes situations where a material is exposed to ambient conditions or vapors are liberated to the atmosphere. Dispensing and use in *open systems*, then, are generally more hazardous situations than handling, storage or use in *closed systems*. The actual use or process could include heating, electric or other sparks, catalytic or reactive materials and many other factors that could affect the hazard and must therefore be thoroughly analyzed.

❖ The owner must be asked how the products will be used in the facility. Tables 5003.1.1(1) and (2) are

based on normal storage arrangements, open systems and closed systems. The amount of chemical allowed per control area is based on how the chemical is being used or stored. Correct interpretation of the tables depends on knowing how the chemicals will be used. Remember that any process that changes the chemical traits must be accounted for. These would include preheating and pressurizing the chemicals.

**E103.1.5 Surrounding conditions.** Conditions such as other materials or processes in the area, type of construction of the structure, fire protection features (e.g., *fire walls*, sprinkler systems, alarms, etc.), occupancy (use) of adjoining areas, normal temperatures, exposure to weather, etc., must be taken into account in evaluating the hazard.

❖ Final elements in determining hazards are the conditions of storage and use. Will the chemical be in outdoor storage, indoor storage or in a detached building? What types of protection for the chemicals are proposed? What types of protection are required for the type of hazard? What are the requirements for temperature control for the chemicals? What types of processes will the chemicals be used in? The answers to these questions will determine whether the proposed structure meets the minimum requirements of the code.

**E103.2 Evaluation questions.** The following are sample evaluation questions:

❖ Evaluating each chemical proposed to be in a structure and determining whether the structure will be a hazardous use group is very important. In today's society, even those occupancies that would normally not be thought of as having hazardous materials can have enough involved in production to change the use group. For example, during review of a dentist's office (normally considered a business use group) MSDS were requested for all chemicals, along with the amounts and storage methods. When the MSDS were received, the chemicals reported included one that was listed as explosive when at room temperature. The occupancy was to have 3 pounds (1.4 kg) of the product.

The introduction of this one chemical made the structure move from a Group B use to a Group H-1 use, and the product had to be stored in a detached storage building. These questions must be asked and evaluated to determine whether a building is a Group H use.

1. What is the material? Correct identification is important; exact spelling is vital. Check labels, MSDS, ask responsible persons, etc.

❖ The properties of chemicals change with the mixture, manufacturer and blends. Generic information cannot be used; information recorded on the MSDS must match the exact chemical that will be used. Currently, there are at least six different blends of diesel fuel that, based on the flash point and boiling point, can range from a Class IC to a Class III flammable liquid;

thus, different protection and exempt amounts are allowed and required for the chemical. It is important to note that the changing of one letter in the chemical name can change a chemical that is not considered hazardous to one that is extremely hazardous. Precise information is required to determine whether a hazardous use group designation is needed.

2. What are the concentration and strength?

❖ Based on the blend, concentration and strength of solution, each chemical takes on different traits. One MSDS does not cover all concentrations and blends; a separate MSDS must be submitted for each specific chemical.

3. What is the physical form of the material? Liquids, gases and finely divided solids have differing requirements for spill and leak control and containment.

❖ The physical form of the material is important from the standpoint of hazards and the concept of fire. Gases are more dangerous than liquids and liquids are more dangerous than solids. Understanding the form and makeup of the chemical will assist in determining the danger to the structure and the community. Each physical form will have its own problems with protection and containment that must be considered in the review.

4. How much material is present? Consider in relation to permit amounts, *maximum allowable quantity per control area* (from Group H occupancy requirements), amounts that require detached storage and overall magnitude of the hazard.

❖ A review of the chemicals and amounts of product that will be present will raise some questions: Will the chemicals be in an open or closed container? What type of protection will be provided? Will the chemical be placed in control areas in accordance with Section 5003.8.2? Will the amounts be more than the exempt amounts allowed by Tables 5003.1.1 and 5003.1.1(2) or be one of the exceptions listed in Section 5001.1? The answers to these questions will govern the types of requirements that must be addressed.

5. What other materials (including furniture, equipment and building components) are close enough to interact with the material?

❖ Will other items be stored close to the chemical storage? Will the storage of other chemicals that are normally not hazardous cause a more hazardous condition when mixed with the hazardous chemicals in an emergency? Is the fire load of the area increased by the presence of the chemicals and general storage? If so, additional protection may be required based on the additional fire loading and hazards created.

6. What are the likely reactions?

❖ Will the mixing of chemical or fire protection features create a dangerous or hazardous condition if the chemicals are not separated into different contain-

ment areas? Checking the MSDS for adverse reactions to other products in the storage area is extremely important.

7. What is the activity involving the material?
- ❖ What process will the chemical be used in? Will the physical conditions of the chemical be changed by heating, pressurizing or other methods during the use, process or manufacturing of the final product? It is important to note that some nonhazardous chemicals, through the processing phases, can create a hazardous atmosphere. As much information and knowledge as possible of the processing system and use of the chemical must be gained for a good review/inspection process.
  8. How does the activity impact the hazardous characteristics of the material? Consider vapors released or hazards otherwise exposed.
- ❖ Is the chemical being used in an open atmosphere? Chemicals in an open system are normally much more dangerous than they would be in a closed system. When dealing with a toxic chemical, what types of filters are required to protect personnel and the environment?
  9. What must the material be protected from? Consider other materials, temperature, shock, pressure, etc.
- ❖ High explosives can be detonated by light to moderate shock. Some chemicals can react to changes in temperatures. Containers under pressure can react violently. The MSDS must be checked for these types of hazards to make certain protective storage and use arrangements fit requirements.
  10. What effects of the material must people and the environment be protected from?
- ❖ What are the dangers to the environment or to personnel if there is an emergency release? Dikes, special filters, distance from other structures and other methods of protection may be required to reduce the impact from an emergency release.
  11. How can protection be accomplished? Consider:
    - 11.1. Proper containers and equipment.
      - ❖ Plastic pint bottles, glass bottles, safety cans, drums, barrels, above-ground tanks and underground tanks are just a few of the types of containers that may be used for storage. Each type of container has special requirements for size and methods of storage. These requirements can be found in Chapter 50 and other related references.
        - 11.2. Separation by distance or construction.
      - ❖ Group H-1 use areas must be located in a detached building. Outdoor storage must be separated from other buildings and property lines by distances as outlined in Section 5003.12 and other related sections.

11.3. Enclosure in cabinets or rooms.

- ❖ Third-party tested hazardous materials storage cabinets can be used to increase the exempt amounts allowed by Tables 5003.1.1(1) and (2). These cabinets must meet the minimum requirements of Sections 5003.8.4, 6004.1.2 and other related sections. Gas rooms must meet the requirements of Sections 5003.8.3, 6004.1.2 and other related sections. Flammable liquid storage rooms must meet the requirements of Section 5704.3.7.3 and related codes.

11.4. Spill control, drainage and containment.

- ❖ If one can minimize the spill area and contain any accidental release, the amount of potential damage will be greatly reduced. Cleanup will be easier and the hazard reduced for fire service and emergency workers. Spill control, drainage and containment must meet the minimum requirements of Section 5004.2 and related sections. Remember that the containment area is, in a lot of cases, more hazardous than the initial storage area.

11.5. Control systems—ventilation, special electrical, detection and alarm, extinguishment, explosion venting, limit controls, exhaust scrubbers and excess flow control.

- ❖ The methods of control, how much ventilation, special detection and alarms will be obtained from the MSDS. Section 5003 contains guidance into requirements for additional protection.

11.6. Administrative (operational) controls—signs, ignition source control, security, personnel training, established procedures, storage plans and emergency plans.

Evaluation of the hazard is a strongly subjective process; therefore, the person charged with this responsibility must gather as much relevant data as possible so that the decision will be objective and within the limits prescribed in laws, policies and standards.

It could be necessary to cause the responsible persons in charge to have tests made by qualified persons or testing laboratories to support contentions that a particular material or process is or is not hazardous. See Section 104.7.2 of the *International Fire Code*.

- ❖ Posting signs, as required by Section 5003.5, is an important component to alert emergency response personnel to possible dangers to them and the community. Section 5003.7 contains guidance on the requirements for ignition source controls. Section 5003.9.1 contains information on personnel training. Section 5003.9.2 contains information on security. Storage plans and emergency plans requirements can be found in Sections 407, 408 and 5001.4.1 and other related sections. Having an up-to-date emergency plan is very important to both the community and emergency services; however, it is often overlooked.

# Appendix F: Hazard Ranking

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

The presence of hazardous materials in all types of occupancies is becoming more common. While industrial facilities are constantly developing and expanding their use of hazardous materials, significant quantities of an ever-increasing variety of materials can also be found in other occupancies, such as hospitals, research laboratories and even mercantile uses. Knowledge of hazardous materials within a given occupancy is essential not only for proper code enforcement but also for prefire planning purposes. Although submittal of Material Safety Data Sheets (MSDS) and compliance with right-to-know legislation are necessary to determine the proper mitigation means for all hazardous materials, it is also true that in an emergency response situation, responders must have a clear and readily available warning of the material hazards that confront them. The NFPA 704 hazard classification system was developed for that express purpose and it is the intent of this appendix to provide the fire code official with a ready reference tool for approval of the hazard warnings required by Chapter 50, among others.

## Purpose

The code regulates the storage, dispensing and use of all hazardous materials classified as either physical or health hazards. These materials pose diverse hazards, including instability, reactivity, flammability, oxidizing potential or toxicity; therefore, identifying them by hazard ranking is essential. The information in this appendix is intended to be a companion to the specific requirements of Chapters 51 through 67.

The table included in this appendix lists the various hazardous materials categories that are defined in Chapter 2 of the code, along with the NFPA 704 hazard ranking for each. Once a specific material is properly identified and categorized as meeting a given hazardous material definition, the appropriate flammability, health, reactivity, oxidizing and special hazard designations of the NFPA 704 system can be readily found in the table.

---

## SECTION F101 GENERAL

**F101.1 Scope.** Assignment of levels of hazards to be applied to specific hazard classes as required by NFPA 704 shall be in accordance with this appendix. The appendix is based on application of the degrees of hazard as defined in NFPA 704 arranged by hazard class as for specific categories defined in Chapter 2 of the *International Fire Code* and used throughout.

❖ This paragraph establishes the relationship between the hazardous materials definitions found in Chapter 2 and the methods used in NFPA 704 to establish the degree of hazard for a wide variety of hazardous materials.

**F101.2 General.** The hazard rankings shown in Table F101.2 have been established by using guidelines found within NFPA 704. As noted in Section 4.2 of NFPA 704, there could be specific reasons to alter the degree of hazard assigned to a specific material; for example, ignition temperature, flammable range or susceptibility of a container to rupture by an internal combustion explosion or to metal failure while under pressure or because of heat from external fire. As a result, the

degree of hazard assigned for the same material can vary when assessed by different people of equal competence.

The hazard rankings assigned to each class represent reasonable minimum hazard levels for a given class based on the use of criteria established by NFPA 704. Specific cases of use or storage may dictate the use of higher degrees of hazard in certain cases.

❖ These two paragraphs explain the rationale for the hazard rankings shown in Table F101.2. The word of caution sounded here is that rankings will vary depending on the circumstances of each individual application. In addition, because fire code officials are required to use personal judgement to determine rankings, those rankings may vary from one official to another because of their differing personal backgrounds and experience.

The message given in the last sentence of the first paragraph is very significant. The fire code official will be called upon to use every bit of knowledge gained through years of experience to make judgments of hazards on a case-by-case basis. The rankings shown in Table F101.2 are minimums. The fire code official

APPENDIX F

may decide that circumstances in individual cases require higher rankings than are shown in the table.

As an example of how conditions can cause a change in ranking, consider this. The method of storage and processing of a chemical can greatly change the ranking. If a Class IIIB combustible liquid is preheated to its flashpoint, or pressurized to greater than 15 psi (103 kPa), it will exhibit the same traits as a Class IA flammable liquid. Thus, the ranking would change from a 1 (F1) in the flammable diamond to a 4 (F4). This increase in ranking is a result of the change of storage method and process, not any change in the chemical makeup of the combustible liquid.

Diamond” sign depicted in Chapter 9 of NFPA 704 and required by Sections 407.3 and 5003.5. Consistent with Section 5001.2.2, the materials listed in this table may possess multiple hazard characteristics that must be displayed in additional quadrants of the “NFPA 704 Diamond.” The construction and content of the signs must be approved by the fire code official as required by Section 5003.6. Note that the designations in this table are not to be confused with occupancy group designations established by Chapter 3 of the *International Building Code*® (IBC®).

TABLE F101.2. See below.

❖ The alpha-numeric designations indicated in this table represent the primary hazard information that is to appear in the various quadrants of the “NFPA 704

TABLE F101.2  
FIRE FIGHTER WARNING PLACARD DESIGNATIONS BASED ON HAZARD CLASSIFICATION CATEGORIES

HAZARD CATEGORY	DESIGNATION
	F2
	F2
Combustible liquid II	F1
Combustible liquid IIIA	F4
Combustible liquid IIIB	F3
Combustible dust	F4, H3
Combustible fiber	OX, H3
Cryogenic flammable	R4
Cryogenic oxidizing	F2
Explosive	F4
Flammable solid	F4
Flammable gas (gaseous)	F4
Flammable gas (liquefied)	F4
Flammable liquid IA	F3
Flammable liquid IB	F3
Flammable liquid IC	R4
Organic peroxide, UD	F4, R3
Organic peroxide I	F3, R3
Organic peroxide II	F2, R2
Organic peroxide III	F1, R1
Organic peroxide IV	None
Organic peroxide V	OX
Oxidizing gas (gaseous)	OX
Oxidizing gas (liquefied)	OX
Oxidizer 4	OX4
Oxidizer 3	OX3
Oxidizer 2	OX2
Oxidizer 1	OX1
Pyrophoric gases	F4
Pyrophoric solids, liquids	F3
Unstable reactive 4D	R4
Unstable reactive 3D	R4
Unstable reactive 3N	R4
Unstable reactive 2	R2
Unstable reactive 1	R2
Water reactive 3	None
Water reactive 2	W3
Corrosive	W2
Toxic	H3, COR
Highly toxic	H3
	H4

F—Flammable category.  
R—Reactive category.  
H—Health category.  
W—Special hazard: water reactive.  
OX—Special hazard: oxidizing properties.

COR—Corrosive.  
UD—Unclassified detonable material.  
4D—Class 4 detonable material.  
3D—Class 3 detonable material.  
3N—Class 3 nondetonable material.

# Appendix G: Cryogenic Fluids—Weight and Volume Equivalents

*This appendix is for information purposes and is not intended for adoption.*

## General Comments

Chapter 55 of the code regulates cryogenic fluids (liquefied gases) that are used to provide very low temperatures in a variety of scientific and industrial processes. Low temperatures in cryogenic processes are achieved primarily by the liquefaction of gases, resulting in the family of hazardous materials known as cryogenic fluids (see the commentary to the definition of “Cryogenic fluid” in Section 202). More than 25 such cryogenics are currently in use in the cryogenic industry; however, this appendix focuses on the six that account for the greatest volume of use and application in research and industry: helium, hydrogen, nitrogen, argon, oxygen and liquefied natural gas (LNG; methane).

Although cryogenic fluids are characterized by extreme low temperatures, ranging from a boiling point of 258.5°F (161.4°C) for LNG to 453.1°F (269.5°C) for helium, they also possess another hazard characteristic: a high volume expansion ratio from liquid to gas, from approximately 696 to 1 for nitrogen, to 860 to 1 for oxygen. And while argon, helium, oxygen and nitrogen in the cryogenic range are not toxic or flammable, they can cause asphyxiation by displacing the air necessary for the support of life when released. Even pure oxygen, an oxidizer, may have harmful physiological effects if it is breathed over an extended period.

There is also the flammable gas hazard when cryogenic fluids, such as hydrogen and LNG, are stored or used. However, the fire hazard may also be greatly increased when cryogenic fluids normally thought to be

nonflammable are used. The presence of oxygen, for example, will greatly increase the combustibility of ordinary combustible materials, and may even cause some noncombustible materials like carbon steel to burn readily under the right conditions. Liquefied inert gases, such as liquid nitrogen or liquid helium, are also capable, under the right conditions, of condensing oxygen from the atmosphere and causing unsuspected oxygen enrichment or entrapment in areas where there may be ignition sources. Reduction of such conditions, and the potential asphyxiation hazard of cryogenic fluids (liquefied gases) discussed above, may be accomplished, in part, by a properly designed ventilation system.

To properly apply the requirements of Chapter 55 to reduce the hazards discussed here, the volume of gas capable of being generated by a cryogenic fluid installation must be determined. Rather than leaving such determination to case-by-case mathematical calculation, this appendix gives the fire code official and design professional a convenient tool for determining the correct gas volumes for selected cryogenic fluids. For further discussion of cryogenic fluids, see the commentary to Chapter 55.

## Purpose

This appendix gives the fire code official a ready reference tool for the conversion of the liquid weight and volume of cryogenic fluid to their corresponding volume of gas and vice versa.

---

## SECTION G101 GENERAL

**G101.1 Scope.** This appendix is used to convert from liquid to gas for *cryogenic fluids*.

- ❖ This appendix gives the liquid volume for the most frequently used cryogenic fluids for a given weight at the normal boiling point of the liquid, and then shows the volume of gas that will expand from that volume of liquid at normal temperature and pressure (NTP). An example showing how to use the table is given in the paragraphs that follow.

Anyone who has followed a truck containing liquid nitrogen down a highway has seen the vapor plume venting from the tank. Anyone who has watched the launch of a liquid-fueled rocket, such as the space shuttle booster or the Saturn V used to put Apollo capsules in moon orbit, has seen a vapor plume coming from the liquid oxygen tanks. In both cases the plume is water vapor that has been condensed from the air by the cold gas escaping from the tanks through overpressure valves.

All of these common cryogenics represent hazards of one kind or another. LNG and hydrogen are both

flammable and present combustion and explosion hazards at concentrations that are addressed in Chapter 55. Oxygen can also contribute tremendously to the intensity of a fire, its size and its spread. On the other hand, helium, argon and nitrogen are nonflammable, but are not breathable. Helium, being lighter than air, would rise to the highest levels of the storage space, presenting a minimal hazard unless the concentration became so large that it displaced breathable air at lower levels. Nitrogen and argon are heavier and would concentrate at lower levels, displacing breathable air.

**G101.2 Conversion.** Table G101.2 shall be used to determine the equivalent amounts of *cryogenic fluids* in either the liquid or gas phase.

❖ Table G101.2 is a convenient reference to determine the volume of gas that will expand from a given volume of cryogenic fluid. This kind of information is important to the decision of what quantities can be safely stored or used under any set of conditions and also to the determination of what ventilation capacity would be required for those storage or use conditions.

**G101.2.1 Use of the table.** To use Table G101.2, read horizontally across the line of interest. For example, to determine the number of cubic feet of gas contained in 1.0 gallon (3.785 L) of liquid argon, find 1.000 in the column entitled “Volume of Liquid at Normal *Boiling Point*.” Reading across the line under the column entitled “Volume of Gas at NTP” (70°F and 1 atmosphere/14.7 psia), the value of 112.45 cubic feet (3.184 m<sup>3</sup>) is found.

❖ This example emphasizes the importance of expansion volume of these cryogenic liquids to determining safe storage and use conditions. Leakage of as little as 10 gallons (38 L) of liquid argon would displace all air in a space measuring 10 feet by 10 feet by 10 feet (3048 mm by 3048 mm by 3048 mm), unless the ventilation system for this space is sized to remove the expanding gas as it escapes from its container or transport system.

**G101.2.2 Other quantities.** If other quantities are of interest, the numbers obtained can be multiplied or divided to obtain the quantity of interest. For example, to determine the number of cubic feet of argon gas contained in a volume of 1,000 gallons (3785 L) of liquid argon at its normal *boiling point*, multiply 112.45 by 1,000 to obtain 112,450 cubic feet (3184 m<sup>3</sup>).

❖ This example shows that the basic numbers in the table can be used to calculate the effect of any quantity of cryogenic liquid on any given storage or work space.

The table can also be used to calculate needed information about design requirements. Consider this simplified example:

Assume a cryogenic tank that holds 75 gallons (284 L) of liquid oxygen (LOX) and weighs 200 pounds (91 kg) empty. The tank is to be located in a room in an existing retirement home building to fill

portable oxygen bottles for individuals needing breathing assistance. An exhaust hood will be installed over the tank to assist in carrying off any oxygen vapors. To be determined is whether the floor structure of the existing room will carry the added load of the filled tank and also what volume of oxygen gas would have to be exhausted in case of a valve failure.

Table G101.2 shows that 1 gallon (3.785 L) of LOX weighs 9.527 pounds (4.3 kg). The weight of the tank and its contents may then be calculated as follows:

$$\begin{aligned} 75 \text{ gal.} \times 9.527 \text{ lb/gal} &= 714.525 \text{ lb (324.4 kg)} \\ 714.525 \text{ lb} + 200 \text{ lb} &= 915 \text{ lb (415 kg)} \\ \text{Add safety factor of } 2 &= 1,830 \text{ lb (831 kg)} \end{aligned}$$

The floor structure would have to support the added load of the LOX tank and its contents having a weight of approximately 2,000 pounds (1080 kg) [see the commentary to Chapter 16 of the *International Building Code*® (IBC®) for discussion of structural loads].

Table G101.2 also shows that 1 gallon (3.785 L) of LOX will expand to 115.05 cubic feet (3.26 m<sup>3</sup>) of gas. Assuming the tank is full and a valve failure would result in the tank emptying completely in 2 hours, the exhaust hood would have to be able to remove the following volume of gas:

$$\begin{aligned} 75 \text{ gal.} \times 115.05 \text{ cu. ft./gal.} &= 8628.75 \text{ cu. ft.} \\ &= (244.4 \text{ m}^3) \text{ total} \\ 8628.75 \text{ cu. ft.} \div 120 \text{ min.} &= 71.9 \text{ cfm (2 m}^3\text{/min)} \end{aligned}$$

The exhaust hood fan would have to be able to remove 72 cubic feet per minute (cfm) (0.03 m<sup>3</sup>/s) of gas from the room.

This example is obviously a simplified version of a real problem. In real-world terms, more information would be needed about the volume of the room the tank is in, and additional safety features to make sure no spark sources or flammable materials are added where concentrations of oxygen could intensify a fire would need to be considered. But it does serve to show how Table G101.2 can be used to help designers, contractors, inspectors, plans examiners and building owners and tenants determine whether planned installations meet minimum safety requirements.

**TABLE G101.2  
WEIGHT AND VOLUME EQUIVALENTS FOR COMMON CRYOGENIC FLUIDS**

CRYOGENIC FLUID	WEIGHT OF LIQUID OR GAS		VOLUME OF LIQUID AT NORMAL BOILING POINT		VOLUME OF GAS AT NTP	
	Pounds	Kilograms	Liters	Gallons	Cubic feet	Cubic meters
Argon	1.000	0.454	0.326	0.086	9.67	0.274
	2.205	1.000	0.718	0.190	21.32	0.604
	3.072	1.393	1.000	0.264	29.71	0.841
	11.628	5.274	3.785	1.000	112.45	3.184
	10.340	4.690	3.366	0.889	100.00	2.832
	3.652	1.656	1.189	0.314	35.31	1.000
	1.000	0.454	3.631	0.959	96.72	2.739
Helium	2.205	1.000	8.006	2.115	213.23	6.038
	0.275	0.125	1.000	0.264	26.63	0.754
	1.042	0.473	3.785	1.000	100.82	2.855
	1.034	0.469	3.754	0.992	100.00	2.832
	0.365	0.166	1.326	0.350	35.31	1.000
	1.000	0.454	6.409	1.693	191.96	5.436
	2.205	1.000	14.130	3.733	423.20	11.984
Hydrogen	0.156	0.071	1.000	0.264	29.95	0.848
	0.591	0.268	3.785	1.000	113.37	3.210
	0.521	0.236	3.339	0.882	100.00	2.832
	0.184	0.083	1.179	0.311	35.31	1.000
	1.000	0.454	0.397	0.105	12.00	0.342
	2.205	1.000	0.876	0.231	26.62	0.754
	2.517	1.142	1.000	0.264	30.39	0.861
Oxygen	9.527	4.321	3.785	1.000	115.05	3.250
	8.281	3.756	3.290	0.869	100.00	2.832
	2.924	1.327	1.162	0.307	35.31	1.000
	1.000	0.454	0.561	0.148	13.80	0.391
	2.205	1.000	1.237	0.327	30.43	0.862
	1.782	0.808	1.000	0.264	24.60	0.697
	6.746	3.060	3.785	1.000	93.11	2.637
Nitrogen	7.245	3.286	4.065	1.074	100.00	2.832
	2.558	1.160	1.436	0.379	35.31	1.000
	1.000	0.454	1.052	0.278	22.968	0.650
	2.205	1.000	2.320	0.613	50.646	1.434
	0.951	0.431	1.000	0.264	21.812	0.618
	3.600	1.633	3.785	1.000	82.62	2.340
	4.356	1.976	4.580	1.210	100.00	2.832
LNG <sup>a</sup>	11.501	5.217	1.616	0.427	35.31	1.000

For SI: 1 pound = 0.454 kg, 1 gallon = 3.785 L, 1 cubic foot = 0.02832 m<sup>3</sup>, °C = [(°F)-32]/1.8, 1 pound per square inch atmosphere = 6.895 kPa.

a. The values listed for liquefied natural gas (LNG) are "typical" values. LNG is a mixture of hydrocarbon gases, and no two LNG streams have exactly the same composition.

# Appendix H: Hazardous Materials Management Plan (HMMP) and Hazardous Materials Inventory Statement (HMIS) Instructions

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

The requirements for a Hazardous Materials Management Plan (HMMP) or Hazardous Materials Inventory Statement (HMIS) have existed in some form since the 1988 edition of the legacy *Uniform Fire Code*. HMMP and HMIS must be submitted with permit applications when required by the fire code official. Appendix H provides an example format for these documents and clarifies the information to be submitted to the building code official for review of plans to determine compliance with the hazardous material requirements in *International Building Code*® (IBC®) Sections 414 and 415.

Appendix H was developed to provide a standard reporting format for businesses submitting an HMMP or HMIS to the fire or building code official based on the classification and quantities of materials that would be found on site for storage or use. Appendix H is not mandatory unless it is adopted by the jurisdiction. Some jurisdictions have already developed standard formats for submittal of HMMP and HMIS. Appendix H can be amended to provide this information to the regulated community.

Appendix H is divided into four distinct sections:

1. H101: Hazardous Materials Management Plan
2. H102: Hazardous Materials Inventory Statement

3. H103: Emergency Plan

4. H104: Referenced Standards

The sample forms in this appendix and available Material Safety Data Sheets (MSDS) provide the basis for the evaluations. The use of the forms should promote uniformity in the manner that hazardous materials information is provided, stored and used.

## Purpose

Sections 407.5 and 407.6 of the *International Fire Code*® (IFC®) require that HMIS and HMMP be provided. Sections 5001.5.1 and 5001.5.2 specify their contents when these documents are required to be submitted with a permit application by the fire code official. They focus on three important goals. First, the HMIS is formatted so that plan reviewers can determine the correct occupancy classification of the building based on material hazards. Second, the HMMP and HMIS provide hazardous materials storage and use information necessary for inspectors. Third, the HMMP includes information that fire department operations personnel need before and during an emergency response.

The amounts of each hazard class in storage and use and the applicable maximum allowable quantities are provided in the HMIS.

---

## SECTION H101 HMMP

❖HMMP have commonly been used as a tool to help facilitate tactical preplanning of Group H occupancies or facilities storing and handling large amounts of hazardous materials, such as petroleum storage terminals. They can be beneficial when preparing tactical preplans, but can be cumbersome if actually used as such. For example, consider a typical water treatment plant that could have large amounts of anhydrous chlorine, sulfur dioxide, sodium hydroxide and hydrofluorosilic acid. To comply with all of the require-

ments of an HMMP for the various storage and process piping drawings, plant layout and process details could easily result in over 100 pages of information that would need to be read and understood. This level of information has not always been beneficial to emergency responders, especially given that Section 5003.9.1.1 requires that the permit holder designate responsible persons to serve as fire department liaisons in the event of an incident. It is expected that these responsible persons have a good understanding of the hazardous materials and the processes involving their storage and use.

**H101.1 Part A** (See Example Format in Figure 1).

1. Fill out items and sign the declaration.
  2. Part A of this section is required to be updated and submitted annually, or within 30 days of a process or management change.
- ❖ The business information portion of the plan is to identify the business, location and responsible people who will interact with the fire department, both during normal review periods and during an emergency incident. Also included is general information regarding the type of process, procedures and storage; and the number of people normally in the facility during each shift and time period the business is open to assist in accounting for them during an emergency. This plan assists not only the fire department, but also the business to establish a listing of employees to be accounted for during an emergency. The plan must be continually reviewed by the company to ensure the information is current and reviewed by the fire department during inspections.

**H101.2 Part B—General Facility Description/Site Plan** (See Example Format in Figure 2).

1. Provide a site plan on 8<sup>1</sup>/<sub>2</sub> by 11 inch (215 mm by 279 mm) paper, showing the locations of all buildings, structures, outdoor chemical control or storage and use areas, parking lots, internal roads, storm and sanitary sewers, wells and adjacent property uses. Indicate the approximate scale, northern direction and date the drawing was completed.
- ❖ The facility description and site plan is a description of what occurs at the facility and where. This form must correlate the processes and procedures with locations on the building and site plans to be provided on Figure 3 (see commentary, Section H101.3).

**H101.3 Part C—Facility Storage Map—Confidential Information** (See Example Format in Figure 3).

1. Provide a floor plan of each building identified on the site plan as containing hazardous materials on 8<sup>1</sup>/<sub>2</sub>-inch by 11-inch (215 mm by 279 mm) paper, identifying the northern direction, and showing the location of each storage and use area.
2. Identify storage and use areas, including hazard waste storage areas.
3. Show the following:
  - 3.1. Accesses to each storage and use area.
  - 3.2. Location of emergency equipment.
  - 3.3. Location where liaison will meet emergency responders.
  - 3.4. Facility evacuation meeting point locations.
  - 3.5. The general purpose of other areas within the building.
  - 3.6. Location of all aboveground and underground tanks to include sumps, vaults, below-grade treatment systems, piping, etc.

- 3.7. Show hazard classes in each area.
- 3.8. Show locations of all Group H occupancies, control areas, and exterior storage and use areas.
- 3.9. Show emergency exits.

- ❖ In creating the facility map, it is usually best to follow the map maker's guide of orientating the site so that North is at the top of the page, identified by the use of a compass arrow pointing toward the top of the page. Wherever possible, standard map symbols should be used. In any event, clear identification of required features is essential to the effectiveness of the map. NFPA 170, *Fire Safety and Emergency Symbols*, may be useful in map preparation.

Identify the use, storage and waste storage using different symbols. With the areas identified, it is important to identify the access to each area and emergency exits, and the location of emergency equipment that is available for the hazard. The designated location for the facility liaison to meet the fire department is important for the prompt exchange of information regarding the facility and as a location where employees are to go to be safe and out of the way of emergency responders.

The location of tanks at the facility, especially the underground tanks, piping and valves, and the material classes are needed in addition to the control areas or Group H occupancies within the buildings. Exterior storage and use areas also need to be clearly identified.

**SECTION H102  
HMIS**

- ❖ HMIS are commonly used for determining a building's occupancy classification and to satisfy the requirements in Section 105 for operational permits to store, handle, dispense and use hazardous materials. Section 5001.5.2 previously required that product information, the MSDS for each product, the hazard classification of the material using the criteria in Section 5001.2.2 and the maximum quantity stored on site be reported. While this information is helpful in understanding the hazards that may be associated with a particular occupancy or premises, it does not require reporting amounts in open or closed systems or the identification of the control areas locations.

**H102.1 Inventory statement contents.**

1. HMIS Summary Report (see Example Format in Figure 4).
  - 1.1. Complete a summary report for each control area and Group H occupancy.
  - 1.2. The storage summary report includes the HMIS Inventory Report amounts in storage, use-closed and use-open conditions.
  - 1.3. Provide separate summary reports for storage, use-closed and use-open conditions.

- 1.4. IBC/IFC Hazard Class.
  - 1.5. Inventory Amount. [Solid (lb), Liquid (gal), Gas (cu ft, gal or lbs)].
  - 1.6. IBC/IFC Maximum Allowable Quantity per control area (MAQ). (If applicable, double MAQ for sprinkler protection and/or storage in cabinets. For wholesale and retail sales occupancies, go to Tables 5003.11.1 and 5704.3.4.1 of the *International Fire Code* for MAQs.)
2. HMIS Inventory Report (see Example Format in Figure 5).
    - 2.1. Complete an inventory report by listing products by location.
    - 2.2. Product Name.
    - 2.3. Components. (For mixtures specify percentages of major components if available.)
    - 2.4. Chemical Abstract Service (CAS) Number. (For mixtures list CAS Numbers of major components if available.)
    - 2.5. Location. (Identify the control area or, if it is a Group H occupancy, provide the classification, such as H-2, H-3, etc.)
    - 2.6. Container with a capacity of greater than 55 gallons (208 L). (If product container, vessel or tank could exceed 55 gallons, indicate yes in column.)
    - 2.7. Hazard Classification. (List applicable classifications for each product.)
    - 2.8. Stored. (Amount of product in storage conditions.)
    - 2.9. Closed. (Amount of product in use-closed systems.)
    - 2.10. Open. (Amount of product in use-open systems.)

Facilities that have prepared, filed and submitted a Tier II Inventory Report required by the U.S. Environmental Protection Agency (USEPA) or required by a state that has secured USEPA approval for a similar form shall be deemed to have complied with this section.

- ❖ Facilities that have prepared, filed and submitted a Tier II Inventory Report required by the U.S. Environmental Protection Agency (U.S. EPA) or required by a state which has secured U.S. EPA approval for a similar form shall be deemed to have complied with this section.

The HMIS Report is a comprehensive summary of the hazardous materials to be found at the facility for each control area or Group H occupancy area, and is to contain all of the information listed in Items 1 and 2 of this section (see also Section 5001.5.2). Note that this section of the HMIS is only needed if a SARA Tier II Report has not been filed.

### SECTION H103 EMERGENCY PLAN

1. Emergency Notification. (See Example Format in Figure 6.)
  2. Where OSHA or state regulations require a facility to have either an Emergency Action Plan (EAP) or an Emergency Response Plan (ERP), the EAP or ERP shall be included as part of the HMMP.
- ❖ When state or Occupational Safety and Health Administration (OSHA) regulations require an Emergency Action Plan or Emergency Response Plan, the plan must provide contact information for liaisons of the business to the appropriate response agencies.

# Appendix I: Fire Protection Systems— Noncompliant Conditions

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Appendix I addresses unsafe conditions for fire protection systems. This particular appendix was developed by the ICC Hazard Abatement in Existing Buildings Committee to help building owners and fire code officials improve their awareness of fire protection system deficiencies that have a high probability of causing a system to be inoperative.

Appendix I does not contain any requirements for identifying unsafe conditions in alternative fire-extinguishing systems such as dry chemical, carbon dioxide or clean agent systems or wet chemical alternative fire extinguishing systems designed to protect commercial kitchen cooking activities.

While it is not a comprehensive list of inspection and maintenance requirements for fire protection systems, Appendix I is intended to identify problems that are readily observable during fire inspections and can be used in conjunction with Chapter 9 of the and the applicable NFPA standards for the indicated fire protection equipment and systems and their maintenance. For example, water supply reliability data for water-based fire protection systems show that the major causes for failure of automatic sprinkler systems include shutting

off the source of the water supply, not extending sprinkler protection into rooms or areas that are not protected, or the introducing goods or commodities that cannot be controlled based on the sprinkler system's discharge density.

Excluding the general provision in Section I101.1, the appendix is divided into two sections. Section I101.2 addresses noncompliant conditions that require the replacement of sprinklers and system gauges, including sprinklers that are damaged, painted or improperly oriented. It also requires sprinklers manufactured in 1919 or earlier to be replaced. Section I101.3 addresses noncompliant conditions for automatic sprinkler systems, standpipes, their fire department connections, fire pumps, fire alarm and detections systems and portable fire extinguishers.

## Purpose

The requirements in Appendix I focus on the identification of unsafe conditions for water-based fire protection systems including automatic sprinkler systems, standpipes, fire pumps and automatic fire detection and signaling systems. It also identifies unsafe conditions for portable fire extinguishers.

## SECTION I101 NONCOMPLIANT CONDITIONS

**I101.1 General.** This appendix is intended to identify conditions that can occur where fire protection systems are not properly maintained or components have been damaged. This appendix is not intended to provide comprehensive inspection, testing and maintenance requirements, which are found in NFPA 10, 25 and 72. Rather, its intent is to identify problems that are readily observable during fire inspections.

❖ During inspections, it is important to observe and report conditions that may lead to failure of fire protection systems. Section 901.6 references the system installation standards that refer to maintenance of the equipment and or system(s) being reviewed. This section lists items to be included. Note the list includes some, but not all, of the items that might need review. The ICC has published a document, *Fire Plan Review and Inspection Guidelines*, that provides a more comprehensive look at this issue.

**I101.2 Noncompliant conditions requiring component replacement.** The following conditions shall be deemed noncompliant and shall cause the related component(s) to be replaced to comply with the provisions of this code:

1. Sprinkler heads having any of the following conditions:
  - 1.1. Signs of leakage.
  - 1.2. Paint or other ornamentation that is not factory applied.
  - 1.3. Evidence of corrosion including, but not limited to, discoloration or rust.
  - 1.4. Deformation or damage of any part.
  - 1.5. Improper orientation of sprinkler head.
  - 1.6. Empty glass bulb.
  - 1.7. Sprinkler heads manufactured prior to 1920.
  - 1.8. Replacement sprinkler heads that do not match existing sprinkler heads in orifice size, K-factor temperature rating, coating or deflector type.

## APPENDIX I

- 1.9. Sprinkler heads for the protection of cooking equipment that have not been replaced within one year.
  2. Water pressure and air pressure gauges that have been installed for more than 5 years and have not been tested to within 3 percent accuracy.
- ❖ Item 1 addresses sprinkler heads only, as they are the component that is replaced in the system after activation and where an error may be made in the process replacing of a sprinkler head. Note that some of the items are easily found by a visual inspection, while others will require a review of the inspection file (1.7, 1.8, and 1.9) to determine if the sprinkler heads are in compliance. Item 2 also belongs to the group that will need to be validated from information in the inspection file.
- I101.3 Noncompliant conditions requiring component repair or replacement.** The following shall be deemed non-compliant conditions and shall cause the related component(s) to be repaired or replaced to comply with the provisions of this code:
1. Sprinkler and standpipe system piping and fittings having any of the following conditions:
    - 1.1. Signs of leakage.
    - 1.2. Evidence of corrosion.
    - 1.3. Misalignment.
    - 1.4. Mechanical damage.
  2. Sprinkler piping support having any of the following conditions:
    - 2.1. Materials resting on or hung from sprinkler piping.
    - 2.2. Damaged or loose hangers or braces.
  3. Class II and Class III standpipe systems having any of the following conditions:
    - 3.1. No hose or nozzle, where required.
    - 3.2. Hose threads incompatible with fire department hose threads.
    - 3.3. Hose connection cap missing.
    - 3.4. Mildew, cuts, abrasions and deterioration evident.
    - 3.5. Coupling damaged.
    - 3.6. Gaskets missing or deteriorated.
    - 3.7. Nozzle missing or obstructed.
  4. Hose racks and cabinets having any of the following conditions:
    - 4.1. Difficult to operate or damaged.
    - 4.2. Hose improperly racked or rolled.
    - 4.3. Inability of rack to swing 90 degrees (1.57 rad) out of the cabinet.
    - 4.4. Cabinet locked, except as permitted by this code.
    - 4.5. Cabinet door will not fully open.
    - 4.6. Door glazing cracked or broken.
  5. Portable fire extinguishers having any of the following conditions:
    - 5.1. Broken seal or tamper indicator.
    - 5.2. Expired maintenance tag.
    - 5.3. Pressure gauge indicator in “red.”
    - 5.4. Signs of leakage or corrosion.
    - 5.5. Mechanical damage, denting or abrasion of tank.
    - 5.6. Presence of repairs such as welding, soldering or brazing.
    - 5.7. Damaged threads.
    - 5.8. Damaged hose assembly, couplings or swivel joints.
  6. Fire alarm and detection control equipment, initiating devices and notification appliances having any of the following conditions:
    - 6.1. Corroded or leaking batteries or terminals.
    - 6.2. Smoke detectors having paint or other ornamentation that is not factory-applied.
    - 6.3. Mechanical damage to heat or smoke detectors.
    - 6.4. Tripped fuses.
  7. Fire department connections having any of the following conditions:
    - 7.1. Fire department connections are not visible or accessible from the fire apparatus access road.
    - 7.2. Couplings or swivels are damaged.
    - 7.3. Plugs and caps are missing or damaged.
    - 7.4. Gaskets are deteriorated.
    - 7.5. Check valve is leaking.
    - 7.6. Identification signs are missing.
  8. Fire pumps having any of the following conditions:
    - 8.1. Pump room temperature is less than 40°F (4.4°C).
    - 8.2. Ventilating louvers are not freely operable.
    - 8.3. Corroded or leaking system piping.
    - 8.4. Diesel fuel tank is less than two-thirds full.
    - 8.5. Battery readings, lubrication oil or cooling water levels are abnormal.
- ❖ This section lists inspection items for components in various types of fire protection systems. All of these are visual or manipulative items that can be easily verified during an inspection.

**SECTION I102  
REFERENCED STANDARDS**

NFPA 10—13	Standard for Portable Fire Extinguishers	I101.1
NFPA 25—13	Standard for the Inspection, Testing and Maintenance of Water-based Fire Protection Systems	I101.1
NFPA 72—13	National Fire Alarm and Signaling Code	I101.1

# Appendix J: Building Information Signs

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Prefire or preincident planning is a long-standing operational tool wherein information is collected by fire code officials and fire department personnel to assist in identifying hazards and the equipment, supplies, personnel, skills and procedures needed to deal with a potential incident in a building.

## Purpose

The purpose of Appendix J is to establish standard guidelines for prefire plans. It sets forth requirements for a building information sign (BIS) that may be useful to fire fighters in understanding basic information about the building where the sign is posted. The provisions provide a uniform format so that the type of information provided to emergency responders is consistent across the jurisdiction's territory.

## SECTION J101 GENERAL

**J101.1 Scope.** New buildings shall have a building information sign(s) that shall comply with Sections J101.1.1 through J101.7. Existing buildings shall be brought into conformance with Sections J101.1 through J101.9 when one of the following occurs:

1. The fire department conducts an annual inspection intended to verify compliance with this section, or any required inspection.
2. When a change in use or occupancy has occurred.

### Exceptions:

1. Group U occupancies.
2. One- and two-family dwellings.

❖ Because building information is critical to executing an effective fire attack, with the exception of one- and two-family dwellings and Group U occupancies, the provisions in Section J101.1 are applicable to all new buildings and are retroactive to any building that undergoes a fire inspection or change of occupancy.

**J101.1.1 Sign location.** The building information sign shall be placed at one of the following locations:

1. Upon the entry door or sidelight at a minimum height of 42 inches (1067 mm) above the walking surface on the address side of the building or structure.
2. Upon the exterior surface of the building or structure on either side of the entry door, not more than 3 feet (76 mm) from the entrance door, at a minimum height of 42 inches (1067 mm) above the walking surface on the address side of the building or structure.

3. Conspicuously placed inside an enclosed entrance lobby, on any vertical surface within 10 feet (254 mm) of the entrance door at a minimum height of 42 inches (1067 mm) above the walking surface.
4. Inside the building's fire command center.
5. On the exterior of the fire alarm control unit or on the wall immediately adjacent to the fire alarm control unit door where the alarm panel is located in the enclosed main lobby.

❖ Acceptable sign locations are specified in Section J101.1.1 and include the entrance to a building on the side that has the posted address, the interior of a building's enclosed entrance lobby, the fire command center or at a building's fire alarm control unit. The chosen location should be approved by both the fire code official and the fire chief so that it is consistent with the tactical approaches to the building.

**J101.1.2 Sign features.** The building information sign shall consist of all of the following:

1. White reflective background with red letters.
2. Durable material.
3. Numerals shall be Roman or Latin numerals, as required, or alphabet letters.
4. Permanently affixed to the building or structure in an approved manner.

❖ Section J101.1.2 specifies the materials of construction of the BIS and requires that it be permanently attached to the building in a manner acceptable to the fire code official based on the materials of construction of the building.

**J101.1.3 Sign shape.** The building information sign shall be a Maltese cross as shown in Figure J101.1.3.

❖ The BIS is configured as a Maltese cross which is a traditional symbol universally recognized by the U.S. fire service.

**J101.1.4 Sign size and lettering.** The minimum size of the building information sign and lettering shall be in accordance with the following:

1. The width and height shall be 6 inches by 6 inches (152 mm by 152 mm).
2. The height or width of each Maltese cross wing area shall be 1<sup>1</sup>/<sub>8</sub> inches (29 mm) and have a stroke width of 1/2 inch (13 mm).
3. The center of the Maltese cross, a circle or oval, shall be 3 inches (76 mm) in diameter and have a stroke width of 1/2 inch (6 mm).
4. All Roman numerals and alphabetic designations, shall be 1<sup>1</sup>/<sub>4</sub> inch (32 mm) height and have a stroke width of 1/4 inch (6 mm).

❖ The BIS must meet the dimensional requirements in Section J101.1.4 and be assembled using reflective materials that are visible in the dark (see Section J101.1.2).

**J101.2 Sign designations.** Designations shall be made based upon the construction type, content, hazard, *fire protection systems*, life safety and occupancy. Where multiple designations occur within a classification category, the designation used shall be based on the greatest potential risk.

❖ Section J101.2 requires the sign to convey pertinent information about the building to assist the incident commander in sizing up the incident and deploying resources safely and effectively.

**J101.3 Construction type (top wing).** The construction types shall be designated by assigning the appropriate Roman numeral, and letter, placed inside the top wing of the Maltese cross. The hourly rating provided is for the structural framing in accordance with Table 601 of the *International Building Code*.

CONSTRUCTION TYPE	FIRE-RESISTANCE RATING
IA—Noncombustible	3 Hours
IB—Noncombustible	2 Hours
IIA—Noncombustible	1 Hour
IIB—Noncombustible	0 Hours
IIIA—Noncombustible/combustible	1 Hour
IIIB—Noncombustible/combustible	0 Hours
IV—Heavy timber (HT)	HT
VA—Combustible	1 Hour
VB—Combustible	0 Hours

❖ Section J101.3 requires the sign to convey the building's construction type based on its *International Building Code*® (IBC®) construction classification. See Chapter 6 of the IBC for detailed descriptions of the construction types.

**J101.4 Fire protection systems (right wing).** The *fire protection system* shall be designated by determining its level of protection and assigning the appropriate designation to the right wing of the Maltese cross. Where multiple systems are provided, all shall be listed:

- AS Automatic sprinkler system installed throughout
- DS Dry sprinkler system and designated areas
- FA Fire alarm system

**FIGURE J101.1.3**  
**EXAMPLE OF COMPLETED BUILDING INFORMATION SIGN**

FP	Fire pump
FW	<i>Fire wall</i> and designated areas
PAS	Pre-action sprinkler system and designated floor
PS	Partial <i>automatic sprinkler system</i> , and designate floor
CES	Chemical extinguishing system and designated area
CS	Combination sprinkler and standpipe system
S	Standpipe system
NS	No system installed

- ❖ Section J101.4 requires the sign to convey the type of fire protection systems in the building. If a building, even a nonsprinklered building, is partially protected by an automatic sprinkler system, the areas or floors of the building that are protected must be identified.

**J101.5 Occupancy type (bottom wing).** The occupancy of a building or structure shall be designated in accordance with the occupancy classification found in Section 302.1 of the *International Building Code* and the corresponding designation shall be placed in the bottom wing of the Maltese cross. Where a building or structure contains a mixture of uses and occupancies; all uses and occupancies shall be identified.

A	Assembly
B	Business
E	Educational
F	Factory or Industrial
H	High Hazard
I	Institutional
M	Mercantile
R	Residential

- ❖ Section J101.5 requires the sign to convey the occupancy classification. In mixed-occupancy buildings all occupancy groups are required to be identified on the sign. See the definitions of "Occupancy classification" in Chapter 2 of the code or Chapter 3 of the IBC.

**J101.6 Hazards of content (left wing).** The hazards of building contents shall be designated by one of the following classifications as defined in NFPA 13 and the appropriate designation shall be placed inside the left wing of the Maltese cross:

LH	Light hazard
MH	Moderate hazard
HH	High hazard

- ❖ Section J101.6 requires the sign to convey an estimation of the building's fuel load using the hazard classification criteria of NFPA 13 for light, ordinary and extra-hazard occupancies. The section does not align the classifications with the NFPA 13 definitions for occupancy hazard classifications; however, the intent is to provide a standard method for estimating a

building's fuel load. Fire code officials should ensure that the selected fuel load classification system is consistent so its application in applying a designation to the information sign is uniform to avoid confusion among emergency responders.

**J101.7 Tactical considerations (center circle).** The center circle shall include the name of the local fire service and when required the letters TC for tactical considerations. Where fire fighters conduct preplan operations, a unique situation(s) for tactical considerations shall be identified and the information provided to the fire dispatch communications center to further assist fire fighters in identifying that there is special consideration(s) for this occupancy. Special consideration designations include, but are not limited to:

1. Impact-resistant drywall.
2. Impact-resistant glazing, such as blast or hurricane-type glass.
3. All types of roof and floor structural members including but not limited to post-tension concrete, bar joists, solid wood joists, rafters, trusses, cold-formed galvanized steel, I-joists and I-beams; green roof with vegetation, soil and plants.
4. Hazardous materials (explosives, chemicals, plastics, etc.).
5. Solar panels and DC electrical energy.
6. HVAC system; and smoke management system for pressurization and exhaust methods.
7. Other unique characteristic(s) within the building that are ranked according to a potential risk to occupants and fire fighters.

- ❖ Section J101.7 requires the sign to convey relevant tactical information that can be used by fire fighters prior to commencing an interior fire attack. This could include the use of terrorism-resistant building materials; impact-resistant glazing or construction; the storage or use of hazardous materials; certain types of structural components that may have a propensity for rapid failure under fire exposure or any other potential hazards that could impact the health and safety of emergency responders.

**J101.8 Sign classification maintenance, building information.** Sign maintenance shall comply with each of the following:

1. Fire departments in the jurisdiction shall define the designations to be placed within the sign.
2. Fire departments in the jurisdiction shall conduct annual inspections to verify compliance with this section of the code and shall notify the *owner*, or the *owner's* agent, of any required updates to the sign in accordance with fire department designations and the *owner*, or the *owner's* agent, shall comply within 30 days.

APPENDIX J

3. The owner of a building shall be responsible for the maintenance and updates to the sign in accordance with fire department designations.

❖ Prior to implementing the requirements for building information signs, Section J101.8 requires that the fire department define unique or special designations required on signs. If a building warrants this particular sign, the owner has 30 days to provide and install it. As with other warning signage and markings required throughout the code, this section also requires that the BIS be maintained so that it continues to be effective in providing important tactical information to first responders.

**J101.9 Training.** Jurisdictions shall train fire department personnel on Sections J101.1 through J101.9.

❖ Section J101.9 requires the jurisdiction to train all fire department personnel on the provisions in Appendix J to maximize the effectiveness of the BIS. Jurisdictions should also consider cross-training with neighboring fire departments that are part of the area's mutual-aid network.

**SECTION J102

NFPA	13—13	Standard for the Installation of Sprinkler Systems	J101.6

# Appendix K: Construction Requirements for Existing Ambulatory Care Facilities

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

This is an especially important option for federal authorities having jurisdiction (AHJ), which have long-standing minimum fire and life safety standards for ambulatory care facilities. Those federal standards were applied to new and existing construction long before the creation of the ambulatory care facility use that currently exists in the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>). Therefore, we have a situation where some (but not all) ambulatory care facilities were built with very specific defend-in-place features. This subset of facilities were certified by the federal government as “ambulatory surgical facilities.” Many other medical facilities that would be classified today as ambulatory care were not required to have defend-in-place features, such as smoke compartmentation. The federal AHJ highly value these defend-in-place concepts and need retroactive requirements.

This appendix would also be useful for those local and state jurisdictions that are specifically focused on ensuring safety for existing ambulatory care facilities. Surgery centers constructed as recently as 2009 would not have defend-in-place features required by the ICC family of codes. This appendix could be used to assess

post-2009 surgery centers and freestanding emergency departments. It could also be used to bring those earlier facilities into compliance with current standards at the discretion of the adopting jurisdiction.

The technical requirements are based on current IBC language. The significant difference from the IBC is a relaxation of the sprinkler requirement for existing facilities. This appendix would only require retroactive sprinkling of unprotected construction, which is consistent with the overall concept of current federal requirements.

## Purpose

This section is intended to provide jurisdictions an option for assessing minimum fire and life safety requirements for buildings containing ambulatory care facilities. While this appendix is written with the intent to apply retroactive minimum standards, it is recognized that ambulatory care requirements are relatively recent additions to the code. For that reason, these requirements are presented as an appendix, so that the adopting authority can exercise judgment in the adoption and application of this section.

---

## SECTION K101 GENERAL

**K101.1 Scope.** The provisions of this chapter shall apply to existing buildings containing ambulatory care facilities in addition to the requirements of Chapter 11 of the *International Fire Code*. Where the provisions of this chapter conflict with either the construction requirements in Chapter 11 of the *International Fire Code* or the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

❖ These provisions are similar in application to those found in Chapter 11 for Group I-2 occupancies. In other words, they are construction requirements for existing buildings. Chapter 11 provides various requirements that apply to a number of different occupancy classifications for existing buildings. Section 1105 is unique to Group I-2 occupancies. This appen-

dix is focused on ambulatory care facilities and helps those jurisdictions that want such facilities to be consistent with federal requirements. This section basically states that compliance with Chapter 11 and this appendix is necessary to fully address existing ambulatory care facilities. If there is a conflict, the most restrictive provision would apply.

It should be noted that the *International Existing Building Code*<sup>®</sup> (IEBC<sup>®</sup>) work-area method would specifically require compliance with IBC Section 422 where the change of occupancy (whether use or occupancy classification) is to an ambulatory care facility. In other words, if an office building was changed to an ambulatory care facility, IBC Section 422, which is more restrictive than this appendix, would apply.

**K101.2 Intent.** The intent of this appendix is to provide a minimum degree of fire and life safety to persons occupying

and existing buildings containing ambulatory care facilities where such buildings do not comply with the minimum requirements of the *International Building Code*.

- ❖ This appendix is primarily applicable to ambulatory care facilities that were not regulated by the federal requirements for healthcare and built prior to publication of the 2009 IBC. Most ambulatory care facilities will already meet these minimum requirements and no changes will be necessary.

## SECTION K102 FIRE SAFETY REQUIREMENTS FOR EXISTING AMBULATORY CARE FACILITIES

**K102.1 Separation.** Ambulatory care facilities where the potential exists for four or more care recipients to be incapable of self-preservation at any time, whether rendered incapable by staff or staff has accepted responsibility for a care recipient already incapable, shall be separated from adjacent spaces, corridors or tenants with a fire partition installed in accordance with Section 708 of the *International Building Code*.

- ❖ This section is consistent with IBC Section 422.2. Many existing facilities may already meet this requirement. This applies only to those that were not addressed by the CMS program standards.

**K102.2 Smoke compartments.** Where the aggregate area of one or more ambulatory care facilities is greater than 10,000 square feet (929 m<sup>2</sup>) on one story, the story shall be provided with a *smoke barrier* to subdivide the *story* into no fewer than two *smoke compartments*. The area of any one such *smoke compartment* shall be not greater than 22,500 square feet (2092 m<sup>2</sup>). The travel distance from any point in a *smoke compartment* to a *smoke barrier* door shall be not greater than 200 feet (60 960 mm). The *smoke barrier* shall be installed in accordance with Section 709 of the *International Building Code* with the exception that *smoke barriers* shall be continuous from an outside wall to an outside wall, a floor to a floor, or from a *smoke barrier* to a *smoke barrier* or a combination thereof.

- ❖ This section is the same as that required for new ambulatory care facilities in IBC Section 422.3.

**K102.2.1 Refuge area.** Not less than 30 net square feet (2.8 m<sup>2</sup>) for each nonambulatory care recipient shall be provided within the aggregate area of *corridors*, care recipient rooms, treatment rooms, lounge or dining areas and other low-hazard areas within each *smoke compartment*. Each occupant of an ambulatory care facility shall be provided with access to a refuge area without passing through or utilizing adjacent tenant spaces.

- ❖ As with smoke compartments and separation, this requirement is the same as that for a new building. The requirements are the same as IBC Section 422.3.2.

**K102.2.2 Independent egress.** A *means of egress* shall be provided from each *smoke compartment* created by smoke barriers without having to return through the *smoke compartment* from which *means of egress* originated.

- ❖ This section is the same as that required for new buildings. It would not be appropriate to have to egress back through the smoke compartment of egress origin. IBC Section 422.3.3 provides the same limitation.

**K102.3 Automatic sprinkler systems.** An *automatic sprinkler system* shall be provided throughout the entire floor containing an ambulatory care facility in Type IIB, IIIB and VB construction where either of the following conditions exist at any time:

1. Four or more care recipients are incapable of self-preservation, whether rendered incapable by staff or staff has accepted responsibility for care recipients already incapable.
2. One or more care recipients that are incapable of self-preservation are located at other than the *level of exit discharge* serving such a facility.

In buildings where ambulatory care is provided on levels other than the *level of exit discharge*, an *automatic sprinkler system* shall be installed throughout the entire floor where such care is provided and all floors below, and all floors between the level of ambulatory care and the nearest *level of exit discharge*, including the *level of exit discharge*.

- ❖ This section is less restrictive than Section 903.2.2. It focuses on combustible construction and whether the ambulatory care facility is located on a level other than the level of exit discharge. Unlike Group I-2 occupancies, ambulatory care facilities can often be located in buildings housing other types of occupancies. Therefore, compliance with retroactive sprinkler requirements becomes more difficult. If, at a minimum, combustible construction and ambulatory care facilities located on other than the level of exit discharge are addressed, compliance with federal requirements is addressed.

**K102.4 Automatic fire alarm system.** *Fire areas* containing ambulatory care facilities shall be provided with an electronically supervised automatic smoke detection system installed within the ambulatory care facility and in public use areas outside of tenant spaces, including *public corridors* and elevator lobbies.

**Exception:** Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 of the *International Fire Code*, provided the occupant notification appliances will activate throughout the notification zones upon sprinkler waterflow.

- ❖ These requirements for smoke detection systems are the same as those in Section 907.2.2.1. The retroactive installation of a fire alarm system is more feasible than an automatic sprinkler system.

### SECTION K103 INCIDENTAL USES IN EXISTING AMBULATORY CARE FACILITIES

**K103.1 General.** Incidental uses associated with and located within existing ambulatory care facilities required to be separated by Section 422 in the *International Building Code*, and that generally pose a greater level of risk to such occupancies, shall comply with the provisions of Sections K103.2 through K103.4.2.1. Incidental uses in ambulatory care facilities required to be separated by Section 422 of the *International Building Code* are limited to those listed in Table K103.1.

❖ Incidental use area provisions are applicable to new construction in IBC Section 509; however, similar provisions are needed for existing ambulatory care facilities since the hazards posed by such rooms or spaces are no different than in new buildings. Section and Table K103.1 are very similar to and based upon IBC Section and Table 509, except that references to occupancies other than ambulatory care are not included. The basic requirements proposed for incidental uses in existing healthcare occupancies rely upon the provisions of the IBC for the specifics of construction and protection. Sections K103.2 through K103.4.2.1 are based on IBC Sections 509.2 through 509.4.2.1. These provisions will provide correlation with not only the IBC but also with the operational and CMS program standards for existing ambulatory care facilities.

This section establishes the scope of Section K103 and its applicability to ambulatory care facilities. Incidental uses are rooms or areas that constitute special hazards or risks to life safety not typically addressed by the provisions for the occupancy group in which they occur, even though such rooms or areas may functionally be an extension of the primary use. Only those rooms or areas indicated in Table K103.1 are to be regulated as incidental uses. Incidental uses can be located in both single- and mixed-occupancy

buildings. The concern is that those areas designated as incidental uses pose a risk to the remainder of the building and, as such, some degree of protection is required. The nature of these incidental uses is such that they are small areas not frequented by building occupants in which a fire could start and go unnoticed for a longer time than in a part of the building that is constantly occupied.

**K103.2 Occupancy classification.** Incidental uses shall not be individually classified in accordance with Section 302.1 of the *International Building Code*. Incidental uses shall be included in the building occupancies in which they are located.

❖ Consistent with the IBC, this section expressly states that incidental uses are not considered as separate and distinct occupancy classifications but, rather, are classified the same as the occupancies in which they are located. For example, a waste and linen collection room in an ambulatory care facility would be classified as a portion of the ambulatory care facility even though it may present a level of hazard more akin to a Group S-1 occupancy if it were to be classified separately.

**K103.3 Area limitations.** Incidental uses shall not occupy more than 10 percent of the building area of the story in which they are located.

❖ The proposed floor-area limitation of 10 percent for incidental uses emphasizes the ancillary nature of such rooms and areas and correlates with the IBC. Each incidental use would be limited to a maximum of 10 percent of the floor area of the story in which it is located. Where there are two or more tenants located on the same story, the 10-percent limitation is based upon the floor area of each individual tenant space rather than that of the entire story. The application of the limit on a tenant-by-tenant basis is consistent with the concept of incidental uses typically being ancillary

TABLE K103.1  
INCIDENTAL USES IN EXISTING AMBULATORY CARE FACILITIES

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input	1 hour or provide automatic sprinkler system
Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic sprinkler system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen fuel gas rooms, not classified as Group H	1 hour in ambulatory care facilities
Incinerator rooms	2 hours and provide automatic sprinkler system
Laboratories not classified as Group H	1 hour or provide automatic sprinkler system
Laundry rooms over 100 square feet	1 hour or provide automatic sprinkler system
Waste and linen collection rooms with containers with total volume of 10 cubic feet or greater	1 hour or provide automatic sprinkler system
Storage rooms greater than 100 square feet	1 hour or provide automatic sprinkler system
Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons for flooded lead-acid, nickel cadmium or VRLA, or more than 1,000 pounds for lithium-ion and lithium metal polymer used for facility standby power, emergency power or uninterruptible power supplies	1 hour in ambulatory care facilities

For SI: 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

only to a portion of the building, i.e., the specific tenant occupancy.

**K103.4 Separation and protection.** The incidental uses listed in Table K103.1 shall be separated from the remainder of the building or equipped with an *automatic sprinkler system*, or both, in accordance with the provisions of that table.

❖ In addition to identifying those rooms or areas that warrant regulation as incidental uses, Table K103.1 also indicates the required degree of protection or separation. The requirements identified in Table K103.1 vary depending on the incidental use. In some cases, a specific type of separation and/or protection is required, while in others there is an option.

**K103.4.1 Separation.** Where Table K103.1 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building in accordance with Section 509.4.1 of the *International Building Code*.

❖ Where a fire-resistance rated separation would be required, the incidental use would need to be separated from other portions of the building in accordance with assemblies complying with the IBC.

**K103.4.2 Protection.** Where Table K103.1 permits an *automatic sprinkler system* without a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building by construction capable of resisting the passage of smoke in accordance with Section 509.4.2 of the *International Building Code*.

❖ In this section, where Table K103.1 would allow protection by an automatic sprinkler system without a fire-resistance-rated separation, the construction enclosing the incidental use would still need to resist the passage of smoke. Construction details for resisting the passage of smoke are provided in the IBC. Note that this requirement is not specifying a smoke partition. IBC Section 710 provides specific smoke partition requirements that must be directly referenced.

**K103.4.2.1 Protection limitation.** Except as otherwise specified in Table K103.1 for certain incidental uses, where an *automatic sprinkler system* is provided in accordance with Table K103.1, only the space occupied by the incidental use need be equipped with such a system.

❖ This section makes it clear that the sprinkler systems stipulated in Table K103.1 are required for the incidental use area only.

## SECTION K104 MEANS OF EGRESS REQUIREMENTS FOR EXISTING AMBULATORY CARE FACILITIES

**K104.1 Size of doors.** The minimum width of each door opening shall be sufficient for the *occupant load* thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). In ambulatory care facili-

ties, doors serving as *means of egress* from patient treatment rooms shall provide a clear width of not less than 32 inches (813 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. The height of doors openings shall be not less than 80 inches (2032 mm).

### Exceptions:

1. Door openings to storage closets less than 10 square feet (0.93 m<sup>2</sup>) in area shall not be limited by the minimum width.
2. Width of door leaves in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
3. *Exit access* doors serving a room not larger than 70 square feet (6.5 m<sup>2</sup>) shall be not less than 24 inches (610 mm) in door width.
4. Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the door.

❖ This section is quite similar to Section 1104.7 and generally these requirements would therefore already be applicable without this appendix. However, the exceptions are specific to ambulatory care facilities. The height is also consistent with Section 1010.1.1 for new buildings.

**K104.2 Corridor and aisle width.** *Corridor* width shall be as determined in Section 1005.1 of the *International Fire Code* and this section. The minimum width of *corridors* and *aisles* that serve gurney traffic in areas where patients receive care that causes them to be incapable of self-preservation shall be not less than 72 inches (1829 mm).

❖ This section is consistent with new building requirements. Reference is made to Section 1005.1 and a corridor width of 72 inches is prescribed. Table 1020.2 requires a 72-inch width for corridors and areas serving stretcher traffic in ambulatory care facilities.

**K104.3 Existing elevators.** Existing elevators, escalators, dumbwaiters and moving walks shall comply with the requirements of Sections K104.3.1 and K104.3.2.

❖ Sections K104.3.1 and K104.3.2 set forth some minimum requirements for existing elevators. Of primary importance are the emergency operation features.

**K104.3.1 Elevators, escalators, dumbwaiters and moving walks.** Existing elevators, escalators, dumbwaiters and moving walks in ambulatory care facilities required to be separated by Section 422 of the *International Building Code* shall comply with ASME A17.3.

❖ Not only are existing elevators required to comply with ASME A17.3, but escalators and moving walks must also comply. Note that IBC Section 3001.2 requires ongoing maintenance of all elevators and conveying systems. This section specifically calls out ASME A17.3 for such maintenance.

The healthcare industry has historically been required to comply with regulations set forth by accreditation and certification agencies, such as The Joint Commission. ASME A17.3 has been referenced by guidelines adopted by The Joint Commission for

more than a decade and this code change will correlate the IFC with the mandated healthcare industry standard.

Adding a reference to ASME A17.3 will require that existing elevators, escalators and moving walks and their related operating equipment in ambulatory care facilities comply with a minimum level of safety. Because the occupants of these types of facilities are often incapable of self-preservation, this reference provides important features essential for occupant safety, including escalator and moving walk emergency stop buttons and automatic skirt obstruction stop features.

**K104.3.2 Elevator emergency operation.** Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

❖ This section is consistent with Section 1103.3.2, which applies to any elevator that travels 25 feet or more above or below the main floor or other level of a building. It should be noted, however, that the exceptions found in Section 1103.3.2 are not located in this appendix. Therefore, there are no specific exceptions to this requirement.

# Appendix L: Requirements for Fire Fighter Air Replenishment Systems

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Breathing air is critical for fire-fighting operations. Historically, fire departments have supplied air bottles by means of a “bottle brigade,” whereby fire fighters manually transport air bottles up stairways. This is usually accomplished by stationing a fire fighter on alternating floors, and each fire fighter carries two to four bottles at a time up two floors, passes them to the next fire fighter, then goes down two flights of stairs and receives more air bottles from the fire fighter stationed below. This process is extraordinarily fire-fighter intensive, and takes fire fighters away from their primary mission of rescue and fire fighting. Even when fires are insignificant or controlled by sprinklers, copious amounts of smoke and other combustion byproducts require the use of self-contained breathing apparatus (SCBA) for extended periods of time to conduct search, rescue, suppression and overhaul. These extended missions require a large number of air bottles to be transported to support the operation. Transporting bottles is not the highest and best use of highly trained fire fighters. It is a costly solution to a serious problem that can be addressed by installing fire fighter air replenishment systems.

Technology exists at this point in time to address the issue using in-building air supply systems. Fire fighter Breathing Air Systems were introduced in the late 1980’s. These systems are now required in a number of communities throughout the United States, and several

hundred systems have been installed and are now operational. The system has been called a “standpipe for air,” which is an accurate description. The system consists of stainless steel, high-pressure piping that is supplied by on-site air storage, fire department air supply units, or both; a few systems have breathing air compressors installed. Air filling stations are then strategically located throughout the building, using either quick fill connections or rupture containment fill stations complying with NFPA 1901. These systems allow fire fighters to refill breathing air cylinders inside the fire building, negating the required “bottle brigade”, and making more fire fighters available for search, rescue, and fire suppression operations.

## Purpose

While not every jurisdiction will necessarily embrace this technology, there is a need to standardize the installation criteria in jurisdictions that determine the systems are needed. It is now being recognized as a basic principle of fire protection that, once a community has identified an unacceptable risk, risk mitigation must occur to reduce that risk to a level that allows the fire department to be both efficient and effective in coping with it. Therefore, this appendix provides model requirements to jurisdictions considering fire fighter air replenishment systems.

---

## SECTION L101 GENERAL

**L101.1 Scope.** Fire fighter air replenishment systems (FARS) shall be provided in accordance with this appendix. The adopting ordinance shall specify building characteristics or special hazards that establish thresholds triggering a requirement for the installation of a FARS. The requirement shall be based upon the fire department’s capability of replenishing fire fighter breathing air during sustained emergency operations. Considerations shall include:

1. Building characteristics, such as number of stories above or below grade plane, floor area, type of construction and fire-resistance of the primary structural *frame* to allow sustained fire-fighting operations based on a rating of not less than 2 hours.

2. Special hazards, other than buildings, that require unique accommodations to allow the fire department to replenish fire fighter breathing air.
  3. Fire department staffing level.
  4. Availability of a fire department breathing air replenishment vehicle.
- ❖ This section clarifies that such systems are required when the appendix is adopted. The adopting ordinance must specify when such systems are required. Many buildings (e.g., a two-story Group B occupancy) would not need such systems. Therefore, the applicability must clearly be provided. Suggestions are provided as to what types of buildings and facilities may need such systems.

## SECTION L102 DEFINITIONS

**L102.1 Definitions.** For the purpose of this appendix, certain terms are defined as follows:

**FIRE FIGHTER AIR REPLENISHMENT SYSTEM (FARS).** A permanently installed arrangement of piping, valves, fittings and equipment to facilitate the replenishment of breathing air in self contained breathing apparatus (SCBA) for fire fighters engaged in emergency operations.

- ❖ This definition describes what is considered part of the fire fighter air replenishment systems (FARS) as far as the code is concerned. It also explains that the purpose of such systems is to provide breathing air to fire fighters.

## SECTION L103 PERMITS

**L103.1 Permits.** Permits shall be required to install and maintain a FARS. Permits shall be in accordance with Sections L103.2 and L103.3.

- ❖ These systems need to be installed and modified appropriately and be maintained for the successful long term use of such systems. Permits facilitate these activities occurring.

**L103.2 Construction permit.** A construction permit is required for installation of or modification to a FARS. The construction permit application shall include documentation of an acceptance and testing plan as specified in Section L105.

- ❖ This permit is for the initial installation and for modifications to such systems. This will include documentation to demonstrate that they have been appropriately tested and installed as designed.

**L103.3 Operational permit.** An operational permit is required to maintain a FARS.

- ❖ Quality installation and modifications to the system are important but just as important is the long term maintenance of such systems to make sure they remain in operating condition. This also reminds the fire department that such systems are provided at those locations.

## SECTION L104 DESIGN AND INSTALLATION

**L104.1 Design and installation.** A FARS shall be designed and installed in accordance with Sections L104.2 through L104.15.

- ❖ These sections contain the various design criteria, standards and other considerations such as location, security measures and compatibility with the fire departments equipment.

**L104.2 Standards.** Fire fighter air replenishment systems shall be in accordance with Sections L104.2.1 and L104.2.2.

- ❖ Sections L104.2.1 and L104.2.2 set out the basic design standards for such systems within the building. Later sections will prescribe standard for onsite stored pressure air supply.

**L104.2.1 Pressurized system components.** Pressurized system components shall be designed and installed in accordance with ASME B31.3.

- ❖ This standard reference addresses the quality of the piping and connections used.

**L104.2.2 Air quality.** The system shall be designed to convey breathing air complying with NFPA 1989.

- ❖ Such systems in order to be of assistance to the fire service must meet minimum air quality standards. NFPA 1989 provides these minimum requirements. This standard prescribes the type of pipes such air can be conveyed through.

**L104.3 Design and operating pressure.** The minimum design pressure shall be 110 percent of the fire department's normal SCBA fill pressure. The system design pressure shall be marked in an approved manner at the supply connections, and adjacent to pressure gauges on any fixed air supply components. Pressure shall be maintained in the system within 5 percent of the design pressure.

- ❖ This section sets the minimum design pressure for the system to ensure that the appropriate pressurized air can be provided during refills. There is a 10-percent level of flexibility provided at any time in the system.

**L104.4 Cylinder refill rate.** The FARS shall be capable of refilling breathing air cylinders of a size and pressure used by the fire department at a rate of not less than two empty cylinders in 2 minutes.

- ❖ For practical use of such systems, the FARS must be able to fill two empty cylinders in a defined amount of time. This must be tested once the installation is complete (see Section L105.1).

**L104.5 Breathing air supply.** Where a fire department mobile air unit is available, the FARS shall be supplied by an external mobile air connection in accordance with Section L104.14. Where a fire department mobile air unit is not available, a stored pressure air supply shall be provided in accordance with Section L104.5.1. A stored pressure air supply shall be permitted to be added to a system supplied by an external mobile air connection provided that a means to bypass the stored pressure air supply is located at the external mobile air connection.

- ❖ There are two sources from which breathing air can originate: a mobile air unit or an on-site stored pressure air supply.

**L104.5.1. Stored pressure air supply.** A stored pressure air supply shall be designed based on Chapter 24 of NFPA 1901

except that provisions applicable only to mobile apparatus or not applicable to system design shall not apply. A stored pressure air supply shall be capable of refilling not less than 50 empty breathing air cylinders of a size and pressure used by the fire department.

- ❖ The design standard for on-site pressure air supply along with the capacity of storage is specified in this section. The stored supply must fill a minimum of 50 cylinders based upon the type the fire department uses.

**L104.5.2. Retrofit of external mobile air connection.** A FARS not initially provided with an external mobile air connection due to the lack of a mobile air unit shall be retrofitted with an external mobile air connection where a mobile air unit becomes available. Where an external mobile air connection is provided, a means to bypass the stored pressure air supply shall be located at the external mobile air connection. The retrofit shall be completed not more than 12 months after notification by the *fire code official*.

- ❖ This section mandates a mobile air connection to be provided to a system that was initially only designed for on-site pressure air when such units become available. This also involves some reworking of the system to provide a bypass of the on-site air. Flexibility is provided to building owners to comply with this based upon notice from the fire code official.

**L104.6 Isolation valves.** System isolation valves that are accessible to the fire department shall be installed on the system riser to allow piping beyond any air cylinder refill panel to be blocked.

- ❖ This section requires that isolation of the system in terms of valving is provided.

**L104.7 Pressure relief valve.** Pressure relief valves shall be installed at each point of supply and at the top or end of every riser. The relief valve shall meet the requirements of CGA S-1.3 and shall not be field adjustable. Pressure relief valves shall discharge in a manner that does not endanger personnel who are in the area. Valves, plugs or caps shall not be installed in the discharge of a pressure relief valve. Where discharge piping is used the end shall not be threaded.

- ❖ It is necessary for such systems to provide pressure relief valves. This specifies where they are to be located and that they cannot be adjusted in the field.

**L104.8 Materials and equipment.** Pressurized system components shall be *listed* or *approved* for their intended use and rated for the maximum allowable design pressure in the system. Piping and fittings shall be stainless steel.

- ❖ This section prevents system failure based on inappropriately rated piping and fittings. Stainless steel is necessary for air quality purposes.

**L104.9 Welded connections.** Piping connections that are concealed shall be welded.

- ❖ Welded connections are less likely to fail than threaded connections. When located within a wall, where failures can go undetected, this is critical.

**L104.10 Protection of piping.** System piping shall be protected from physical damage in an *approved* manner.

- ❖ This section provides protection from physical damage that can occur to elements of a building and its systems due to human error.

**L104.11 Compatibility.** Fittings and connections intended to be used by the fire department shall be compatible with the fire department's equipment.

- ❖ This section ensures that the wide variety of fire-fighting components associated with buildings will be compatible with the building's fittings and connections. Section 912 addresses similar concerns.

**L104.12 Security.** Connections to a FARS shall be safeguarded from unauthorized access in an *approved* manner.

- ❖ This section addresses intentional damage inflicted on or general unauthorized use of such systems. Some type of safeguard is necessary to protect such systems. However, such protection must take into account how the fire department can access such systems. A specific method is not prescribed. The term "approved manner" acknowledges that safeguarding methods will vary based on each situation.

**L104.13 Fill stations.** Fire fighter air replenishment fill stations shall comply with Section L104.13.1 through L104.13.3.

- ❖ The next several sections address the location and features of the fire fighter interface with such systems.

**L104.13.1 Location.** Fill stations for refilling breathing air cylinders shall be located as follows:

1. Fill stations shall be provided at the fifth floor above and below the ground level floor and every third floor level thereafter.
2. On floor levels requiring fill stations, one fill station shall be provided adjacent to a required exit stair at a location designated by the *fire code official*. In buildings required to have three or more exit stairs, additional fill stations shall be provided at a ratio of one fill station for every three stairways.

- ❖ This section details where filling stations must be located both vertically (see Commentary Figure L104.13) and on any floor in a building. In most buildings where the floor must be provided with a filling station only one will be required. The filling station must be located next to a required interior exit stairway. In buildings with many stairways, one filling station is required for each three interior exit stairways.

**L104.13.2 Design.** Fill stations for breathing air cylinders shall be designed to meet the following requirements:

1. A pressure gauge and pressure-regulating devices and controls shall be provided to allow the operator to control the fill pressure and fill rate on each cylinder fill hose.
2. Valves controlling cylinder fill hoses shall be slow-operating valves.

APPENDIX L

3. A separate flow restriction device shall be provided on each fill hose.
4. A method shall be provided to bleed each cylinder fill hose.
5. The fill station shall be designed to provide a containment area that fully encloses any cylinder being filled and flexible cylinder fill hoses, and directs the energy from a failure away from personnel. Fill stations shall be designed to prohibit filling of cylinders that are not enclosed within the containment area.

**Exception:** Where required or *approved* by the fire chief, fill stations providing for the direct refilling of the fire fighters' breathing air cylinders using Rapid Intervention Crew/Company Universal Air Connection (RIC/UAC) fittings shall be used in lieu of cylinder fill stations that utilize containment areas.

- ❖ This section provides specific design specifications for fill stations. This addresses the various features needed, such as slow-operating valves and the ability to bleed each cylinder fill hose. All of these features

must be verified during the design and installation process.

**L104.13.3 Cylinder refill rate.** Fill stations shall be capable of simultaneously filling two or more empty breathing air cylinders equivalent to those used by the fire department to the cylinders' design pressure within 2 minutes.

- ❖ This section echoes the design criteria in Section L104.4, which mandates the ability to fill two cylinders within 2 minutes. Speed is essential fire fighting and filling the cylinders should be a quick process. The overall intent of such systems is to make obtaining breathing air faster and less labor intensive.

**L104.14 External mobile air connection.** An external mobile air connection shall be provided for fire department mobile air apparatus where required by Section L104.5 to supply the system with breathing air.

- ❖ This section requires that the mobile air apparatus can be connected to the system. This is similar to the concept of a standpipe connection for a standpipe

Figure L104.13  
FILL STATION LOCATIONS

system except that this system supplies critical breathing air rather than fire-fighting water.

**L104.14.1 Location.** The location of the external mobile air connection shall be accessible to mobile air apparatus and *approved* by the fire chief.

❖ The FARS is critical to fire-fighting operations. The connection must be located where it is feasible for the mobile air apparatus to make a connection. Approval from the fire chief is specifically called out as this is a fire-fighter operations issue.

**L104.14.2 Protection from vehicles.** A means of vehicle impact protection in accordance with Section 312 shall be provided to protect mobile air connections that are subject to vehicular impact.

❖ Similar requirements are found for other building connections related to fire department connections. Impact protection helps to ensure that connections will be in usable condition to make a proper connection to the mobile air apparatus.

**L104.14.3 Clear space around connections.** A working space of not less than 36 inches (914 mm) in width, 36 inches (914 mm) in depth and 78 inches (1981 mm) in height shall be provided and maintained in front of and to the sides of external mobile air connections.

❖ This section is very similar to Section 912.4 for access to fire department connections. Space must be provided to manipulate equipment and make proper connections.

**L104.15 Air monitoring system.** An *approved* air monitoring system shall be provided. The system shall automatically monitor air quality, moisture and pressure on a continual basis. The air monitoring system shall be equipped with not less than two content analyzers capable of detecting carbon monoxide, carbon dioxide, nitrogen, oxygen, moisture and hydrocarbons.

❖ In addition to the testing and maintenance required by Section L106.1, this section requires monitoring of the air at all times. The focus is on making sure that the air is of the correct quality, moisture content and pressure. Sections L105.15.1 through L105.15.3 focus on the actual alarm system requirements. The requirements address what creates an alarm condition (L104.15.1), where notification of a problem is communicated (L104.15.2) and that air quality status shall be visually communicated at the mobile air connection to let fire fighters know of any problem (L105.15.3).

**L104.15.1 Alarm conditions.** The air monitoring system shall transmit a supervisory signal when any of the following levels are detected:

1. Carbon monoxide exceeds 5 ppm.
2. Carbon dioxide exceeds 1,000 ppm.
3. An oxygen level below 19.5 percent or above 23.5 percent.

4. A nitrogen level below 75 percent or above 81 percent.
5. Hydrocarbon (condensed) content exceeds 5 milligrams per cubic meter of air.
6. The moisture concentration exceeds 24 ppm by volume.
7. The pressure falls below 90 percent of the maintenance pressure specified in Section L104.3.

❖ This section simply provides the criteria as to what constitutes a hazard and should initiate an alarm.

**L104.15.2 Alarm supervision, monitoring and notification.** The air monitoring system shall be electrically supervised and monitored by an *approved* supervising station, or where *approved*, shall initiate audible and visual supervisory signals at a constantly attended location.

❖ This section requires supervision and monitoring but does not mandate an audible or visual alarm. If approved, in place of a supervising station a local audible and visual signal may be provided at a constantly attended location. This could be in a security office within a building that is staffed 24 hours.

**L104.15.3 Air quality status display.** Air quality status shall be visually displayed at the external mobile air connection required by Section L104.14.

❖ In addition to monitoring and supervision at the connection for the mobile air apparatus, a visual display of current air quality is required. This is a location easily identified by the fire department.

## SECTION L105 ACCEPTANCE TESTS

**L105.1 Acceptance tests.** Upon completion of the installation, a FARS shall be acceptance tested to verify compliance with equipment manufacturers' instructions and design documents. Oversight of the acceptance tests shall be provided by a registered design professional. Acceptance testing shall include all of the following:

1. A pneumatic test in accordance with ASME B31.3 of the complete system at a minimum test pressure of 110 percent of the system design pressure using oil free dry air, nitrogen or argon shall be conducted. Test pressure shall be maintained for not less than 24 hours. During this test, all fittings, joints and system components shall be inspected for leaks. Defects in the system or leaks detected shall be documented and repaired.
2. A cylinder-filling performance test shall be conducted to verify compliance with the required breathing air cylinder refill rate from the exterior mobile air connection and, where provided, a stored air pressure supply system.
3. The air quality monitoring system shall be tested to verify both of the following conditions:
  - 3.1. Visual indicators required by Section L104.15.1 function properly.

3.2. Supervisory signals are transmitted as required by Section L104.15.2 for each sensor based on a sensor function test.

4. Connections intended for fire department use shall be confirmed as compatible with the fire department's mobile air unit, SCBA cylinders and, where provided, RIC/UAC connections.
  5. Air samples shall be taken from not less than two fill stations and submitted to an *approved* gas analysis laboratory to verify compliance with NFPA 1989. The FARS shall not be placed into service until a written report verifying compliance with NFPA 1989 has been provided to the *fire code official*.
- ❖ This section provides specific testing requirements regarding the installation and modification of such systems. Section L103.2 requires a construction permit along with documentation to show compliance with this section.

**SECTION L106  
INSPECTION, TESTING AND MAINTENANCE**

**L106.1 Periodic inspection, testing and maintenance.** A FARS shall be continuously maintained in an operative condition and shall be inspected not less than annually. Not less than quarterly, an air sample shall be taken from the system and tested to verify compliance with NFPA 1989. The laboratory test results shall be maintained on site and readily available for review by the *fire code official*.

- ❖ Ongoing maintenance is critical to the success of the air replenishment systems, which rely on consistent air quality and pressure. Operational permits help ensure that quarterly air samples are taken and annual inspections made.

# Appendix M: High-rise Buildings—Retroactive Automatic Sprinkler Requirement

*The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.*

## General Comments

Modern fire and building codes require complete automatic fire sprinkler protection and a variety of other safety features in new high-rise construction. Many older high-rise buildings lack automatic fire sprinkler protection and other basic fire protection features necessary to protect occupants, emergency responders, and the structure itself. Without complete automatic fire sprinkler protection, fire departments cannot provide the level of protection that high-rise buildings demand.

Existing high-rise buildings that are not protected with fire sprinklers represent a significant hazard to occupants and fire fighters. Additionally, high-rise fires can significantly impact a community's infrastructure and economic viability.

Between 2003 and 2006, there was an average of 13,400 reported structure fires in high-rise buildings annually. These incidents resulted in 62 civilian deaths, 490 civilian injuries, and \$179 million in direct property damage per year. Furthermore, from 1977 to 2009, 25 fire fighters died from nonstress-related cardiac death during fire suppression operations in high-rise buildings.

By their very nature, high-rise fires present unique fire-fighting challenges that are extremely difficult for fire fighters to mitigate without the presence of automatic sprinkler systems. Some of these challenges include:

- High-rise structure fires require significantly more resources, such as personnel and equipment, to extinguish than do fires in other types of occupancies. This further strains the responding fire department and fire fighters.
- Due to their height, smoke movement in high-rise structures is very different from that of other structures. Temperature gradients result in varying pressures throughout the structure, which can allow for the rapid, uncontrolled movement of smoke and flame (known as the "stack effect"). By design, exits from high-rise structures are limited.

In an emergency, the movement of people out of a building is particularly difficult. A prime example of this hazard is the One Meridian Plaza fire. This fire occurred on the 22nd floor of the 38-story Meridian Bank Building and was reported to the Philadelphia Fire Department on February 23, 1991 and burned for more than 19 hours. The fire caused three fire-fighter fatalities and injuries to 24 fire fighters. The 12 alarms brought 51 engine companies, 15 ladder companies, 11 specialized units, and more than 300 fire fighters to the scene. It was the largest high-rise office building fire in modern American history, completely consuming eight floors of the building, and was only controlled only when it reached a floor that was protected by automatic sprinklers. In 1999, the building was torn down amidst a storm of litigation.

- The HVAC and other utilities in some high-rises service multiple levels and can facilitate the spread of smoke and flame through a building.
- Due to the height of the building, response times for the fire department to reach the actual fire itself are extended, contributing to larger fire growth and more extensive smoke spread.

## Purpose

This appendix provides model code text for adoption by jurisdictions that choose to require existing high-rise buildings to be retrofitted with fire sprinklers. It is recognized that not all jurisdictions may choose to or have legal authority to enact a retroactive construction requirement of this nature, so an adoptable appendix has been provided. This appendix will provide the basic tools to those jurisdictions that have the ability to adopt such requirements. The appendix contains the basic automatic sprinkler system requirements and provides reasonable timeframes for building owners to meet such requirements.

### SECTION M101 SCOPE

**M101.1 Scope.** An *automatic sprinkler system* shall be installed in all existing high-rise buildings in accordance with the requirements and compliance schedule of this appendix.

- ❖ This section provides a tool for jurisdictions to implement a retroactive requirement for the installation of an automatic sprinkler system in high-rise buildings. This appendix also provides a method for building owners to file a compliance schedule for their building.

### SECTION M102 WHERE REQUIRED

**M102.1 High-rise buildings.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.1 of the *International Fire Code* shall be provided throughout existing high-rise buildings.

#### Exceptions:

1. Airport traffic control towers.
  2. Open parking structures.
  3. Group U occupancies.
  4. Occupancies in Group F-2.
- ❖ This section contains the focus of the appendix, which is the enabling language for a jurisdiction to require an NFPA 13 automatic sprinkler system to be installed in existing high-rise buildings. In jurisdictions that use this appendix, the enabling language will be consistent. Several exceptions are similar to the exceptions in Section 403.1 addressing the applicability of the high-rise special use requirements.

### SECTION M103 COMPLIANCE

**M103.1 Compliance schedule.** Building owners shall file a compliance schedule with the *fire code official* not later than 365 days after the first effective date of this code. The compliance schedule shall not exceed 12 years for an *automatic sprinkler system* retrofit.

- ❖ The requirement for the retroactive installation of a sprinkler system in a high-rise building is one that is costly and often a disruption to the use of the building. This is understood and flexibility is built into the appendix to ease the burden and recognize such installations cannot occur overnight. Instead, it provides some reasonable limits as to when a compliance schedule is to be provided to a jurisdiction (1 year after effective date). Additionally, this section allows up to 12 years for the installation process to be completed. The owners may prioritize based, for example, on changing tenants or planned renovations as to which portion of the building will be retrofitted first.

 Buildings under construction or demolition . . . . . 3305  
 Classified locations . . . . . 5703.1.1  
 Defined . . . . . 202  
 Dispensing, use, mixing and handling . . . . . 5705.3, 5705.3.8  
 In construction and demolition operations . . . . . 3305  
 Indoor storage . . . . . 5704.3.3  
 Labeling and signage . . . . . 5703.5  
 Motor fuel . . . . . 2306  
 Outdoor storage . . . . . 5704.4  
 Permit . . . . . 105.6.17, 105.7.8  
 Portable fire extinguisher . . . . . 5706.2.7  
 Special operations . . . . . 5706  
 Tank storage . . . . . 5704.2  
 Tents, air-supported, air-inflated and tensioned membrane structures . . . . . 3104.17  
 Waste control . . . . . 5706.3.3  
 Wholesale and resale use . . . . . 5704.3.6

**FLAMMABLE MATERIAL**

Defined ..... 202

**FLAMMABLE SOLID** ..... Chapter 59

Defined ..... 202

Indoor storage ..... 5904.1

Magnesium ..... 5906

Outdoor storage ..... 5906

Requirements ..... 5903

Use ..... 5905

**FLAMMABLE VAPOR AREA**

Alarms ..... 2404.8.1.1

Defined ..... 202

Electrical equipment ..... 2403.2.1

Ignition sources ..... 2403.2

Ventilation ..... 2404.7, 2405.7

Warning signs ..... 2403.2.7

**FLAMMABLE VAPORS OR FUMES**

Defined ..... 202

**FLASH POINT**

Defined ..... 202

**FLEET VEHICLE MOTOR FUEL-DISPENSING FACILITY**

Defined ..... 202

Tanks ..... 2306.2.4.2

**FLEXIBLE JOINTS** ..... 2306.7.9.1.4, 5703.6.9

**FLIGHT (stairs)**

Defined ..... 202

**FLOOR AREA, GROSS**

Defined ..... 202

**FLOOR AREA, NET**

Defined ..... 202

**FLOOR CONSTRUCTION** ..... 2309.5.1.1, 5004.2.1, 5004.12, 6003.1.4.1, 6304.1.3

**FLOOR COVERING (interior finish)** ..... 804.3

**FLOOR FINISHING** ..... 2410

Permit ..... 105.6.18

**FLOOR IDENTIFICATION SIGNS** ..... 1023.9, 1031.9, 1104.24

**FLOOR OPENINGS AND SHAFTS** ..... 704, 1103.4

**FLUE SPACES** ..... 3208.3

Defined ..... 202

**FLUIDIZED BED**

Defined ..... 202

**FOAM-EXTINGUISHING SYSTEMS** ..... 904.7

Defined ..... 202

**FOAM PLASTICS** ..... 803.7, 804.2, 807.4.2.1, 808.3

**FOGGING, INSECTICIDAL (see FUMIGATION AND INSECTICIDAL FOGGING)**

**FOLDING AND TELESCOPIC SEATING**

Defined ..... 202

**FOSTER CARE FACILITIES (Occupancy Group I)**

Defined ..... 202

**FRUIT AND CROP RIPENING** ..... Chapter 25

Ethylene gas ..... 2503

Heating ..... 2504.5

Permit ..... 105.6.19

Sources of ignition ..... 2504

Warning signs ..... 2507

**FUEL-FIRED APPLIANCES** ..... 603

Chimneys ..... 603.2, 603.6

Heating ..... 603.5

Installation ..... 603.1

**FUEL LIMIT SWITCH**

Defined ..... 202

**FUEL OIL**

Grade ..... 603.1.4

Storage ..... 603.3

**FUMIGANT**

Defined ..... 202

**FUMIGATION AND**

**INSECTICIDAL FOGGING** ..... Chapter 26

Breathing apparatus ..... 2603.3.2

Clean up ..... 2603.6

Defined ..... 202

Fire safety requirements ..... 2603

Notification ..... 2603.3

Permit ..... 105.6.20

Sealing of buildings ..... 2603.5

Warning signs ..... 2603.3.1

Watch personnel ..... 2603.3.3

**FURNACE CLASS A, B, C, D**

Defined ..... 202

**FURNISHINGS** ..... 808, 1031.6

**FURNITURE, UPHOLSTERED** ..... 805, 903.2.4, 903.2.7, 903.2.9

**HARDWARE, EXIT DOOR** . . . . . 1010.1.9  
**HARDWARE, PANIC** . . . . . 1010.1.10  
**HAY**  
 Combustible fiber . . . . . 5203.4  
 Combustible waste . . . . . 304.1.1  
 Storage . . . . . 3104.5, 5203.4  
**HAZARD COMMUNICATION** . . . . . 407  
 Hazardous Materials Inventory Statement . . . . . 407.5, 5001.5.2  
 Hazardous Materials Management Plan . . . . . 407.6, 5001.5.1  
 Training . . . . . 407.4  
**HAZARDOUS MATERIALS**  
 Defined . . . . . 202  
 Fire-extinguishing systems . . . . . 5004.5, 5005.1.8  
 General . . . . . Chapter 50  
 Groups M and S . . . . . 5003.11  
 Identification signs . . . . . 5003.5  
 Mixtures . . . . . 5001.2.1  
 Outdoor control areas . . . . . 5003.12  
 Permit . . . . . 105.6.21, 105.7.10  
 Personnel training . . . . . 407.4  
 Power systems . . . . . 604.2.8  
 Requirements . . . . . 5003  
 Storage . . . . . 5004  
 Use, dispensing and handling . . . . . 5005  
**HAZARDOUS MATERIALS INVENTORY STATEMENT** . . . . . 407.5, 5001.5.2  
**HAZARDOUS MATERIALS MANAGEMENT PLAN** . . . . . 407.6, 5001.5.1  
**HAZARDOUS PRODUCTION MATERIAL (HPM)**  
 Defined . . . . . 202  
 Permit . . . . . 105.6.22  
**HAZARDS TO FIRE FIGHTERS** . . . . . 316  
**HEALTH HAZARD** . . . . . 5001.2.2.2, Table 5003.1.1(2), Table 5003.1.1(4)  
 Defined . . . . . 202  
**HEAT VENTS (see SMOKE AND HEAT VENTS)**  
**HEATERS, PATIO (see PORTABLE OUTDOOR GAS-FIRED HEATING APPLIANCES)**  
**HEATERS, PORTABLE ELECTRIC SPACE** . . . . . 605.10  
**HEATERS, PORTABLE UNVENTED** . . . . . 603.4  
**HEATING APPLIANCES** . . . . . 603.5

**HEATING EQUIPMENT, TEMPORARY, DURING CONSTRUCTION** . . . . . 3303

**HEIGHT, BUILDING**  
 Defined . . . . . 202

**HELIPORT** . . . . . 2007  
 Defined . . . . . 202  
 Permit for rooftop heliport . . . . . 105.6.42

**HELISTOP** . . . . . 2007  
 Defined . . . . . 202

**HI-BOY**  
 Construction . . . . . 303.7  
 Defined . . . . . 202

**HIGH-PILED COMBUSTIBLE STORAGE** . . . . . Chapter 32  
 Aisles . . . . . 3206.9  
 Automated storage . . . . . 3209  
 Automatic sprinklers . . . . . 3206.4, 3209.2  
 Classifications, commodities . . . . . 3203  
 Defined . . . . . 202  
 Fire protection . . . . . 3206, Table 3206.2  
 Housekeeping . . . . . 3205  
 Pallets . . . . . 3206.4.1  
 Plastic pallets . . . . . 3206.4.1.1

**HIGH-PILED STORAGE AREA**  
 Defined . . . . . 202  
 Designations . . . . . 3204  
 Permit . . . . . 105.6.23

**HIGH-RISE BUILDING**  
 Automatic sprinkler system . . . . . 903.2.11.3, 914.3.1  
 Automatic sprinkler system, floor control valves required . . . . . 903.4.3  
 Automatic sprinkler system, secondary water supply required . . . . . 914.3.2  
 Defined . . . . . 202  
 Emergency responder radio coverage . . . . . 914.3.5  
 Emergency voice/alarm communications system . . . . . 907.2.13, 914.3.4  
 Fire alarm system . . . . . 907.2.13, 914.3.2  
 Fire alarm system zoning . . . . . 907.6.3.2  
 Fire command center . . . . . 508.1, 914.3.6  
 Fire department communications system . . . . . 907.2.13.2  
 Fire safety and evacuation plans . . . . . 403.11.2  
 Smokeproof exit stairway enclosures . . . . . 1023.11  
 Standby power system . . . . . 604.2.10  
 Standpipe system . . . . . 905.3.1

**HIGH-VOLTAGE TRANSMISSION LINE**  
 Defined . . . . . 202  
 Storage under . . . . . 315.5, 316.6

**HIGHLY TOXIC AND TOXIC MATERIALS** . . . . . Chapter 60  
 Compressed gases . . . . . 6004

Defined . . . . . 202  
 Indoor storage and use . . . . . 6003.1  
 Outdoor storage and use . . . . . 6003.2  
 Solids and liquids . . . . . 6003

**HIGHWAY**  
 Defined . . . . . 202

**HISTORIC BUILDINGS** . . . . . 102.6  
 Defined . . . . . 202

**HOGGED MATERIALS** . . . . . 2807, 2808  
 Defined . . . . . 202

**HOOD** . . . . . 609  
 Defined . . . . . 202

**HORIZONTAL ASSEMBLY**  
 Defined . . . . . 202

**HORIZONTAL PROJECTIONS** . . . . . 1003.3.3

**HOSE** . . . . . 2307.5.2, 2310.3.3  
 Aircraft fueling . . . . . 2006  
 Conductive . . . . . 2006.5.2.1  
 Connections for standpipes . . . . . 905.3.4.1, 905.4, 905.5, 905.6  
 Dispensing . . . . . 2006.3.3, 2306.7.5  
 Protection . . . . . 2006.7, 5706.6.1.11  
 Removal of occupant hose lines . . . . . 901.8.2  
 System . . . . . 904.8.4, 904.9.3, 904.10.3  
 Threads . . . . . 903.3.6, 912.3

**HOSPITALS AND PSYCHIATRIC HOSPITALS (Group I-2)**  
 Defined . . . . . 202

**HOT WORK (see WELDING AND OTHER HOT WORK)**  
 Defined . . . . . 202  
 Permit . . . . . 105.6.24

**HOT WORK AREA**  
 Defined . . . . . 202

**HOT WORK EQUIPMENT**  
 Defined . . . . . 202

**HOT WORK PERMITS**  
 Defined . . . . . 202

**HOT WORK PROGRAM**  
 Defined . . . . . 202

**HPM FACILITY (see SEMICONDUCTOR FABRICATION FACILITY)**

**HPM ROOM**  
 Defined . . . . . 202

**HYDRANTS (see FIRE HYDRANT)**

**HYDROGEN** . . . . . 5501.1, 5801.1

**HYDROGEN FUEL GAS ROOMS** . . . . . 5808  
 Defined . . . . . 202

**HYDROGEN MOTOR FUEL-DISPENSING FACILITIES** . . . . . 2309

**HYPERBARIC FACILITIES** . . . . . 611

**I**

**IDENTIFICATION**

Alcohol-blended fuel-dispensing facilities . . . . . 2306.8.3  
 Building (address) . . . . . 505.1  
 Elevator lobby . . . . . 1023.10  
 Exit discharge . . . . . 1023.8, 1104.21  
 Floor level . . . . . 1023.9, 1031.9  
 Fire protection equipment . . . . . 509.1, 905.7.1  
 Hazardous materials . . . . . 5003.5, 5503.4, 5703.5.4, 6005.4.3  
 Hot work hazards . . . . . 3503.6  
 Streets and roads . . . . . 505.2  
 Tenant spaces in covered malls . . . . . 403.11.1.5  
 Utilities . . . . . 509.1.1  
 Vacant premises . . . . . 311.5.4

**IGNITION SOURCES . . . . . 305, 3703.7**

**IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH)**

Defined . . . . . 202

**IMPACT PROTECTION, VEHICLE . . . . . 312, 6107.4, 6109.13**

**IMPAIRMENT COORDINATOR . . . . . 901.7.1**  
 Defined . . . . . 202

**INCAPABLE OF SELF-PRESERVATION (Occupancy Group I)**

Defined . . . . . 202

**INCINERATORS . . . . . 603.8, 1103.4.10**

Room egress . . . . . 1006.2.2.1
