Because of concerns of school campus safety serving kindergarten through 12th grade students, specific requirements were put into the 2012 edition of the IBC and the code for enhanced communication between the school administrators, teachers and students when a lockdown plan is activated in Group E occupancies. As a result, emergency voice/alarm communication systems (EV/ACS) are prescribed in Group E occupancies. Previously the code would have permitted the manual fire alarm system to use audible and visible alarm notification appliances and did not require the added capabilities that an EV/ACS provides.

This section sets forth the requirements for automatic fire alarm and detection system requirements in Group E occupancies and prescribes the installation of an EV/ACS as opposed to a traditional horn/strobe occupant notification system.

Exception 1 exempts Group E occupancies from requiring a fire alarm system when the occupant load is less than 50. This would exempt small day care centers that serve children older than 2½ years of age or a small Sunday school classroom at a place of religious worship.

Exception 2 provides relief for smaller schools. If the occupant load is 100 or less, notification is not

required to be via an emergency voice/alarm communication system. A school with 100 occupants only has a few classrooms of children. Communication is simplified and an emergency voice/alarm communication system is considered to be excessive.

Exception 3 exempts manual fire alarm boxes in interior corridors, laboratories, auditoriums, cafeterias, gymnasiums and similar spaces based on the installation of heat/smoke detectors. This is not an exception from the EV/ACS but simply an exemption of locations requiring manual fire alarm boxes. The applicability of Exception 2 is independent of whether an automatic sprinkler system is installed. If an automatic smoke detection system is installed, it must be connected to the building fire alarm system.

Exception 4 allows the omission of the manual fire alarm boxes in Group E occupancies equipped throughout with an automatic sprinkler system if the actuation of the sprinkler system will activate the EV/ACS. See Section 903.2.3 for sprinkler requirements in Group E buildings.

**907.2.4 Group F.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group F occupancies where both of the following conditions exist:

- 1. The Group F occupancy is two or more stories in height.
- 2. The Group F occupancy has a combined *occupant load* of 500 or more above or below the lowest *level of exit discharge*.

**Exception:** Manual fire alarm boxes are not required where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

❖ This section is intended to apply to large multistory manufacturing facilities. For this reason, a manual fire alarm system would be required only if the building were at least two stories in height and had 500 or more occupants above or below the level of exit discharge. An unlimited area, two-story Group F occupancy complying with Section 507.5 of the IBC would be indicative of an occupancy requiring a manual fire alarm system.

Buildings in compliance with Section 507.5 of the IBC, and large manufacturing facilities in general, however, must be fully sprinklered and would thus be eligible for the exception. The exception does not eliminate the fire alarm system but rather permits it to be initiated automatically by the sprinkler system waterflow switch(es) instead of by the manual fire alarm boxes.

**907.2.5 Group H.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group H-5 occupancies and in occupancies used for the manufacture of organic coatings. An automatic smoke detection system shall be installed for

highly toxic gases, organic peroxides and oxidizers in accordance with Chapters 60, 62 and 63, respectively.

- ❖ Because of the nature and potential quantity of hazardous materials in Group H-5 occupancies, a manual means of activating an occupant notification system is essential for the safety of the occupants. In accordance with Section 2703.11, the activation of the alarm system must initiate a local alarm and transmit a signal to the emergency control station. The manual fire alarm system requirement for the building is in addition to the emergency alarm requirements in Section 2703.12 (see Section 908.2).

Occupancies involved in the manufacture of organic coatings present special hazardous conditions because of the unstable character of the materials, such as nitrocellulose. Good housekeeping and control of ignition sources is critical. Chapter 29 contains additional requirements for organic coating manufacturing processes.

This section also requires an automatic smoke detection system in certain occupancy conditions involving either highly toxic gases or organic peroxides and oxidizers. The need for the automatic smoke detection system may depend on the class of materials and additional levels of fire protection provided. This requirement also assumes the quantity of materials is in excess of the maximum allowable quantities shown in Tables 5003.1.1(1) and 5003.1.1(2).

**907.2.6 Group I.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group I occupancies. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in accordance with Sections 907.2.6.1, 907.2.6.2 and 907.2.6.3.3.

#### Exceptions:

1. Manual fire alarm boxes in *sleeping units* of Group I-1 and I-2 occupancies shall not be required at *exits* if located at all care providers' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that the distances of travel required in Section 907.4.2.1 are not exceeded.
  2. Occupant notification systems are not required to be activated where private mode signaling installed in accordance with NFPA 72 is *approved* by the *fire code official* and staff evacuation responsibilities are included in the fire safety and evacuation plan required by Section 404.
- ❖ Because the protection and possible evacuation of the occupants in Group I occupancies are most often dependent on the response by care providers, occupancies in Group I must be protected with a manual fire alarm system and in certain instances, as described in Sections 907.2.6.1, 907.2.6.2 and 907.2.6.3, an automatic smoke detection system. In Group I-1, smoke alarms are also required in accordance with Section 907.6.1.1.

It is not the intent of this section to require a smoke detection system throughout all Group I occupancies. Smoke detectors are only generally required in the corridors and in waiting rooms that are open to corridors, unless noted otherwise. IFC Committee Interpretation No. 36-03 makes it clear that the Group I provisions only require a manual fire alarm system with smoke detectors in selected areas.

To reduce the potential for unwanted alarms, manual fire alarm boxes may be located at the care providers' control stations or another constantly attended location.

Exception 1 reduces the likelihood of accidental or malicious false alarm system activations by manual means by allowing the pull stations to be located in a more controlled area. It assumes the approved location is always accessible by care providers and within a distance of travel of 200 feet (60 960 mm).

Exception 2 allows the common practice in Group I occupancies of only notifying the care providers instead of all building occupants in the event of a fire, subject to the approval of the fire code official. In order to have confidence that the actions taken will be appropriate, the code also requires that the responsibilities of the staff be documented in the fire safety and evacuation plan for the facility. These requirements are found in Section 404. This will increase the likelihood for any staff training to be linked to the allowance of private mode signaling.

**907.2.6.1 Group I-1.** An automatic smoke detection system shall be installed in *corridors*, waiting areas open to *corridors* and *habitable spaces* other than *sleeping units* and kitchens. The system shall be activated in accordance with Section 907.5.

#### Exceptions:

1. For Group I-1 Condition 1 occupancies, smoke detection in *habitable spaces* is not required where the facility is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
  2. Smoke detection is not required for exterior balconies.
- ❖ Occupancies in Group I-1 tend to be compartmentalized into small rooms so that a fire in one area of the building would not easily be noticed by occupants in another part of the building. Therefore, smoke detection is required in areas other than sleeping units and kitchens. Sleeping units are required by Section 907.2.6.1.1 to be equipped with single- and multiple station smoke alarms in accordance with Section 907.2.11.
- Since Group I-1 occupancies may not be supervised by care providers and to reduce the likelihood that a fire within a waiting area open to the corridor or the corridor itself could develop beyond the incipient stage, thereby jeopardizing the building egress, these areas must be equipped with automatic smoke detection.

Exception 1 allows smoke detectors to be eliminated from habitable spaces of Group I-1 Condition 1 occupancies if the building is equipped throughout with an NFPA 13 automatic sprinkler system. The sprinkler system should control any fire and perform occupant notification through actuation of the waterflow switch and subsequent activation of the building alarm notification appliances. A sprinkler system is required for all Group I occupancies in accordance with Section 903.2.6. It should be noted that Group I-1 Condition 1 is the lower risk Group I-1 occupancy where residents are able to evacuate without assistance. See the commentary for Section 308.3 of the IBC.

Exception 2 allows for omitting smoke detectors from exterior balconies for environmental reasons and does not require the installation of an alternative type of detector. The exterior balconies are assumed to be sufficiently open to the atmosphere to readily allow the dissipation of smoke and hot gases.

**907.2.6.1.1 Smoke alarms.** Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

❖ As with dwelling units or sleeping units in any occupancy, this section requires that single- and multiple-station smoke alarms be installed in accordance with Section 907.2.11. Section 907.2.11.2 deals specifically with the requirements for Group I-1.

**907.2.6.2 Group I-2.** An automatic smoke detection system shall be installed in *corridors* in Group I-2 Condition 1 facilities and spaces permitted to be open to the *corridors* by Section 407.2 of the *International Building Code*. The system shall be activated in accordance with Section 907.4. Group I-2 Condition 2 occupancies shall be equipped with an automatic smoke detection system as required in Section 407 of the *International Building Code*.

**Exceptions:**

1. *Corridor* smoke detection is not required in smoke compartments that contain *sleeping units* where such units are provided with smoke detectors that comply with UL 268. Such detectors shall provide a visual display on the *corridor* side of each *sleeping unit* and shall provide an audible and visual alarm at the care providers' station attending each unit.
  2. *Corridor* smoke detection is not required in smoke compartments that contain *sleeping units* where *sleeping unit* doors are equipped with automatic door-closing devices with integral smoke detectors on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.
- ❖ Automatic smoke detection is required in areas permitted to be open to corridors in occupancies classified as Group I-2 Condition 2 and corridors in Group I-2 Condition 1 occupancies (e.g., nursing homes, long-term care facilities and detoxification facilities). In recognition of quick-response sprinkler technology and the fact that the sprinkler system is electronically supervised, and because the doors to care recipient

sleeping units are continuously supervised by care providers when in the open position, smoke detectors are not required for adequate fire safety in care recipient sleeping units.

In Group I-2 Condition 1 occupancies (e.g., nursing homes long-term care facilities and detoxification facilities), however, some redundancy is appropriate because such facilities typically have less control over furnishings and personal items, thereby resulting in a less predictable and usually higher fire hazard load than a Group I-2 Condition 2 occupancy (hospitals). Also, there is generally less care provider's supervision in these facilities than in other health care facilities and thus less control over care recipient smoking and other fire causes. Therefore, to provide additional protection against fires spreading from the room of origin, smoke detection is required in corridors of nursing homes, long-term care facilities and detoxification facilities.

Smoke detection is not required in corridors of other Group I-2 Condition 2 occupancies except where otherwise specifically required in the code. Similarly, because areas open to the corridor very often are the room of fire origin, and such areas are no longer required by the code to be under visual supervision by care providers, some redundancy to protection by the sprinkler system is requested. Accordingly, all areas open to corridors must be protected by an automatic smoke detection system. This requirement provides an additional level of protection against sprinkler system failures or lapses in care provider supervision.

These requirements are not applicable to Group I-2 Condition 2 occupancies (hospitals). The scope of this section clearly indicates that its provisions are only applicable to detoxification facilities and nursing homes. Hospitals are noted as being subject to the provisions in Section 407.2 of the IBC. IFC Committee Interpretation No. 37-03 addresses this issue. Section 407.2 of the IBC notes that smoke detection is only required for spaces open to corridors, such as waiting areas and mental health treatment areas where patients are not capable of self-preservation (see commentary, Section 407.2 of the IBC).

There are two exceptions to the requirement for an automatic fire detection system in corridors of nursing homes, long-term care facilities and detoxification facilities. Both exceptions provide an alternative method for redundant protection in care recipient sleeping units. For this reason, they provide either a backup to the notification of a fire or containment of fire in the room of origin.

Exception 1 requires smoke detectors in sleeping units that activate both a visual display on the corridor side of the care recipient sleeping unit and a visual and audible alarm at the care provider's station serving or attending the room. Detectors complying with UL 268 are intended for open area protection and for connection to a normal power supply or as part of a fire alarm system. This exception, however, is specifi-

cally designed not to require the detectors to activate the building fire alarm system where approved care recipient sleeping unit smoke detectors are installed and where visual and audible alarms are provided. This is in response to the concern over unwanted alarms. The required alarm signals will not necessarily indicate to care providers that a fire emergency exists because the care provider call system may typically be used to identify numerous conditions within the room.

Exception 2 addresses the situation where smoke detectors are incorporated within automatic door-closing devices. The units are acceptable as long as the required alarm functions are still provided. Such units are usually listed as combination door closer and hold-open devices.

**907.2.6.3 Group I-3 occupancies.** Group I-3 occupancies shall be equipped with a manual fire alarm system and automatic smoke detection system installed for alerting staff.

❖ Because of the evacuation difficulties associated with Group I-3 occupancies and the dependence on adequate staff response, a manual fire alarm system and an automatic fire detection system are required subject to the special occupancy conditions in Sections 907.2.6.3.1 through 907.2.6.3.3. This section recognizes that the evacuation of Group I-3 occupancies depends on an effective staff response. The requirements in Chapter 4 and specifically Section 403.8.3 of the code contain the requirements for an emergency plan, including employee training, staff availability, the need for occupants to notify staff and the need for the proper keys for unlocking doors for staff in Group I-3 occupancies.

**907.2.6.3.1 System initiation.** Actuation of an automatic fire-extinguishing system, *automatic sprinkler system*, a manual fire alarm box or a fire detector shall initiate an approved fire alarm signal that automatically notifies staff.

❖ This section specifies the systems that, upon activation, must initiate the required alarm signal immediately and automatically to the staff so that staff will respond in a timely manner.

**907.2.6.3.2 Manual fire alarm boxes.** Manual fire alarm boxes are not required to be located in accordance with Section 907.4.2 where the fire alarm boxes are provided at staff-attended locations having direct supervision over areas where manual fire alarm boxes have been omitted.

❖ Because of the potential for intentional false alarms and the resulting disruption to the facility, manual fire alarm boxes in Group I-3 occupancies may be either locked or made inaccessible to the occupants.

**907.2.6.3.2.1 Manual fire alarms boxes in detainee areas.** Manual fire alarm boxes are allowed to be locked in areas occupied by detainees, provided that staff members are pres-

ent within the subject area and have keys readily available to operate the manual fire alarm boxes.

❖ The locking of manual fire alarm boxes is permitted only in areas where staff members are present and keys are readily available to them to unlock the boxes, or where the alarm boxes are located in a manned staff location that has direct supervision of the Group I-3 area.

**907.2.6.3.3 Automatic smoke detection system.** An automatic smoke detection system shall be installed throughout resident housing areas, including *sleeping units* and contiguous day rooms, group activity spaces and other common spaces normally accessible to residents.

**Exceptions:**

1. Other *approved* smoke detection arrangements providing equivalent protection, including, but not limited to, placing detectors in exhaust ducts from cells or behind protective guards *listed* for the purpose, are allowed when necessary to prevent damage or tampering.
  2. *Sleeping units* in Use Conditions 2 and 3 as described in Section 308 of the *International Building Code*.
  3. Smoke detectors are not required in *sleeping units* with four or fewer occupants in smoke compartments that are equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
- ❖ Evacuation of Group I-3 facilities is impractical because of the need to maintain security. An automatic smoke detection system is therefore required to provide early warning of a fire.
- As indicated in Exception 1, the installation of automatic smoke detectors must take into account the need to protect the detector from vandalism by residents. As a result, detectors may have to be located in return air ducts or be protected by a substantial physical barrier.
- Since occupants in Use Condition 2 or 3 are not locked in their sleeping units, Exception 2 reduces the need for smoke detection.
- Exception 3 allows smoke detectors to be omitted in sleeping units housing no more than four occupants on the basis that in a building that is protected throughout with an approved automatic sprinkler system, the system will provide both detection and suppression functions. Group I facilities are assumed to be fully sprinklered throughout in accordance with NFPA 13 as required by Section 903.2.6. The limitation of four occupants reduces the potential fuel load (mattresses, clothes, etc.) and the likelihood of involvement over an extended area.

**907.2.7 Group M.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group M occupancies where one of the following conditions exists:

1. The combined Group M *occupant load* of all floors is 500 or more persons.
2. The Group M *occupant load* is more than 100 persons above or below the lowest *level of exit discharge*.

**Exceptions:**

1. A manual fire alarm system is not required in covered or open mall buildings complying with Section 402 of the *International Building Code*.
  2. Manual fire alarm boxes are not required where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 and the occupant notification appliances will automatically activate throughout the notification zones upon sprinkler water flow.
- ❖ Group M occupancies have the potential for large numbers of occupants who may not be familiar with their surroundings. The installation of a fire alarm system increases the ability to alert the occupants of a fire. Note that the occupant thresholds must be considered independently. If the total occupant load is 500 or more persons a manual fire alarm system is required. If more than 100 persons are above or below the level of exit discharge, a manual fire alarm system is required.

This section also specifies that the manual fire alarm boxes must, upon activation, provide occupant notification throughout the Group M occupancy.

The extent of fire alarm application is based upon the area in which the Group M occupancy is located. If the building is considered as a separated mixed occupancy then the fire alarm system is only required in the individual occupancy in which the occupant load exceeds the threshold quantity. The rest of the building would not require a fire alarm system. This approach is noted in Section 508.4.1 of the IBC, which states that each separated space must comply with the code based upon the occupancy classification of that portion of the building. If the Group M occupancy was part of a nonseparated mixed-use building, then the alarm system would be required in the entire building in accordance with Section 508.3.1 of the IBC. The determination as to when such a system is required would be based solely upon the Group M occupant load.

Exception 1 recognizes the increased level of fixed automatic protection inherently required in covered and open mall buildings including an automatic sprinkler system, and, possibly, a smoke control system. Covered and open mall buildings are also required to contain an emergency voice/alarm communication system (see Section 907.2.20).

Exception 2 does not eliminate the fire alarm system, but rather allows it to be initiated automatically

by sprinkler system water flow switch(es) instead of by manual fire alarm boxes. Buildings with a fire area containing a Group M occupancy in excess of 12,000 square feet (1115 m<sup>2</sup>) must be equipped with an automatic sprinkler system complying with Section 903.2.6.

**907.2.7.1 Occupant notification.** During times that the building is occupied, the initiation of a signal from a manual fire alarm box or from a waterflow switch shall not be required to activate the alarm notification appliances when an alarm signal is activated at a constantly attended location from which evacuation instructions shall be initiated over an emergency voice/alarm communication system installed in accordance with Section 907.5.2.2.

❖ Occupants in a mercantile occupancy may assume the alarm is a false alarm or act inappropriately and thus delay evacuation of the building. To prevent such a dangerous situation, the manual fire alarm system may be part of an EV/ACS. The signal is to be sent to a constantly attended location on site from which evacuation instructions can be given.

It should be noted that, although the alarm notification alternative allows for the manual use of an EV/ACS, the alternative does not remove the requirement for audible and visual notification devices.

**907.2.8 Group R-1.** Fire alarm systems and smoke alarms shall be installed in Group R-1 occupancies as required in Sections 907.2.8.1 through 907.2.8.3.

❖ Because residents of Group R-1 occupancies may be asleep and are usually transients who are unfamiliar with the building, and because such buildings contain numerous small rooms so that the occupants may not notice a fire in another part of the building, occupancies in Group R-1 must have a manual fire alarm system and an automatic smoke detection system installed throughout. Requirements for single- or multiple-station smoke alarms in sleeping units are contained in Section 907.2.11.1.

**907.2.8.1 Manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-1 occupancies.

**Exceptions:**

1. A manual fire alarm system is not required in buildings not more than two stories in height where all individual *sleeping units* and contiguous attic and crawl spaces to those units are separated from each other and public or common areas by not less than 1-hour *fire partitions* and each individual *sleeping unit* has an *exit* directly to a *public way*, *egress court* or yard.
2. Manual fire alarm boxes are not required throughout the building where all of the following conditions are met:
  - 2.1. The building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

2.2. The notification appliances will activate upon sprinkler water flow.

2.3. Not fewer than one manual fire alarm box is installed at an *approved* location.

❖ This section is specific to manual fire alarm systems and requires such systems in all Group R-1 occupancies, with two exceptions.

Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system water flow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system and at least one manual fire alarm box shall be installed at an approved location. See the commentary to Section 907.2 for a discussion of the single manual fire alarm box.

The exceptions do not affect the independent provision in Section 907.2.11 for single- or multiple-station smoke alarms.

**907.2.8.2 Automatic smoke detection system.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed throughout all interior *corridors* serving *sleeping units*.

**Exception:** An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *sleeping units* and where each *sleeping unit* has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an *exit*.

❖ This section requires an automatic smoke detection system within interior corridors. Such systems make use of smoke detectors for alarm initiation in accordance with Section 907.2, with one exception.

The exception provides that automatic fire detectors are not required in motels and hotels that do not have interior corridors and in which sleeping units have a door opening directly to an exterior exit access that leads directly to the exits. The intent of the exception is that the exit access from the sleeping unit door be exterior and not require reentering the building prior to entering the exit. Since the exit access is outside, the need for detectors other than the smoke alarms required by Section 907.2.8.3 in sleeping units is greatly reduced.

**907.2.8.3 Smoke alarms.** Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

❖ The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11.

That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

**907.2.9 Group R-2.** Fire alarm systems and smoke alarms shall be installed in Group R-2 occupancies as required in Sections 907.2.9.1 and 907.2.9.3.

❖ This section introduces the fire alarm system and smoke alarm requirements for Group R-2 occupancies. This includes Group R-2 occupancies in general and also Group R-2 college and university buildings.

**907.2.9.1 Manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-2 occupancies where any of the following conditions apply:

1. Any *dwelling unit* or *sleeping unit* is located three or more stories above the lowest *level of exit discharge*.
2. Any *dwelling unit* or *sleeping unit* is located more than one story below the highest *level of exit discharge* of *exits* serving the *dwelling unit* or *sleeping unit*.
3. The building contains more than 16 *dwelling units* or *sleeping units*.

**Exceptions:**

1. A fire alarm system is not required in buildings not more than two stories in height where all *dwelling units* or *sleeping units* and contiguous attic and crawl spaces are separated from each other and public or common areas by not less than 1-hour *fire partitions* and each *dwelling unit* or *sleeping unit* has an *exit* directly to a *public way*, *egress court* or yard.
  2. Manual fire alarm boxes are not required where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2 and the occupant notification appliances will automatically activate throughout the notification zones upon a sprinkler water flow.
  3. A fire alarm system is not required in buildings that do not have interior *corridors* serving *dwelling units* and are protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, provided that *dwelling units* either have a *means of egress* door opening directly to an exterior *exit access* that leads directly to the *exits* or are served by open-ended *corridors* designed in accordance with Section 1027.6, Exception 3.
- ❖ The occupants of Group R-2 occupancies are not considered to be as transient as those of Group R-1, which increases the probability that residents can more readily notify each other of a fire. Therefore, Group R-1 occupancies must have a manual fire alarm system with audible and visual notification appliances subject to the exceptions in Section 907.2.8.1, whereas Group R-2 occupancies are

required to have only a manual fire alarm system as stipulated in one of the three listed conditions. The threshold conditions are meant to be applied independently of each other.

Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system water flow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system. This exception does not affect the independent provisions of Section 907.2.11.

Exception 3 allows the omission of a fire alarm system in fully sprinklered buildings (NFPA 13 or 13R) with no interior corridors and that exit directly to an exterior exit access or have open-ended corridors. The important thing to note is that the sprinkler system is not required to activate alarm notification appliances since a fire alarm system would not be required. Only the sprinkler alarms required by Section 903.4 would be required.

**907.2.9.2 Smoke alarms.** Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

❖ The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11. That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

**907.2.9.3 Group R-2 college and university buildings.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-2 occupancies operated by a college or university for student or staff housing in all of the following locations:

1. Common spaces outside of *dwelling units* and *sleeping units*.
2. Laundry rooms, mechanical equipment rooms and storage rooms.
3. All interior corridors serving *sleeping units* or *dwelling units*.

**Exception:** An automatic smoke detection system is not required in buildings that do not have interior corridors serving *sleeping units* or *dwelling units* and where each *sleeping unit* or *dwelling unit* either has a *means of egress* door opening directly to an

exterior *exit access* that leads directly to an *exit* or a *means of egress* door opening directly to an *exit*.

Required smoke alarms in *dwelling units* and *sleeping units* in Group R-2 occupancies operated by a college or university for student or staff housing shall be interconnected with the fire alarm system in accordance with NFPA 72.

❖ This section requires an automatic smoke detection system in Group R-2 occupancies that are operated by a college or university to provide student or staff housing. It also requires the smoke alarms in individual units to be interconnected with the fire alarm system. This interconnection is only for the purpose of making occupants within each unit aware of the fire alarm activation in the building. The intent was not to activate the building fire alarm system by smoke alarms in each unit. This is more restrictive than a Group R-2 occupancy in general as typically the requirements are limited to a manual fire alarm system and smoke alarms in the individual sleeping or dwelling units.

The smoke detection system is focused on common areas, such as interior corridors, lounge areas, laundry, and areas such as mechanical rooms, which could be the source of a fire, especially in these specific types of Group R-2 occupancies.

In a study completed by the New York State Governor's Task Force on Campus Fire Safety it was cited that 43 percent of fires in college dormitories are located in dorm rooms or kitchens, leaving the other 57 percent to be located in areas that would not require smoke detection under the current code. The study also showed that there were approximately 300 fires on college campus over a three-year period while only 160 were reported to the fire department. The Center for Campus Fire Safety states 99 deaths have been "reported" in fires in student housing since 2000.

An NFPA study on student housing showed 3,300 structural fires in dormitories, fraternities, sororities and barracks between 2002 and 2005. Since 1980, there has been an increase of 3 percent in reported fires in dormitory-type occupancies, while there has been a 52-percent decrease in overall reported structural fires.

The requirements in this section are very similar to the recommendations of the study done in New York State. It is important to note that the recommendations for that study were specifically aimed at the properties of the colleges and universities so it was not the study's intent to cover off-campus housing in this particular regard. There were recommendations for off-campus housing, such as sororities and fraternities to have annual inspections. This particular distinction was not addressed in detail during the code development process initially; however, since this is somewhat of a continuation of requirements that were added into Chapter 4 of the 2006 edition of the IFC for emergency preparedness and planning, and those requirements were intended to deal with buildings that were college or university property, it

seemed reasonable to interpret that this requirement is also limited to the buildings that are college or university property and does not apply to Group R-2 occupancies that are not college or university property. This has since been clarified through the code development process and the section now specifically notes that the Group R-2 occupancies are specifically operated by a college or university.

The exception allows for the elimination of the smoke detection system in a specific situation where there are no interior corridors and the occupants essentially exit directly to the outside. The lack of interior corridors and exterior exits reduces the amount of smoke one unit will expose onto another. Note that smoke alarms within the units are still required by Section 907.2.11.2. Note also that it is entirely possible that some areas that are required to have smoke detection may have ambient conditions that warrant a different type of alarm-initiating device. Section 907.4.3 addresses this concern.

**907.2.10 Group R-4.** Fire alarm systems and smoke alarms shall be installed in Group R-4 occupancies as required in Sections 907.2.10.1 through 907.2.10.3.

❖ This section, based on the Group R-2 requirements for manual fire alarm systems and Group I-1 requirements for automatic smoke detection systems, contains manual fire alarm and automatic smoke detection system requirements for new Group R-4 occupancies. Reviewing the occupancy categories in Chapter 3 of the IBC, a Group R-4 can be considered either a small Group I-1 or a Group R-2 with occupants that have special needs or limitations. A further review found that both Group I-1 and Group R-2 occupancies have fire alarm requirements for new buildings, but Group R-4 did not, even though the code required a fire alarm system retroactively in existing Group R-4 occupancies (see Section 1103.7.7).

**907.2.10.1 Manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-4 occupancies.

**Exceptions:**

1. A manual fire alarm system is not required in buildings not more than two stories in height where all individual *sleeping units* and contiguous attic and crawl spaces to those units are separated from each other and public or common areas by not less than 1-hour *fire partitions* and each individual *sleeping unit* has an *exit* directly to a *public way*, *egress court* or yard.
2. Manual fire alarm boxes are not required throughout the building where all of the following conditions are met:
  - 2.1. The building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

2.2. The notification appliances will activate upon sprinkler water flow.

2.3. Not fewer than one manual fire alarm box is installed at an *approved* location.

3. Manual fire alarm boxes in resident or patient sleeping areas shall not be required at *exits* where located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that the distances of travel required in Section 907.4.2.1 are not exceeded.

❖ This section is specific to manual fire alarm systems and requires such systems in all Group R-4 occupancies, with three exceptions.

Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system water flow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system and at least one manual fire alarm box shall be installed at an approved location. See the commentary to Section 907.2 for a discussion of the single manual fire alarm box.

Exception 3 reduces the likelihood of accidental or malicious false alarm system activations by manual means by allowing the pull stations to be located in a more controlled area. It assumes the approved location is always accessible by staff and within a distance of travel of 200 feet (60 960 mm).

**907.2.10.2 Automatic smoke detection system.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in *corridors*, waiting areas open to *corridors* and *habitable spaces* other than *sleeping units* and kitchens.

**Exceptions:**

1. Smoke detection in *habitable spaces* is not required where the facility is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
2. An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *sleeping units* and where each *sleeping unit* has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an exit.

❖ Occupancies in Group R-4 can be compartmentalized into small rooms so that a fire in one area of the

building would not easily be noticed by occupants in another part of the building. Therefore, smoke detection is required in areas other than sleeping units and kitchens. Sleeping units are required by Section 907.2.10.3 to be equipped with single- and multiple station smoke alarms in accordance with Section 907.2.11.

Since Group R-4 occupancies may not be supervised by staff and to reduce the likelihood that a fire within a waiting area open to the corridor or the corridor itself could develop beyond the incipient stage, thereby jeopardizing the building egress, these areas must be equipped with automatic smoke detection.

Exception 1 allows smoke detectors to be eliminated from habitable spaces if the building is equipped throughout with an NFPA 13 automatic sprinkler system. The sprinkler system should control any fire and perform occupant notification through actuation of the water flow switch and subsequent activation of the building alarm notification appliances. A sprinkler system is required for all Group R occupancies in accordance with Section 903.2.8.

The exception provides that automatic fire detectors are not required in buildings that do not have interior corridors and in which sleeping units have a door opening directly to an exterior exit access that leads directly to the exits. The intent of the exception is that the exit access from the sleeping unit door be exterior and not require reentering the building prior to entering the exit. Since the exit access is outside, the need for detectors other than the smoke alarms required by Section 907.2.10.3 in sleeping units is greatly reduced.

**907.2.10.3 Smoke alarms.** Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

- ❖ The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11. That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

**907.2.11 Single- and multiple-station smoke alarms.** *Listed* single- and multiple-station smoke alarms complying with UL 217 shall be installed in accordance with Sections 907.2.11.1 through 907.2.11.6 and NFPA 72.

- ❖ Single- and multiple-station smoke alarms have evolved as one of the most important fire safety features in residential and similar occupancies having sleeping occupants. The value of early fire warning in these occupancies has been repeatedly demonstrated in fires involving both successful and unsuccessful smoke alarm performance.

For successful smoke alarm operation and performance, single- and multiple-station smoke alarms must be listed in accordance with UL 217 and installed to comply with the code and Chapter 11 of NFPA 72, which contains the minimum requirements

for the selection, installation, operation and maintenance of fire warning equipment for use in family living units. These devices are called “smoke alarms” rather than “smoke detectors” because they are independent of a fire alarm system and include an integral alarm notification device.

**907.2.11.1 Group R-1.** Single- or multiple-station smoke alarms shall be installed in all of the following locations in Group R-1:

1. In sleeping areas.
2. In every room in the path of the *means of egress* from the sleeping area to the door leading from the *sleeping unit*.
3. In each story within the *sleeping unit*, including *basements*. For *sleeping units* with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

- ❖ Because the occupants of a sleeping unit or suite may be asleep and unaware of a fire developing in the room or in the egress path, single- or multiple-station smoke alarms must be provided in the sleeping unit and in any intervening room between the sleeping unit and the exit access door from the room. If the sleeping unit or suite involves more than one level, a smoke alarm must also be installed on every level. See the commentary to Section 202 definition of “Sleeping unit.”

Smoke alarms are required in split-level arrangements, except those that meet the conditions described in Item 3. In accordance with Section 907.2.11.5, all smoke alarms within a sleeping unit or suite must be interconnected so that actuation of one alarm will actuate the alarms in all smoke alarms within the sleeping unit or suite.

**907.2.11.2 Groups R-2, R-3, R-4 and I-1.** Single or multiple-station smoke alarms shall be installed and maintained in Groups R-2, R-3, R-4 and I-1 regardless of *occupant load* at all of the following locations:

1. On the ceiling or wall outside of each separate sleeping area in the immediate vicinity of bedrooms.
2. In each room used for sleeping purposes.
3. In each story within a *dwelling unit*, including *basements* but not including crawl spaces and uninhabitable attics. In *dwellings* or *dwelling units* with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

- ❖ Because the occupants of a dwelling unit may be asleep and unaware of a fire developing in the room or in an area within the dwelling unit that will affect their ability to escape, single- or multiple-station smoke alarms must be installed in every bedroom, in the vicinity of all bedrooms (e.g., hallways leading to

the bedrooms) and on each story of the dwelling unit (see Commentary Figure 907.2.11.2 and the commentary to Section 202 for the definition of "Dwelling unit").

If a sprinkler system was installed throughout the building in accordance with NFPA 13, 13R or 13D, if applicable, smoke alarms would still be required in the bedrooms even if residential sprinklers were used.

Smoke alarms are required in split-level arrangements. As required by Section 907.2.11.5, all smoke alarms within a dwelling unit must be interconnected so that actuation of one alarm will actuate the alarms in all detectors within the dwelling unit.

These provisions do not apply to one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories in height with a separate means of egress that are regulated by the IRC. The IRC is intended to be a stand-alone document but if the residential units do not fall within the scope of the IRC or for other reasons are intended to be subject to this code, then the requirements of this section would apply. IFC Committee Interpretation No. 42-03 addresses this condition and contains additional explanatory information about the IRC and its relationship to the other *International Codes*.

Although the occupants of a sleeping unit in a Group I-1 occupancy may be asleep, they are still considered capable of self-preservation. Regardless, smoke alarms are required in sleeping units. The exception allows single- or multiple-station smoke alarms to be eliminated in the room if an automatic fire detection system that includes in-room system smoke detectors is installed as required by Section 907.2.6.

**907.2.11.3 Installation near cooking appliances.** Smoke alarms shall not be installed in the following locations unless

this would prevent placement of a smoke alarm in a location required by Section 907.2.11.1 or 907.2.11.2:

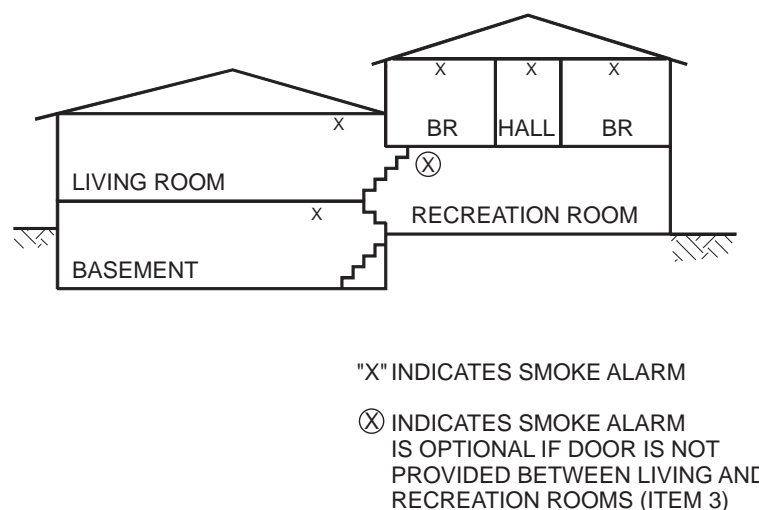

1. Ionization smoke alarms shall not be installed less than 20 feet (6096 mm) horizontally from a permanently installed cooking appliance.
2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3048 mm) horizontally from a permanently installed cooking appliance.
3. Photoelectric smoke alarms shall not be installed less than 6 feet (1829 mm) horizontally from a permanently installed cooking appliance.

❖ This requirement is intended to reduce nuisance alarms attributed to locating smoke alarms in close proximity to cooking appliances and bathrooms in which steam is produced. These provisions are based on the findings in the Task Group Report "Minimum Performance Requirements for Smoke Alarm Detection Technology," February 22, 2008, and are consistent with similar requirements included in Section 29.8.3.4 of NFPA 72.

**907.2.11.4 Installation near bathrooms.** Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by Section 907.2.11.1 or 907.2.11.2.

❖ See the commentary for Section 907.2.11.3. Sections 907.2.11.3 and 907.2.11.4 are provided to reduce nuisance alarms.

**907.2.11.5 Interconnection.** Where more than one smoke alarm is required to be installed within an individual *dwelling unit* or *sleeping unit* in Group R or I-1 occupancies, the smoke alarms shall be interconnected in such a manner that the activation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are

**Figure 907.2.11.2**  
**LOCATION OF SMOKE ALARMS IN A DWELLING UNIT**

installed and all alarms sound upon activation of one alarm. The alarm shall be clearly audible in all bedrooms over background noise levels with all intervening doors closed.

- ❖ The installation of smoke alarms in areas remote from the sleeping area will be of minimal value if the alarm is not heard by the occupants. Interconnection of multiple smoke alarms within an individual dwelling unit or sleeping unit is required in order to alert a sleeping occupant of a remote fire within the unit before the combustion products reach the smoke alarm in the sleeping area and thus provide additional time for evacuation.

The term “interconnection” refers to either hard-wired systems or listed wireless systems. UL has listed smoke detectors that use this technology. It is presumed that on safely evacuating the unit or room of fire origin, an occupant will notify other occupants by actuating the manual fire alarm system or using other available means. Section 907.7.1 addresses the testing of the smoke alarms to demonstrate that interconnection of such smoke alarms is properly functioning.

Similar requirements can now be found in the IRC, the *International Existing Building Code*® (IEBC®) and the code for both new and existing buildings to allow interconnection with wireless technology of smoke alarms. All wirelessly interconnected smoke alarms are listed to UL 217 and are classified by NFPA 72 as low-power systems.

**907.2.11.6 Power source.** In new construction, required smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery back-up shall be connected to an emergency electrical system in accordance with Section 604. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

**Exception:** Smoke alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system that complies with Section 604.

- ❖ Smoke alarms are required to use AC as a primary power source and battery power as a secondary source to improve their reliability. For example, during a power outage, the probability of fire is increased because of the use of candles or lanterns for temporary light. Required backup battery power is intended to provide continued functioning of the smoke alarms. Smoke alarms are commonly designed to emit a recurring signal when batteries are low and need to be replaced.

Certain occupancies may already have an emergency electrical system in the building to monitor other building system conditions. The emergency

electrical system provides a level of reliability equivalent to battery backup.

**907.2.11.7 Smoke detection system.** Smoke detectors listed in accordance with UL 268 and provided as part of the building fire alarm system shall be an acceptable alternative to single- and multiple-station *smoke alarms* and shall comply with the following:

1. The fire alarm system shall comply with all applicable requirements in Section 907.
2. Activation of a smoke detector in a *dwelling unit* or *sleeping unit* shall initiate alarm notification in the *dwelling unit* or *sleeping unit* in accordance with Section 907.5.2.
3. Activation of a smoke detector in a *dwelling unit* or *sleeping unit* shall not activate alarm notification appliances outside of the *dwelling unit* or *sleeping unit*, provided that a supervisory signal is generated and monitored in accordance with Section 907.6.6.

- ❖ This section specifically allows the use of an automatic smoke detection system as an alternative to smoke alarms. In the past, when this concept was proposed it was only specifically allowed through alternative method and materials approach (see Section 104.9 of the code) even though in concept it provides the same level of protection. Such systems provide the same safety features necessary for occupants but are simply part of a fire alarm system. Note that if a detector activates within a sleeping or dwelling unit, the occupant notification system is not intended to activate. This is consistent with the operation of smoke alarms. Item 3 specifically requires the notification to be only to occupants of the sleeping unit or dwelling unit.

**907.2.12 Special amusement buildings.** An automatic smoke detection system shall be provided in special amusement buildings in accordance with Sections 907.2.12.1 through 907.2.12.3.

- ❖ Special amusement buildings are buildings in which the means of egress is not readily apparent, is intentionally confounded or is not readily available. Special amusement buildings must also comply with the provisions of Section 411 of the IBC.

The approved automatic smoke detection system is required to provide early warning of a fire. The detection system is required regardless of the presence of staff in the building. The exception recognizes that the ambient conditions in some special amusement buildings may preclude the use of automatic smoke detectors. In those instances, an alternative detection device must be used for early detection of a fire.

**907.2.12.1 Alarm.** Activation of any single smoke detector, the *automatic sprinkler system* or any other automatic fire detection device shall immediately activate an audible and

visible alarm at the building at a constantly attended location from which emergency action can be initiated, including the capability of manual initiation of requirements in Section 907.2.12.2.

❖ Upon activation of either a smoke detector or other automatic fire detection device or the automatic sprinkler system, an alarm must activate both an audible and visible alarm at a constantly attended location. The staff at the location is expected to be capable of then providing the required egress illumination, stopping the conflicting or confusing sounds and distractions and activating the exit marking required by Section 907.2.12.2. The staff is also expected to be capable of preventing additional people from entering the building.

**907.2.12.2 System response.** The activation of two or more smoke detectors, a single smoke detector equipped with an alarm verification feature, the *automatic sprinkler system* or other *approved* fire detection device shall automatically do all of the following:

1. Cause illumination of the *means of egress* with light of not less than 1 footcandle (11 lux) at the walking surface level.
2. Stop any conflicting or confusing sounds and visual distractions.
3. Activate an *approved* directional *exit* marking that will become apparent in an emergency.
4. Activate a prerecorded message, audible throughout the special amusement building, instructing patrons to proceed to the nearest exit. Alarm signals used in conjunction with the prerecorded message shall produce a sound that is distinctive from other sounds used during normal operation.

❖ Once a fire has been detected, measures must be taken to stop the confusion or distractions. Additionally, the egress path must be illuminated and marked. These measures must occur automatically upon detection of the fire or sprinkler water flow. A prerecorded message that can be heard throughout the building instructing the occupants to proceed to the nearest exit must be automatically activated. The message and alarm signals should be designed to prevent panic. The prerecorded message capability is in addition to the EV/ACS requirement of Section 907.2.12.3. The wiring of all devices must comply with NFPA 72.

**907.2.12.3 Emergency voice/alarm communication system.** An emergency voice/alarm communication system, which is also allowed to serve as a public address system, shall be installed in accordance with Section 907.5.2.2 and be audible throughout the entire special amusement building.

❖ Because of the problem associated with evacuating special amusement buildings, an emergency voice/alarm communication system is required (see also Section 907.5.2.2). This section allows the system to also serve as a public address (PA) system to have the capability to alert the occupants of a fire and give

them evacuation instructions. The system must be designed so that once the voice alarm is activated the typical public address function is superseded by the voice alarm. Because a manual override must be provided, it is possible that the same microphone used for the public address can be used for the override. However, a separate action would be necessary so that the override function can be used once the voice alarm is active.

**907.2.13 High-rise buildings.** High-rise buildings shall be provided with an automatic smoke detection system in accordance with Section 907.2.13.1, a fire department communication system in accordance with Section 907.2.13.2 and an emergency voice/alarm communication system in accordance with Section 907.5.2.2.

**Exceptions:**

1. Airport traffic control towers in accordance with Section 907.2.22 of this code and Section 412 of the *International Building Code*.
  2. Open parking garages in accordance with Section 406.5 of the *International Building Code*.
  3. Buildings with an occupancy in Group A-5 in accordance with Section 303.1 of the *International Building Code*.
  4. Low-hazard special occupancies in accordance with Section 503.1.1 of the *International Building Code*.
  5. Buildings with an occupancy in Group H-1, H-2 or H-3 in accordance with Section 415 of the *International Building Code*.
  6. In Group I-1 and I-2 occupancies, the alarm shall sound at a constantly attended location and occupant notification shall be broadcast by the emergency voice/alarm communication system.
- ❖ High-rise buildings require additional fire protection systems because of the difficulties with smoke movement, egress time and fire department access. As a result, this section requires both an automatic fire alarm system and an EV/ACS (see commentary, Section 907.5.2.2). Exceptions 1 through 5 are the same as those in Section 403.1 of the IBC regarding the applicability of the high-rise provisions.
- Exception 1 addresses airport traffic control towers and is based on the limited fuel load and the limited number of persons occupying the tower.
- Open parking garages and places of outdoor assembly (Group A-5) are exempted by Exceptions 2 and 3, respectively, because of the free ventilation to the outside that exists in such structures.
- In Exception 4, low-hazard special industrial occupancies may be exempted when approved by the fire code official. Such buildings should be evaluated based on the occupant load and the hazards of the occupancy and its contents to determine whether the protection features required by Section 403 of the IBC are necessary.
- Buildings with occupancies in Groups H-1, H-2 and H-3 are excluded from the requirements of this sec-

tion by Exception 5 because the fire hazard characteristics of these occupancies have not yet been considered in high-rise buildings.

Exception 6 recognizes the supervised environment typical of institutional uses and the reliance placed on staff to act appropriately in an emergency. As is the case for most voice alarms, the key is in being able to deliver specific information to the people who can affect a safe egress—whether this is the public or employees, or both.

**907.2.13.1 Automatic smoke detection.** Automatic smoke detection in high-rise buildings shall be in accordance with Sections 907.2.13.1.1 and 907.2.13.1.2.

❖ This section simply introduces the fire alarm and detection system requirements for high-rise buildings.

**907.2.13.1.1 Area smoke detection.** Area smoke detectors shall be provided in accordance with this section. Smoke detectors shall be connected to an automatic fire alarm system. The activation of any detector required by this section shall activate the emergency voice/alarm communication system in accordance with Section 907.5.2.2. In addition to smoke detectors required by Sections 907.2.1 through 907.2.10, smoke detectors shall be located as follows:

1. In each mechanical equipment, electrical, transformer, telephone equipment or similar room that is not provided with sprinkler protection.
2. In each elevator machine room, machinery space, control room and control space and in elevator lobbies.

❖ Automatic smoke detectors are required in all high-rise buildings in certain locations so that a fire will be detected in its early stages of development. The detectors must be connected to the automatic fire alarm system and be capable of initiating operation of the EV/ACS.

This section divides the automatic smoke detection requirement into two categories. Smoke detectors must be installed in rooms that are not typically occupied. This includes rooms used for mechanical equipment, electrical equipment, transformer equipment and telephone equipment where such rooms do not have automatic sprinkler protection. In most cases, these rooms will have sprinkler protection by virtue of being in a high-rise building and will therefore not require smoke detectors. However, in elevator machine rooms, machinery spaces, control rooms, control spaces and elevator lobbies, smoke detectors are required regardless of sprinkler protection.

Note that smoke detection and smoke alarms may be required based upon occupancy related requirements elsewhere in Section 907.2.

**[M] 907.2.13.1.2 Duct smoke detection.** Duct smoke detectors complying with Section 907.3.1 shall be located as follows:

1. In the main return air and exhaust air plenum of each air-conditioning system having a capacity greater than 2,000 cubic feet per minute (cfm) (0.94 m<sup>3</sup>/s). Such

detectors shall be located in a serviceable area downstream of the last duct inlet.

2. At each connection to a vertical duct or riser serving two or more stories from a return air duct or plenum of an air-conditioning system. In Group R-1 and R-2 occupancies, a smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m<sup>3</sup>/s) and serving not more than 10 air-inlet openings.

❖ Smoke detectors must be installed in the main return air and exhaust air plenum of each air-conditioning system having a design capacity exceeding 2,000 cubic feet per minute (cfm) (0.94 m<sup>3</sup>/s). Systems with design capacities equal to or less than 2,000 cfm (0.94 m<sup>3</sup>/s) are exempt from this requirement because their small size limits their capacity for spreading smoke to parts of the building not already involved with fire.

The area that could be served by a 2,000-cfm (0.94 m<sup>3</sup>) system (approximately 5 tons of cooling capacity) is comparatively small; therefore, the distribution of smoke in a system of that size would be minimal. Smoke detectors must be located so that they monitor the total airflow within the system. If a single detector is unable to sample the total airflow at all times, then multiple detectors are required. The smoke detectors must be made accessible for maintenance and inspection. Many failures and false alarms are caused by a lack of maintenance and cleaning of the smoke detectors.

Consistent with Section 606.2.3 of the IMC, return air risers serving two or more stories must have smoke detectors installed at each story. Item 2 allows permits the use of a single listed smoke detector in each return air riser in a Group R-1 or R-2 occupancy if the capacity of each riser does not exceed 5,000 cfm (2.4 m<sup>3</sup>/s) and does not serve more than 10 air-inlet openings. This alternative recognizes that it is not as necessary in buildings dedicated to residential occupancies only to monitor the return air from each story prior to intermixing the return air in the common riser.

**907.2.13.2 Fire department communication system.** Where a wired communication system is *approved* in lieu of an emergency responder radio coverage system in accordance with Section 510, the wired fire department communication system shall be designed and installed in accordance with NFPA 72 and shall operate between a *fire command center* complying with Section 508, elevators, elevator lobbies, emergency and standby power rooms, fire pump rooms, areas of refuge and inside *interior exit stairways*. The fire department communication device shall be provided at each floor level within the *interior exit stairway*.

❖ High-rise buildings have posed a challenge to the traditional communication systems used by the fire service for fire-to-ground communications to assist fire ground officers in communicating with the fire fighters

working in various areas of the building. Where testing using the building's public safety communications system required by Section 510 of the code shows that the signal strengths are not satisfactory, Section 510.1, Exception 1 allows for the alternative of installation of a wired communication system designed in accordance with this section. The system must be capable of operating between the fire command center and every elevator, elevator lobby, emergency/standby power room, fire pump room, area of refuge and exit stairway. Note that this section does not offer specific criteria as to what constitutes an acceptable wired communication system or its components. It could be a component of an emergency voice/alarm communication system that complies with Section 907.5.2.2 or a building's telephone system. In any event, when applying Section 510.1, Exception 1 and this section, the concurrent approval of the fire and building code officials is required.

**907.2.14 Atriums connecting more than two stories.** A fire alarm system shall be installed in occupancies with an atrium that connects more than two stories, with smoke detection in locations required by a rational analysis in Section 909.4 and in accordance with the system operation requirements in Section 909.17. The system shall be activated in accordance with Section 907.5. Such occupancies in Group A, E or M shall be provided with an emergency voice/alarm communication system complying with the requirements of Section 907.5.2.2.

- ❖ Buildings containing an atrium that connects more than two stories are to be equipped with a fire alarm system that can be used to notify building occupants to begin evacuating in case of a fire. The other critical part of such fire alarm systems is to activate the smoke control system. The system is to be activated by smoke detection designed and installed in accordance with the rational analysis as required in Section 909.4. More specifically, smoke control systems are engineered systems that are activated by carefully placed and zoned smoke detection. If improperly designed and installed, the system may not be effective. For instance, wrongly placed or inappropriate smoke detection technology may not activate fast enough and the smoke control system would be overwhelmed. This section goes on to state that the alarm system must be initiated in accordance with Section 907.5, which requires that in buildings containing an atrium, the alarm system is to be initiated by the sprinkler system and any automatic or manual fire alarm-initiating devices found in the atrium as well as elsewhere in the building. It does not intend to require certain features to be installed within the atrium but rather is simply requiring that any such features present initiate the occupant notification system. It would not necessarily be appropriate to also initiate the smoke control system upon activation of the alarm system within a building containing an atrium (see Section 909.12.3). The alarm system needs to be carefully zoned in such buildings to avoid an inappropriate activation of the smoke control system from a

space not associated with the atrium.

Groups A, E and M must have an emergency voice/alarm communication system that complies with Section 907.5.2.2 because of the number of persons to be evacuated and the lack of familiarity with the location of exits that is typical of occupants in Groups A and M.

**907.2.15 High-piled combustibile storage areas.** An automatic smoke detection system shall be installed throughout *high-piled combustibile storage* areas where required by Section 3206.5.

- ❖ Section 3206.5 requires an automatic fire detection system in high-piled combustibile storage areas depending on the commodity class, the size of the high-piled storage area and the presence of an automatic sprinkler system. High-piled storage is the storage of Class I through IV commodities in piles, bin boxes, on pallets or in racks more than 12 feet (3658 mm) high or for high-hazard commodities stored higher than 6 feet (1829 mm). Chapter 32 and NFPA 13 contain additional requirements for all high-piled storage conditions.

**907.2.16 Aerosol storage uses.** Aerosol storage rooms and general-purpose warehouses containing aerosols shall be provided with an *approved* manual fire alarm system where required by this code.

- ❖ Section 3206.5 requires an automatic fire detection system in high-piled combustibile storage areas depending on the commodity class, the size of the high-piled storage area and the presence of an automatic sprinkler system. High-piled storage is the storage of Class I through IV commodities in piles, bin boxes, on pallets or in racks more than 12 feet (3658 mm) high or for high-hazard commodities stored higher than 6 feet (1829 mm). Chapter 32 and NFPA 13 contain additional requirements for all high-piled storage conditions.

**907.2.17 Lumber, wood structural panel and veneer mills.** Lumber, wood structural panel and veneer mills shall be provided with a manual fire alarm system.

- ❖ Any facility using mechanical methods to process wood into finished products produces debris and the potential for combustibile dust. Such facilities include mills that produce solid wood lumber and wood veneers as well as those that manufacture structural wood panels such as waferboard, oriented strandboard, composite wood panels or plywood. Good housekeeping and control of ignition sources are therefore essential. To aid in the quick evacuation of occupants in an emergency, Section 2804.2.1 requires a manual fire alarm system in lumber, wood structural panel and veneer mills that contain product dryers because of their potential as a source of ignition. A manual fire alarm system is not required, however, if the dryers and all other potential sources of ignition are protected by a supervised automatic sprinkler system.

**907.2.18 Underground buildings with smoke control systems.** Where a smoke control system is installed in an underground building in accordance with the *International Building Code*, automatic smoke detectors shall be provided in accordance with Section 907.2.18.1.

❖ As indicated in Section 405.5.2 of the IBC, each compartment of an underground building must have a smoke control/exhaust system that can be activated both automatically and manually. Floor levels more than 60 feet (18 288 mm) below the lowest level of exit discharge must be compartmented. Compartmentation is a key element in the egress and fire access plan for floor areas in an underground building. The smoke control system must not only facilitate egress during a fire, but also improve fire department access to the fire source by maintaining visibility that is otherwise impossible given the inability of the fire service to manually ventilate the underground portion of the building. (see the commentary to Section 405.4.1 of the IBC).

**907.2.18.1 Smoke detectors.** Not fewer than one smoke detector *listed* for the intended purpose shall be installed in all of the following areas:

1. Mechanical equipment, electrical, transformer, telephone equipment, elevator machine or similar rooms.
2. Elevator lobbies.
3. The main return and exhaust air plenum of each air-conditioning system serving more than one story and located in a serviceable area downstream of the last duct inlet.
4. Each connection to a vertical duct or riser serving two or more floors from return air ducts or plenums of heating, ventilating and air-conditioning systems, except that in Group R occupancies, a *listed* smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m<sup>3</sup>/s) and serving not more than 10 air inlet openings.

❖ Automatic smoke detectors are required in certain locations in all underground buildings so that a fire will be detected in its early stages of development. Underground buildings are similar to high-rise buildings in that they present an unusual hazard by being virtually inaccessible to exterior fire department suppression and rescue operations with the increased potential to trap occupants inside the structure. For this reason, the smoke detector location requirements for underground buildings are similar to those in Section 907.2.13.1 for high-rise buildings (see commentary, Section 907.2.13.1).

The requirement for a smoke detector in the main return and exhaust air plenum of an air-conditioning system in an underground building, however, differs from that of a high-rise building in that it is not a function of capacity [2,000 cfm (0.94 m<sup>3</sup>/s)] but rather a function of whether the system serves more than one floor level. There is more concern over the threat of smoke movement from floor to floor because the

products of combustion cannot be vented directly to the atmosphere.

**907.2.18.2 Alarm required.** Activation of the smoke control system shall activate an audible alarm at a constantly attended location.

❖ The audible alarm is required to notify qualified personnel immediately that the smoke control system has been activated and to put emergency procedures into action quickly.

**907.2.19 Deep underground buildings.** Where the lowest level of a structure is more than 60 feet (18 288 mm) below the finished floor of the lowest *level of exit discharge*, the structure shall be equipped throughout with a manual fire alarm system, including an emergency voice/alarm communication system installed in accordance with Section 907.5.2.2.

❖ The ability to communicate and offer warning of a fire can increase the time available for egress from the building. Underground structures located more than 60 feet (18 288 mm) below the level of exit discharge must therefore have a manual fire alarm system. An EV/ACS is also required as part of this system (see commentary, Section 907.5.2.2).

**907.2.20 Covered and open mall buildings.** Where the total floor area exceeds 50,000 square feet (4645 m<sup>2</sup>) within either a covered mall building or within the perimeter line of an open mall building, an emergency voice/alarm communication system shall be provided. Emergency voice/alarm communication systems serving a mall, required or otherwise, shall be accessible to the fire department. The system shall be provided in accordance with Section 907.5.2.2.

❖ Because of the potentially large number of occupants and their unfamiliarity with their surroundings, an EV/ACS, accessible by the fire department, is required to aid in evacuation of covered mall buildings exceeding 50,000 square feet (4645 m<sup>2</sup>) in total floor area or an open mall exceeding 50,000 square feet (4645 m<sup>2</sup>) measured within the perimeter lines of the open mall. Anchor stores are not included as part of the covered or open mall building (see commentary, Section 202 definition of "Covered mall building").

**907.2.21 Residential aircraft hangars.** Not fewer than one single-station smoke alarm shall be installed within a residential aircraft hangar as defined in Chapter 2 of the *International Building Code* and shall be interconnected into the residential smoke alarm or other sounding device to provide an alarm that will be audible in all sleeping areas of the *dwelling*.

❖ Residential aircraft hangars are assumed to be on the same property as a one- or two-family dwelling. Section 412.5 of the IBC contains additional requirements for the construction of residential aircraft hangars. The hangar could be located immediately adjacent to the dwelling unit if it is separated by 1-hour fire-resistance-rated construction. Because of the potentially close proximity of the aircraft and its flammability and fuel source, at least one smoke alarm is required in the hangar that is interconnected

to the residential smoke alarms. It should be noted, however, that the requirement for a smoke alarm is also applicable to residential aircraft hangars that are detached from the dwelling unit. Because a minimum separation distance is not specified, a fire in the hangar could still present a serious fire hazard to the dwelling unit.

**907.2.22 Airport traffic control towers.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in airport control towers in accordance with Sections 907.2.22.1 and 907.2.22.2.

**Exception:** Audible appliances shall not be installed within the control tower cab.

❖ Airport traffic control towers must be designed to comply with Section 412.3 of the IBC. These structures are unique in that they can be built to excessive heights and are often permitted to have one exit stairway. Section 412.3 of the IBC does require that airport traffic control towers with an occupied floor more than 35 feet above fire department vehicle access be equipped throughout with an automatic sprinkler system. The requirements for detection systems and associated occupant notification are addressed based on whether the airport traffic control tower is equipped throughout with an automatic sprinkler system and whether multiple exits are provided.

The exception recognizes the sensitive nature of the operations that take place in the cab located at the top of the tower and prohibits the installation of audible alarm notification devices there. Notification of occupants within the cab is to be by visual notification appliances only.

**907.2.22.1 Airport traffic control towers with multiple exits and automatic sprinklers.** Airport traffic control towers with multiple *exits* and equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 shall be provided with smoke detectors in all of the following locations:

1. Airport traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Outside each opening into *interior exit stairways*.
5. Along the single *means of egress* permitted from observation levels.
6. Outside each opening into the single *means of egress* permitted from observation levels.

❖ This section addresses airport traffic control towers that are equipped throughout with an automatic sprinkler system and provide multiple exits. The requirements are less restrictive than Section 907.2.22.2 because two important safety aspects are provided.

The first three items address occupiable or equipment-related rooms where the fires are more likely to start. The last two items address the paths of egress. Item 4 requires one detector outside each entrance to

the interior stairway. Item 5 is specific to providing detection along the entire means of egress path from the observation levels.

**907.2.22.2 Other airport traffic control towers.** Airport traffic control towers with a single *exit* or where sprinklers are not installed throughout shall be provided with smoke detectors in all of the following locations:

1. Airport traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.
6. *Means of egress*.
7. Accessible utility shafts.

❖ This section addresses airport traffic control towers that have only a single exit or where an automatic sprinkler system is not provided. Essentially all the items addressed are the areas permitted in an airport traffic control tower in accordance with Section 412.3. Items 1 through 3 are the same as Section 907.2.22.1. These are the critical occupiable spaces and equipment spaces where fires have the greatest affect on the operation of airport traffic control towers. Since this is a single exit tower and possibly not equipped throughout with an automatic sprinkler system, other occupiable areas such as offices and lounges for employees must also provide smoke detection. Since there are limited exits or no systems able to control the fire, early warning of a fire becomes more critical. Item 6 requires smoke detection along the means of egress path. The intent is to address the exit access path leading to the interior exit stairway. Finally, Item 7 addresses potential for fires in any utility shaft that may be accessible to building occupants.

**907.2.23 Battery rooms.** An automatic smoke detection system shall be installed in areas containing stationary storage battery systems with a liquid capacity of more than 50 gallons (189 L).

❖ Stationary lead-acid battery systems are commonly used for standby power, emergency power or uninterrupted power supplies. The release of hydrogen gas during battery system operation is usually minimal. Adequate ventilation will disperse the small amounts of liberated hydrogen. Because standby power and emergency power systems control many important building emergency systems and functions, a supervised automatic smoke-detection system is required for early warning notification of a hazardous condition. Section 608 contains additional requirements, including the need for safety venting; room enclosure requirements; spill control and neutralization provisions; ventilation criteria; signage and seismic protection. Section 509 of the IBC also requires that such rooms in certain occupancies be separated by one hour construction.

**907.3 Fire safety functions.** Automatic fire detectors utilized for the purpose of performing fire safety functions shall be connected to the building's fire alarm control unit where a fire alarm system is required by Section 907.2. Detectors shall, upon actuation, perform the intended function and activate the alarm notification appliances or activate a visible and audible supervisory signal at a constantly attended location. In buildings not equipped with a fire alarm system, the automatic fire detector shall be powered by normal electrical service and, upon actuation, perform the intended function. The detectors shall be located in accordance with NFPA 72.

❖ When the code requires installation of automatic fire detectors to perform a specific function, such as elevator recall or smokeproof enclosure ventilation, or when detectors are installed to comply with a permitted alternative, such as door-closing devices, these detectors must be connected to the building's automatic fire alarm system if the building is required by the code to have such a system.

In addition to performing its intended function (for example, closing a door), if a detector is activated, it must also activate either the building alarm devices (if one is present) or a supervisory signal at a constantly attended location. This requirement recognizes that these detectors and the devices they control are part of the building fire protection system and are expected to perform as designed. If they are connected to a fire alarm system, they will have the supervision necessary for operational reliability. If they are not connected to and supervised by a fire alarm system, they still must be supervised through the constantly attended location.

An exception is provided for fire safety function detectors in buildings not required to have a fire alarm system. The fire safety function detectors must be powered by the building electrical system and be located as required by NFPA 72. Without this exception, these detectors could not be expected to perform as intended because there would be no power supply.

**907.3.1 Duct smoke detectors.** Smoke detectors installed in ducts shall be *listed* for the air velocity, temperature and humidity present in the duct. Duct smoke detectors shall be connected to the building's fire alarm control unit when a fire alarm system is required by Section 907.2. Activation of a duct smoke detector shall initiate a visible and audible supervisory signal at a *constantly attended location* and shall perform the intended fire safety function in accordance with this code and the *International Mechanical Code*. In facilities that are required to be monitored by a supervising station, duct smoke detectors shall report only as a supervisory signal and not as a fire alarm. They shall not be used as a substitute for required open area detection.

**Exceptions:**

1. The supervisory signal at a constantly attended location is not required where duct smoke detectors activate the building's alarm notification appliances.

2. In occupancies not required to be equipped with a fire alarm system, actuation of a smoke detector shall activate a visible and an audible signal in an *approved* location. Smoke detector trouble conditions shall activate a visible or audible signal in an *approved* location and shall be identified as air duct detector trouble.

❖ It is not the intent of this section to send a signal to the fire department or to activate the alarm notification devices within a building. Instead, this section requires that a supervisory signal be sent to a constantly attended location. Smoke detectors must be connected to a fire alarm system where such systems are installed. Connection to the fire alarm system will activate a visible and audible supervisory signal at a constantly attended location, which will alert building supervisory personnel that a smoke alarm has activated and will also provide electronic supervision of the duct detectors, thereby indicating any problems that may develop in the detector system circuitry or power supply.

Exception 1 allows activation of the building alarm notification appliances in place of a supervisory signal. Causing the occupant notification system to sound would alert the occupants of the building that an alarm condition exists within the air distribution system, thereby performing the same function as a supervisory signal sent to a constantly attended location.

Exception 2 recognizes the fact that not all buildings are required to have a fire alarm system. A visible and audible signal must be activated at an approved location that will alert building supervisory personnel to take action. Additionally, the duct smoke detectors must be electronically supervised to indicate trouble (system fault) in the detector system circuitry or power supply. A trouble condition must activate a distinct visible or audible signal at a location that will alert the responsible personnel.

**907.3.2 Delayed egress locks.** Where delayed egress locks are installed on *means of egress* doors in accordance with Section 1010.1.9.7, an automatic smoke or heat detection system shall be installed as required by that section.

❖ This section alerts the code user to additional requirements in Section 1010.1.9.7 that tie the operation of egress doors into the activation of an automatic fire detection system. A smoke or heat detection system is required to unlock delayed egress locks upon activation. The heat detection system can be the sprinkler system. For example, Section 1010.1.4.3 requires horizontal sliding doors used as a component of the means of egress, where required to be rated, to be self-closing or automatic-closing upon smoke detection. Also, electrically locked egress doors in occupancies as required by Section 1010.1.9.8 must be capable of being automatically unlocked by activation of an automatic fire detection system, if one is installed.

**907.3.3 Elevator emergency operation.** Automatic fire detectors installed for elevator emergency operation shall be installed in accordance with the provisions of ASME A17.1 and NFPA 72.

❖ This section provides correlation with Section 607.1 by making it clear that automatic fire detection devices used to initiate Phase I emergency recall of elevators are to be installed in accordance with both ASME A17.1 and NFPA 72.

**907.3.4 Wiring.** The wiring to the auxiliary devices and equipment used to accomplish the fire safety functions shall be monitored for integrity in accordance with NFPA 72.

❖ In order to provide a reasonable level of integrity and reliability to the installation of automatic fire detection devices and related equipment installed to perform various fire safety functions in accordance with Section 907.3, this section requires that all wiring interconnecting such devices and equipment be monitored for integrity in accordance with NFPA 72.

**907.4 Initiating devices.** Where manual or automatic alarm initiation is required as part of a fire alarm system, the initiating devices shall be installed in accordance with Sections 907.4.1 through 907.4.3.1.

❖ This section introduces Sections 907.4.1 through 907.4.3 which contain requirements for the various types of manual or automatic fire alarm initiating devices.

**907.4.1 Protection of fire alarm control unit.** In areas that are not continuously occupied, a single smoke detector shall be provided at the location of each fire alarm control unit, notification appliance circuit power extenders and supervising station transmitting equipment.

**Exception:** Where ambient conditions prohibit installation of smoke detector, a *heat detector* shall be permitted.

❖ This section requires a smoke detector at the fire alarm control unit. This is consistent with Section 10.4.4 of NFPA 72. This smoke detector will activate the fire alarm control unit and allow it to either notify occupants or transmit a signal to a remote monitoring location before the fire impairs the fire alarm control unit. The exception parallels Section 907.4.3 by allowing a heat detector to be installed in lieu of a smoke detector in areas where the ambient environment is hostile to smoke detectors and could lead to unwanted alarm activations. This exception is also allowed by NFPA 72.

**907.4.2 Manual fire alarm boxes.** Where a manual fire alarm system is required by another section of this code, it shall be activated by fire alarm boxes installed in accordance with Sections 907.4.2.1 through 907.4.2.6.

❖ This section specifies the requirements for manual fire alarm boxes that are part of a required manual fire alarm system.

**907.4.2.1 Location.** Manual fire alarm boxes shall be located not more than 5 feet (1524 mm) from the entrance to each

*exit*. In buildings not protected by an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2, additional manual fire alarm boxes shall be located so that the *exit access* travel distance to the nearest box does not exceed 200 feet (60 960 mm).

❖ Manual fire alarm boxes must be located in the path of egress and be readily accessible to the occupants. They must be located within 5 feet (1524 mm) of the entrance to each exit on every story of the building. This would include the need to locate manual fire alarm boxes near each horizontal exit, as well as entrances to stairs and exit doors to the exterior.

Manual fire alarm boxes are located near exits so that an adequate number of devices are available in the path of egress to transmit an alarm in a timely manner. These locations also encourage the actuation of a manual fire alarm box on the fire floor prior to entering the stair, resulting in the alarm being received from the actual fire floor and not another floor along the path of egress.

The location also presumes that individuals will be evacuating the area where the fire originated. When evacuation of the fire area is unlikely, consideration could be given to putting manual fire alarm boxes in more convenient places. Examples of such instances would be officer stations in Group I-3 occupancies and care provider stations in Group I-2 occupancies.

The 200-foot (60 960 mm) travel distance limitation is consistent with the exit access travel distance permitted for most nonsprinklered occupancies. If the 200-foot (60 960 mm) travel distance to a manual fire alarm box is exceeded, even in a fully sprinklered building, additional manual fire alarm boxes would be required.

**907.4.2.2 Height.** The height of the manual fire alarm boxes shall be not less than 42 inches (1067 mm) and not more than 48 inches (1372 mm) measured vertically, from the floor level to the activating handle or lever of the box.

❖ Manual fire alarm boxes must be reachable by the occupants of the building. They must also be mounted high enough to reduce the likelihood of damage or false alarms from something accidentally striking the device. Therefore, manual fire alarm boxes must be mounted a minimum of 42 inches (1067 mm) and a maximum of 48 inches (1372 mm) above the floor level. The 48-inch (1372 mm) measurement corresponds to the maximum unobstructed side-reach height by a person in a wheelchair.

**907.4.2.3 Color.** Manual fire alarm boxes shall be red in color.

❖ Manual fire alarm boxes are to be painted or manufactured in a distinctive and traditional red color to provide a visual cue to help building occupants identify the device.

**907.4.2.4 Signs.** Where fire alarm systems are not monitored by a supervising station, an *approved* permanent sign shall be

installed adjacent to each manual fire alarm box that reads: WHEN ALARM SOUNDS—CALL FIRE DEPARTMENT.

**Exception:** Where the manufacturer has permanently provided this information on the manual fire alarm box.

❖ This section has limited application because, as indicated in Section 907.6.6, fire alarm systems generally must be monitored by an approved supervising station. When a system is not monitored, such as possibly a fire alarm system that is not required by code, adequate signage must be displayed to tell occupants what response actions must be taken. Most building occupants assume that when an alarm device is activated, the fire department will automatically be notified as well. The sign must be conspicuously located next to the manual fire alarm box unless the signage is mounted on the manual fire alarm box itself by the manufacturer.

**907.4.2.5 Protective covers.** The *fire code official* is authorized to require the installation of *listed* manual fire alarm box protective covers to prevent malicious false alarms or to provide the manual fire alarm box with protection from physical damage. The protective cover shall be transparent or red in color with a transparent face to permit visibility of the manual fire alarm box. Each cover shall include proper operating instructions. A protective cover that emits a local alarm signal shall not be installed unless *approved*. Protective covers shall not project more than that permitted by Section 1003.3.3.

❖ Although manual fire alarm boxes must be readily available to all occupants in buildings required to have a manual fire alarm system, this section allows the use of protective covers if they are approved by the fire code official. Protective covers are commonly used to reduce either the potential for intentional false alarms or vandalism. They also provide protection in locations where the manual fire alarm boxes may be exposed to physical damage, such as in gymnasiums, indoor tennis courts and the like.

**907.4.2.6 Unobstructed and unobscured.** Manual fire alarm boxes shall be accessible, unobstructed, unobscured and visible at all times.

❖ This section addresses the concern that manual fire alarm boxes be kept clear and unobstructed. It is recommended that a minimum of 3 feet (914 mm) be kept clear but more may be needed. NFPA 72 addresses the need for manual fire alarm boxes to be unobstructed in Section 17.14.8.2 and states that manual fire alarm boxes be conspicuous, unobstructed and accessible. This requirement will assist during the design, construction, inspection and future maintenance of manual fire alarm boxes when they are located where they will be provided with enough space to access and will not be obstructed.

**907.4.3 Automatic smoke detection.** Where an automatic smoke detection system is required it shall utilize smoke detectors unless ambient conditions prohibit such an installation. In spaces where smoke detectors cannot be utilized due

to ambient conditions, *approved automatic heat detectors* shall be permitted.

❖ Smoke detectors must be used, except when ambient conditions would prohibit their use. This section would allow a heat detector to be installed in lieu of a smoke detector in areas where the ambient environment is hostile to smoke detectors and could lead to unwanted alarm activations. The smoke detector manufacturer's literature will identify the limitations on the use of smoke detectors, including environmental conditions such as humidity, temperature and airflow.

**907.4.3.1 Automatic sprinkler system.** For conditions other than specific fire safety functions noted in Section 907.3, in areas where ambient conditions prohibit the installation of smoke detectors, an *automatic sprinkler system* installed in such areas in accordance with Section 903.3.1.1 or 903.3.1.2 and that is connected to the fire alarm system shall be *approved* as automatic heat detection.

❖ This section states that automatic heat detection is not required when buildings are fully sprinklered in accordance with NFPA 13 or 13R. The presence of a sprinkler system exempts areas where a heat detector can be installed in place of a smoke detector, such as in storage or furnace rooms. The sprinkler head in this case essentially acts as a heat detection device. Note that this provision does not apply to the fire safety functions indicated in Section 907.3.

**907.5 Occupant notification systems.** A fire alarm system shall annunciate at the fire alarm control unit and shall initiate occupant notification upon activation, in accordance with Sections 907.5.1 through 907.5.2.3.3. Where a fire alarm system is required by another section of this code, it shall be activated by:

1. Automatic fire detectors.
2. Automatic sprinkler system waterflow devices.
3. Manual fire alarm boxes.
4. Automatic fire-extinguishing systems.

**Exception:** Where notification systems are allowed elsewhere in Section 907 to annunciate at a constantly attended location.

❖ This section makes it clear that fire alarm system activation begins first by activating the fire alarm control unit and then by notifying the occupants of an alarm condition and then goes on to introduce all of the components of an occupant notification system contained in Sections 907.5.1 through 907.5.2.3.3.

It also lists the system components that are to act as alarm initiation devices. The exception is a recognition that there are places in the code where an alternative to occupant notification is an alarm notification at a constantly attended location. The exception is intended to clarify the code so that there is no question as to whether this general provision for alarm activation is superseded by the other sections addressing the alarm notification at a constantly attended location.

**907.5.1 Presignal feature.** A presignal feature shall not be installed unless *approved* by the *fire code official* and the fire department. Where a presignal feature is provided, a signal shall be annunciated at a constantly attended location *approved* by the fire department, so that occupant notification can be activated in the event of fire or other emergency.

❖ A presignal feature on a fire alarm system allows the occupant notification devices to activate in selected, constantly attended locations only and from which human intervention is required to activate a general occupant notification signal. Alternatively, this feature can be programmed to delay the general alarm notification for more than one minute before it will automatically be activated by the control panel. In either presignal scenario, remote transmission of the alarm signal to the fire department is immediate. See NFPA 72 for additional information on the presignal feature.

Improper use of the presignal feature has been a contributing factor in several multiple-death fire incidents. In most instances, the staff failed to activate the general alarm quickly and the occupants of the building were unaware of the fire. Therefore, the use of a presignal feature is discouraged by the code. A presignal feature may be used only if it is approved by the fire code official and the fire department.

**907.5.2 Alarm notification appliances.** Alarm notification appliances shall be provided and shall be *listed* for their purpose.

❖ The code requires that fire alarm systems be equipped with approved alarm notification appliances so that in an emergency, the fire alarm system will notify the occupants of the need for evacuation or implementation of the fire emergency plan. Alarm notification devices required by the code are of two general types: visible and audible. Except for voice/alarm signaling systems, once the system has been activated, all visible and audible alarms are required to activate. Voice/alarm signaling systems are special signaling systems that are activated selectively in response to specific emergency conditions.

**907.5.2.1 Audible alarms.** Audible alarm notification appliances shall be provided and emit a distinctive sound that is not to be used for any purpose other than that of a fire alarm.

**Exceptions:**

1. Audible alarm notification appliances are not required in critical care areas of Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.
2. A visible alarm notification appliance installed in a nurses' control station or other continuously attended staff location in a Group I-2 Condition 2 suite shall be an acceptable alternative to the installation of audible alarm notification appliances throughout the suite in Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.

3. Where provided, audible notification appliances located in each occupant evacuation elevator lobby in accordance with Section 3008.9.1 of the *International Building Code* shall be connected to a separate notification zone for manual paging only.

❖ To attract the attention of building occupants, audible alarms must be distinctive, using a sound that is unique to the fire alarm system and used for no other purpose than alerting occupants to a fire emergency. Other emergencies, such as tornados, etc., must be signaled by another sound different from the fire signal.

Exception 1 recognizes that the occupants in critical care areas of Group I-2 occupancies are usually incapacitated. The audible alarms may have the effect of unnecessarily disrupting the care recipients specific term who are most likely not capable of self-preservation. Likewise, audible alarms in operating theaters of hospitals could be hazardous because an alarm activation could startle a surgeon during a delicate procedure. Critical care areas are also assumed to be adequately staffed at all times. Section 907.2.6 Exception 2 allows the use of private mode signaling in accordance with NFPA 72 and also requires that the staff evacuation responsibilities are included in the fire safety and evacuation plan. See commentary for Section 907.2.6. In private mode, as permitted by Section 907.2.6, there is still a requirement for an audible alarm notification from appliances, though at a much lower decibel level meant to alert staff of the alarm activation. Allowing the audible alarm to be eliminated from critical care areas (operating rooms) in exchange for a visual notification device is also not appropriate since the visual signal device also creates a distraction in critical care areas that may not be able to immediately stop a patient procedure. The emergency action plan would include provisions for alerting of critical area staff and the actions to be taken.

Exception 2 allows hospital care suites to eliminate audible alarms where visible alarm notification appliances are located at a continuously attended staff location or nurses control station. In a suite arrangement, the "control area" is the centrally manned location for staff monitoring patients in the separate rooms. An alarm indicator at this location will alert staff for response in a more effective and efficient manner. Similar to Exception 1, audible alarms can unnecessarily disrupt the care recipients. In addition, simply providing visible alarm notification throughout the suite is not appropriate. The patient's evacuation depends on staff, since they are not capable of self-preservation. As with Exception 1, compliance with Exception 2 to Section 907.2.6 would be required in order to take advantage of this exception.

Exception 3 is intended to address the concern that automatic emergency voice/alarm messages do not interfere with operation of the two-way communica-

tion associated with the occupant evacuation elevators. Live voice messages would be appropriate in the lobbies.

**907.5.2.1.1 Average sound pressure.** The audible alarm notification appliances shall provide a sound pressure level of 15 decibels (dBA) above the average ambient sound level or 5 dBA above the maximum sound level having a duration of not less than 60 seconds, whichever is greater, in every occupiable space within the building.

❖ To attract the attention of building occupants, this section requires that the distinctive audible alarms must be capable of being heard above the ambient noise level in a space. The indicated levels are considered the minimum pressure differential that will be perceivable by most people. It prescribes that the sound pressure level (SPL) for notification appliances shall be a minimum of 15 decibels measured in the A-scale (dBA) above the ambient SPL or 5 dBA above the maximum SPL in every space that can be occupied in a building. These SPLs are based on a minimum 1-minute measurement period. SPLs for Group R and I-1 occupancies, mechanical rooms and other occupancies are no longer stipulated as they had been in previous editions of the IBC.

The values mandated in Section 907.5.2.1.1 in previous editions of the code were not consistent with the notification appliance SPL requirements in NFPA 72. NFPA 72 requirements for the audible notification appliances are based on if the devices emit alert or evacuation tones, voice messages or audible notifications for exit markings. The provisions in Section 907.5.2.1.1 would apply to all notification appliances designed to operate in either public- or private-mode. In sleeping areas, the minimum SPL is no longer specified in Section 907.5.2.1.1; however, for smoke alarms, Section 907.2.11 and NFPA 72 require a minimum 75 dBA SPL at the pillow.

Also note that the 2010 American with Disabilities Act Standard for Accessible Design has an exception for medical care facilities following industry practice that will allow a dependence upon staff. The activation of either audible or visible alarms could be detrimental to the care recipients in locations like operating rooms and intensive or critical care units.

**907.5.2.1.2 Maximum sound pressure.** The maximum sound pressure level for audible alarm notification appliances shall be 110 dBA at the minimum hearing distance from the audible appliance. Where the average ambient noise is greater than 95 dBA, visible alarm notification appliances shall be provided in accordance with NFPA 72 and audible alarm notification appliances shall not be required.

❖ In no case may the sound pressure level exceed 110 dBA at the minimum hearing distance from the audible appliance. This is consistent with Americans with Disabilities Act (ADA) requirements. Sound pressures above that level can cause pain or even permanent hearing loss. In such cases, audible alarms are not required to be installed but visual alarms would be necessary to compensate for the lack of audibility.

It should also be noted that in certain work areas, the Occupational Safety and Health Administration (OSHA) requires employees to wear hearing protection, possibly preventing them from hearing an audible alarm. Additionally, the noise factor in these areas is high enough that an audible alarm may not be discernible. In these areas, as well as in others, the primary method of indicating a fire can be by a visible signal. Employees must be capable of identifying such a signal as indicating a fire.

**907.5.2.2 Emergency voice/alarm communication systems.** Emergency voice/alarm communication systems required by this code shall be designed and installed in accordance with NFPA 72. The operation of any automatic fire detector, sprinkler waterflow device or manual fire alarm box shall automatically sound an alert tone followed by voice instructions giving *approved* information and directions for a general or staged evacuation in accordance with the building's fire safety and evacuation plans required by Section 404. In high-rise buildings, the system shall operate on at least the alarming floor, the floor above and the floor below. Speakers shall be provided throughout the building by paging zones. At a minimum, paging zones shall be provided as follows:

1. Elevator groups.
2. *Interior exit stairways.*
3. Each floor.
4. *Areas of refuge* as defined in Chapter 2.

**Exception:** In Group I-1 and I-2 occupancies, the alarm shall sound in a constantly attended area and a general occupant notification shall be broadcast over the overhead page.

❖ The primary purpose of an EV/ACS is to provide dedicated manual and automatic facilities for the origination, control and transmission of information and instructions pertaining to a fire alarm emergency to the occupants of a building. This section identifies that notification speakers are required throughout the building with a minimum of one speaker in each paging zone when an EV/ACS is required. The system may sound a general alarm or be a selective system in which only selected areas of the building receive the alarm indication for staged evacuation. See Chapter 4 for evacuation plan requirements. The intent is to provide the capability to send out selective messages to individual areas; however, it does not prohibit the same message to be sent to all areas. In high-rise buildings, a minimum area of notification must include the alarming floor and the floors above and below it.

This section also identifies the minimum paging zone arrangement. This does not preclude further zone divisions for logical staged evacuation in accordance with an approved evacuation plan.

This section also indicates that the emergency voice/alarm system is to be initiated as all other fire alarm systems are initiated. The functional operation of the system begins with an alert tone (usually 3 to

10 seconds in duration) followed by the evacuation signal (message). It is important to remember that the voice alarm system is not an “audible alarm.” It has its own specific criteria for installation and approval according to NFPA 72. Consequently, the sound pressure requirements for audible alarms do not apply to voice alarm systems. For voice alarm systems, the intent is communication and an understanding of what is being said, not volume.

The exception is similar to the one to Section 907.5.2.1 and recognizes the supervised environment typical of institutional uses and the reliance placed on staff to act appropriately in an emergency. As is the case for most voice alarms, the key is in being able to deliver specific information to the people who can affect a safe egress—whether this is the public or employees, or both.

**907.5.2.2.1 Manual override.** A manual override for emergency voice communication shall be provided on a selective and all-call basis for all paging zones.

❖ The intent of this section is to provide the ability to transmit live voice instructions over any previously initiated signals or pre-recorded messages for all zones. This would include the ability to override the voice message at once throughout the building or to be able to select individual paging zones for the message override.

**907.5.2.2.2 Live voice messages.** The emergency voice/ alarm communication system shall have the capability to broadcast live voice messages by paging zones on a selective and all-call basis.

❖ This would include the ability to provide the live voice message at once throughout the building or to be able to select individual paging zones to receive the message. Speakers used for background music must not be used unless specifically listed for fire alarm system use. NFPA 72 has additional requirements for the placement, location and audibility of speakers used as part of an emergency voice/alarm communication system.

**907.5.2.2.3 Alternate uses.** The emergency voice/ alarm communication system shall be allowed to be used for other announcements, provided the manual fire alarm use takes precedence over any other use.

❖ In certain circumstances which should be approved by the fire code officials, the emergency voice/alarm communications system could be used to convey information other than fire alarm-related items. This could include severe weather warnings that might require evacuation or relocation, lockdown instructions (see commentary, Section 404.2.3) and similar approved messages. In the event of such usage, the system must respond immediately to manual fire alarm box activations.

**907.5.2.2.4 Emergency voice/alarm communication captions.** Where stadiums, arenas and grandstands are required to caption audible public announcements in accordance with Section 1108.2.7.3 of the *International Building Code*, the

emergency/voice alarm communication system shall be captioned. Prerecorded or live emergency captions shall be from an *approved* location constantly attended by personnel trained to respond to an emergency.

❖ This provision links the EV/ACS with the requirements for captioning in Section 1108.2.7.3 of the IBC. Section 1108.2.7.3 of the IBC requires that stadiums, arenas and grandstands have 15,000 fixed seats to provide captioning for audible announcements (see commentary, Section 907.2.1.2).

**907.5.2.2.5 Emergency power.** Emergency voice/ alarm communications systems shall be provided with emergency power in accordance with Section 604. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

❖ Because the emergency voice/alarm communication system is a critical aid in evacuating the building, the system must be connected to an approved emergency power source complying with Section 604. The section also clarifies that the duration of the load for EV/ACS is a minimum of 24 hours.

**907.5.2.3 Visible alarms.** Visible alarm notification appliances shall be provided in accordance with Sections 907.5.2.3.1 through 907.5.2.3.3.

**Exceptions:**

1. Visible alarm notification appliances are not required in *alterations*, except where an existing fire alarm system is upgraded or replaced, or a new fire alarm system is installed.
2. Visible alarm notification appliances shall not be required in *exits* as defined in Chapter 2.
3. Visible alarm notification appliances shall not be required in elevator cars.
4. Visual alarm notification appliances are not required in critical care areas of Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.

❖ This section contains alarm system requirements for occupants who are hearing impaired. Visible alarm notification appliances are to be installed in conjunction with the audible devices and located and oriented so that they will display alarm signals throughout a space. It is not the intent of the code to offer visible alarm signals as an option to audible alarm signals. Both are required. However, the code acknowledges conditions when audible alarms may be of little or no value, such as when the ambient sound level exceeds 105 dBA. In such cases, Section 907.5.2.1, similar to NFPA 72, allows for visible alarm notification appliances in the area.

Exception 1 states that visible alarm devices are not required in previously approved existing fire alarm systems or as part of minor alterations to existing fire alarm systems. Extensive modifications to an existing fire alarm system such as an upgrade or replacement would require the installation of visible alarm devices even if the previous existing system neither had them

nor required them. The main reason is a combination of simple economics and practical application. Many existing systems that do not have visible signal devices do not have the wiring capability to include such devices in their small alterations. To make the necessary changes to the existing system virtually a total replacement of the existing system may need to take place. In many cases this is cost prohibitive. Thus, if the alteration is small, the system can be left as is, without the visual devices. The second consideration is scope. If the alteration involves only a limited area, it could be confusing to have part of the area equipped with visual devices and part without. This is not good practice, as the alarm could be confusing. If an entire floor is being altered, then it becomes subject to consideration for an upgrade to an alarm system with visual devices. If only an office is being remodeled, then the implication is that the upgrade to visual devices may not be warranted. This determination will be subjective in many cases and should be applied based on the life safety benefit and financial expenses involved and whether adequate audible devices are present for full coverage.

In Exception 2, visible alarm devices are not required in exit elements because of the potential distraction during evacuation. Exits, as defined in Chapter 2, could include interior exit stairways or exit passageways but not exit access corridors. In tall buildings, exiting may be phased based on alarm zone. If the alarm floor and adjacent floors are notified of the emergency but the remainder of the building is not, then a visual device in the stairway would be confusing to those people who may not be coming from the alarm floor.

Previously, some jurisdictions were requiring visible alarm notification appliances to be installed in elevator cars since there was no exception in the code or NFPA 72 to allow omission of this type of notification appliance in elevator cars. Exception 3 eliminates any confusion regarding the need to install visible notification appliances in elevator cars. The rationale for not installing visible notification appliances in elevator cars is the same as for interior exit stairways; high light intensity from these notification appliances may cause confusion and disorientation. Also, elevator passengers are “captive” in that they cannot respond to such devices until the elevator arrives at its destination or is recalled by the Phase I emergency operation feature, which could lead to passenger panic.

Exception 4 was added to eliminate visual alarm notification appliances in critical care areas of Group I-2 Condition 2 occupancies (hospitals) due to the hazards they may pose to the occupants. Such occupancies already have staff procedures in place during

fires that more than compensate for visual alarm notification appliances. In addition, in these areas of the hospital the patients are not typically ambulatory. This allowance includes specific requirements for detailing of the staff evacuation responsibilities based on the requirements in Section 907.2.6. See also commentary to Exception 1 of Section 907.5.2.1.

**907.5.2.3.1 Public use areas and common use areas.** Visible alarm notification appliances shall be provided in *public use areas* and *common use areas*.

**Exception:** Where employee work areas have audible alarm coverage, the notification appliance circuits serving the employee work areas shall be initially designed with not less than 20-percent spare capacity to account for the potential of adding visible notification appliances in the future to accommodate hearing-impaired employee(s).

❖ Visible alarm notification appliances must provide coverage in all areas open to the public, as well as all shared or common areas (e.g., corridors, public restrooms, shared offices, classrooms, medical exam rooms, etc.). Areas where visible alarm notification appliances are not required include private offices, mechanical rooms or similar spaces. The intent with this section is to replicate the provisions included in the Americans with Disabilities Act *Accessibility Guidelines for Buildings and Facilities (ADAAG)*.

The exception allows employee work areas to provide only for spare capacity on notification circuits to allow for those with hearing impairments to be accommodated as necessary. This spare capacity is intended to eliminate the potential for overloading notification circuits when a hearing-impaired person is hired and needs to be accommodated, but reduces the initial construction cost as such alarm notification appliances may not be necessary in every situation.

**907.5.2.3.2 Groups I-1 and R-1.** Group I-1 and R-1 *dwelling units* or *sleeping units* in accordance with Table 907.5.2.3.2 shall be provided with a visible alarm notification appliance, activated by both the in-room smoke alarm and the building fire alarm system.

❖ Fire alarm systems in Group I-1 and R-1 sleeping accommodations must be equipped with visible alarms to the extent stated in Table 907.6.2.3.3. The visible alarm notification devices in these rooms are to be activated by both the required in-room smoke alarm and the building fire alarm system. All visible alarm notification appliances in a building, however, need not be activated by individual room detectors. It is not a requirement that the accessible sleeping units be provided with visible alarm notification appliances even though some elderly patients or residents may be both mobility and hearing impaired.

**TABLE 907.5.2.3.2  
VISIBLE ALARMS**

NUMBER OF SLEEPING UNITS	SLEEPING ACCOMMODATIONS WITH VISIBLE ALARMS
6 to 25	2
26 to 50	4
51 to 75	7
76 to 100	9
101 to 150	12
151 to 200	14
201 to 300	17
301 to 400	20
401 to 500	22
501 to 1,000	5% of total
1,001 and over	50 plus 3 for each 100 over 1,000

❖ This table specifies the minimum number of sleeping units that are to be equipped with visible and audible alarms. The numbers are based on the total number of sleeping accommodations in the facility. The requirements in this table are intended to be consistent with the ADAAG.

**907.5.2.3.3 Group R-2.** In Group R-2 occupancies required by Section 907 to have a fire alarm system, all *dwelling units* and *sleeping units* shall be provided with the capability to support visible alarm notification appliances in accordance with Chapter 10 of ICC A117.1. Such capability shall be permitted to include the potential for future interconnection of the building fire alarm system with the unit smoke alarms, replacement of audible appliances with combination audible/visible appliances, or future extension of the existing wiring from the unit smoke alarm locations to required locations for visible appliances.

❖ At some time during the life of a Group R-2 building, one or more persons who are hearing impaired or deaf may reside in any given unit. As such, Group R-2 occupancies that are required to be equipped with a fire alarm system are also required to have the capability to support visual alarm notification appliances in accordance with Chapter 10 of ICC A117.1. This section is intended to provide guidance as to what is meant by “capability.” If a hearing-impaired occupant moves into the dwelling unit, the audible alarm notification appliances are simply replaced with visual alarm notification appliances. The intent is if one or more hearing impaired individuals move into a dwelling unit or sleeping unit within a Group R-2 occupancy, the circuit serving the occupant alarm notification appliances must be capable of supplying the necessary amperage to provide the required power to the listed visual alarm notification device. The intent is to design the fire alarm and detection system so that the occupant notification appliance circuit can accommodate a limited number of visual alarm notification appliances operating at the required minimum amperage.

Note that this requirement includes all dwelling and

sleeping units, not just those classified as either Type A or B as defined in Chapter 2 of the IBC. Sections 1006.2 through 1006.4.4 of ICC A117.1 address smoke and fire alarm system requirements as they pertain to accessible communication features. More specifically, Section 1006.2 of ICC A117 states that when unit smoke detection is provided, it shall provide audible notification appliances in compliance with NFPA 72. Section 1006.3 of ICC A117 is focused upon buildings where fire alarm systems are provided. If a fire alarm system is provided in the building, ICC A117.1 requires that the wiring be extended to a point within the unit in the vicinity of the smoke alarm or smoke detection system. Based upon the type of unit and the strategy used by the designer, this location may vary. Section 1006.4 of ICC A117 addresses the visible alarm notification appliance requirements specifically and has various issues it addresses, as follows:

1. Complies with Section 702 of ICC A117.1, which focuses on the requirements of NFPA 72 and that such notification devices be hardwired.
2. Addresses the fact that all visible notification devices be activated within the unit either when the smoke alarms in the unit activate or when that portion of the building fire alarm system in that portion of the building activate.
3. Allows the same visible notification for the smoke alarms in the unit and the building fire alarm system.
4. Prohibits the use of the visible notification for anything other than the operation of the smoke alarms in the unit or the building fire alarm system.

In terms of the specific capability requirements this section provides direction as to what may be meant by bringing the wiring to the unit. There has been confusion in the past and it has been interpreted that all units are required to be pre-wired for visible appliances, which was not the intent of ICC A117.1. More specifically, now the requirements provide essentially three options for future capability, as follows:

- Potential for future interconnection of the building fire alarm system with the unit smoke alarms.
- Replacement of audible appliance with combination audible/visible appliances.
- Extension of wiring from the unit smoke alarm locations to required locations of visible appliances.

It is important to remember that the location of visible notification devices, if installed, are driven by the requirements of NFPA 72 and may vary the approach taken, based upon the configuration of the space.

**907.6 Installation and monitoring.** A fire alarm system shall be installed and monitored in accordance with Sections 907.6.1 through 907.6.6.2 and NFPA 72.

❖ This section specifies the requirements for fire alarm system installation and monitoring and also references the installation requirements of NFPA 72.

**907.6.1 Wiring.** Wiring shall comply with the requirements of NFPA 70 and NFPA 72. Wireless protection systems utilizing radio-frequency transmitting devices shall comply with the special requirements for supervision of low-power wireless systems in NFPA 72.

❖ Wiring for fire alarm systems must be installed so that it is secure and will function reliably in an emergency. The code requires that the wiring for fire alarm systems meet the requirements of NFPA 70 and NFPA 72. This requirement is in addition to the general requirements for electrical installations set forth in Chapter 27 of the IBC. For reliability, systems that use radio-frequency transmitting devices for signal transmission are required to have supervised transmitting and receiving equipment that conforms to the special requirements contained in NFPA 72. This requirement is in addition to the general requirements for supervision in Section 907.6.6.

**907.6.2 Power supply.** The primary and secondary power supply for the fire alarm system shall be provided in accordance with NFPA 72.

**Exception:** Backup power for single-station and multiple-station smoke alarms as required in Section 907.2.11.6.

❖ The operation of fire alarm systems is essential to life safety in buildings and must be reliable in the event the normal power supply fails. For proper operation of fire alarm systems, this section requires that the primary and secondary power supplies comply with NFPA 72. This is in addition to the general requirements for electrical installations in Chapter 27 of the IBC. NFPA 72 offers three alternatives for secondary supply: a 24-hour storage battery; storage batteries with a 4-hour capacity; and a generator or multiple generators.

NFPA 72 requires that the primary and secondary power supplies for remotely located control equipment essential to the system operation must conform to the requirements for primary and secondary power supplies for the main system. Also, NFPA 72 contains requirements for monitoring the integrity of primary power supplies and requires a backup power supply.

**907.6.3 Initiating device identification.** The fire alarm system shall identify the specific initiating device address, location, device type, floor level where applicable and status including indication of normal, alarm, trouble and supervisory status, as appropriate.

**Exceptions:**

1. Fire alarm systems in single-story buildings less than 22,500 square feet (2090 m<sup>2</sup>) in area.

2. Fire alarm systems that only include manual fire alarm boxes, waterflow initiating devices and not more than 10 additional alarm-initiating devices.
3. Special initiating devices that do not support individual device identification.
4. Fire alarm systems or devices that are replacing existing equipment.

❖ Current technology makes identification of alarm initiating devices much easier. This section takes advantage of this technology to improve the ability of emergency responders to rapidly identify the location and status of initiating devices at the time of an emergency. It will also help identify problematic alarm initiating devices and thus reduce nuisance alarms. It also eliminates the requirements for providing zone indication of system status. This is considered particularly important in high-rise buildings, where the number of initiating devices and the geometry of the building warrant a need for point monitoring of individual devices, which is not currently accommodated by single floor zones.

This section allows the fire code official the flexibility to not require individual detection device identification in smaller buildings where the source of alarm and trouble signals can be more easily determined.

The 22,500 square foot limitation noted in Exception 1 relates to the size of a typical fire alarm zone (see Section 907.6.4) and represents a small building. Exception 2 addresses manual fire alarm systems in which the location of initiation may not be an indicator of where the fire actually is or an automatic sprinkler waterflow alarm initiating device which could be annunciating an entire building. Along with a very limited number of other alarm initiating devices, Exception 3 recognizes that some devices will not work with this requirement. Finally, Exception 4 provides flexibility to existing system replacement. Replacement should be encouraged and requiring identification of alarm initiating device locations is considered onerous.

**907.6.3.1 Annunciation.** The initiating device status shall be annunciated at an *approved* on-site location.

❖ This section specifically notes that the alarm initiating device status of trouble versus alarm needs to be provided in an approved location to enable rapid identification of problematic devices or alarm conditions by first responders.

**907.6.4 Zones.** Each floor shall be zoned separately and a zone shall not exceed 22,500 square feet (2090 m<sup>2</sup>). The length of any zone shall not exceed 300 feet (91 440 mm) in any direction.

**Exception:** *Automatic sprinkler system* zones shall not exceed the area permitted by NFPA 13.

❖ Since the fire alarm system also aids emergency personnel in locating the fire, the system must be zoned

to shorten response time to the fire location. Zoning is also critical if the fire alarm system initiates certain other fire protection systems or control features, such as smoke control systems.

At a minimum, each floor of a building must constitute one zone of the system. If the floor area exceeds 22,500 square feet (2090 m<sup>2</sup>), additional zones per floor are required. The maximum length of a zone is 300 feet (91 440 mm).

The exception states that NFPA 13 defines the maximum areas to be protected by one sprinkler system and that the sprinkler system need not be designed to meet the 22,500-square-foot (2090 m<sup>2</sup>) area limitations for a fire alarm system zone. For example, NFPA 13 permits a sprinkler system riser in a light-hazard occupancy to protect an area of 52,000 square feet (4831 m<sup>2</sup>) per floor. In accordance with the exception, a single water flow switch, and consequently a single fire alarm system zone, would be acceptable. If other alarm-initiating devices are present on the floor, they would need to be zoned separately to meet the 22,500-square-foot (2098 m<sup>2</sup>) limitation.

It is not intended that this section apply to sprinkler systems. This section only applies where a fire alarm system is required in accordance with Section 907. Unless the building is categorized as a high rise and must comply with Section 907.6.4.2, the code does not mandate the zoning of sprinkler systems per floor. With today's fully addressable fire alarm systems, each detector effectively becomes its own zone. The intent with zoning is to identify and limit the search area for fire alarm systems. Addressable devices will indicate the precise location of the alarm condition, thereby eliminating the need for the zoning contemplated by this section when approved by the fire code official in accordance with Section 104.9.

**907.6.4.1 Zoning indicator panel.** A zoning indicator panel and the associated controls shall be provided in an *approved* location. The visual zone indication shall lock in until the system is reset and shall not be canceled by the operation of an audible alarm-silencing switch.

❖ The zoning indicator panel, which can be the fire alarm control unit or a separate fire alarm annunciator panel (FAAP), must be installed in a location approved by the fire code official. One of the key considerations in determining panel placement is whether or not the panel is located to permit ready access by emergency responders. Once an alarm-initiating device within a zone has been activated, the annunciation of the zone must lock in until the system is reset.

**907.6.4.2 High-rise buildings.** In high-rise buildings, a separate zone by floor shall be provided for each of the following types of alarm-initiating devices where provided:

1. Smoke detectors.
2. Sprinkler waterflow devices.

3. Manual fire alarm boxes.

4. Other *approved* types of automatic fire detection devices or suppression systems.

❖ High-rise buildings must have a separate zone by floor for each indicated type of alarm-initiating device. Although this feature may be desirable in all buildings, the incremental cost difference is substantially higher in low-rise buildings in which basic fire alarm systems are installed. State-of-the-art fire alarm systems installed in high-rise buildings are addressable and by their nature automatically provide this minimum zoning.

**907.6.5 Access.** Access shall be provided to each fire alarm device and notification appliance for periodic inspection, maintenance and testing.

❖ Automatic fire detectors, especially smoke detectors, require periodic cleaning to reduce the likelihood of malfunction. Section 907.8 and NFPA 72 require inspection and testing at regular intervals. Access to perform the required inspections, necessary maintenance and testing is a particularly important consideration for those detectors that are installed within a concealed space, such as an air duct.

**907.6.6 Monitoring.** Fire alarm systems required by this chapter or by the *International Building Code* shall be monitored by an *approved* supervising station in accordance with NFPA 72.

**Exception:** Monitoring by a supervising station is not required for:

1. Single- and multiple-station smoke alarms required by Section 907.2.11.
2. Smoke detectors in Group I-3 occupancies.
3. *Automatic sprinkler systems* in one- and two-family dwellings.

❖ Fire alarm systems required by Section 907 or the IBC are required to be electrically supervised by one of the methods prescribed in NFPA 72.

Exception 1 exempts single- and multiple-station smoke alarms from being supervised due to the potential for unwanted false alarms.

Exception 2 recognizes a similar problem in Group I-3 occupancies. Accordingly, due to the concern over unwanted alarms, smoke detectors in Group I-3 occupancies need only sound an approved alarm signal that automatically notifies staff (see Section 907.2.6.3.1). Smoke detectors in such occupancies are typically subject to misuse and abuse, and frequent unwanted alarms would negate the effectiveness of the system.

Exception 3 clarifies that sprinkler systems in one- and two-family dwellings are not part of a dedicated fire alarm system and are typically designed in accordance with NFPA 13D, which does not require electrical supervision.

**907.6.6.1 Automatic telephone-dialing devices.** Automatic telephone-dialing devices used to transmit an emergency alarm shall not be connected to any fire department telephone number unless *approved* by the fire chief.

- ❖ Upon initiation of an alarm, supervisory or trouble signal, an automatic telephone-dialing device takes control of the telephone line for the reliability of transmission of all signals. The device, however, must not be connected to the fire department telephone number unless specifically approved by the fire department because that could disrupt any potential emergency (911) calls. NFPA 72 contains additional guidance on such devices including digital alarm-communicator systems.

**907.6.6.2 Termination of monitoring service.** Termination of fire alarm monitoring services shall be in accordance with Section 901.9.

- ❖ This section is simply an editorial cross-reference to highlight Section 901.9, which affects the monitoring requirements of Section 907.6.6 (see commentary, Section 901.9).

**907.7 Acceptance tests and completion.** Upon completion of the installation, the fire alarm system and all fire alarm components shall be tested in accordance with NFPA 72.

- ❖ A complete performance test of the fire alarm system must be conducted to determine that the system is operating as required by the code. The acceptance test must include a test of each circuit, alarm-initiating device, alarm notification appliance and any supplementary functions, such as activation of closers and dampers. The operation of the primary and secondary (emergency) power supplies must also be tested, as well as the supervisory function of the control panel. Section 901.5 assigns responsibility for conducting the acceptance tests to the owner or the owner's representative.

NFPA 72 contains specific acceptance test procedures. Additional guidance on periodic testing and inspection can be also obtained from Section 907.8 and NFPA 72.

**907.7.1 Single- and multiple-station alarm devices.** When the installation of the alarm devices is complete, each device and interconnecting wiring for multiple-station alarm devices shall be tested in accordance with the smoke alarm provisions of NFPA 72.

- ❖ To determine that smoke alarms have been properly installed and are ready to function as intended, they must be actuated during an acceptance test. The test also confirms that interconnected detectors will operate simultaneously as required. The responsibility for conducting the acceptance tests rests with the owner or the owner representative as stated in Section 901.5.

**907.7.2 Record of completion.** A record of completion in accordance with NFPA 72 verifying that the system has been

installed and tested in accordance with the *approved* plans and specifications shall be provided.

- ❖ In accordance with NFPA 72, this section requires a written statement from the installing contractor that the fire alarm system has been tested and installed in compliance with the approved plans and the manufacturer's specifications. Any deviations from the approved plans or the applicable provisions of NFPA 72 are to be noted in the record of completion.

**907.7.3 Instructions.** Operating, testing and maintenance instructions and record drawings ("as built") and equipment specifications shall be provided at an *approved* location.

- ❖ To permit adequate testing, maintenance and trouble-shooting of the installed fire alarm system, an owner's manual with complete installation instructions must be kept on site or in another approved location. The instructions include a description of the system, operating procedures and testing and maintenance requirements.

**907.8 Inspection, testing and maintenance.** The maintenance and testing schedules and procedures for fire alarm and fire detection systems shall be in accordance with Sections 907.8.1 through 907.8.5 and NFPA 72. Records of inspection, testing and maintenance shall be maintained.

- ❖ Fire alarms and fire detection systems are to be inspected, tested and maintained in accordance with Sections 907.8.1 through 907.8.5 and the applicable requirements of NFPA 72. It is the building owner's responsibility to keep these systems operable at all times.

**907.8.1 Maintenance required.** Where required for compliance with the provisions of this code, devices, equipment, systems, conditions, arrangements, levels of protection or other features shall thereafter be continuously maintained in accordance with applicable NFPA requirements or as directed by the *fire code official*.

- ❖ Periodic maintenance keeps systems in good working order or allows repair of defects discovered during inspections or testing. Because specialized tools and training are needed, only properly trained technicians or specialists should perform required periodic maintenance. Most maintenance is required only as needed, but many manufacturers suggest or require regular periodic replacement of parts subject to wear or abuse.

**907.8.2 Testing.** Testing shall be performed in accordance with the schedules in NFPA 72 or more frequently where required by the *fire code official*. Records of testing shall be maintained.

**Exception:** Devices or equipment that are inaccessible for safety considerations shall be tested during scheduled shutdowns where *approved* by the *fire code official*, but not less than every 18 months.

- ❖ NFPA 72 includes schedules for testing frequencies of fire alarm and fire detection systems and their

components. Periodic tests that follow standardized methods are intended to confirm the results of inspections, determine that all components function properly and that systems meet their original design specifications. Tools, devices or equipment are usually required to perform tests. Because tests are more detailed than inspections, they are usually done only once or twice per year in most cases. Some tests, however, may be required as frequently as bimonthly or quarterly. Because specialized knowledge and equipment are required, tests must usually be performed by technicians or specialists trained in the test methods involved.

Although Section 907.8.2 specifically addresses testing, NFPA 72 also contains schedules for visual inspection frequencies. An inspection consists of a visual check of a system or device to verify it is in operating condition and free from visible defects or damage.

Obvious damage and the general condition of the system must always be noted and recorded. Partly because of their cursory nature, inspections are conducted more frequently than tests and maintenance. Because special knowledge and tools are not required, inspections may be done by any competent person.

The exception recognizes the impracticality of testing every device or piece of equipment related to a fire alarm or fire detection system. Some devices may be inaccessible for safety considerations, such as those in continuous process operations. Testing, however, must be done during scheduled shutdowns.

**907.8.3 Smoke detector sensitivity.** Smoke detector sensitivity shall be checked within one year after installation and every alternate year thereafter. After the second calibration test, where sensitivity tests indicate that the detector has remained within its *listed* and marked sensitivity range (or 4-percent obscuration light grey smoke, if not marked), the length of time between calibration tests shall be permitted to be extended to not more than 5 years. Where the frequency is extended, records of detector-caused nuisance alarms and subsequent trends of these alarms shall be maintained. In zones or areas where nuisance alarms show any increase over the previous year, calibration tests shall be performed.

❖ Usually, changes in detector sensitivity are caused by inadequate maintenance. Regular sensitivity testing is intended to determine whether detectors require recalibration, maintenance or replacement. This section prescribes the intervals for testing smoke detector sensitivity. Where two successful tests have been conducted, the frequency of the calibration tests can be extended to a maximum of five years. This interval extension recognizes the stability of both the environment and the detector. However, if nuisance alarms occur during this time interval extension, calibration tests may be needed because of potential changes in the environment where the detector is located or in the performance of the detector itself.

**907.8.4 Sensitivity test method.** To verify that each smoke detector is within its *listed* and marked sensitivity range, it shall be tested using one of the following methods:

1. A calibrated test method.
2. The manufacturer's calibrated sensitivity test instrument.
3. *Listed* control equipment arranged for the purpose.
4. A smoke detector/control unit arrangement whereby the detector causes a signal at the control unit where the detector's sensitivity is outside its acceptable sensitivity range.
5. Another calibrated sensitivity test method acceptable to the *fire code official*.

Detectors found to have a sensitivity outside the *listed* and marked sensitivity range shall be cleaned and recalibrated or replaced.

**Exceptions:**

1. Detectors *listed* as field adjustable shall be permitted to be either adjusted within the *listed* and marked sensitivity range and cleaned and recalibrated or they shall be replaced.
  2. This requirement shall not apply to single-station smoke alarms.
- ❖ This section prescribes acceptable test methods to verify that each smoke detector is within its listed and marked sensitivity range; any of the listed test methods may be used.

With regard to a calibration test method, many manufacturers have designed their devices to be tested by the application of a magnet at a test point on the outside of the detector. This activates a reed switch or pulls a fine wire into the detection chamber to simulate a predetermined level of obscuration.

Another test method may require that a test device such as a key-type tool be inserted in a test port. This either activates a test switch or produces the desired level of obscuration directly.

One detector manufacturer supplies an interface device for connecting a volt-ohm-amp meter to a test port. Pressing a button on the interface device permits a direct reading of detector chamber voltage in an alarm condition.

Other detectors must be removed and inserted in or connected to a device used to calibrate and test the device. The calibrated sensitivity test instrument must satisfy the manufacturer's recommendation for a specific detector.

Addressable/analog-type detectors produce direct readings of the chamber voltage by the control unit. Many of these systems permit sensitivity adjustments within acceptable limits from the control unit as well. This test method essentially allows remote sensitivity testing.

A system control/detector combination unit detects changes in the environment and in the detector by

comparing current readings to previously stored information in the memory of the control unit. Significant changes would indicate that the stability of either the environment or the detector has changed and that further maintenance or recalibration is required.

Any other method or device that permits the user to check the voltage drop across a smoke detection chamber is acceptable subject to the approval of the fire code official. Test devices should be manufactured and supplied by the smoke detector manufacturer.

Exception 1 recognizes that some smoke detectors may be listed as being field-adjustable. If, however, such devices cannot be adjusted to their listed sensitivity, then they must be replaced.

Exception 2 exempts single station smoke alarms from sensitivity testing because these devices are not designed with the same level of technical sophistication as system smoke detectors. Smoke alarm manufacturers also recommend that the devices be discarded and replaced at regular intervals to reduce the likelihood of failure.

**907.8.4.1 Sensitivity testing device.** Smoke detector sensitivity shall not be tested or measured using a device that administers an unmeasured concentration of smoke or other aerosol into the detector.

❖ Functional testing using smoke or a smoke substitute, such as aerosols, must comply with the manufacturer's recommended test procedures. A precisely measured amount of smoke or other aerosol product must be used to adequately determine detector sensitivity. Some detector manufacturers do not accept testing with aerosol products and void detector warranties when this product is used. The functional test method selected should not permanently affect detector performance.

**907.8.5 Inspection, testing and maintenance.** The building owner shall be responsible to maintain the fire and life safety systems in an operable condition at all times. Service personnel shall meet the qualification requirements of NFPA 72 for inspection, testing and maintenance of such systems. Records of inspection, testing and maintenance shall be maintained.

❖ This section clearly indicates that it is the responsibility of the building owner to maintain all fire alarm systems in proper working order. Often, an outside agency that employs adequately trained personnel will provide any maintenance and testing that is needed. NFPA 72 contains additional guidance on the qualifications for service personnel. Some examples include factory trained and certified individuals; individuals certified for fire alarm by the NICET or other individuals tested and certified by the local authority. Proper maintenance of fire alarm systems is essential so that the systems will perform as intended.

Inspection and test records provide a means for determining compliance with the requirements of the code. Inspectors should be prepared to determine

that inspection, test and maintenance logs are accurate and complete. Records must include the nature of the activity or service performed; when the activity occurred; who performed the activity and who witnessed testing or approved the work upon completion.

**907.9 Where required in existing buildings and structures.** An approved fire alarm system shall be provided in existing buildings and structures where required in Chapter 11.

❖ Retroactive requirements for fire alarms are found in Section 1103.7. All the retroactive code requirements are found in Chapter 11 for convenience and to help with consistent enforcement.

## SECTION 908 EMERGENCY ALARM SYSTEMS

**908.1 Group H occupancies.** Emergency alarms for the detection and notification of an emergency condition in Group H occupancies shall be provided as required in Chapter 50.

❖ Emergency alarm systems provide indication and warning of emergency situations involving hazardous materials. An emergency alarm system is required in all Group H occupancies as indicated in Sections 5004.9 and 5005.4.4 as well as Group H-5 HPM facilities as indicated in Section 908.2. The Group H occupancy classification assumes the storage or use of hazardous materials exceeds the maximum allowable quantities specified in Tables 5003.1.1(1) and 5003.1.1(2).

An emergency alarm system should include an emergency alarm-initiating device outside each interior door of hazardous material storage areas, a local alarm device and adequate supervision.

Even though ozone gas-generator rooms (Section 908.4), repair garages (Section 908.5) and refrigeration systems (Section 908.6) are not typically classified as Group H occupancies, the potential hazards associated with these occupancy conditions are great enough to require additional means of early warning detection.

**908.2 Group H-5 occupancy.** Emergency alarms for notification of an emergency condition in an HPM facility shall be provided as required in Section 2703.12. A continuous gas detection system shall be provided for HPM gases in accordance with Section 2703.13.

❖ In addition to hazardous material storage areas as regulated by Section 5004.9, Section 2703.12.1 also requires emergency alarms for service corridors, exit access corridors and interior exit stairways because of the potential transport of hazardous materials through these areas. Section 2703.13 requires a continuous gas detection system for early detection of leaks in areas where HPM gas is used. Gas detection systems are required to initiate a local alarm and

transmit a signal to the emergency control station upon detection (see commentary, Sections 2703.12 and 2703.13).

**908.3 Highly toxic and toxic materials.** Where required by Section 6004.2.2.10, a gas detection system shall be provided for indoor storage and use of highly toxic and toxic *compressed gases*.

- ❖ A gas detection system in the room or area utilized for indoor storage or the use of highly toxic or toxic gases provides early notification of a leak that is occurring before the escaping gas reaches hazardous exposure concentration levels. The exception recognizes that certain toxic compressed gases do not pose a severe exposure hazard. Those toxic gases whose properties under standard conditions are still below the 8-hour weighted average concentration for the permitted exposure limit (PEL) are exempt from the requirement for a gas detection system.

This section also specifies the discharge requirements for treatment system performance to establish a maximum allowable concentration of highly toxic or toxic gases at the point of discharge to the atmosphere. The concentration level of one-half the immediately dangerous to life and health (IDLH) limit represents a minimum acceptable level of dilution at the point of discharge where the location of discharge is away from the general public. Where the treatment system processes more than one type of compressed gas, the maximum allowable concentration must be based on the release rate, quantity and IDLH for the gas that poses the worst-case release scenario.

**908.4 Ozone gas-generator rooms.** A gas detection system shall be provided in ozone gas-generator rooms in accordance with Section 6005.3.2.

- ❖ To monitor the potential buildup of dangerous levels of ozone, a gas detection system is required to, upon actuation, shut off the generator and sound a local alarm. Ozone gas generators are commonly used in water treatment applications. The ozone gas-generator room should not be a normally occupied area or be used for the storage of combustibles or other hazardous materials. Section 6005 contains additional requirements for ozone gas generators.

**908.5 Repair garages.** A flammable-gas detection system shall be provided in repair garages for vehicles fueled by nonodorized gases in accordance with Section 2311.7.2.

- ❖ As indicated in Section 2311.7.2, an approved flammable-gas detection system is required for garages used for repair of vehicles fueled by nonodorized gases, such as hydrogen and nonodorized LNG. To prevent a hazardous potential buildup of flammable gas caused by normal leakage and use conditions, the flammable-gas detection system is required to activate when the level of flammable gas exceeds 25 percent of the lower explosive limit (LEL) (see commentary, Section 2311.7.2).

**908.6 Refrigeration systems.** Refrigeration system machinery rooms shall be provided with a refrigerant detector in accordance with Section 606.9.

- ❖ A refrigerant-specific detector is required for leak detection, early warning and actuation of emergency exhaust systems. Because most general machinery rooms are unoccupied for long periods of time, a refrigeration leak may go undetected, allowing a buildup of refrigerant that can pose a threat to building occupants and the maintenance personnel who must enter the machinery room. Also, the refrigerants may or may not be detectable by the sense of smell, depending on the chemical nature and concentration in the air of the refrigerant. This can be especially critical when a toxic refrigerant is used in the refrigeration system (see commentary, Section 606.8). Even where the refrigerant is not toxic, sufficient quantities can displace oxygen and create an untenable environment. Detection is necessary to avoid a condition where the oxygen level drops below safe levels.

**908.7 Carbon dioxide (CO<sub>2</sub>) systems.** Emergency alarm systems in accordance with Section 5307.5.2 shall be provided where required for compliance with Section 5307.5.

- ❖ This is simply cross references to requirements in Chapter 53 related to the danger of CO<sub>2</sub> asphyxiation and intended to address fatal CO<sub>2</sub> poisoning incidents in restaurants where CO<sub>2</sub> leaked from large storage tanks for beverage mixing and displaced oxygen in these areas. See the commentary to Section 5307.5.

## SECTION 909 SMOKE CONTROL SYSTEMS

**909.1 Scope and purpose.** This section applies to mechanical or passive smoke control systems where they are required for new buildings or portions thereof by provisions of the *International Building Code* or this code. The purpose of this section is to establish minimum requirements for the design, installation and acceptance testing of smoke control systems that are intended to provide a tenable environment for the evacuation or relocation of occupants. These provisions are not intended for the preservation of contents, the timely restoration of operations or for assistance in fire suppression or overhaul activities. Smoke control systems regulated by this section serve a different purpose than the smoke- and heat-venting provisions found in Section 910. Mechanical smoke control systems shall not be considered exhaust systems under Chapter 5 of the *International Mechanical Code*.

- ❖ This section is clarifying the intent of smoke control provisions, which is to provide a tenable environment to occupants during evacuation and relocation and not to protect the contents, enable timely restoration of operations or facilitate fire suppression and overhaul activities. There are provisions for high rise buildings in Section 403.4.7 of the IBC that are focused upon the removal of smoke for post fire and overhaul operations which is very different than the

smoke control provisions in Section 909. Another element addressed in this section is that smoke control systems serve a different purpose than smoke and heat vents (see Section 910). This eliminates any confusion that smoke and heat vents can be used as a substitution for smoke control. Additionally, a clarification is provided to note that smoke control systems are not considered an exhaust system in accordance with Chapter 5 of the IMC. This is due to the fact that such systems are unique in their operation and are not necessarily designed to exhaust smoke but are focused upon tenability for occupants during egress. It should be noted that the smoke control provisions are duplicated in Chapter 5 of the IMC.

It is important to note that these provisions only apply when smoke control is required by other sections of the code. The code requires smoke management within atrium spaces (see Section 404.5 of the IBC) and underground buildings (see Section 405.5 of the IBC). High-rise facilities require smokeproof exit enclosures in accordance with Sections 909.20 of the IBC and 1019.1.8 (see Section 403.5.4 of the IBC). Also, covered mall buildings that contain atriums that connect more than two stories require smoke control (see Section 402.7.2 of the IBC).

Section 909 focuses primarily on mechanical smoke control systems but there are many instances within the code where smoke is required to be managed in a passive way through the use of concepts such as smoke compartments. Smoke compartments are formed through the use of smoke barriers in accordance with Section 709 of the IBC. Smoke barriers can be used simply as a passive smoke management system or can be a design component of a mechanical smoke control system in accordance with Section 909. Some examples of occupancies requiring passive systems include hospitals, nursing and similar facilities (Group I-2 occupancies) and detention facilities (Group I-3 occupancies) (see Sections 407.5 and 408.6 of the IBC).

In some cases, mechanical smoke control in accordance with Section 909 is allowed as an option for compliance. More specifically if a Group I-3 contains windowless areas of the facility natural or mechanical smoke management is required (see Section 408.9 of the IBC).

In the last several years, smoke control provisions have become more complex. The reason is related to the fact that smoke is a complex problem, while a generic solution of six air changes has repeatedly and scientifically been shown to be inadequate. Six air changes per hour does not take into account factors such as buoyancy; expansion of gases; wind; the geometry of the space and of communicating spaces; the dynamics of the fire, including heat release rate; the production and distribution of smoke and the interaction of the building systems.

Smoke control systems can be either passive or active. Active systems are sometimes referred to as mechanical. Passive smoke control systems take

advantage of smoke barriers surrounding the zone in which the fire event occurs or high bay areas that act as reservoirs to control the movement of smoke to other areas of the building. Active systems utilize pressure differences to contain smoke within the event zone or exhaust flow rates sufficient to slow the descent of the upper-level smoke accumulation to some predetermined position above necessary exit paths through the event zone. On rare occasions, there is also a possibility of controlling the movement of smoke horizontally by opposed airflow, but this method requires a specific architectural geometry to function properly that does not create an even greater hazard.

Essentially, there are three methods of mechanical or active smoke control that can be used separately or in combination within a design: pressurization, exhaust and, in rare and very special circumstances, opposed airflow.

Of course, all of these active approaches can be used in combination with the passive method.

Typically, the mechanical pressurization method is used in high-rise buildings when pressurizing stairways and for zoned smoke control. Pressurization is not practical in large open spaces such as atriums or malls, since it is difficult to develop the required pressure differences due to the large volume of the space.

The exhaust method is typically used in large open spaces such as atriums and malls. As noted, the pressurization method would not be practical within large spaces. The opposed airflow method, which basically uses a velocity of air horizontally to slow the movement of smoke, is typically applied in combination with either a pressurization method or exhaust method within hallways or openings into atriums and malls.

The application of each of these methods will be dependent on the specifics of the building design. Smoke control within a building is fundamentally an architecturally driven problem. Different architectural geometries first dictate the need or lack thereof for smoke control, and then define the bounds of available solutions to the problem.

**909.2 General design requirements.** Buildings, structures, or parts thereof required by the *International Building Code* or this code to have a smoke control system or systems shall have such systems designed in accordance with the applicable requirements of Section 909 and the generally accepted and well-established principles of engineering relevant to the design. The *construction documents* shall include sufficient information and detail to describe adequately the elements of the design necessary for the proper implementation of the smoke control systems. These documents shall be accompanied with sufficient information and analysis to demonstrate compliance with these provisions.

❖ This section simply states that when smoke control systems are required by the code, the design is required to be in accordance with the provisions of

this section. As noted in the commentary to Section 909.1, there are instances within the code that have smoke management systems that are purely passive in nature and do not reference Section 909.

This section stresses that such designs need to follow “generally accepted and well-established principles of engineering relevant to the design,” essentially requiring a certain level of qualifications in the applicable areas of engineering to prepare such designs. The primary engineering disciplines tend to be fire engineering and mechanical engineering. It should be noted that each state in the U.S. typically requires minimum qualifications to undertake engineering design. Two important resources when designing smoke control systems are the International Code Council’s (ICC) *Guide to Smoke Control in the 2006 IBC* and *American Society of Heating, Refrigerating and Air-Conditioning Engineers’ (ASHRAE) Design of Smoke Management Systems*. Additionally, Section 909.8 requires the use of NFPA 92 for the design of smoke control systems using the exhaust method. This standard has many relevant aspects beyond the design that are beneficial. In particular, Annex B provides resources in terms of determination of fire size for design. ICC’s *Guide to Smoke Control in the 2006 IBC* also provides guidance on design fires.

A key element covered in this section is the need for detailed and clear construction documents so that the system is installed correctly. In most complex designs, the key to success is appropriate communication to the contractors as to what needs to be installed. The more complex a design becomes, the more likely there is to be construction errors. Most smoke control systems are complex, which is why special inspections in accordance with Section 909.3 and Chapter 17 of the IBC are critical for smoke control systems. Additionally, in order for the design to be accepted, analyses and justifications need to be provided in enough detail to evaluate for compliance. Adequate documentation is critical to the commissioning, inspection, testing and maintenance of smoke control systems and significantly contributes to the overall reliability and effectiveness of such systems.

**909.3 Special inspection and test requirements.** In addition to the ordinary inspection and test requirements that buildings, structures and parts thereof are required to undergo, smoke control systems subject to the provisions of Section 909 shall undergo special inspections and tests sufficient to verify the proper commissioning of the smoke control design in its final installed condition. The design submission accompanying the *construction documents* shall clearly detail procedures and methods to be used and the items subject to such inspections and tests. Such commissioning shall be in accordance with generally accepted engineering practice and, where possible, based on published standards for the particular testing involved. The special inspections and tests

required by this section shall be conducted under the same terms as in Section 1704 of the *International Building Code*.

❖ Due to the complexity and uniqueness of each design, special inspection and testing must be conducted. The designer needs to provide specific recommendations for special inspection and testing within his or her documentation. In fact, the code specifies in Chapter 17 of the IBC that special inspection agencies for smoke control have expertise in fire protection engineering, mechanical engineering and certification as air balancers. Since the designs are unique to each building, there probably will not be a generic approach available to inspect and test such systems. The designer can and should, however, use any available published standards or guides when developing the special inspection and testing requirements for that particular design. ICC’s *Guide to Smoke Control in the 2006 IBC* provides some background on such inspections. Also, ASHRAE Guideline 5 is a good starting place but only as a general outline. In addition, NFPA 92A and NFPA 92B also have extensive testing, documentation and maintenance requirements that may be a good resource. NFPA 92B is referenced in Section 909.8 for the design of smoke control systems using the exhaust method. Each system will require a unique commissioning plan that can be developed only after careful and thoughtful examination of the final design and all of its components and interrelationships. Generally, these provisions may be included in design standards or engineering guides.

**909.4 Analysis.** A rational analysis supporting the types of smoke control systems to be employed, the methods of their operations, the systems supporting them and the methods of construction to be utilized shall accompany the *construction documents* submission and include, but not be limited to, the items indicated in Sections 909.4.1 through 909.4.7.

❖ This section indicates that simply determining airflow, exhaust rates and pressures to maintain tenable conditions is not adequate. There are many factors that could alter the effectiveness of a smoke control system, including stack effect, temperature effect of fire, wind effect, heating, ventilating and air-conditioning (HVAC) system interaction and climate, as well as the placement, quantity of inlets/outlets and velocity of supply and exhaust air. These factors are addressed in the sections that follow. Additionally, the duration of operation of any smoke control system is mandated at a minimum of 20 minutes or 1.5 times the egress time, whichever is less. The code cannot reasonably anticipate every conceivable building arrangement and condition the building may be subject to over its life and must depend on such factors being addressed through a rational analysis.

**909.4.1 Stack effect.** The system shall be designed such that the maximum probable normal or reverse stack effect will not adversely interfere with the system’s capabilities. In deter-

mining the maximum probable stack effect, altitude, elevation, weather history and interior temperatures shall be used.

❖ Stack effect is the tendency for air to rise within a heated building when the temperature is colder on the exterior of the building. Reverse stack effect is the tendency for air to flow downward within a building when the interior is cooler than the exterior of the building. This air movement can affect the intended operation of a smoke control system. If stack effect is great enough, it may overcome the pressures determined during the design analyses and allow smoke to enter areas outside the zone of origin (see Commentary Figure 909.4.1).

**909.4.2 Temperature effect of fire.** Buoyancy and expansion caused by the design fire in accordance with Section 909.9 shall be analyzed. The system shall be designed such that these effects do not adversely interfere with the system’s capabilities.

❖ This section requires that the design account for the effect temperature may have on the success of the system. When air or any gases are heated, they will expand. This expansion makes the gases lighter and, therefore, more buoyant. The buoyancy of hot gases is important when the design is to exhaust such gases from a location in or close to the ceiling; therefore, if sprinklers are part of the design, as required by Section 909, the gases may be significantly cooler than an unsprinklered fire, making it more difficult to remove the smoke and alter the plume dynamics. The fact that air expands when heated needs to be accounted for in the design.

When using the pressurization method, the expansion of hot gases needs to be accounted for, since it will take a larger volume of air to create the necessary pressure differences to maintain the area of fire origin in negative pressure. The expansion of the gases has the effect of pushing the hot gases out of the area of fire origin. Since sprinklers will tend to cool the gases, the effect of expansion is lower. The pressure differences required in Section 909.6.1 are

specifically based on a sprinklered building. If the building is nonsprinklered, higher pressure differences may be required. The minimum pressure difference for certain unsprinklered ceiling height buildings is as follows:

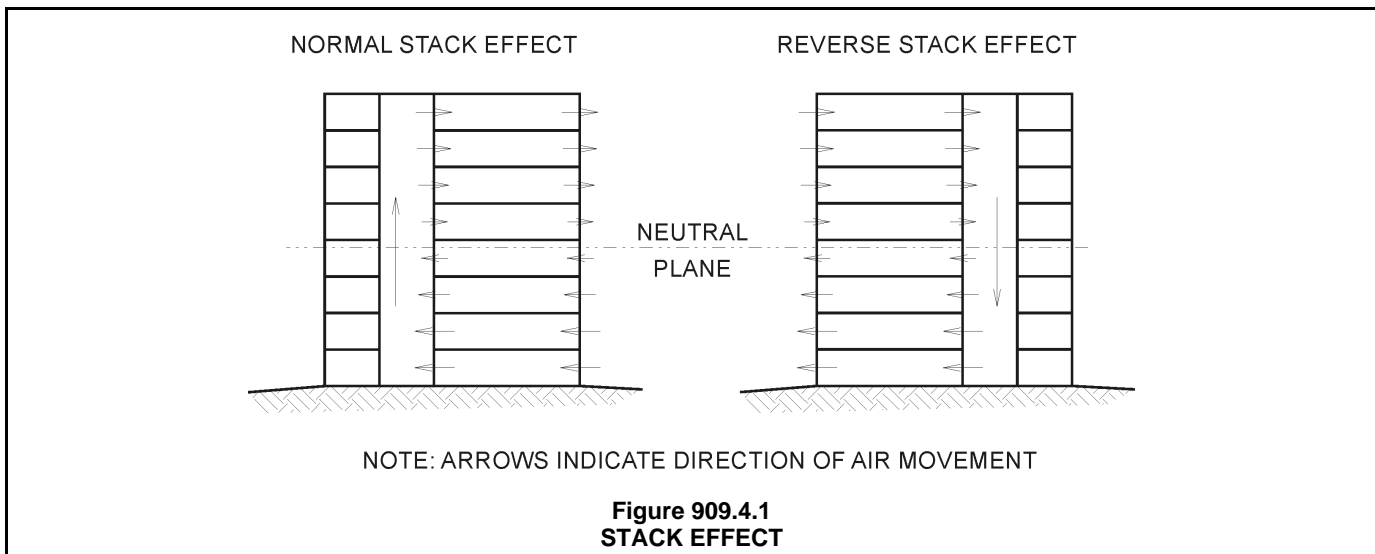

Ceiling height (feet)	Minimum pressure difference (inch water gage)
9	0.10
15	0.14
21	0.18

This is a very complex issue that needs to be part of the design analysis. It needs to address the type and reaction of the fire protection systems, ceiling heights and the size of the design fire.

**909.4.3 Wind effect.** The design shall consider the adverse effects of wind. Such consideration shall be consistent with the wind-loading provisions of the *International Building Code*.

❖ The effect of wind on a smoke control system within a building is very complex. It is generally known that wind exerts a load upon a building. The loads are looked at as windward (positive pressure) and leeward (negative pressure). The velocity of winds will vary based on the terrain and the height above grade; therefore, the height of the building and surrounding obstructions will have an effect on these velocities. These pressures alter the operation of fans, especially propeller fans, thus altering the pressure differences and airflow direction in the building. There is not an easy solution to dealing with these effects. In fact, little research has been done in this area.

It should be noted that in larger buildings a wind study is normally undertaken for the structural design. The data from those studies can be used in the analysis of the effects on the pressures and airflow within the building with regard to the performance of the smoke control system.

**909.4.4 Systems.** The design shall consider the effects of the heating, ventilating and air-conditioning (HVAC) systems on both smoke and fire transport. The analysis shall include all permutations of systems status. The design shall consider the effects of the fire on the heating, ventilating and air-conditioning systems.

❖ If not properly configured to shut down or be included as part of the design, the HVAC system can alter the smoke control design. More specifically, if dampers are not provided between smoke zones within the HVAC system ducts, smoke could be transported from one zone to another. Additionally, if the HVAC system places more supply air than assumed for the smoke control system design, the velocity of the air may adversely affect the fire plume or a positive pressure may be created. Generally, an analysis of the smoke control design and the HVAC system in all potential modes should occur and be noted within the design documentation as well as incorporated into inspection, testing and maintenance procedures. This is critical as these systems need to be maintained and tested to help ensure that they operate and shut down systems as required.

**909.4.5 Climate.** The design shall consider the effects of low temperatures on systems, property and occupants. Air inlets and exhausts shall be located so as to prevent snow or ice blockage.

❖ This section is focused on properly protecting equipment from weather conditions that may affect the reliability of the design. For instance, extremely cold or hot air may damage critical equipment within the system when pulled directly from the outside. Some listings of duct smoke detectors are for specific temperature ranges; therefore, placing such detectors within areas exposed to extreme temperatures may void the listing. Also, the equipment and air inlets and outlets should be designed and located so as to not collect snow and ice that could block air from entering or exiting the building.

**909.4.6 Duration of operation.** All portions of active or engineered smoke control systems shall be capable of continued operation after detection of the fire event for a period of not less than either 20 minutes or 1.5 times the calculated egress time, whichever is greater.

❖ The intent of the smoke control provisions is to provide a tenable environment for occupants to either evacuate or relocate to a safe place. Evacuation and relocation activities include notifying occupants, possible investigation time for occupants, decision time and the actual travel time. In order to achieve this goal, the code has established 20 minutes or 1.5 times the calculated egress time, whichever is greater, as a minimum time for evacuation or relocation. Basically, this allows a designer to undertake an analysis to more closely determine the necessary time required. The code provides a safety factor of 1.5 times the egress time to account for uncertainty related to human behavior. It is stressed that the 20-

minute duration as well as the calculated egress time, whichever approach is chosen, begins after the detection of the fire event and notification to the building occupants to evacuate has occurred, since occupants need to be alerted before evacuation can occur. The calculation of evacuation time needs to include delays with notification and the start of evacuation (i.e., premovement time, etc.). It is stressed that the code states 20 minutes or 1.5 times the egress time, whichever is greater (i.e., 20 minutes is a minimum). Egress of occupants can be addressed through hand calculations or through the use of computerized egress models. Some of the more advanced models can address a variety of factors, including the building layout, different sizes of people, different movement speeds and different egress paths available. With these types of programs, the actual time can be even more precisely calculated. Of course it is cautioned that in many cases these models provide the optimal time for egress. The safety factor of 1.5 within the code is intended to address many of these uncertainties.

Note that this section applies to all types of smoke control designed in accordance with Section 909. Also, most smoke control systems will typically have the ability to run for much longer than 20 minutes as they are on standby power and may be able to continue to achieve the tenability goals.

System response as required in Section 909.17 needs to be accounted for when determining the ability of the smoke control system to keep the smoke layer interface at the appropriate level (see commentary, Section 909.17).

**909.4.7 Smoke control system interaction.** The design shall consider the interaction effects of the operation of multiple smoke control systems for all design scenarios.

❖ The focus of this section is related to the interaction of multiple mechanical smoke control systems by asking for a specific analysis of the interaction of such systems similar to that required for the interaction of HVAC systems. Where hoistway pressurization is chosen as an option for compliance with the hoistway opening protection requirements, the potential exists for a pressurized stair system to also be present. These two systems need to be able to operate at the same time without a negative impact on either system. It is also possible that an atrium with a smoke control system is located in a building containing a stair pressurization system.

**909.5 Smoke barrier construction.** *Smoke barriers* required for passive smoke control and a smoke control system using the pressurization method shall comply with Section 709 of the *International Building Code*. *Smoke barriers* shall be constructed and sealed to limit leakage areas exclusive of protected openings. The maximum allowable leakage area shall be the aggregate area calculated using the following leakage area ratios:

1. Walls:  $A/A_w = 0.00100$

2. Interior *exit stairways* and *ramps* and *exit passageways*:  $A/A_w = 0.00035$
3. Enclosed *exit access stairways* and *ramps* and all other shafts:  $A/A_w = 0.00150$
4. Floors and roofs:  $A/A_F = 0.00050$

where:

$A$  = Total leakage area, square feet ( $m^2$ ).

$A_F$  = Unit floor or roof area of barrier, square feet ( $m^2$ ).

$A_w$  = Unit wall area of barrier, square feet ( $m^2$ ).

The leakage area ratios shown do not include openings due to gaps around doors and operable windows. The total leakage area of the *smoke barrier* shall be determined in accordance with Section 909.5.1 and tested in accordance with Section 909.5.2.

❖ Part of the strategy of smoke control systems, particularly smoke control systems using the pressurization method (often termed zoned smoke control) is the use of smoke barriers to divide a building into separate smoke zones (or compartments). This strategy is used in both passive and mechanical systems. It should be noted that not all walls, ceilings or floors would be considered smoke barriers. Only walls that designate separate smoke zones within a building need to be constructed as smoke barriers. This section is simply providing requirements for walls, floors and ceilings that are used as smoke barriers. It should be noted that it is possible that a smoke control system utilizing the exhaust method may not need to utilize a smoke barrier to divide the building into separate smoke zones; therefore, the evaluation of barrier construction and leakage area may not be necessary and as noted are primarily focused on designs using the pressurization method.

In order for smoke to not travel from one smoke zone to another, specific construction requirements are necessary in accordance with the code. It should be noted that openings such as doors and windows are dealt with separately within Section 909.5.3 from openings such as cracks or penetrations.

**909.5.1 Total leakage area.** Total leakage area of the barrier is the product of the *smoke barrier* gross area multiplied by the allowable leakage area ratio, plus the area of other openings such as gaps around doors and operable windows.

❖ It is impossible for walls and floors to be constructed that are completely free from openings that may allow the migration of smoke; therefore, leakage needs to be compensated for within the design by calculating the leakage area of walls, ceilings and floors. The factors provided in Section 909.5, which originate from ASHRAE's provisions on leaky buildings, are used to calculate the total leakage area. The total leakage area is then used in the design process to determine the proper amount of air to create the required pressure differences across these surfaces that form smoke zones.

Additionally, Section 909.5 provides ratios to determine the maximum allowable leakage in walls, interior

exit stairways, shafts, floors and roofs. These leakage areas are critical in determining whether the proper pressure differences are provided when utilizing the pressurization method of smoke control. Pressure differences will decrease as the openings get larger.

**909.5.2 Testing of leakage area.** Compliance with the maximum total leakage area shall be determined by achieving the minimum air pressure difference across the barrier with the system in the smoke control mode for mechanical smoke control systems utilizing the pressurization method. Compliance with the maximum total leakage area of passive smoke control systems shall be verified through methods such as door fan testing or other methods, as *approved* by the *fire code official*.

❖ These leakage criteria need to be evaluated through testing. For the case of a pressurization system, pressure differences need to be verified when the system is in smoke control mode. In the case of passive smoke control systems, pressure testing through tests such as the door fan method is necessary.

**909.5.3 Opening protection.** Openings in *smoke barriers* shall be protected by automatic-closing devices actuated by the required controls for the mechanical smoke control system. Door openings shall be protected by fire door assemblies complying with Section 716.5.3 of the *International Building Code*.

**Exceptions:**

1. Passive smoke control systems with automatic-closing devices actuated by spot-type smoke detectors *listed* for releasing service installed in accordance with Section 907.3.
2. Fixed openings between smoke zones that are protected utilizing the airflow method.
3. In Group I-1 Condition 2, Group I-2 and ambulatory care facilities, where a pair of opposite-swinging doors are installed across a corridor in accordance with Section 909.5.3.1, the doors shall not be required to be protected in accordance with Section 716 of the *International Building Code*. The doors shall be close-fitting within operational tolerances and shall not have a center mullion or undercuts in excess of  $3/4$ -inch (19.1 mm) louvers or grilles. The doors shall have head and jamb stops and astragals or rabbets at meeting edges and, where permitted by the door manufacturer's listing, positive-latching devices are not required.
4. In Group I-2 and ambulatory care facilities, where such doors are special-purpose horizontal sliding, accordion or folding door assemblies installed in accordance with Section 1010.1.4.3 and are automatic closing by smoke detection in accordance with Section 716.5.9.3 of the *International Building Code*.
5. Group I-3.
6. Openings between smoke zones with clear ceiling heights of 14 feet (4267 mm) or greater and bank-

down capacity of greater than 20 minutes as determined by the design fire size.

- ❖ Similar to concerns of smoke leakage between smoke zones, openings may compromise the necessary pressure differences between smoke zones. Openings in smoke barriers, such as doors and windows, must be either constantly or automatically closed when the smoke control system is operating. This section requires that doors be automatically closed through the activation of an automatic closing device linked to the smoke control system. Essentially, when the smoke control system is activated, all openings are automatically closed. This most likely would mean that the mechanism that activates the smoke control system would also automatically close all openings. The smoke control system will be activated by a specifically zoned smoke detection or sprinkler system as required by Sections 909.12.3 and 909.12.4.

In terms of actual opening protection, Section 909.5.2 is simply referring the user to Section 716.5.3 of the IBC for specific construction requirements for doors located in smoke barriers. Note that smoke barriers are different from fire barriers, since the intended measure of performance is different. One is focused on fire spread from the perspective of heat, the other from the perspective of smoke passage. Smoke barriers do require a 1-hour fire-resistance rating.

There are several exceptions to this particular section. Exception 1 is specifically for passive systems. Passive systems, as noted, are systems in which there is no use of mechanical systems. Instead, the system operates primarily upon the configuration of barriers and layout of the building to provide smoke control. Passive systems can use spot-type detectors to close doors that constitute portions of a smoke barrier. Essentially, this means a full fire alarm system would not be required. Instead, single station detectors would be allowed to close the doors. Such doors would need to fail in the closed position if power is lost. The specifics as to approved devices would be found in NFPA 72.

Exception 2 is based on the fact that some systems take advantage of the opposed airflow method such that smoke is prevented from migrating past the doors. Therefore, since the design already accounts for potential smoke migration at these openings through the use of air movement, it is unnecessary to require the barrier to be closed.

Exception 3 is specifically related to the unique requirements for Group I-1 Condition 2, I-2 and ambulatory care occupancies. Essentially, a very specific alternative, which meets the functional needs of these occupancy types, is provided. Opposite swinging doors are allowed without meeting the specific requirements of Section 716. Note that Group I-2 and ambulatory care facilities do utilize the concept of smoke compartments which is a form of a passive smoke control system. The requirements of this sec-

tion are focused on openings in smoke barriers that need to close on activation of a pressurization system.

Exception 4 provides a specific allowance for horizontal sliding doors in Group I-2 Condition 2 occupancies and ambulatory care occupancies. These doors are commonly used in such occupancies and have very specific installation requirements in Section 1010.1.4.3. These doors are an alternative to pivoted or side-hinged swinging type doors. This exception does require compliance with Section 716.5.9.3 for automatic closing upon detection of smoke.

Exception 5 allows an exemption from the automatic-closing requirements for all Group I-3 occupancies. This is related to the fact that facilities that have occupants under restraint or with specific security restrictions have unique requirements in accordance with Section 408 of the code. These requirements accomplish the intent of providing reliable barriers between each smoke zone since, for the most part, such facilities will have a majority of doors closed and in a locked position due to the nature of the facility. The staff very closely controls these types of facilities.

Exception 6 relates to the behavior of smoke. The assumption is that smoke rises due to the buoyancy of hot gases, and if the ceiling is sufficiently high, the smoke layer will be contained for a longer period of time before it begins to move into the next smoke zone. Therefore, it is not as critical that the doors automatically close. This allowance is dependent on the specific design fire for a building. See Section 909.9 for more information on design fire determination. Different size design fires create different amounts of smoke that, depending on the layout of the building, may migrate in different ways throughout the building. This section mandates that smoke cannot begin to migrate into the next smoke zone for at least 20 minutes. This is consistent with the 20-minute minimum duration of operation of smoke control systems required in Section 909.4.6. It should be noted that a minimum of 14-foot (4267 mm) ceilings are required to take advantage of this exception. This exception would require an engineering analysis.

**909.5.3.1 Group I-1 Condition 2, Group I-2 and ambulatory care facilities.** In Group I-1 Condition 2, Group I-2 and ambulatory care facilities, where doors are installed across a corridor, the doors shall be automatic closing by smoke detection in accordance with Section 716.5.9.3 of the *International Building Code* and shall have a vision panel with fire-protection-rated glazing materials in fire-protection-rated frames, the area of which shall not exceed that tested.

- ❖ Part of the alternative allowed for horizontal sliding doors in Exception 3 of Section 909.5.3 for Group I-1 Condition 2, Group I-2 and ambulatory care facilities is the requirement that vision panels be provided. These vision panels need to be approved fire-protection-rated glazing and be within frames of a size that does not exceed the frame size that was used for testing of the glazing.

**909.5.3.2 Ducts and air transfer openings.** Ducts and air transfer openings are required to be protected with a minimum Class II, 250°F (121°C) smoke damper complying with Section 717 of the *International Building Code*.

❖ Another factor that adds to the reliability of smoke barriers is the protection of ducts and air transfer openings within smoke barriers. Left open, these openings may allow the transfer of smoke between smoke zones. These ducts and air transfer openings most often are part of the HVAC system. Damper operation and the reaction with the smoke control system will be evaluated during acceptance testing. It should be noted that there are duct systems used within a smoke control design that are controlled by the smoke control system and should not automatically close upon detection of smoke via a smoke damper.

It should be noted that a smoke damper works differently than a fire damper. Fire dampers react to heat via a fusible link, while smoke dampers activate upon the detection of smoke. The smoke dampers used should be rated as Class II, 250°F (121°C). The class of the smoke damper refers to its level of performance relative to leakage. The temperature rating is related to its ability to withstand the heat of smoke resulting from a fire. It should be noted that although smoke barriers are only required to utilize smoke dampers, there may be many instances where a fire damper is also required. For instance, the smoke barrier may also be used as a fire barrier. Also, Section 717.5.3 of the IBC would require penetration of shafts to contain both a smoke and fire damper. Therefore, in some cases both a smoke damper and fire damper would be required. There are listings specific to combination smoke and fire dampers.

More specific requirements about dampers can be found in Chapter 7 of the IBC and Chapter 6 of the IMC.

**909.6 Pressurization method.** The primary mechanical means of controlling smoke shall be by pressure differences across *smoke barriers*. Maintenance of a tenable environment is not required in the smoke-control zone of fire origin.

❖ There are several methods or strategies that may be used to control smoke movement. One of these methods is pressurization, wherein the system primarily utilizes pressure differences across smoke barriers to control the movement of smoke. Basically, if the area of fire origin maintains a negative pressure, then the smoke will be contained to that smoke zone. A typical approach used to obtain a negative pressure is to exhaust the fire floor. This is a fairly common practice in high-rise buildings. Interior exit stairways also utilize the concept of pressurization by keeping the interior exit stairways under positive pressure. The pressurization method in large open spaces, such as malls and atria, is impractical since it would take a large quantity of supply air to create the necessary pressure differences. It should be noted

that pressurization is mandated as the primary method for mechanical smoke control design but this is related to the primary methods historically used for smoke control in high rise buildings. Currently high-rise buildings do not require smoke control. Airflow and exhaust methods are only allowed when appropriate. The exhaust method is the most commonly applied method due to the use of the atrium provisions in Section 404.5 of the IBC.

The pressurization method does not require that tenable conditions be maintained in the smoke zone where the fire originates. Maintaining this area tenable would be impossible, based on the fact that pressures from the surrounding smoke zones would be placing a negative pressure within the zone of origin to keep the smoke from migrating.

Pressurization is used often with interior exit stairways. This method provides a positive pressure within the interior exit stairways to resist the passage of smoke. Stair pressurization is one method of compliance for stairways in high-rise or underground buildings where the floor surface is located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access or more than 30 feet (9144 mm) below the floor surface of the lowest level of exit discharge. It should be noted that there are two methods found in the code that address smoke movement—smokeproof enclosures or pressurized stairs. A smokeproof enclosure requires a certain fire-resistance rating along with access through a ventilated vestibule or an exterior balcony. The vestibule can be ventilated in two ways: using natural ventilation or mechanical ventilation as outlined in Sections 909.20.3 and 909.20.4 of the IBC. The pressurization method requires a sprinklered building and a minimum pressure difference of 0.15 inch (37 Pa) of water and a maximum of 0.35 inch (87 Pa) of water. These pressure differences are to be available with all doors closed under maximum stack pressures (see Sections 909.20 of the IBC and 1023.11 of the code for more details).

As noted, the pressurization method utilizes pressure differences across smoke barriers to achieve control of smoke. Sections 909.6.1 and 909.6.2 provide the criteria for smoke control design in terms of minimum and maximum pressure differences.

In summary, the pressurization method is used in two ways. The first is through the use of smoke zones where the zone of origin is exhausted, creating a negative pressure. The second is stair pressurization that creates a positive pressure within the stair to avoid the penetration of smoke. Note that the code allows the use of a smokeproof enclosure instead of pressurization.

**909.6.1 Minimum pressure difference.** The minimum pressure difference across a *smoke barrier* shall be 0.05-inch water gage (0.0124 kPa) in fully sprinklered buildings.

In buildings allowed to be other than fully sprinklered, the smoke control system shall be designed to achieve pressure

differences not less than two times the maximum calculated pressure difference produced by the design fire.

- ❖ The minimum pressure difference is established as 0.05-inch water gage (12 Pa) in fully sprinklered buildings. This particular criterion is related to the pressures needed to overcome buoyancy and the pressures generated by the fire, which include expansion. This particular criterion is based upon a sprinklered building. The pressure difference would need to be higher in a building that is not sprinklered. Additionally, the pressure difference needs to be provided based upon the possible stack and wind effects present.

**909.6.2 Maximum pressure difference.** The maximum air pressure difference across a *smoke barrier* shall be determined by required door-opening or closing forces. The actual force required to open *exit* doors when the system is in the smoke control mode shall be in accordance with Section 1010.1.3. Opening and closing forces for other doors shall be determined by standard engineering methods for the resolution of forces and reactions. The calculated force to set a side-hinged, swinging door in motion shall be determined by:

$$F = F_{dc} + K(WA\Delta P)/2(W - d) \quad \text{(Equation 9-1)}$$

where:

$A$  = Door area, square feet ( $m^2$ ).

$d$  = Distance from door handle to latch edge of door, feet (m).

$F$  = Total door opening force, pounds (N).

$F_{dc}$  = Force required to overcome closing device, pounds (N).

$K$  = Coefficient 5.2 (1.0).

$W$  = Door width, feet (m).

$\Delta P$  = Design pressure difference, inches of water (Pa).

- ❖ The maximum pressure difference is based primarily upon the force needed to open and close doors. The code establishes maximum opening forces for doors. This maximum opening force cannot be exceeded, taking into account the pressure differences across a doorway in a pressurized environment. Essentially, based on the opening force requirements of Section 1010.1.3, the maximum pressure difference can be calculated in accordance with Equation 9-1. In accordance with Chapter 10, the maximum opening force of a door has three components, including:

- Door latch release:  
Maximum of 15 pounds (67 N)
- Set door in motion:  
Maximum of 30 pounds (134 N)
- Swing to full open position:  
Maximum of 15 pounds (67 N)

Equation 9-1 is used to calculate the total force to set the door into motion when in the smoke control mode; therefore, the limiting criteria would be 30 pounds (134 N). It should be noted that although the accessibility requirements related to door opening

force are more restrictive in Section 404.2.8 of ICC A117.1 fire doors do not require compliance with these requirements.

### 909.6.3 Pressurized stairways and elevator hoistways.

Where stairways or elevator hoistways are pressurized, such pressurization systems shall comply with Section 909 as smoke control systems, in addition to the requirements of Section 909.21 of this code and Section 909.20 of the *International Building Code*.

- ❖ The purpose of this section is to clarify that pressurized stairways and pressurized hoistways are smoke control systems and must be addressed in the same way that a pressurization system in accordance with Section 909.6 addresses such systems. This would require compliance with various sections but in particular the requirements for a rational analysis in accordance with Section 909.4.

**909.7 Airflow design method.** Where *approved* by the *fire code official*, smoke migration through openings fixed in a permanently open position, which are located between smoke control zones by the use of the airflow method, shall be permitted. The design airflow shall be in accordance with this section. Airflow shall be directed to limit smoke migration from the fire zone. The geometry of openings shall be considered to prevent flow reversal from turbulent effects. Smoke control systems using the airflow method shall be designed in accordance with NFPA 92.

- ❖ This method is only allowed when approved by the fire code official. As the title states, this method utilizes airflow to avoid the migration of smoke across smoke barriers. This has been referred to as opposed airflow. Specifically, this method is suited for the protection of smoke migration through doors and related openings fixed in a permanently open position. This method consists of providing a particular velocity of air based upon the temperature of the smoke and the height of the opening. The temperature of the smoke will depend on the design fire that is established for the particular building. The higher the temperature of the smoke and the larger the opening, the higher the velocity necessary to maintain the smoke from migrating into the smoke zone. It should be noted that the airflow method seldom works for large openings, since the velocity to oppose the smoke becomes too high. This method tends to work better for smaller openings, such as pass-through windows. Reference is made to NFPA 92 to determine the minimum velocity required to limit smoke spread.

**909.7.1 Prohibited conditions.** This method shall not be employed where either the quantity of air or the velocity of the airflow will adversely affect other portions of the smoke control system, unduly intensify the fire, disrupt plume dynamics or interfere with exiting. In no case shall airflow toward the fire exceed 200 feet per minute (1.02 m/s). Where the calculated airflow exceeds this limit, the airflow method shall not be used.

- ❖ The airflow method has a limitation on maximum velocity. This limitation is because air may distort the

flame and cause additional entrainment and turbulence; therefore, having a high velocity of air entering the zone of fire origin has the potential of increasing the amount of smoke produced. The velocity may also interact with other portions of the smoke control design. For instance, the pressure differences in other areas of the building may be altered, which may exceed the limitations of Sections 909.6.1 and 909.6.2. This section requires that when a velocity of over 200 feet per minute (1.02 m/sec) is calculated, the airflow method is not allowed. The solution may result in requiring a barrier such as a wall or door.

If the airflow design method is chosen to protect areas communicating with an atrium, the air added to the smoke layer needs to be accounted for in the exhaust rate.

**909.8 Exhaust method.** Where *approved* by the fire code official, mechanical smoke control for large enclosed volumes, such as in atriums or malls, shall be permitted to utilize the exhaust method. Smoke control systems using the exhaust method shall be designed in accordance with NFPA 92.

❖ This method is only allowed when approved by the building official. The primary application of the exhaust method is in large spaces, such as atriums and malls and is the most widely used method in the IBC. The strategy of this method is to keep the smoke layer at a certain level within the space. This is primarily accomplished through exhausting smoke. The amount of exhaust depends upon the design fire [see Commentary Figure 909.8(1)]. Essentially, fires produce different amounts and properties of smoke based on the material being burned, size of the fire and the placement of the fire; therefore, NFPA 92 is referenced for the design of such systems. NFPA 92

presents several ways to address the control of smoke, which includes the use of the following tools:

- Scale Modeling (Small scale testing)—Utilizes the concept of scaling to allow small scale tests to be conducted to understand the smoke movement within a space.
  - Benefits—More realistic understanding of smoke movement in spaces with unusual configurations or projections than algebraic calculations.
  - Disadvantages—Expensive and the application of results is limited to the uniqueness of the space being analyzed.
- Algebraic Calculations—Empirically derived (based upon testing) modeling in its simplest form.
  - Benefits—Simple, cost-effective analysis.
  - Disadvantages—Limited applicability due to the range of values they were derived from, only appropriate with certain types of design fires, typically over conservative outputs that increase equipment needs, equipment costs and can impact aesthetics and architectural design.
- Computer Modeling [Computational fluid dynamics (CFD) or zone models]—Combination of theory and empirical values to determine the smoke movement and fire induced conditions within a space and effectiveness of the smoke control system.
  - Benefits—More realistic understanding of smoke movement in spaces with unusual configurations or projections and less expensive than scale modeling. Helps sig-

nificantly in designing smoke control systems tailored to spaces and achieving cost-effective designs, and can help limit the impact to architectural design.

- Disadvantages—Computing time and cost can be longer than algebraic calculations but benefits typically outweigh this disadvantage. Early planning is important and can limit these adverse impacts.

In terms of computer modeling, as noted, there are essentially two methods that include zone models and CFD models. Zone models are based upon the unifying assumption that in any room or space where the effects of the fire are present there are distinct layers (hot upper layer, cool lower layer). In real life such distinct layers do not exist. Some examples of zone models used in such applications include Consolidated Model of Fire Growth And Smoke Transport (C-FAST) and Available Safe Egress Time (ASET). See Section 3-7 of the *SFPE Handbook of Fire Protection Engineering* for further information. CFD models take this much further and actually divide the space into thousands or millions of interconnected “cells” or “fields.” The model then evaluates the fire dynamics and heat and mass in each individual cell and how it interacts with those adjacent to it. The use of such models becomes more accurate with more numerous and smaller cells but the computing power and expertise required is much higher than for zone models. As noted the use of either types of models can be advantageous but such use must be undertaken by someone qualified. Proper review and verification of the input and output is critical. The most popular model in the area of CFD with regard to fire is the Fire Dynamics Simulator

(FDS) developed by NIST. Other models such as Fluent are sometimes used (Fluent Inc.).

Depending upon the space being evaluated some design strategies may provide a better evaluated approach than others. Past editions of the IBC smoke control provisions for the exhaust method mandated the use of the algebraic methods with a steady fire. This of course also mandated a mechanical system be used whereas NFPA 92 allows an overall review of smoke layer movement and whether the design goals, which in this case are mandated by the code, can be met. Therefore, if it can be shown that the smoke layer interface can be held at the 6 feet (1829 mm) as mandated in Section 909.8.1 for the design operation time required by Section 909.4.6 without mechanical ventilation then the space would comply with Section 909. NFPA 92 presents several design approaches. This allows more flexibility in design than that found in previous editions of the IBC.

NFPA 92B as a standard does not set the minimum smoke layer interface height or duration for system operation. Such criteria is found within Sections 909.8.1 and 909.4.6, respectively. See the commentary for those sections.

If the algebraic approach is used, consideration of three types of fire plumes may be required to determine which one is the most demanding in terms of smoke removal needs based upon the space being assessed. They include:

Axisymmetric plumes—Smoke rises unimpeded by walls, balconies or similar projections [see Commentary Figure 909.8(2)].

Balcony spill plumes—Smoke flows under and around edges of a horizontal projection [see Commentary Figure 909.8(3)].

Window plumes—Smoke flows through an opening into a large-volume space [see Commentary Figure 909.8(4)].

It should be noted that prior to the reference to NFPA 92 in the code, the balcony spill and window plume calculations had been eliminated from the smoke control requirements of the code due to concerns with the applicability of those calculations. The major difference is that NFPA 92 does not mandate the use of such equations as did previous editions of the IBC. The use of such equations will depend upon the design fires agreed upon for the particular design and whether an algebraic approach is chosen. These equations are used to determine a mass flow rate of smoke to ultimately determine the required exhaust volume for that space. If the potential for a balcony or window spill plumes are known to exist within the space, then appropriate measures need to be taken to address these, as they typically result in more onerous exhaust and supply requirements. Part of the reason for the initial deletion of these equations was the fact that such scenarios are not as likely or their impact is significantly reduced in sprinklered buildings. There is also some concern with the applicability of the balcony spill plume equation in a variety of applications. These potential fire scenarios and resulting plumes may further the need to undertake a CFD analysis to address such hazards more appropriately and effectively.

Another key aspect that NFPA 92 included within the algebraic methods is equations to determine that a minimum number of exhaust inlets are available to prevent plugholing. Plugholing occurs when air from below the smoke layer is pulled through the smoke

layer into the smoke exhaust inlets. As such, if plugholing occurs, some of the fan capacity is used to exhaust air rather than smoke and thus can affect the ability to maintain the smoke layer at or above the design height. Scale modeling and computer fire modeling would demonstrate these potential problems during the testing and analysis, respectively [see Commentary Figure 909.8(5)].

It should be noted that this section specifically references NFPA 92 for the design of smoke control using the exhaust method. Therefore the

Figure 909.8(4)  
WINDOW PLUME

Figure 909.8(5)  
PLUGHOLING

requirements in NFPA 92 related to testing, documentation and maintenance would not be applicable though they may be a good resource. Equipment and controls would be part of the design; therefore, related provisions of NFPA 92 would apply. Generally the IBC addresses equipment and controls in a similar fashion.

**909.8.1 Smoke layer.** The height of the lowest horizontal surface of the smoke layer interface shall be maintained not less than 6 feet (1829 mm) above a walking surface that forms a portion of a required egress system within the smoke zone.

❖ The design criteria to be used when applying NFPA 92B is to maintain the smoke layer interface at least 6 feet (1829 mm) above any walking surface that is considered part of the required egress within the particular smoke zone, such as an atrium, for 20 minutes or 1.5 times the calculated egress time (see Section 909.4.6). Chapter 10 considers the majority of occupiable space as part of the means of egress system. Also keep in mind that the criteria of 6 feet (1829 mm) does not apply just to the main floor surface of the mall or atrium but to any level where occupants may be exposed (for example, balconies) see Commentary Figure 909.8.1(1).

The code uses the terminology “lowest horizontal surface of the accumulating smoke layer interface.”

NFPA 92 has several definitions related to smoke layer, which include the following:

**Smoke layer.** The accumulated thickness of smoke below a physical or thermal barrier.

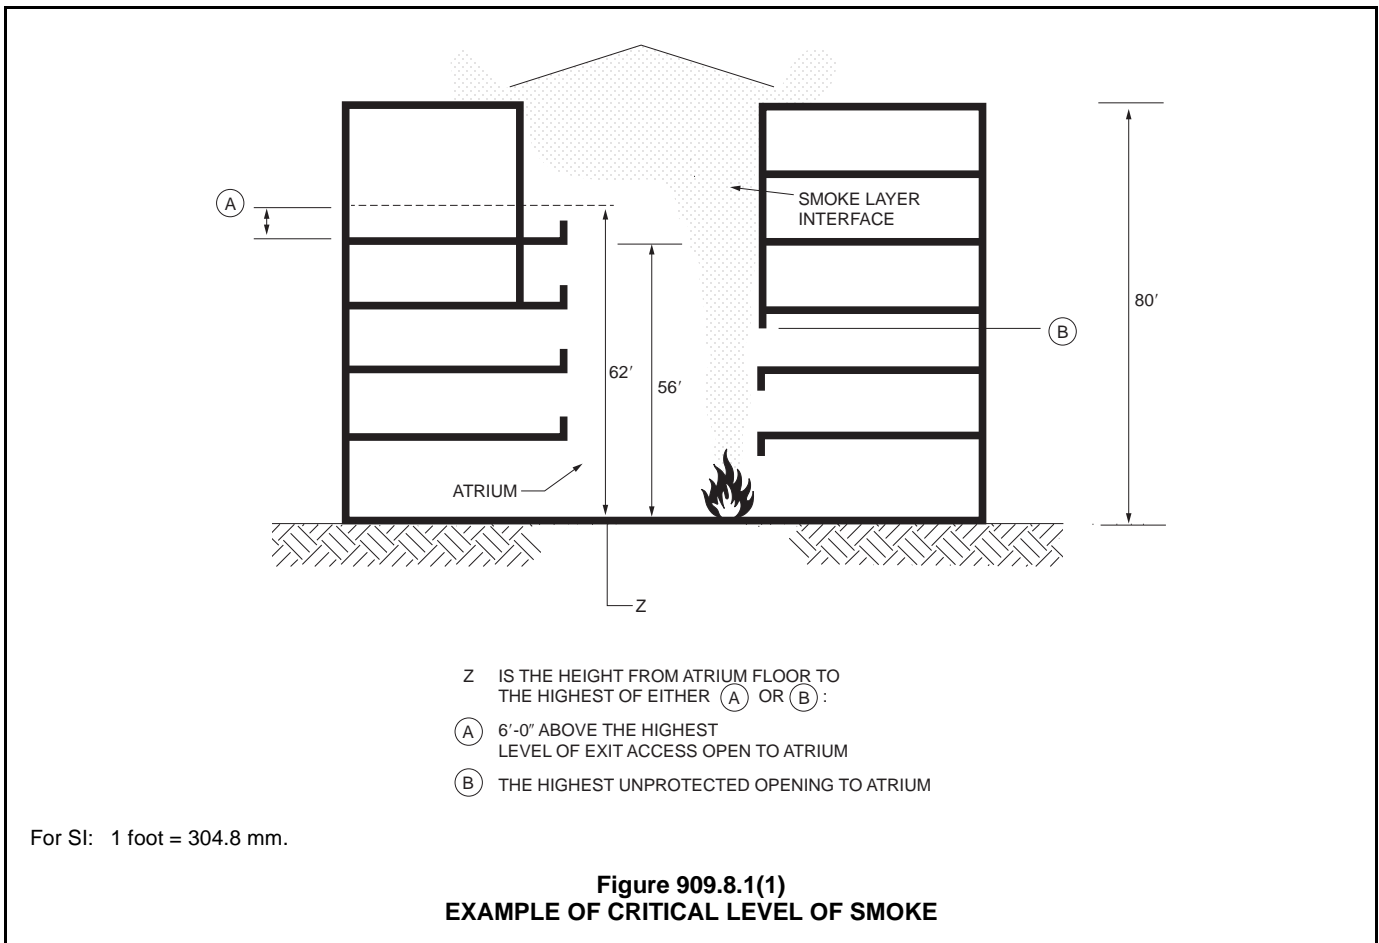

**Smoke layer interface.** The theoretical boundary between a smoke layer and the smoke-free air. (Note: This boundary is at the beginning of the transition zone.)

**First indication of smoke.** The boundary between the transition zone and the smoke-free air.

**Transition zone.** The layer between the smoke layer interface and the first indication of smoke in which the smoke layer temperature decreases to ambient.

The transition zone may be several feet thick (large open space) or may barely exist (small area with intense fire) [see also Commentary Figure 909.8.1(2)].

NFPA 92 provides algebraic equations to determine first indication of smoke but is limited to very specific conditions such as a uniform cross section, specific aspect ratios, steady or unsteady fires and no smoke exhaust operating. When using algebraic equations for smoke layer interface looking

at different types of plumes the smoke layer interface terminology is used and the user enters the desired smoke layer interface height. Zone models use simplifying assumptions so the layers are distinct from one another. In contrast, when CFD or scale modeling is used, the data must be analyzed to verify that the smoke layer interface is located at or above the 6 feet (1829 mm) during the event. This is not a simple analysis as CFD and scale modeling provide more detail on actual smoke behavior; therefore, the location of the smoke layer interface may not be initially clear without some level of analysis. Again it depends on the depth of the transition layer. This may require reviewing tenability within the transition zone. Tenability limits need to be agreed upon by the stakeholders involved. Using CFD or scale modeling would likely need to occur through the alternative methods and materials section (Section 104.9) due to the need to review tenability limits. It should be noted that NFPA 92 Annex A suggests that there are methods to determine where the smoke layer interface and first indication of smoke are located when undertaking CFD and scale modeling using a limited number of point measurements.

Also, Section 909.8.1 specifies a minimum distance for the smoke layer interface from any walking surface whereas Section 4.5.4.2 of NFPA 92 has provisions that simply allows the analysis to demonstrate tenability regardless of where the layer height is located above the floor. Defining tenability can be more difficult as there is not a standard definition as to what is considered tenable. Any design using that approach would need to be addressed through Section 104.9.

Note that the response time of the system

components (detection, activation, ramp up time, shutting down HVAC, opening/closing doors and dampers, etc.) needs to be accounted for when analyzing the location of the smoke layer interface in relation to the duration of operations stated in Section 909.4.6 (see commentary, Section 909.17).

**909.9 Design fire.** The design fire shall be based on a rational analysis performed by the registered design professional and approved by the fire code official. The design fire shall be based on the analysis in accordance with Section 909.4 and this section.

❖ The design fire is the most critical element in the smoke control system design. The fire is what produces the smoke to be controlled by the system; thus, the size of the fire directly impacts the quantity of smoke being produced. This section ensures that the design fire be determined through a rational analysis by a registered design professional with knowledge in this area. Such professionals should have experience in the area of fire dynamics, fire engineering and general building design, including mechanical systems. When determining the design fire, the designer should work with various stakeholders to determine the types of hazards and combustible materials (fire scenarios) on a permanent as well as temporary basis (i.e., Christmas/holiday decorative materials or scenery, temporary art exhibits) that may be present throughout the use of the building once occupied. Those hazards then need to be translated to potential design fires to be used when determining the smoke layer interface height for the duration as determined by Section 909.4.6. See the commentary for Section 909.9.3 for potential sources when determining design fires.

This section also does not mandate the type of fire

**Figure 909.8.1(2)**  
**SMOKE LAYER INTERFACE**

(i.e., steady versus unsteady). A steady fire assumes a constant heat release rate over a period of time, where unsteady fires do not. An unsteady fire includes the growth and decay phases of the fire, as well as the peak heat release rate. An unsteady fire will hit a peak heat release rate when burning in the open, like an axisymmetric fire. An unsteady fire is a more realistic view of how fires actually burn. It should be noted that fires can be a combination of unsteady and steady fires when the sufficient fuel is available. In other words, the fire initially grows (unsteady) then reaches a steady state and burns for sometime at a particular heat release rate before decay occurs.

Design fire information should therefore typically include growth rate, peak heat release rate, duration and decay as well as information related to fire locations and products of combustion yield (CO, smoke, etc.) that are produced by the various design fires that are deemed credible for the space.

To provide an order of magnitude of fire sizes obtained from various combustibles, the following data from fire tests is provided. The following heat release rates, found in Section 3, Chapter 3-1 of the 4th edition of the *SFPE Handbook of Fire Protection Engineering*, are peak heat release rates:

Plastic trash bags/paper trash:

Approximately 120-350 kw

Latex foam pillow:

Approximately 120 kw

Dry Douglas fir Christmas tree:

Approximately 3000 kw at 20 percent moisture

Polyurethane foam (PVC Ticking material) Mattress:

approximately 2630 kw

Plywood wardrobe:

approximately 2900-6,400 kw

**909.9.1 Factors considered.** The engineering analysis shall include the characteristics of the fuel, fuel load, effects included by the fire and whether the fire is likely to be steady or unsteady.

❖ This section simply provides more detail on the factors that should be taken under consideration when determining the design fire size. To determine the appropriate fire size, an engineering analysis is necessary that takes into account the following elements: fuel (potential burning rates), fuel load (how much), effects included by the fire (smoke particulate size and density), steady or unsteady (burn steadily or simply peak and dissipate) and likelihood of sprinkler activation (based on height and distance from the fire).

**909.9.2 Design fire fuel.** Determination of the design fire shall include consideration of the type of fuel, fuel spacing and configuration.

❖ The design fire size may also be affected by surrounding combustibles, which may have the effect of increasing the fire size. More specifically, there is

concern that if sufficient separation is not maintained between combustibles, then a larger design fire is likely. The code does not provide extensive detail on this as such determination is left to the rational analysis undertaken by the design professional. NFPA 92B provides one method in which you determine the critical separation distance,  $R$ . This is based upon fire size and the critical radiant heat flux for nonpiloted ignition. Nonpiloted ignition means the radiated heat from the fire without direct flame contact will ignite adjacent combustibles.

**909.9.3 Heat-release assumptions.** The analysis shall make use of best available data from *approved* sources and shall not be based on excessively stringent limitations of combustible material.

❖ This section is merely stressing the fact that data obtained for use in a rational analysis needs to come from relevant and appropriate sources. Data can be obtained from groups such as the NIST or from Annex B of NFPA 92B. Data from fire tests is available and is a good resource for such analysis. As noted earlier, such data is not prevalent [see also Chapter 8 (“Analysis of Design Fires”) of the *Guide to Smoke Control in the 2006 IBC* and Section 3, Chapter 3-1 of the *SFPE Handbook of Fire Protection Engineering*].

**909.9.4 Sprinkler effectiveness assumptions.** A documented engineering analysis shall be provided for conditions that assume fire growth is halted at the time of sprinkler activation.

❖ This section raises a few questions regarding activation of sprinklers and their impact on the fire both in terms of their ability to “control” as well as “extinguish” a fire. The first is concerning an assumption that sprinklers will immediately control the fire as soon as they are activated (i.e., control results in limiting further growth and maintaining the heat release rate at approximately the same fire size as when the sprinklers activated). This assumption may be true in some cases, but for high ceilings the sprinkler may not activate or may be ineffective. Sprinklers may be ineffective in high spaces, since by the time they are activated the fire is too large to control. Essentially, the fire plume may push away and evaporate the water before it actually reaches the seat of the fire. Additionally the fire may be shielded from sprinkler spray so that insufficient quantities of water reach the fuel. These are common problems with high-piled storage as well as other fires including retail and has been shown in actual tests. Also, if the fire becomes too large before the sprinklers are activated, the available water supply and pressure for the system may be compromised. Additionally, based on the layout of the room and the movement of the fire effluents, the wrong sprinklers could be activated, which leads to a larger fire size and depletion of the available water supply and pressure.

Another issue is whether the sprinklers “control” or “extinguish” the fire. Typical sprinklers are assumed

only to control fires as opposed to extinguishing them. Sprinklers may be able to extinguish the fire, but it should not automatically be assumed. A fire that is controlled will achieve steady state and maintain a certain fire size, which is very different from a fire that is actually extinguished.

Based upon these concerns, each scenario needs to be looked at individually to determine whether sprinklers would be effective in halting the growth or extinguishing the fire. More specifically, the evaluation should include droplet size, density and area of coverage and should also be based on actual test results.

**909.10 Equipment.** Equipment including, but not limited to, fans, ducts, automatic dampers and balance dampers shall be suitable for their intended use, suitable for the probable exposure temperatures that the rational analysis indicates, and as approved by the fire code official.

❖ Section 909.10 and subsequent sections are primarily related to the reliability of the system components to provide a smoke control system that works according to the design. One of the largest concerns when using smoke control provisions is the overall reliability of the system. Such systems have many different components, such as smoke and fire dampers; fans; ducts and controls associated with such components. The more components a system has, the less reliable it becomes. In fact, one approach in providing a higher level of reliability is utilizing the normal building systems such as the HVAC to provide the smoke control system. Basically, systems used every day are more likely to be working appropriately, since they are essentially being tested daily; however, there are many components that are specific to the smoke control system, such as exhaust fans in an atrium or the smoke control panel.

Also, there is not a generic prescriptive set of requirements as to how all smoke control system elements should operate, since each design may be fairly unique. The specifics on operation of such a system need to be included within the design and construction documents. Most components used in smoke control systems are elements used in many other applications such as HVAC systems; therefore, the basic mechanisms of a fan used in a smoke control system may not be different, although they may be applied differently.

**909.10.1 Exhaust fans.** Components of exhaust fans shall be rated and certified by the manufacturer for the probable temperature rise to which the components will be exposed. This temperature rise shall be computed by:

$$T_s = (Q_c/mc) + (T_a) \quad \text{(Equation 9-2)}$$

where:

$c$  = Specific heat of smoke at smoke layer temperature, Btu/lb°F • (kJ/kg • K).

$m$  = Exhaust rate, pounds per second (kg/s).

$Q_c$  = Convective heat output of fire, Btu/s (kW).

$T_a$  = Ambient temperature, °F (K).

$T_s$  = Smoke temperature, °F (K).

**Exception:** Reduced  $T_s$  as calculated based on the assurance of adequate dilution air.

❖ Fans used for smoke control systems must be able to tolerate the possible elevated temperatures to which they will be exposed. Again, like many other factors this depends upon the specifics of the design fire. Essentially, Equation 9-2 requires the calculation of the potential temperature rise. The exhaust fans must be specifically rated and certified by the manufacturer to be able to handle these rises in temperature. There is an exception that allows reduction of the temperature if it can be shown that adequate temperature reduction will occur. In many cases if the exhaust fans are near the ceiling, the smoke will be much cooler than the value resulting from Equation 9-2 since the smoke may cool considerably by the time it reaches the ceiling. Also, sprinkler activation will assist in cooling the smoke further.

**909.10.2 Ducts.** Duct materials and joints shall be capable of withstanding the probable temperatures and pressures to which they are exposed as determined in accordance with Section 909.10.1. Ducts shall be constructed and supported in accordance with the *International Mechanical Code*. Ducts shall be leak tested to 1.5 times the maximum design pressure in accordance with nationally accepted practices. Measured leakage shall not exceed 5 percent of design flow. Results of such testing shall be a part of the documentation procedure. Ducts shall be supported directly from fire-resistance-rated structural elements of the building by substantial, noncombustible supports.

**Exception:** Flexible connections, for the purpose of vibration isolation, complying with the *International Mechanical Code* and that are constructed of approved fire-resistance-rated materials.

❖ The next essential component of a smoke control system is the integrity of the ducts to transport supply and exhaust air. The integrity of ducts is also important for an HVAC system, but is more critical in this case since it is not simply a comfort issue but one of life safety. The key concern with ducts in smoke control systems is that they can withstand elevated temperatures and that there will be minimal leakage. The concern with leakage is the potential of leaking smoke into another smoke zone or not providing the proper amount of supply air to support the system.

More specifically, all ducts need to be leak tested to 1.5 times the maximum static design pressure. The leakage resulting should be no more than 5 percent of the design flow. For example, a duct that has a design flow of 300 cubic feet per minute (cfm) (0.141 m<sup>3</sup>/s) would be allowed 15 cfm (0.007 m<sup>3</sup>/s) of leakage when exposed to a pressure equal to 1.5 times the design pressure for that duct. The tests should be

in accordance with nationally accepted practices. This criterion will often limit ductwork for smoke control systems to lined systems, since the amount of leakage in such systems is much less.

As part of the concern for possible exposure to fire and fire products, the ducts are required to be supported by way of substantial noncombustible supports connected to the fire-resistance-rated structural elements of the building. As noted, the system needs to be able to run for 20 minutes starting from the detection of the fire. The supports are allowed to be other than noncombustible when they are flexible connections provided to mitigate the effects of vibration, perhaps as part of a building exposed to seismic loads. The flexible connections still need to be constructed of approved fire-resistance-rated materials.

NFPA 92B also references NFPA 90A for ducts conveying smoke and is part of the design requirements for exhaust systems.

As part of the concern for possible exposure to fire and fire products, the ducts are required to be supported by way of substantial noncombustible supports connected to the fire-resistance-rated structural elements of the building. As noted, the system needs to be able to run for 20 minutes starting from the detection of the fire. The exception to this section is really more of an acknowledgement that flexible connections for vibration isolation are acceptable when constructed of approved fire-resistance-rated materials. More specifically, it is often necessary to use such connections for connecting the duct to the fan. These connections cannot necessarily meet the requirements of the main section, but are a minimal part of the ductwork and as long as they perform adequately with regard to fire resistance they are permitted. Note that the term "approved" is used to determine the required fire resistance, therefore, flexibility is provided. The code does not specifically address this determination but perhaps a relationship to the duration or operation and these flexible connections could be made to determine the necessary performance.

**909.10.3 Equipment, inlets and outlets.** Equipment shall be located so as to not expose uninvolved portions of the building to an additional fire hazard. Outside air inlets shall be located so as to minimize the potential for introducing smoke or flame into the building. Exhaust outlets shall be so located as to minimize reintroduction of smoke into the building and to limit exposure of the building or adjacent buildings to an additional fire hazard.

❖ The intent of this section is to minimize the likelihood of smoke being reintroduced into the building due to poorly placed outdoor air inlets and exhaust air outlets; therefore, placing one right next to another on the exterior of the building would be inappropriate. Additionally, wind and other adverse conditions should be considered when choosing locations for these inlets and outlets. Particular attention should be paid to introducing exhausted smoke into another smoke zone. Also, smoke should be exhausted in a

direction that will not introduce it into surrounding buildings or facilities. Within the building itself, the supply air and exhaust outlets should also be strategically located. The exhaust inlets and supply air should be evenly distributed to reduce the likelihood of a high velocity of air that may disrupt the fire plume and also push smoke back into occupied areas. See the commentary for Section 909.8 for discussion on avoiding plugholing.

**909.10.4 Automatic dampers.** Automatic dampers, regardless of the purpose for which they are installed within the smoke control system, shall be *listed* and conform to the requirements of *approved* recognized standards.

❖ This section addresses the reliability of any dampers used within a smoke control system. This particular provision requires that the dampers be listed and conform to the appropriate recognized standards. More specifically, Section 717 of the IBC contains more detailed information on the specific requirements for smoke and fire dampers. Smoke and fire dampers should be listed in accordance with UL 555S and 555, respectively. Also, remember that each smoke control design is unique and the sequence and methods used to activate the dampers may vary from design to design. This information needs to be addressed in the construction documents.

Another factor to take into account, with regard to timing of the system, is the fact that some dampers react more quickly than others, simply due to the particular smoke damper characteristics. Additionally, during the commissioning of the system, the damper is going to be exposed to many repetitions. These repetitions need to be accounted for in the overall reliability of the system.

**909.10.5 Fans.** In addition to other requirements, belt-driven fans shall have 1.5 times the number of belts required for the design duty with the minimum number of belts being two. Fans shall be selected for stable performance based on normal temperature and, where applicable, elevated temperature. Calculations and manufacturer's fan curves shall be part of the documentation procedures. Fans shall be supported and restrained by noncombustible devices in accordance with the structural design requirements of Chapter 16 of the *International Building Code*.

Motors driving fans shall not be operated beyond their nameplate horsepower (kilowatts) as determined from measurement of actual current draw and shall have a minimum service factor of 1.15.

❖ Part of the overall reliability requires that fans used to provide supply air and exhaust capacity will be functioning when necessary; therefore, a safety factor of 1.5 is placed upon the required belts for fans. All fans used as part of a smoke control system must provide 1.5 times the number of required belts with a minimum of two belts for all fans.

This section also points out that the fan chosen should fit the specific application. It should be able to

withstand the temperature rise as calculated in Section 909.10.1 and generally be able to handle typical exposure conditions, such as location and wind. For instance, propeller fans are highly sensitive to the effects of wind. When located on the windward side of a building, wall-mounted, nonhooded propeller fans are not able to compensate for wind effects. Additionally, even hooded propeller fans located on the leeward side of the building may not adequately compensate for the decrease in pressure caused by wind effects. In general, when designing a system, it should be remembered that field conditions might vary from the calculations; therefore, flexibility should be built into the design that would account for things, such as variations in wind conditions.

Finally, this section stresses that fan motors not be operated beyond their rated horsepower.

**909.11 Standby power.** Smoke control systems shall be provided with standby power in accordance with Section 604.

❖ This section references Section 604 for the specifics as to what is required for standby power. As with any life safety system, a level of redundancy with regard to power supply is required to enable the functioning of the system during a fire. The primary source is the building's normal power system. The secondary power system is by means of standby power. One of the key elements is that standby power systems are intended to operate within 60 seconds of loss of primary power. It should be noted that the primary difference between standby power and emergency power is that emergency power must operate within 10 seconds of loss of primary power versus 60 seconds.

**909.11.1 Equipment room.** The standby power source and its transfer switches shall be in a room separate from the normal power transformers and switch gears and ventilated directly to and from the exterior. The room shall be enclosed with not less than 1-hour fire barriers constructed in accordance with Section 707 of the *International Building Code* or horizontal assemblies constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ This section requires isolation from normal building power systems via a 1-hour fire barrier, 1-hour horizontal assembly, or both, depending upon the location within the building. This increases the reliability and reduces the likelihood that a single event could remove both power supplies. The intent of the ventilation is focused on the proper function of the standby power source in terms of engine-driven generators having appropriate cooling air and combustion air. The requirement that it be from the outside is related to the protection of such ventilation from the effects of the fire.

**909.11.2 Power sources and power surges.** Elements of the smoke control system relying on volatile memories or the like shall be supplied with uninterruptible power sources of sufficient duration to span 15-minute primary power interruption. Elements of the smoke control system susceptible to power

surges shall be suitably protected by conditioners, suppressors or other *approved* means.

❖ Smoke control systems have many components, sometimes highly sensitive electronics, that are adversely affected by any interruption in or sudden surges of power. Therefore, Section 909.11.1 requires that any components of a smoke control system, such as volatile memories, be supplied with an uninterruptible power system for the first 15 minutes of loss of primary power. Volatile memory components will lose memory upon any loss of power no matter how short the time period. Once the 15 minutes elapses, these elements can be transitioned to the already operating standby power supply.

With regard to components sensitive to power surges, they need to be provided with surge protection in the form of conditioners, suppressors or other approved means.

**909.12 Detection and control systems.** Fire detection systems providing control input or output signals to mechanical smoke control systems or elements thereof shall comply with the requirements of Section 907. Such systems shall be equipped with a control unit complying with UL 864 and *listed* as smoke control equipment.

❖ This section is focused on proper monitoring of the fire detection systems that activate the smoke control system through compliance with Section 907 and UL 864. This requires a specific listing of the fire alarm control unit as smoke control equipment. UL 864 has a subcategory (UUKL) specific to fire alarm control panels for smoke control system applications.

**909.12.1 Verification.** Control systems for mechanical smoke control systems shall include provisions for verification. Verification shall include positive confirmation of actuation, testing, manual override and the presence of power downstream of all disconnects. A preprogrammed weekly test sequence shall report abnormal conditions audibly, visually and by printed report. The preprogrammed weekly test shall operate all devices, equipment, and components used for smoke control.

**Exception:** Where verification of individual components tested through the preprogrammed weekly testing sequence will interfere with, and produce unwanted effects to, normal building operation, such individual components are permitted to be bypassed from the preprogrammed weekly testing, where *approved* by the *fire code official* and in accordance with both of the following:

1. Where the operation of components is bypassed from the preprogrammed weekly test, presence of power downstream of all disconnects shall be verified weekly by a listed control unit.
2. Testing of all components bypassed from the preprogrammed weekly test shall be in accordance with Section 909.20.6.

❖ This section addresses the function of the mechanical elements of the smoke control system once the

system is activated. In particular, there is a focus on verification of activities. Verification would include the following two aspects:

1. The system is able to verify actuations, testing, manual overrides and the presence of power downstream. This would require information reported back to the smoke control panel, which can be accomplished via the weekly test sequence or through full electronic monitoring of the system.
2. Conduct a preprogrammed weekly test that simulates an actual (smoke) event to test the components of the system. These components would include elements such as smoke dampers, fans and doors. Abnormal conditions need to be reported in three ways:
  - a. Audibly;
  - b. Visually; and
  - c. Printed report.

It should be noted that electrical monitoring of the control components is not required (supervision). Such supervision verifies integrity of the conductors from a fire alarm control unit to the control system input. The weekly test is considered sufficient verification of system performance and is often termed end-to-end verification. In other words, the control system input provides the expected results. Verification can be accomplished through any sensor that is calibrated to distinguish between the difference between proper operation and a fault condition. For fans, proper operation means that the fan is moving air within the intent of its design. Fault conditions include power failure, broken fan belts, adverse wind effects, a locked rotor condition and/or filters or large ducts that are blocked causing significantly reduced airflow. In addition to differential pressure transmitters and sail switches, this can be accomplished by the present state of the art current sensors. More discussion on verification for elements such as ducts and fire doors is discussed in Chapter 9 of *A Guide to Smoke Control in the 2006 IBC*.

Also, the fact that a smoke control system is non-dedicated (integrated with an HVAC system) does not mean that it is automatically being tested on a daily basis. It is cautioned that simply depending on occupant discomfort, for example, is sometimes an insufficient indicator of a fully functioning smoke control system. There may be various modes in which the HVAC system could operate that may not exercise the smoke control features and the sequence in which the system should operate. An example is an air-conditioning system operating only in full recirculating mode versus exhaust mode. This failure will likely not affect occupants and will not exercise the exhaust function. Plus, doors, which may be part of the smoke barrier, may not need to be closed in normal building operations but would need to be closed

during smoke control system operation. This is why this section does not necessarily differentiate between dedicated and non-dedicated smoke control systems and requires the system components to be tested.

It is important to note that this weekly test sequence is not an actual smoke event and is only intended to activate the system to ensure that the components are working correctly.

The exception addresses the impracticality of requiring a weekly test for many buildings. For many systems, the weekly test requires the introduction of untreated air into the smoke zone. This can be impractical in areas with cold or hot climates, and for buildings that require close control of temperature and humidity, such as art museums and similar facilities. The introduction of the untreated air can also result in wasting energy to reheat, recool, humidify, or dehumidify the smoke control zone.

The intent of the exception is to provide means to verify that the required systems will be available when needed. The code requires control units to comply with UL 864, thus all components of the control system will be supervised. The exception includes requirements for verification of the power downstream of all disconnects such as power breakers, power disconnects, automatic transfer switches, motor starters, and motor controls. This will provide reasonable assurance that power will be available for all smoke control components, such as fans, dampers, doors, and windows. The exception also adds the semiannual requirement for a complete system test by reference to Section 909.20.6. This allows the building owner to schedule complete system testing on days that will reduce the impact to the building and energy needs. The combination of additional supervision and additional testing provides a reasonable alternative to weekly testing.

**909.12.2 Wiring.** In addition to meeting requirements of NFPA 70, all wiring, regardless of voltage, shall be fully enclosed within continuous raceways.

❖ Wiring is required to be placed within continuous raceways which provides an additional level of reliability for the system. The definition of the term “raceway” in NFPA 70 lists several acceptable types of complying raceway that can be used, however manufactured cable assemblies such as metal-clad cable (Type MC) or armored cable (Type AC) are not included.

**909.12.3 Activation.** Smoke control systems shall be activated in accordance with this section.

❖ The activation of a smoke control system is dependent on when such a system is required. Mechanical smoke control systems, which could include pressurization, airflow or exhaust methods, require an automatic activation mechanism. When using a passive system, which depends upon compartmentation, spot-type detectors are acceptable for the release of door closers and similar openings. Whereas with

more complex mechanical systems such activation needs to go beyond single station detectors and be part of an automatic coordinated system.

**909.12.3.1 Pressurization, airflow or exhaust method.**

Mechanical smoke control systems using the pressurization, airflow or exhaust method shall have completely automatic control.

❖ Automatic activation of such systems is especially critical as tenability is much more difficult to achieve if a delay occurred waiting for manual activation of the system. See Sections 909.6 for the pressurization method, 909.7 for the airflow design method and 909.8 for the exhaust method.

**909.12.3.2 Passive method.** Passive smoke control systems actuated by *approved* spot-type detectors *listed* for releasing service shall be permitted.

❖ This section recognizes that a passive system does not address smoke containment through mechanical means; therefore, it does not need to be “automatically activated” except in cases where smoke barriers have openings. These openings would be required to have smoke detectors to close openings where required by the design. Although spot type detectors are technically automatic they are not part of a more coordinated system of activation as needed for mechanical smoke control systems. Such detectors are simply standalone devices that fail in the fail safe position. In other words if the power were lost a door on a magnetic hold would simply close.

**909.12.4 Automatic control.** Where completely automatic control is required or used, the automatic-control sequences shall be initiated from an appropriately zoned *automatic sprinkler system* complying with Section 903.3.1.1, manual controls that are readily accessible to the fire department and any smoke detectors required by the engineering analysis.

❖ When automatic activation is required, it must be accomplished by a properly zoned automatic sprinkler system and, if the engineering analysis requires them, smoke detectors. Manual control for the fire department needs to be provided. An important point with this particular requirement is that smoke control systems are engineered systems and a prescribed smoke detection system may not fit the needs of the specific design. Other types of detectors, such as beam detectors (within an atrium), may be used and could be more useful and be more practical from a maintenance standpoint. Also, it may not be practical or appropriate for the building’s fire alarm system to activate such systems as it may alter the effectiveness of the system by pulling smoke through the building versus removing or containing the smoke. For example, a building with an atrium may have several floors below the space. If a fire occurs in one of the floors not associated with the atrium the atrium smoke control system could possibly pull smoke throughout the building if the detection is zoned incorrectly.

**909.13 Control air tubing.** Control air tubing shall be of sufficient size to meet the required response times. Tubing shall be flushed clean and dry prior to final connections and shall be adequately supported and protected from damage. Tubing passing through concrete or masonry shall be sleeved and protected from abrasion and electrolytic action.

❖ Control tubing is a method that uses pneumatics to operate components such as the opening and closing of dampers. Due to the sophistication of electronic systems today, control tubing is becoming less common.

These particular requirements provide the criteria for properly designing and installing control tubing. Essentially, it is up to the design professional to determine the size requirements and to properly design appropriate supports. This information needs to be detailed within the construction documents. Additionally, due to the effect of moisture and other contaminants on control tubing, it must be flushed clean then dried before installation.

**909.13.1 Materials.** Control air tubing shall be hard drawn copper, Type L, ACR in accordance with ASTM B 42, ASTM B 43, ASTM B 68, ASTM B 88, ASTM B 251 and ASTM B 280. Fittings shall be wrought copper or brass, solder type, in accordance with ASME B 16.18 or ASME B 16.22. Changes in direction shall be made with appropriate tool bends. Brass compression-type fittings shall be used at final connection to devices; other joints shall be brazed using a BCuP5 brazing alloy with solidus above 1,100°F (593°C) and liquidus below 1,500°F (816°C). Brazing flux shall be used on copper-to-brass joints only.

**Exception:** Nonmetallic tubing used within control panels and at the final connection to devices, provided all of the following conditions are met:

1. Tubing shall comply with the requirements of Section 602.2.1.3 of the *International Mechanical Code*.
2. Tubing and the connected device shall be completely enclosed within a galvanized or paint-grade steel enclosure having a minimum thickness of 0.0296 inch (0.7534 mm) (No. 22 gage). Entry to the enclosure shall be by copper tubing with a protective grommet of neoprene or Teflon or by suitable brass compression to male-barbed adapter.
3. Tubing shall be identified by appropriately documented coding.
4. Tubing shall be neatly tied and supported within the enclosure. Tubing bridging cabinets and doors or moveable devices shall be of sufficient length to avoid tension and excessive stress. Tubing shall be protected against abrasion. Tubing serving devices on doors shall be fastened along hinges.

❖ This section addresses the materials allowed for control air tubing along with approved methods of connection. All of this information needs to be documented, as it will be subject to review by the special inspector.

**909.13.2 Isolation from other functions.** Control tubing serving other than smoke control functions shall be isolated by automatic isolation valves or shall be an independent system.

- ❖ This section requires separation of control tubing used for other functions through the use of isolation valves or a completely separate system. This is due to the difference in requirements for control tubing used in a smoke control system versus other building systems. The isolation of the control air tubing for a smoke control system needs to be specifically noted on the construction documents.

**909.13.3 Testing.** Control air tubing shall be tested at three times the operating pressure for not less than 30 minutes without any noticeable loss in gauge pressure prior to final connection to devices.

- ❖ As part of the acceptance testing of the smoke control system, the control air tubing will be pressure tested three times the operating pressure for 30 minutes or more. The performance criteria as to whether the control tubing is considered a failure is when there is any noticeable loss in gauge pressure prior to final connection of devices during the 30-minute duration test.

**909.14 Marking and identification.** The detection and control systems shall be clearly marked at all junctions, accesses and terminations.

- ❖ This section requires that all portions of the fire detection system that activate the smoke control system be marked and identified appropriately. This includes all applicable fire alarm-initiating devices, the respective junction boxes, all data-gathering panels and fire alarm control panels. Additionally, all components of the smoke control system, which are not considered a fire detection system, are required to be properly identified and marked. This would include all applicable junction boxes, control tubing, temperature control modules, relays, damper sensors, automatic door sensors and air movement sensors.

**909.15 Control diagrams.** Identical control diagrams showing all devices in the system and identifying their location and function shall be maintained current and kept on file with the *fire code official*, the fire department and in the *fire command center* in a format and manner *approved* by the fire chief.

- ❖ The purpose of control diagrams is to provide consistent information on the system in several key locations, including the building department, the fire department and the fire command center. If a fire command center is not required or provided, the diagrams need to be located such that they can be readily accessed during an emergency. Some possible locations may be the security office, the building manager's office or, if possible, within the smoke control panel. This information is intended to assist in the use and operation of the smoke control system. The format of the control diagram is as approved by the fire

chief. This is necessary since the fire department is the agency that will be using such a system during a fire and when the system is tested in the future. The more clearly the information is communicated, the more effective the smoke control system will be.

It should be noted that the fire department may want all smoke control systems within a jurisdiction to follow a particular protocol for control diagrams. Generally, the control diagrams should indicate the required reaction of the system in all scenarios. The status or position of every fan and damper in every scenario must be clearly identified.

**909.16 Fire fighter's smoke control panel.** A fire fighter's smoke control panel for fire department emergency response purposes only shall be provided and shall include manual control or override of automatic control for mechanical smoke control systems. The panel shall be located in a *fire command center* complying with Section 508 in high-rise buildings or buildings with smoke-protected assembly seating. In all other buildings, the fire fighter's smoke control panel shall be installed in an *approved* location adjacent to the fire alarm control panel. The fire fighter's smoke control panel shall comply with Sections 909.16.1 through 909.16.3.

- ❖ One of the elements that makes a smoke control system effective is that its activity is successfully communicated to the fire department and the fire department is able to manually operate the system. The following sections provide requirements for a control panel specifically for smoke control systems. This panel is required to be located within a fire command center when it is located in a high-rise building or there is smoke-protected seating. Section 403.4.6 of the IBC would require a fire command center for high-rise buildings. Smoke-protected seating does not require a fire command center in Chapter 10 but this provision would ensure that one exists and contains the smoke control panel. Facilities with smoke-protected seating tend to be larger facilities that, at the very least, would already have a central security center if not a fire command center as required by the jurisdiction. All other locations would only need to provide the panel in an approved location as long as it is located with the fire alarm panel. The specific location will depend on the needs of the fire department in that jurisdiction. The reason not all fire-fighter smoke control panels need to be located in a fire command center is that many smoke control systems are located in a building containing an atrium that may only be three stories in height. A 200-square-foot (19 m<sup>2</sup>) fire command center would be excessive for such buildings. There are two components that include the requirements for the display and for the controls. This control panel will provide an ability to override any other controls whether manual or automatic within the building as they relate to the smoke control system.

Note that the publication *A Guide to Smoke Control in the 2006 IBC* goes into more detail about the fire fighter smoke control panel requirements.

**909.16.1 Smoke control systems.** Fans within the building shall be shown on the fire fighter’s control panel. A clear indication of the direction of airflow and the relationship of components shall be displayed. Status indicators shall be provided for all smoke control equipment, annunciated by fan and zone and by pilot-lamp-type indicators as follows:

1. Fans, dampers and other operating equipment in their normal status—WHITE.
2. Fans, dampers and other operating equipment in their off or closed status—RED.
3. Fans, dampers and other operating equipment in their on or open status—GREEN.
4. Fans, dampers and other operating equipment in a fault status—YELLOW/AMBER.

❖ This section denotes what should be displayed on the control panel. The display is required to include all fans, an indication of the direction of airflow and the relationship of the components. Also, status lights are required, and this section sets out specific standardized colors to indicate normal status, closed status, open status and fault status. A standardized approach increases the likelihood that the fire department will be able to quickly become familiar with a system. Since the fire department has the ability to override the automatic functions of the system, this information is critical.

**909.16.2 Smoke control panel.** The fire fighter’s control panel shall provide control capability over the complete smoke control system equipment within the building as follows:

1. ON-AUTO-OFF control over each individual piece of operating smoke control equipment that can also be controlled from other sources within the building. This includes *stairway* pressurization fans; smoke exhaust fans; supply, return and exhaust fans; elevator shaft fans; and other operating equipment used or intended for smoke control purposes.
2. OPEN-AUTO-CLOSE control over individual dampers relating to smoke control and that are also controlled from other sources within the building.
3. ON-OFF or OPEN-CLOSE control over smoke control and other critical equipment associated with a fire or smoke emergency and that can only be controlled from the fire fighter’s control panel.

**Exceptions:**

1. Complex systems, where *approved*, where the controls and indicators are combined to control and indicate all elements of a single smoke zone as a unit.
2. Complex systems, where *approved*, where the control is accomplished by computer interface using *approved*, plain English commands.

❖ This section sets the requirements as to which controls need to be provided for the fire department on the control panel.

There are two aspects to the controls. The controls will include on-auto-off and open-auto-close settings or will be strictly on-off or open-close. If the system or component can be set on automatic (auto), it can be controlled from other locations beyond the fire command center. This would include an automatic smoke detection system or by manual activation. If a control only contains on-off or open-close settings, the only way the system component can be controlled is in the fire command center.

It should be noted that components such as fans are usually associated with on-off-type controls, whereas components such as dampers are associated with open-close-type controls.

**909.16.3 Control action and priorities.** The fire fighter’s control panel actions shall be as follows:

1. ON-OFF and OPEN-CLOSE control actions shall have the highest priority of any control point within the building. Once issued from the fire fighter’s control panel, automatic or manual control from any other control point within the building shall not contradict the control action. Where automatic means are provided to interrupt normal, nonemergency equipment operation or produce a specific result to safeguard the building or equipment including, but not limited to, duct freezestats, duct smoke detectors, high-temperature cutouts, temperature-actuated linkage and similar devices, such means shall be capable of being overridden by the fire fighter’s control panel. The last control action as indicated by each fire fighter’s control panel switch position shall prevail. Control actions shall not require the smoke control system to assume more than one configuration at any one time.

**Exception:** Power disconnects required by NFPA 70.

2. Only the AUTO position of each three-position fire-fighter’s control panel switch shall allow automatic or manual control action from other control points within the building. The AUTO position shall be the NORMAL, nonemergency, building control position. Where a fire fighter’s control panel is in the AUTO position, the actual status of the device (on, off, open, closed) shall continue to be indicated by the status indicator described in Section 909.16.1. Where directed by an automatic signal to assume an emergency condition, the NORMAL position shall become the emergency condition for that device or group of devices within the zone. Control actions shall not require the smoke control system to assume more than one configuration at any one time.

❖ This section clarifies that when a component of the system is placed in an on-off or open-close configuration, no other control point in the building, whether automatic or manual, can override the action established in the fire command center. If a system component is configured in auto mode, it can be controlled from locations within the building beyond the fire command center. Some controls are specifically

designed to only allow an action from the fire command center.

**909.17 System response time.** Smoke-control system activation shall be initiated immediately after receipt of an appropriate automatic or manual activation command. Smoke control systems shall activate individual components (such as dampers and fans) in the sequence necessary to prevent physical damage to the fans, dampers, ducts and other equipment. For purposes of smoke control, the fire fighter's control panel response time shall be the same for automatic or manual smoke control action initiated from any other building control point. The total response time, including that necessary for detection, shutdown of operating equipment and smoke control system startup, shall allow for full operational mode to be achieved before the conditions in the space exceed the design smoke condition. The system response time for each component and their sequential relationships shall be detailed in the required rational analysis and verification of their installed condition reported in the required final report.

❖ This particular section provides the criteria as to when the smoke control system is required to begin operation. Whether or not the activation is manual or automatic, this criteria clarifies that the system be initiated immediately. Also, it requires that components activate in a sequence that will not potentially damage the fans, dampers, ducts and other equipment. Unrealistic timing of the system has the potential of creating an unsuccessful system. Delays in the system can be seen in slow dampers, fans that ramp up or down, systems that poll slowly and intentional built-in delays. These factors can add significantly to the reaction time of the system and may hamper achieving the design goals.

The key element is that the system be fully operational before the smoke conditions exceed the design parameters. The design should include these possible delays when analyzing the smoke layer interface location. The sequence of events need to be justified within the design analysis and described clearly in the construction documents.

**909.18 Acceptance testing.** Devices, equipment, components and sequences shall be individually tested. These tests, in addition to those required by other provisions of this code, shall consist of determination of function, sequence and, where applicable, capacity of their installed condition.

❖ In order to achieve a certain level of performance, the smoke control system needs to be thoroughly tested. Section 909.18 requires that all devices, equipment components and sequences be individually tested.

**909.18.1 Detection devices.** Smoke or fire detectors that are a part of a smoke control system shall be tested in accordance with Chapter 9 in their installed condition. Where applicable, this testing shall include verification of airflow in both minimum and maximum conditions.

❖ Detection devices are required to be tested in accordance with the fire protection requirements found in Chapter 9. Also, since such detectors may be subject to higher air velocities than typical detectors, their

operation needs to be verified in the minimum and maximum anticipated airflow conditions.

**909.18.2 Ducts.** Ducts that are part of a smoke control system shall be traversed using generally accepted practices to determine actual air quantities.

❖ This section requires ducts that are part of the smoke control system to be tested to show that the proper amount of air is flowing. It should be noted that Section 909.10.2 requires that the ducts be leak tested to 1.5 times the maximum design pressure. Such leakage is not allowed to exceed 5 percent of the design flow.

**909.18.3 Dampers.** Dampers shall be tested for function in their installed condition.

❖ This section notes that all dampers need to be inspected to meet the function for which they are installed. For instance, a damper that is to be open when the system is in smoke control mode should be verified to be open when testing the system. Also, a damper may have a specific timing associated with its operation that would need to be verified though testing.

**909.18.4 Inlets and outlets.** Inlets and outlets shall be read using generally accepted practices to determine air quantities.

❖ Similar to ducts, the appropriate amount of air that is entering or exiting the inlets and outlets, respectively, must be checked.

**909.18.5 Fans.** Fans shall be examined for correct rotation. Measurements of voltage, amperage, revolutions per minute and belt tension shall be made.

❖ This section requires the testing of fans for the following: correct rotation, voltage, amperage, revolutions per minute and belt tension. These features are key in having the system run as designed.

A common problem with fans is that they are often installed in the reverse direction. Also, to verify the reliability of the fans, elements such as the appropriate voltage and belt tension need to be tested.

**909.18.6 Smoke barriers.** Measurements using inclined manometers or other *approved* calibrated measuring devices shall be made of the pressure differences across *smoke barriers*. Such measurements shall be conducted for each possible smoke control condition.

❖ As discussed in Section 909.5.2, the testing of pressure differences across smoke barriers needs to be measured in the smoke control mode. As noted in Section 909.18.6, such testing is to be performed for every possible smoke control condition, and the measurements will be taken using an inclined manometer or other approved methods. Electronic devices are also available. Qualified individuals must calibrate these types of devices. Additionally, before using an alternative method of testing, the fire code official needs to approve such a method.

**909.18.7 Controls.** Each smoke zone equipped with an automatic-initiation device shall be put into operation by the actu-

ation of one such device. Each additional device within the zone shall be verified to cause the same sequence without requiring the operation of fan motors in order to prevent damage. Control sequences shall be verified throughout the system, including verification of override from the fire fighter's control panel and simulation of standby power conditions.

❖ This section requires the overall testing of the system. More specifically, each zone needs to individually initiate the smoke control system by the activation of an automatic initiation device. Once that has occurred, all other devices within each zone need to be verified that they will activate the system, but to avoid damage, the fans do not need to be activated.

In addition to determining that all the appropriate devices initiate the system, it must also be verified that all of the controls on the fire-fighter control panel initiate the appropriate aspects of the smoke control system, including the override capability.

Finally, the initiation and availability of the standby power system need to be verified.

**909.18.8 Testing for smoke control.** Smoke control systems shall be tested by a special inspector in accordance with Section 1705.18 of the *International Building Code*.

❖ Smoke control systems require special inspection since they are unique and complex life safety systems. Section 1705.18 of the IBC provides the same requirements for special inspection as presented in Sections 909.18.8.1 and 909.18.8.2.

**909.18.8.1 Scope of testing.** Testing shall be conducted in accordance with the following:

1. During erection of ductwork and prior to concealment for the purposes of leakage testing and recording of device location.
2. Prior to occupancy and after sufficient completion for the purposes of pressure-difference testing, flow measurements, and detection and control verification.

❖ Special inspections need to occur at two different stages during construction to facilitate the necessary inspections. The first round of special inspections occurs before concealment of the ductwork or fire protection elements. The special inspector needs to verify the leakage as noted in Section 909.10.2. Additionally, the location of all fire protection devices needs to be verified and documented at this time.

The second round of special inspections occurs just prior to occupancy. The inspections include the verification of pressure differences across smoke barriers as required in Sections 909.5.2 and 909.18.6, the verification of appropriate volumes of airflow as noted in the design and finally the verification of the appropriate operation of the detection and control mechanisms as required in Sections 909.18.1 and 909.18.7. These tests need to occur just prior to occupancy, since the test result will more clearly represent actual conditions. This also makes a robust design and quality assurance during construction critical as it is very costly and difficult in most cases to

make changes at this stage. Note that the test does not actually place smoke into the space and demonstrate the smoke layer interface location. Instead, the testing is focused on all the elements of the design such as airflow and duct closure as prescribed by the specific design.

**909.18.8.2 Qualifications.** *Approved* agencies for smoke control testing shall have expertise in fire protection engineering, mechanical engineering and certification as air balancers.

❖ As noted in Section 909.3, special inspections are required for smoke control systems. This means a certain level of qualification that would include the need for expertise in fire protection engineering, mechanical engineering and certification as air balancers.

**909.18.8.3 Reports.** A complete report of testing shall be prepared by the approved agency. The report shall include identification of all devices by manufacturer, nameplate data, design values, measured values and identification tag or mark. The report shall be reviewed by the responsible registered design professional and, when satisfied that the design intent has been achieved, the responsible registered design professional shall sign, seal and date the report.

❖ Once the testing by the special inspector is complete, documentation of the activity is required. This documentation is to be prepared in the form of a report that identifies all devices by manufacturer, nameplate data, design values, measured values and identification or mark.

**909.18.8.3.1 Report filing.** A copy of the final report shall be filed with the *fire code official* and an identical copy shall be maintained in an *approved* location at the building.

❖ The report needs to be reviewed, approved and then signed, sealed and dated. This report is to be provided to the building official and a copy is also to remain in the building in an approved location. When a fire command center is required this is the best location for such documents. Otherwise, a location such as the security office or building manager's office might be appropriate.

**909.18.9 Identification and documentation.** Charts, drawings and other documents identifying and locating each component of the smoke control system, and describing their proper function and maintenance requirements, shall be maintained on file at the building as an attachment to the report required by Section 909.18.8.3. Devices shall have an *approved* identifying tag or mark on them consistent with the other required documentation and shall be dated indicating the last time they were successfully tested and by whom.

❖ Additional documentation that needs to be maintained includes charts, drawings and other related documentation that assists in the identification of each aspect of the smoke control system. This documentation is where information, such as the last time a device or component was successfully tested and by whom, is recorded. This will serve as the main

documentation for the system. Again, the fire command center, if required, is the most appropriate location for such information (see commentary, Section 909.18.8.3.1).

**909.19 System acceptance.** Buildings, or portions thereof, required by this code to comply with this section shall not be issued a certificate of occupancy until such time that the *fire code official* determines that the provisions of this section have been fully complied with and that the fire department has received satisfactory instruction on the operation, both automatic and manual, of the system and a written maintenance program complying with the requirements of Section 909.20.1 has been submitted and *approved* by the *fire code official*.

**Exception:** In buildings of phased construction, a temporary certificate of occupancy, as *approved* by the *fire code official*, shall be allowed, provided that those portions of the building to be occupied meet the requirements of this section and that the remainder does not pose a significant hazard to the safety of the proposed occupants or adjacent buildings.

❖ This section stipulates that the certificate of occupancy cannot be issued unless the smoke control system has been accepted. It is essential that the system be inspected and approved since it is a life safety system. There is an exception for buildings that are constructed in phases where a temporary certificate of occupancy is allowed. For example, a building where the portion requiring smoke control is not yet occupied so egress concerns through that space are not relevant. This space needs to be separated by smoke barriers (different smoke zone). The code also requires a maintenance program for smoke control systems since the long-term success of such systems depends heavily on proper maintenance in addition to rigorous acceptance testing. The IBC simply provides a reference to that section of the code.

**909.20 Maintenance.** Smoke control systems shall be maintained to ensure to a reasonable degree that the system is capable of controlling smoke for the duration required. The system shall be maintained in accordance with the manufacturer's instructions and Sections 909.20.1 through 909.20.6.

❖ Routine maintenance and testing of smoke control systems is essential to ensure their performance, as designed, under fire conditions. Maintenance practices must be consistent with the manufacturer's recommendations and as indicated in Sections 909.20.1 through 909.20.5. Note that Section 909.12.1 requires weekly preprogrammed tests which report abnormal conditions.

**909.20.1 Schedule.** A routine maintenance and operational testing program shall be initiated immediately after the smoke control system has passed the acceptance tests. A written schedule for routine maintenance and operational testing shall be established.

❖ Operational testing and maintenance must be performed on the smoke control system periodically to

verify that it still operates as required by the approved design. A written schedule must be maintained.

**909.20.2 Records.** Records of smoke control system testing and maintenance shall be maintained. The record shall include the date of the maintenance, identification of the servicing personnel and notification of any unsatisfactory condition and the corrective action taken, including parts replaced.

❖ This section prescribes the desired content of the written record for the smoke control testing and maintenance program. Test results and maintenance activities should be clearly documented. The written record should be available for inspection and reviewed by the fire code official.

**909.20.3 Testing.** Operational testing of the smoke control system shall include all equipment such as initiating devices, fans, dampers, controls, doors and windows.

❖ Smoke control systems are made up of components and equipment that are an integral part of other building systems such as fire alarm systems, heating, ventilating and air-conditioning (HVAC) equipment and automatic sprinkler systems. For this reason, operational testing of all related system components must ensure that the system as a whole will perform as intended.

**909.20.4 Dedicated smoke control systems.** Dedicated smoke control systems shall be operated for each control sequence semiannually. The system shall be tested under standby power conditions.

❖ Because dedicated smoke control systems are designed for smoke control only, the operation of these systems does not adversely affect other building systems or operations. The control sequence for these systems must be tested semiannually to check for system component failures that may not get noticed because dedicated smoke control systems are independent of building HVAC systems.

**909.20.5 Nondedicated smoke control systems.** Non-dedicated smoke control systems shall be operated for each control sequence annually. The system shall be tested under standby power conditions.

❖ Contrary to dedicated smoke control systems identified in Section 909.20.4, smoke control systems that are not dedicated share system components with other building systems including the HVAC system. Consequently, testing of the control sequence of systems that are not dedicated can be done annually, rather than semiannually, because equipment failures related to other building systems would most likely be noticed and corrected when those other systems were tested or maintained.

Simply because a system is nondedicated does not guarantee that failures will be detected easier. This relates to the fact that when a system is in smoke control mode it may have very different demands than when simply operating as a traditional HVAC system (see commentary, Section 909.12).

**909.20.6 Components bypassing weekly test.** Where components of the smoke control system are bypassed by the pre-programmed weekly test required by Section 909.12.1, such components shall be tested semiannually. The system shall be tested under standby power conditions.

❖ This section is specifically linked to the exception in Section 909.12.1 that allows the elimination of the weekly test of the system. In order to allow the elimination of the weekly test, Section 909.12.1 provides additional monitoring features and requires more frequent testing of the overall system by a special inspector. This will primarily affect nondedicated systems which are currently only required to be tested annually. Dedicated systems are already required to be tested semiannually.

**[BF] 909.21 Elevator hoistway pressurization alternative.** Where elevator hoistway pressurization is provided in lieu of required enclosed elevator lobbies, the pressurization system shall comply with Sections 909.21.1 through 909.21.11.

❖ This section sets out the requirements for hoistway pressurization when used as a method to protect hoistway openings as required in Section 3006. The minimum and maximum pressures are similar to those for pressurized stairs in Section 909.20.5 of the IBC. The provisions are located in Section 909 to group all the smoke control techniques and requirements into the same section. This will promote more consistency in code application when addressing smoke control.

**[BF] 909.21.1 Pressurization requirements.** Elevator hoistways shall be pressurized to maintain a minimum positive pressure of 0.10 inch of water (25 Pa) and a maximum positive pressure of 0.25 inch of water (67 Pa) with respect to adjacent occupied space on all floors. This pressure shall be measured at the midpoint of each hoistway door, with all elevator cars at the floor of recall and all hoistway doors on the floor of recall open and all other hoistway doors closed. The pressure differential shall be measured between the hoistway and the adjacent elevator landing. The opening and closing of hoistway doors at each level must be demonstrated during this test. The supply air intake shall be from an outside, uncontaminated source located a minimum distance of 20 feet (6096 mm) from any air exhaust system or outlet.

**Exceptions:**

1. On floors containing only Group R occupancies, the pressure differential is permitted to be measured between the hoistway and a *dwelling unit* or *sleeping unit*.
2. Where an elevator opens into a lobby enclosed in accordance with Section 3007.6 or 3008.6 of the *International Building Code*, the pressure differential is permitted to be measured between the hoistway and the space immediately outside the door(s) from the floor to the enclosed lobby.

3. The pressure differential is permitted to be measured relative to the outdoor atmosphere on floors other than the following:

- 3.1. The fire floor.
- 3.2. The two floors immediately below the fire floor.
- 3.3. The floor immediately above the fire floor.

4. The minimum positive pressure of 0.10 inch of water (25 Pa) and a maximum positive pressure of 0.25 inch of water (67 Pa) with respect to occupied floors is not required at the floor of recall with the doors open.

❖ This section states the minimum and the maximum positive pressure that must be achieved by the smoke control mechanical pressurization system. The minimum positive pressure is 0.10 inch of water column (0.02 kPa), the same as required for stairway pressurization in Section 909.20.5 of the IBC. The maximum pressure is 0.25 inch of water column (0.06 kPa) which is a little less than the maximum allowed for stairway pressurization. The minimum pressure is to ensure that the stack effect is overcome and the maximum pressure is an upper limit to ensure that the doors will operate properly. This section requires a test when the system is complete. The pressures are measured at the midpoint of each hoistway door with all elevator cars at the recall floor and all the hoistway doors open on that level. This simulates the Phase I recall requirements in Section 3003.2 of the IBC. Hoistway doors are then tested on each level to ensure proper operation.

The supply air intake for the pressurization system must be located at least 20 feet (6096 mm) away from any source of contamination to ensure that the hoistway remains tenable through the fire event or well into it before the elevators can no longer be used. Also, if smoke is drawn into the supply air, the system will only spread smoke and not prevent fire spread.

There are four exceptions to the requirements of this section. The first two provide exceptions as to where the pressure differential can be measured. Exception 3 allows the pressure differences only to be measured at the fire floor and several designated floors. Finally, Exception 4 allows the pressure differential measurement to be omitted for the floor of recall.

The first three exceptions originated from the City of Seattle, WA which has had a long history of requiring pressurized hoistways in high rise buildings to prevent smoke migration. In 2005, the City of Seattle Department of Planning & Development (DPD) convened a committee which included representatives from the industry, the Seattle Fire Department and DPD, to decide whether to recommend changes to

the high-rise smoke migration control requirements in place at that time. The committee also consulted with Dr. John Klote, who suggested the approach that Seattle eventually adopted with some small modifications. These requirements are an adaptation of the Seattle approach.

During the 2009/2010 code change cycle, a proposal was made to delete the hoistway pressurization requirements in the IBC without substitution (FS51-09/10), based on a study conducted by Drs. Miller and Beasley. This study showed that requiring the pressure differential of 0.10 inches of water column to be maintained at the recall floor with the elevator doors in the open position resulted in over-pressurization of all the other floors—meaning the current standards in the code cannot be met. Based on further modeling by Dr. Miller, the proponent for FS51-09/10 submitted a public comment introducing Seattle's requirements into the IBC. The reason statement for the public comment stated Dr. Miller "concluded that the 'Seattle approach' does indeed meet all the prescriptive requirements of the IBC 2009." The proposal and its public comment were ultimately withdrawn by the proponent in anticipation of further review of the overall elevator lobby provisions.

The intent of the code is to keep smoke out of the hoistway, so the pressure should be measured between the elevator hoistway and the elevator landing/lobby. However, Exception 1 allows the pressure to be measured between the hoistway and sleeping or dwelling units in residential buildings, since they are highly compartmented. In addition, the fire source is most likely to be in the dwelling or sleeping unit, and providing positive pressure in the corridor/hallway outside the units (via leakage through the elevator hoistway doors) will help reduce the smoke migrating from the affected unit. Exception 2, which is specific to elevator lobbies associated with fire service access elevators (FSAE) and occupant evacuation elevators, allows the pressure to be measured between the hoistway and the space on the outside of the smoke barrier that forms the lobby. It should be noted that hoistway pressurization is not a design alternative to enclosed lobbies for FSAEs and Occupant evacuation elevators. Enclosed elevator lobbies are always required for these types of elevators. This exception would only apply if such a system was provided.

Exception 3 allows the 0.10 inch water column pressure differential between the hoistway and the floor be met only on the four most critical floors—the floor of fire origin, the two floors immediately below, and one floor immediately above. For all other stories, the pressure differential is allowed to be measured between the hoistway and the outside of the building. The purpose of this requirement is to maintain a slightly positive pressure in the building relative to atmospheric pressure, so as to lower the neutral pressure plane in the building, which then reduces the driving force of stack effect. This exception is

intended to be permitted to be used in conjunction with Exceptions 1 and 2. The engineers who design this system begin by modeling one floor as the "notionalized" fire floor, and designing the system (fans, dampers, etc.) accordingly. Each floor is subsequently modeled as the notionalized fire floor, and the system is checked to make sure the maximum and minimum pressure differentials are met. (Note that actual models may not have to be run for each floor, if it is clear the worst case has been covered.) Ultimately, the system will need to be designed so it will correctly configure itself for a fire originating on any floor in the building.

Exception 4 omits the need to measure the pressure differential at the floor of elevator recall where the door is typically open. Section 909.21.1 requires the pressure difference, prescribed for the pressurization alternative, to be measured at the midpoint of each hoistway door, with all elevator cars at the floor of recall and all hoistway doors on the floor of recall open and all other hoistway doors closed.

Elevator hoistway pressurization is intended to minimize smoke movement into an elevator shaft when a lobby is not provided. Meeting the required pressure difference on the recall floor with the hoistway doors open is not necessary, because the recall floor is protected by smoke detectors that will not allow the hoistway doors to open if smoke is present.

The pressurization method is based on using pressure differences produced by fans to minimize the spread of smoke across a barrier. A barrier will not exist on the recall floor when the hoistway doors are open and smoke detectors used for elevator recall prevent the doors from opening when smoke is present.

**[BF] 909.21.1.1 Use of ventilation systems.** Ventilation systems, other than hoistway supply air systems, are permitted to be used to exhaust air from adjacent spaces on the fire floor, two floors immediately below and one floor immediately above the fire floor to the building's exterior where necessary to maintain positive pressure relationships as required in Section 909.21.1 during operation of the elevator shaft pressurization system.

❖ This section allows the use of the general building HVAC system to exhaust air to create/maintain the required pressure differential. It is to be noted that the requirements of the rest of Section 909.21, in particular, Section 909.21.10 regarding protection of equipment, would still apply to these components.

**[BF] 909.21.2 Rational analysis.** A rational analysis complying with Section 909.4 shall be submitted with the *construction documents*.

❖ Section 909.4 recognizes that there are many factors involved in a smoke control system, including stack effect due to height, temperature effect of fire, wind effect, interaction of the HVAC system, the weather and the egress time, all of which must be evaluated. The report must be submitted with the permit docu-

ments. Most importantly, the duration of operation of the smoke control system is a function of 1.5 times the egress time or 20 minutes, whichever is less. More discussion on the duration of operation is found in the commentary for Section 909.4.6.

**[BF] 909.21.3 Ducts for system.** Any duct system that is part of the pressurization system shall be protected with the same *fire-resistance rating* as required for the elevator shaft enclosure.

- ❖ All ductwork necessary for hoistway pressurization must be protected from the effects of fire by enclosure in fire-resistance-rated construction equivalent to that required for the elevator hoistway shaft enclosure.

**[BF] 909.21.4 Fan system.** The fan system provided for the pressurization system shall be as required by Sections 909.21.4.1 through 909.21.4.4.

- ❖ This section details the requirements for the mechanical system used for pressurization of the hoistway enclosure.

**[BF] 909.21.4.1 Fire resistance.** Where located within the building, the fan system that provides the pressurization shall be protected with the same *fire-resistance rating* required for the elevator shaft enclosure.

- ❖ The only way to ensure that the mechanical pressurization system can operate during a fire is to locate it in a safe place. If located within the building, it must be in an enclosed room protected with the same fire-resistance-rated construction required for the hoistway enclosure.

**[BF] 909.21.4.2 Smoke detection.** The fan system shall be equipped with a smoke detector that will automatically shut down the fan system when smoke is detected within the system.

- ❖ The airflow must be free of smoke or it will only increase the likelihood of smoke spreading throughout the building. The smoke detector required by this section should be located on the intake side of the blower fan.

**[BF] 909.21.4.3 Separate systems.** A separate fan system shall be used for each elevator hoistway.

- ❖ This section requires that each hoistway enclosure have its own mechanical system. This provides a more redundant system and helps to increase the likelihood that fans will be operational during a fire.

**[BF] 909.21.4.4 Fan capacity.** The supply fan shall be either adjustable with a capacity of not less than 1,000 cfm (0.4719 m<sup>3</sup>/s) per door, or that specified by a *registered design professional* to meet the requirements of a designed pressurization system.

- ❖ The fan capacity should be as specified by the registered design professional to meet the operational ranges of pressure at each door or be adjustable with

a capacity of at least 1,000 cfm (0.4719 m<sup>3</sup>/s) per hoistway door. In either case, it is subject to field testing and adjustments to meet the pressure ranges.

**[BF] 909.21.5 Standby power.** The pressurization system shall be provided with standby power in accordance with Section 604.

- ❖ The elevator hoistway pressurization system is an emergency system and must have provisions for standby power like other emergency systems. Section 604 states the requirements that standby power systems must meet. It is consistent with other smoke control systems required by Section 909 in that such systems have standby power as they are life-safety systems.

**[BF] 909.21.6 Activation of pressurization system.** The elevator pressurization system shall be activated upon activation of either the building fire alarm system or the elevator lobby smoke detectors. Where both a building fire alarm system and elevator lobby smoke detectors are present, each shall be independently capable of activating the pressurization system.

- ❖ This section requires that the pressurization system will be activated when the general building fire alarm system or an elevator lobby smoke detector is activated. All buildings using this pressurization option will more than likely be required to have both. High-rise buildings require elevator lobby smoke detectors, but other buildings may not. Section 909.12 requires smoke detectors to activate the pressurization system if the design requires it to operate to remove the smoke.

**[BF] 909.21.7 Testing.** Testing for performance shall be required in accordance with Section 909.18.8. System acceptance shall be in accordance with Section 909.19.

- ❖ Testing will be required to evaluate the performance of the completed system (see commentary, Sections 909.18 and 909.19).

**[BF] 909.21.8 Marking and identification.** Detection and control systems shall be marked in accordance with Section 909.14.

- ❖ See the commentary to Section 909.14.

**[BF] 909.21.9 Control diagrams.** Control diagrams shall be provided in accordance with Section 909.15.

- ❖ See the commentary to Section 909.15.

**[BF] 909.21.10 Control panel.** A control panel complying with Section 909.16 shall be provided.

- ❖ See the commentary to Section 909.16.

**[BF] 909.21.11 System response time.** Hoistway pressurization systems shall comply with the requirements for smoke control system response time in Section 909.17.

- ❖ See the commentary to Section 909.17.

## SECTION 910 SMOKE AND HEAT REMOVAL

**910.1 General.** Where required by this code, smoke and heat vents or mechanical smoke removal systems shall conform to the requirements of this section.

- ❖ This section essentially requires either smoke and heat vents or a mechanical smoke removal system where required by Section 910.2. It should be noted that where high piled combustible storage is involved, Chapter 32 of the IFC also applies.

The purpose of smoke and heat vents or smoke removal systems has historically been related to the needs of fire fighters. More specifically, smoke and heat vents or smoke removal systems, when activated, have the potential effect of lifting the height of the smoke layer and providing more tenable conditions to undertake fire-fighting activities. Other potential benefits include a reduction in property damage and the creation of more tenable conditions for occupants.

These provisions are based upon research on the interaction of sprinklers, roof vents and draft curtains funded by the National Fire Protection Research Foundation (NFPRF) and conducted at Underwriters Laboratories (UL) in 1997/1998. This research is summarized in a document referred to as National Institute of Science and Technology Interagency Report (NISTIR) 6196-1 dated September, 1998. The current provisions were also based on the following:

- Provisions for the use of roof vents in sprinklered buildings included in the 2010 and 2013 edition of NFPA 13, including the substantiation statement for the NFPA 13 roof vent provisions.
- The capability of standard spray sprinklers to both control and extinguish a fire within 30 minutes of sprinkler operation without supplemental fire department activity has been documented.
- Recommendations contained in National Institute for Occupational Safety and Health (NIOSH) 2005-132, *Preventing Injuries and Deaths of Fire Fighters Due to Truss Systems*, and NIOSH 2010-153, *Preventing Deaths and Injuries of Fire Fighters using Risk Management Principles at Structure Fires*.
- Recommendations contained in the Initial Report of the Federal Emergency Management Agency (FEMA)/National Fallen Firefighter Foundation (NFFF®) Firefighter Life Safety Summit held on April 14, 2004 in Tampa, Florida.

The primary purpose of smoke and heat removal from the perspective of the building code requirement is to assist fire-fighting operations after control of the fire has been achieved by the automatic sprinkler system. Automatic smoke and heat vents and automatic sprinkler systems were developed independently of one another and their interaction has been a concern for many years. Even today, there is no accepted method of analyzing their interaction and, therefore,

the installation standards for each (NFPA 204 and NFPA 13, respectively) give cautions to the designers of buildings having both systems. Note that NFPA 204 is not referenced in Section 910.

A manually activated mechanical smoke removal system can perform the same function as roof vents. Mechanical smoke removal systems, as required in Section 910, provide fire-rated, grade-level enclosures for the control of the mechanical smoke removal system. This provides greater control of the system for the fire incident commander and reduces the need to place fire fighters on roofs or in other hazardous situations to operate smoke and heat venting systems. This methodology is consistent with the latest recommendations from NIOSH and NFFF for fire fighter safety, risk management and recommended fire-fighting tactics.

**910.2 Where required.** Smoke and heat vents or a mechanical smoke removal system shall be installed as required by Sections 910.2.1 and 910.2.2.

### Exceptions:

1. Frozen food warehouses used solely for storage of Class I and II commodities where protected by an *approved automatic sprinkler system*.
  2. Smoke and heat removal shall not be required in areas of buildings equipped with early suppression fast-response (ESFR) sprinklers.
  3. Smoke and heat removal shall not be required in areas of buildings equipped with control mode special application sprinklers with a response time index of  $50 (m \cdot S)^{1/2}$  or less that are listed to control a fire in stored commodities with 12 or fewer sprinklers.
- ❖ Sections 910.2.1 and 910.2.2 provide the locations where such smoke removal or smoke and heat vents would be required. There are three overall exceptions to the application of Section 910.

Exception 1 recognizes the “building-within-a-building” nature of typical frozen food warehouses. As such, smoke from a fire within a freezer would be contained within the freezer, thus negating the usefulness of smoke and heat vents at the roof level.

Exception 2 recognizes the negative effect that smoke and heat vents can have on the operation of early suppression fast response (ESFR) sprinklers. Those negative effects include diverting heat away from the sprinklers, which could delay their activation or result in the activation of more sprinklers in areas away from the source of the fire, which may overwhelm the system.

Exception 3 recognizes a new category of automatic sprinkler that shares the key characteristics of ESFR sprinklers, i.e., thermal elements that have a response time index (RTI) of 50 or less and are listed to protect a design area that involves 12 or fewer sprinklers. These control mode special application (CMSA) sprinklers, while not called ESFR, still require similar precautions to ESFR sprinklers with

respect to not introducing unknowns, such as smoke and heat removal, that were not present in the full-scale fire tests that determined their listing parameters. Such unknowns can lead to sprinkler “skipping” and exceeding the 12 sprinkler design area, which was the exact concern that led to the ESFR-related provisions that are currently in this chapter and Chapter 32. Note that CMSA sprinklers must have both an RTI of 50 or less and be listed to control/suppress a fire with 12 or fewer sprinklers to qualify for this exception. Any sprinkler listed as “quick response” will satisfy the “50 RTI or less” criterion, based on the definition of “quick response” in NFPA 13 Section 3.6.4.7. The number of operating sprinklers will be indicated in the listing criteria for each sprinkler.

**910.2.1 Group F-1 or S-1.** Smoke and heat vents installed in accordance with Section 910.3 or a mechanical smoke removal system installed in accordance with Section 910.4 shall be installed in buildings and portions thereof used as a Group F-1 or S-1 occupancy having more than 50,000 square feet (4645 m<sup>2</sup>) of undivided area. In occupied portions of a building equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, where the upper surface of the story is not a roof assembly, a mechanical smoke removal system in accordance with Section 910.4 shall be installed.

**Exception:** Group S-1 aircraft repair hangars.

❖ Large-area buildings with moderate to heavy fire loads present special challenges to the fire department in disposing of the smoke generated in a fire. In order to provide the fire department with the ability to rapidly and efficiently dispose of smoke in large-area Groups F-1 and S-1 buildings exceeding 50,000 square feet (4645 m<sup>2</sup>) in undivided area without the exposure of personnel to the dangers associated with cutting ventilation holes in the roof, smoke and heat vents or a smoke removal system must be provided.

The code is not clear on what is meant by the term “undivided area.” However the intent is to provide the ability to manage the smoke in large spaces. Draft curtains or potentially any physical separation (regardless of rating) would provide such division. Draft curtains are typically constructed of sheet metal, lath and plaster, gypsum board or other materials that resist the passage of smoke. Typically draft curtains are at least 6 feet deep (1829 mm) from the ceiling. To keep with the concern for managing smoke, the joints and connections should be smoke tight.

Based on the intent of “undivided area,” a fire barrier, smoke barrier, fire partition or smoke partition would be more than what is required and would therefore be an acceptable method of dividing the area.

This requirement is independent of the requirements related to high-piled storage in Section 910.2.2. High-piled combustible storage is not occupancy-specific.

This section also addresses multistory buildings where the Group F-1 or S-1 occupancy is not the uppermost story and therefore would not have a roof in which to place smoke and heat vents. This section would require that a smoke removal system be installed. This issue was not clearly addressed in previous editions of the IBC.

**910.2.2 High-piled combustible storage.** Smoke and heat removal required by Table 3206.2 for buildings and portions thereof containing high-piled combustible storage shall be installed in accordance with Section 910.3 in unsprinklered buildings. In buildings and portions thereof containing high-piled combustible storage equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, a smoke and heat removal system shall be installed in accordance with Section 910.3 or 910.4. In occupied portions of a building equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 where the upper surface of the story is not a roof assembly, a mechanical smoke removal system in accordance with Section 910.4 shall be installed.

❖ This section requires smoke and heat removal as it is required in Chapter 32 for high piled combustible storage. Specifically, Table 3206.2 sets out when smoke and heat removal is required. If Table 3206.2 does not require such protection, compliance with Section 910 is not necessary. The requirement in Table 3206.2 is based primarily on the size of the high-piled combustible storage area and whether or not the area is equipped with an automatic sprinkler system.

There are several requirements provided within this section. The first addresses nonsprinklered high-piled storage areas. Such areas are required to use smoke and heat vents as mechanical smoke removal systems and are designed for use in sprinklered buildings. The rationale for this provision is that a mechanical smoke removal system capable of handling temperatures between 1,000° F and 2,000° F cannot be practically provided at a reasonable cost.

Where high-piled storage areas are equipped with an automatic sprinkler system, smoke and heat vents or a smoke removal system are required to comply with this section. However, if the high-piled storage area is located in a multistory building where the storage area is not located on the upper most story, this section requires that a smoke removal system be used. This was not clearly addressed in past editions of the code.

**910.3 Smoke and heat vents.** The design and installation of smoke and heat vents shall be in accordance with Sections 910.3.1 through 910.3.3.

❖ This section simply sets out the subsections that must be addressed to comply with the requirements for the installation of smoke and heat vents.

**910.3.1 Listing and labeling.** Smoke and heat vents shall be *listed* and labeled to indicate compliance with UL 793 or FM 4430.

❖ This section specifically requires that all smoke and heat vents be both listed and labeled in accordance with UL 793 or FM 4430. This provides consistency and a level of quality when smoke and heat vents are required. The standard addresses smoke and heat vents that automatically operate during fires via non-electrical means. Automatic vents listed and labeled to this standard can be operated both automatically and manually. There are two main mechanisms for activation that include a heat-responsive device or the action of a plastic cover shrinking and falling out of place, due to fire exposure.

**910.3.2 Smoke and heat vent locations.** Smoke and heat vents shall be located 20 feet (6096 mm) or more from adjacent *lot lines* and *fire walls* and 10 feet (3048 mm) or more from *fire barriers*. Vents shall be uniformly located within the roof in the areas of the building where the vents are required to be installed by Section 910.2, with consideration given to roof pitch, sprinkler location and structural members.

❖ This section has two functions, the first being to focus on hazards to adjacent buildings and the second being proper function of smoke and heat vents through proper placement.

In terms of adjacent properties, this section requires a minimum distance to lot lines and fire walls and then a minimum distance to fire barriers. The first set of distances focuses on separate buildings and exposures, whereas the distance to fire barriers is less restrictive since it focuses on different uses and

occupancies within the same building (see Commentary Figure 910.3.2).

To enhance vent performance within the area containing the smoke and heat vents, such vents need to be uniformly spaced. Consideration of issues such as sprinkler location and roof pitch are also essential to proper vent location.

**910.3.3 Smoke and heat vents area.** The required aggregate area of smoke and heat vents shall be calculated as follows:

For buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1:

$$A_{VR} = V/9000 \quad \text{(Equation 9-4)}$$

where:

$A_{VR}$  = The required aggregate vent area (ft<sup>2</sup>).

$V$  = Volume (ft<sup>3</sup>) of the area that requires smoke removal.

For unsprinklered buildings:

$$A_{VR} = AFA/50 \quad \text{(Equation 9-5)}$$

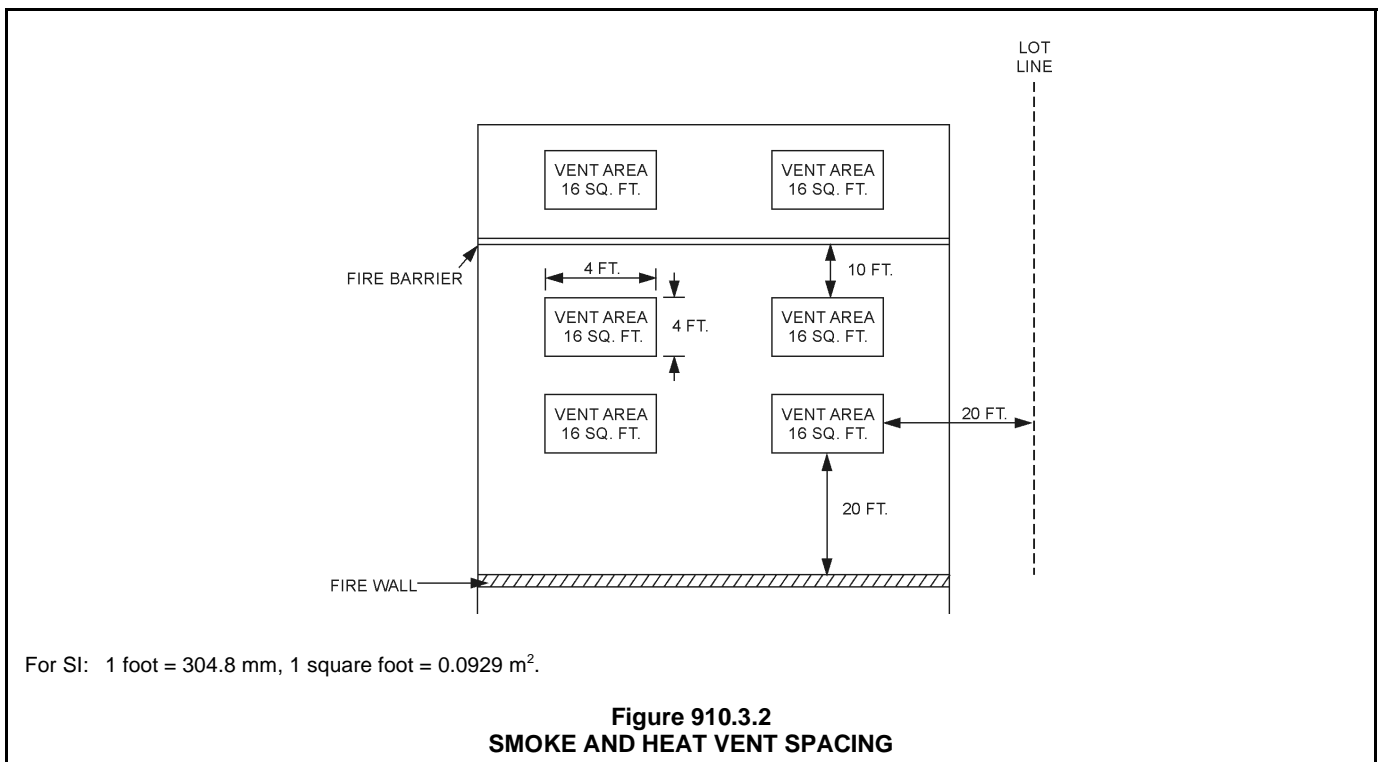

where:

$A_{VR}$  = The required aggregate vent area (ft<sup>2</sup>).

$A_{FA}$  = The area of the floor in the area that requires smoke removal.

❖ This section provides the design criteria to determine the area of smoke and heat vents required. The requirements are based on whether the area requiring smoke and heat vents is equipped with an automatic sprinkler system.

The design of roof vents in buildings protected by an automatic sprinkler system requires that the area

of roof vents provide equivalent venting to that required for the mechanical smoke removal system (2 air changes per hour) based on an assumption that each square foot of vent area will provide 300 cubic feet per minute (cfm) of ventilation. The reason for this requirement is that the roof vents should at least provide venting equivalent to the minimum venting provided by the mechanical smoke removal system. A factor of 300 cfm of venting per square foot of vent area was included in the 2012 edition of the code, although the use of this conversion factor is questionable at best. The actual ventilation provided by each square foot of vent area will depend on the temperature differential between ambient conditions and the smoke layer under the roof deck or the pressure achieved if positive pressure ventilation is utilized. If the prescribed value is not practical for a given building design, designers have the option of demonstrating other values which provide the same performance under Section 104.9 of the code, which allows alternative methods and designs.

The design of roof vents in buildings not protected by a sprinkler system requires that the ratio of the area of the vents to the floor area be a minimum of 1:50. The rationale is that the case where roof vents will be provided without sprinkler protection will be rare: buildings which contain high-piled storage with an area between 2,500 and 12,000 square feet. Given that this situation will be rare, a complex analysis to determine the required area of roof vents was felt to be unnecessary. The ratio of vent area to floor area of 1:50 is conservative based on the requirements that were included in the 2012 code and the IBC.

**910.4 Mechanical smoke removal systems.** Mechanical smoke removal systems shall be designed and installed in accordance with Sections 910.4.1 through 910.4.7.

❖ Mechanical smoke removal systems are considered to be equivalent to smoke and heat vents in terms of code compliance. In multistory buildings, those areas requiring smoke and heat removal will require the use of a mechanical smoke removal system due to location on other than the uppermost story. This section provides the various design requirements for such systems.

**910.4.1 Automatic sprinklers required.** The building shall be equipped throughout with an approved *automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ The rationale for this provision is that a mechanical smoke removal system capable of handling temperatures between 1,000° F and 2,000° F cannot be practically provided at a reasonable cost. Therefore, in order to allow the use of a mechanical smoke removal system, the building is required to be equipped throughout with an automatic sprinkler system.

**910.4.2 Exhaust fan construction.** Exhaust fans that are part of a mechanical smoke removal system shall be rated for

operation at 221°F (105°C). Exhaust fan motors shall be located outside of the exhaust fan air stream.

❖ This section requires exhaust fan motors to be located out of the exhaust stream to protect the mechanical equipment from excessive heat. Provisions for the mechanical smoke removal system permit the system to be designed to handle air at ambient temperature, provided that the fan motors are located outside the air stream. The basis for this provision is the thermocouple temperature data for the large-scale fire tests conducted at UL in 1997/1998, specifically Tests P-1 and P-4. (In Tests P-1 and P-4, no vents opened so the ceiling temperatures recorded would be unaffected by the activation of vents. See pages 40 and 52 of the NISTIR 6196-1 report dated September, 1998 for the thermocouple temperature data recorded as a function of time.)

The exposing temperatures and time periods were reviewed and not considered to pose a threat to the building structure, fans or power wiring.

The sprinkler activation times and ceiling temperature data for the five large-scale fire tests summarized in NISTIR 6196-1 indicate that the exposure of mechanical exhaust fans and ducts located at the ceiling to high temperatures will be relatively short. Since it is anticipated that the exhaust system will only be activated after the arrival of fire fighters at the scene (estimated to be 7 minutes or longer after ignition), ceiling temperatures should be reduced sufficiently to allow fans rated for only ambient temperatures to be used for the exhaust system.

**910.4.3 System design criteria.** The mechanical smoke removal system shall be sized to exhaust the building at a minimum rate of two air changes per hour based upon the volume of the building or portion thereof without contents. The capacity of each exhaust fan shall not exceed 30,000 cubic feet per minute (14.2 m<sup>3</sup>/sec).

❖ Sections 910.4.3 and 910.4.3.1 specify the design requirement for the minimum number of air changes, maximum fan capacity and requirements for the provision of make-up air.

These provisions require that the mechanical smoke removal system be sized to provide a minimum exhaust rate of two air changes per hour based on the enclosed volume of the building space to be exhausted, without any deductions for the space occupied by storage or equipment. An exhaust rate of two air changes per hour is based on an analysis assuming a conservative approach using a Factory Mutual Research Corporation (FMRC) Standard Plastic Commodity (polystyrene cups in compartmented cartons). This commodity is recognized to represent a severe fire hazard of high density plastics.

In a calculation based on this commodity, a maximum of 68,960 cfm of smoke was generated by the design fire. Based on an empty building volume of 2.659 million cubic feet, the exhaust rate required to achieve two air changes per hour is 88,633 cfm.

Because no single fan can exceed 30,000 cfm, this building required five fans, each exhausting 25,570 cfm for a total of 127,850 cfm. This exceeds the minimum two air changes per hour by more than 40 percent. Even at the minimum required rate of two air changes per hour, the calculation results show that the mechanical smoke removal system will be capable of removing the smoke from the building faster than it will be generated, ultimately removing smoke from the building.

**910.4.3.1 Makeup air.** Makeup air openings shall be provided within 6 feet (1829 mm) of the floor level. Operation of makeup air openings shall be manual or automatic. The minimum gross area of makeup air inlets shall be 8 square feet per 1,000 cubic feet per minute (0.74 m<sup>2</sup> per 0.4719 m<sup>3</sup>/s) of smoke exhaust.

❖ In order for a mechanical smoke removal system to work properly, makeup air at the proper location and volume of air need to be provided. Generally, makeup air inlets need to be located much lower than where the smoke is exhausted to get the proper movement of air. In this case, the required location is within 6 feet of the floor.

The derivation of the gross vent area is based on NFPA 92-2012. Specifically, Annex Section A-4.4.4.1.4 states that the maximum air velocity through the make-up air inlet is 1 m/sec or 200 ft/min. This is the same limitation found in Section 909.7.1, which is for the airflow method of smoke control. The area requirement is then derived as follows:

- Effective Vent Area = (1000 ft<sup>3</sup>/min)/(200 ft/min) = 5 ft<sup>2</sup> per 1000 cfm
- Assume an orifice coefficient of 0.6
- Gross Vent Area = 5 ft<sup>2</sup>/(0.6) = 8.33 ft<sup>2</sup> per 1000 cfm, which is rounded down due to the conservative nature of the requirement

The reason for this limitation is to prevent significant deflection of the plume, which will cause more air entrainment into the plume and more smoke production. This is the same limitation found in Section 909.7.1, which is for the airflow method of smoke control. This criterion is conservative as the requirement above assumes an active fire and the design philosophy for this requirement is to provide post-fire smoke exhaust.

**910.4.4 Activation.** The mechanical smoke removal system shall be activated by manual controls only.

❖ This section requires that mechanical systems are to be activated manually so that the fire department is in control of the system. In some situations, automatic operation could cause a fire to grow or spread, opening an excessive number of sprinklers. Automatic operation of the mechanical smoke removal system could also be detrimental to the operation of the sprinkler system in a manner similar to draft curtains. The effect of the automatic mechanical smoke

removal system on sprinkler operation would depend on when the system was activated. The sooner the system is automatically activated, the greater the detrimental effect. The fire department will retain the option to shut down the exhaust system, as well.

**910.4.5 Manual control location.** Manual controls shall be located so as to be accessible to the fire service from an exterior door of the building and protected against interior fire exposure by not less than 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ This section establishes the required placement, access and protection of the manual controls to ensure the fire fighters will have quick and protected access to them.

**910.4.6 Control wiring.** Wiring for operation and control of mechanical smoke removal systems shall be connected ahead of the main disconnect in accordance with Section 701.12E of NFPA 70 and be protected against interior fire exposure to temperatures in excess of 1,000°F (538°C) for a period of not less than 15 minutes.

❖ Unless the mechanical smoke removal system also functions as a component of a smoke control system, standby power is not specifically required (see commentary, Sections 604 and 909.11). In order to provide an enhanced level of operational reliability, this section requires that the power supply to smoke exhaust fans must be provided from a circuit connected on the supply side (i.e., ahead of) the building's main electrical service disconnecting means. Note that this is one of the sources of standby power recognized by NFPA 70, Section 701.12(E). Such a circuit connected "ahead of the main" must still have its own approved overcurrent protection.

The provisions for the design of a mechanical smoke removal system indicate that wiring providing power to exhaust fans located in the interior of the building is to be protected by materials which will provide a 15-minute finish-rating protection. The ceiling temperature data collected in the five large-scale fire tests summarized in NISTIR 6196-1 (cited above) show that temperatures at the ceiling will be far less than the exposure temperatures defined by the ASTM E119 time-temperature curve and that the ceiling temperatures will rapidly decrease once sprinklers activate. The ceiling temperature data included in NISTIR 6196-1 indicates that providing 15-minute finish-rating protection for the interior electrical power supply is more than adequate to prevent damage to the power supply wiring for the exhaust system.

**910.4.7 Controls.** Where building air-handling and mechanical smoke removal systems are combined or where independent building air-handling systems are provided, fans shall automatically shut down in accordance with the *International Mechanical Code*. The manual controls provided for the smoke removal system shall have the capability to override

the automatic shutdown of fans that are part of the smoke removal system.

- ❖ This section requires that if a mechanical smoke removal system is integrated with a standard HVAC system, then the system must shut down upon detection of smoke as required by the IMC. This relates to the requirement in Section 910.4.4 that mechanical smoke removal systems shall be manually operated only.

The concern is that HVAC systems should not work against the intended operation of the smoke exhaust system. In some cases, the system may be a combination system where shutdown is not necessary or appropriate. It really depends on how the smoke exhaust system has been designed.

**910.5 Maintenance.** Smoke and heat vents and mechanical smoke removal systems shall be maintained in an operative condition in accordance with Section 910.5.1 or 910.5.2, respectively.

- ❖ Routine maintenance and testing of smoke removal systems is essential to ensure their performance, as designed, under fire conditions. Maintenance practices for these systems must be consistent with their design and any manufacturer's recommendations and as indicated in Section 910.5.1 or 910.5.2.

**910.5.1 Smoke and heat vents.** Smoke and heat vents shall be maintained in an operative condition in accordance with NFPA 204 and Section 910.5.1.1

- ❖ This section requires smoke and heat vents to be maintained in operating condition and incorporates NFPA 204 as the referenced standard for the maintenance of smoke and heat vents (see Section 901.6.1). Routine inspection, testing and maintenance of these devices is essential since they are typically only found in the largest commercial structures, and the amount of fire loading is usually very high (i.e., high-piled combustible storage). Ensuring that these devices are inspected, tested and maintained in proper working order by the building's owner also has positive effects on fire-fighter safety. These benefits include:

- Easy identification of the location of the fire within the structure.
- Release of excess heat within the structure.
- Decreasing fire severity.
- Increased visibility for fire fighters within the structure.
- Reduction of toxic products of combustion within the structure.

Additionally, the maintenance of these devices will have a mitigating effect on damage to the structure and/or its contents should a fire occur. These benefits include decreased likelihood of structural failure from heat retained within the structure and reduced damage to the structure and stored materials from smoke.

**910.5.1.1 Fusible links.** Fusible links for smoke and heat vents shall be replaced whenever fused, damaged or painted.

- ❖ The sensing elements of fusible link devices installed as part of smoke and heat vents must be routinely visually inspected and replaced as needed to increase the likelihood that the vents will operate in a timely fashion when needed.

**910.5.2 Mechanical smoke removal systems.** Mechanical smoke removal systems shall be maintained in accordance with the equipment manufacturer's maintenance instructions and Sections 910.5.2.1 through 910.5.2.4.

- ❖ The previously included reference to NFPA 204 for mechanical smoke removal systems was removed and replaced with the prescriptive testing and maintenance requirements in Sections 910.5.2.1 through 910.5.2.4. This was done because it was determined that the maintenance requirements in NFPA 204 were not specific enough to ensure the necessary maintenance of the mechanical smoke removal systems.

**910.5.2.1 Frequency.** Systems shall be operationally tested not less than once per year. Testing shall include the operation of all system components, including control elements.

- ❖ Annual operational exercising of the entire mechanical smoke removal system must be performed to verify that it still operates as required by the approved design.

**910.5.2.2 Testing.** Operational testing of the mechanical smoke removal system shall include all equipment such as fans, controls and make-up air openings.

- ❖ Because mechanical smoke removal systems are designed for smoke removal only, the operation of these systems does not adversely affect other building systems or operations. The control sequence for these systems must be included in the annual operational test to check for system component failures that may not get noticed because mechanical smoke removal systems are independent of building HVAC systems and operate only in emergency situations.

**910.5.2.3 Schedule.** A routine maintenance and operational testing program shall be initiated and a written schedule for routine maintenance and operational testing shall be established.

- ❖ Routine operational testing and maintenance must be performed on the mechanical smoke removal system periodically to verify that it still operates as required by the approved design. A written schedule must be established and maintained.

**910.5.2.4 Written record.** A written record of mechanical smoke exhaust system testing and maintenance shall be maintained on the premises. The written record shall include the date of the maintenance, identification of the servicing personnel and notification of any unsatisfactory condition and the corrective action taken, including parts replaced.

- ❖ This section prescribes the desired content of the written record for the mechanical smoke removal sys-

tem testing and maintenance program. Test results and maintenance activities should be clearly documented. The written record should be available for inspection and reviewed by the fire code official.

## SECTION 911 EXPLOSION CONTROL

**911.1 General.** Explosion control shall be provided in the following locations:

1. Where a structure, room or space is occupied for purposes involving explosion hazards as identified in Table 911.1.
2. Where quantities of hazardous materials specified in Table 911.1 exceed the maximum allowable quantities in Table 5003.1.1(1).

Such areas shall be provided with explosion (*deflagration*) venting, explosion (*deflagration*) prevention systems or *barricades* in accordance with this section and NFPA 69, or NFPA 495 as applicable. *Deflagration* venting shall not be utilized as a means to protect buildings from *detonation* hazards.

❖ It is usually impractical to design a building to withstand the pressure created by an explosion. Therefore, this section requires an explosion relief system for structures, rooms or spaces with occupancies involving explosion hazards. Explosions may result from the overpressurization of a containing structure, by physical/chemical means or by a chemical reaction. During an explosion, a sudden release of a high-pressure gas occurs and the energy is dissipated in the form of a shock wave.

Structures, rooms or spaces with occupancies involving explosion hazards must be equipped with some method of explosion control as required by the material-specific requirements in the code. Table 911.1 also specifies when explosion control is required based on certain materials or occupancies where the quantities of hazardous materials involved exceed the maximum allowable quantities in Table 5003.1.1(1). Section 911 recognizes explosion (*deflagration*) venting and explosion (*deflagration*) prevention systems as acceptable methods of explosion control where appropriate. The use of barricades or other explosion protective devices, such as magazines, may be permitted as the means of explosion control where indicated in the code as an acceptable alternative and when approved by the fire code official.

**TABLE 911.1.** See page 9-136.

❖ This table designates when some methods of explosion control are required for specific material or special use conditions. This table applies when the quantities of hazardous materials involved exceed the maximum allowable quantities in Table 5003.1.1(1). Section 911.2 contains design criteria for explosion (*deflagration*) venting. Explosion prevention (*suppression*) systems, where used, must com-

ply with NFPA 69. Barricade construction must be designed and installed to comply with NFPA 495. Chapters 50 through 67 of the code contain additional guidance on the applicability and design criteria for explosion control methods that depend on the specific type of hazardous material involved.

**911.2 Required deflagration venting.** Areas that are required to be provided with *deflagration* venting shall comply with the following:

1. Walls, ceilings and roofs exposing surrounding areas shall be designed to resist a minimum internal pressure of 100 pounds per square foot (psf) (4788 Pa). The minimum internal design pressure shall be not less than five times the maximum internal relief pressure specified in Item 5 of this section.
2. *Deflagration* venting shall be provided only in exterior walls and roofs.

**Exception:** Where sufficient *exterior wall* and roof venting cannot be provided because of inadequate exterior wall or roof area, *deflagration* venting shall be allowed by specially designed shafts vented to the exterior of the building.

3. *Deflagration* venting shall be designed to prevent unacceptable structural damage. Where relieving a *deflagration*, vent closures shall not produce projectiles of sufficient velocity and mass to cause life threatening injuries to the occupants or other persons on the property or adjacent *public ways*.
4. The aggregate clear area of vents and venting devices shall be governed by the pressure resistance of the construction assemblies specified in Item 1 of this section and the maximum internal pressure allowed by Item 5 of this section.
5. Vents shall be designed to withstand loads in accordance with the *International Building Code*. Vents shall consist of any one or any combination of the following to relieve at a maximum internal pressure of 20 pounds per square foot (958 Pa), but not less than the loads required by the *International Building Code*:
  - 5.1. *Exterior walls* designed to release outward.
  - 5.2. Hatch covers.
  - 5.3. Outward swinging doors.
  - 5.4. Roofs designed to uplift.
  - 5.5. Venting devices *listed* for the purpose.

6. Vents designed to release from the *exterior walls* or roofs of the building when venting a *deflagration* shall discharge directly to the exterior of the building where an unoccupied space not less than 50 feet (15 240 mm) in width is provided between the exterior walls of the building and the lot line.

**Exception:** Vents complying with Item 7 of this section.

7. Vents designed to remain attached to the building when venting a *deflagration* shall be so located that the discharge opening shall be not less than 10 feet (3048 mm)

## FIRE PROTECTION SYSTEMS

vertically from window openings and *exits* in the building and 20 feet (6096 mm) horizontally from *exits* in the building, from window openings and *exits* in adjacent buildings on the same lot and from the lot line.

8. Discharge from vents shall not be into the interior of the building.

❖ This section prescribes the basic design criteria necessary for deflagration venting.

Deflagration venting limits the deflagration pressure in a certain area so that, in case of an explosion, the damage to that enclosed area is minimized or eliminated. Because there are so many variables involved for adequate deflagration venting, the parameters for each design should fit the individual situation. NFPA 68 contains additional guidance on

the design and use of deflagration venting systems.

The area of the vent must be adequate to relieve the pressure before it reaches a level in excess of what can be withstood by the weakest building member. The vent area, therefore, is dependent on the actual construction of the enclosed area and the anticipated pressure. The vent panel should be of light-weight construction so that it can easily release at low pressures. Because the lightweight panels have little structural strength, railings may be required along the floor edge to prevent people or objects from falling against the panel.

Item 5 indicates that the vents are to be designed to relieve at a maximum internal pressure of 20 pounds per square foot (psf) (958 Pa) but not less

**TABLE 911.1  
EXPLOSION CONTROL REQUIREMENTS<sup>f</sup>**

MATERIAL	CLASS	EXPLOSION CONTROL METHODS	
		Barricade construction	Explosion (deflagration) venting or explosion (deflagration) prevention systems
<b>Hazard Category</b>			
Combustible dusts <sup>a</sup>	—	Not required	Required
Cryogenic fluids	Flammable	Not required	Required
Explosives	Division 1.1	Required	Not required
	Division 1.2	Required	Not required
	Division 1.3	Not required	Required
	Division 1.4	Not required	Required
	Division 1.5	Required	Not required
	Division 1.6	Required	Not required
Flammable gas	Gaseous	Not required	Required
	Liquefied	Not required	Required
Flammable liquids	IA <sup>b</sup>	Not required	Required
	IB <sup>c</sup>	Not required	Required
Organic peroxides	Unclassified detonable	Required	Not permitted
	I	Required	Not permitted
Oxidizer liquids and solids	4	Required	Not permitted
Pyrophoric	Gases	Not required	Required
Unstable (reactive)	4	Required	Not permitted
	3 detonable	Required	Not permitted
	3 nondetonable	Not required	Required
Water-reactive liquids and solids	3	Not required	Required
	2 <sup>e</sup>	Not required	Required
<b>Special Uses</b>			
Acetylene generator rooms	—	Not required	Required
Grain processing	—	Not required	Required
Liquefied petroleum gas distribution facilities	—	Not required	Required
Where explosion hazards exist <sup>d</sup>	Detonation	Required	Not permitted
	Deflagration	Not required	Required

a. Combustible dusts that are generated during manufacturing or processing. See definition of “Combustible dust” in Chapter 2.

b. Storage or use.

c. In open use or dispensing.

d. Rooms containing dispensing and use of hazardous materials where an explosive environment can occur because of the characteristics or nature of the hazardous materials or as a result of the dispensing or use process.

e. A method of explosion control shall be provided where Class 2 water-reactive materials can form potentially explosive mixtures.

f. Explosion venting is not required for Group H-5 Fabrication Areas complying with Chapter 27 and the *International Building Code*.

than the load design requirements in Chapter 16 of the IBC. In areas commonly subject to high winds, the release pressure has to be increased accordingly to prevent the vents from being actuated by wind forces. Even though the release pressure should be as low as practical, it must always be higher than the external wind pressure.

Venting devices must be located to discharge directly to the open air or to an unoccupied space at least 50 feet (15 240 mm) in width on the same lot. To minimize damage and maintain the integrity of the existing system, window openings and egress facilities are not to be within 10 feet (3048 mm) vertically or 20 feet (6096 mm) horizontally of the vent. The spatial distance will permit the pressure to decrease and not to cause additional damage.

**911.3 Explosion prevention systems.** Explosion prevention systems shall be of an *approved* type and installed in accordance with the provisions of this code and NFPA 69.

❖ Depending on the conditions of the anticipated explosion hazard, the use of an explosion prevention system may be an effective means of explosion control. An explosion prevention system is most effective in confined spaces or enclosures in which combustible gases, mists or dusts are subject to deflagration in a gas-phase oxidant. Explosion prevention systems are intended to prevent an explosion hazard by combating the process of combustion at its incipient stage.

NFPA 69 contains further information on the installation, operation and design considerations for explosion prevention systems. Explosion prevention systems are commonly used to protect laboratory equipment, such as reactor vessels, mills and dust collectors.

**911.4 Barricades.** *Barricades* shall be designed and installed in accordance with NFPA 495.

❖ As indicated in Table 911.1, depending on the type of materials involved, barricade construction may be an acceptable method of explosion control. Barricade construction is an effective method of screening a building containing explosives from other buildings, magazines or public rights-of-way. The barricade could be either natural or artificial, where applicable, as specified in NFPA 495.

## SECTION 912 FIRE DEPARTMENT CONNECTIONS

**912.1 Installation.** Fire department connections shall be installed in accordance with the NFPA standard applicable to the system design and shall comply with Sections 912.2 through 912.7.

❖ An FDC is required as part of a water-based suppression system as the auxiliary water supply. These connections give the fire department the capability of supplying the necessary water to the automatic sprinkler or standpipe system at a sufficient pressure with-

out pressurizing the underground supply. The FDC also serves as an alternative source of water should a valve in the primary water supply be closed. A fire department connection does not, however, constitute an automatic water source. See Commentary Figure 903.3.1.1 for a typical FDC arrangement on a wet pipe sprinkler system.

The requirements for the FDC depend on the type of sprinkler system installed and whether a standpipe system is installed. NFPA 13 and 13R, for example, include design considerations for FDCs that are an auxiliary water supply source for automatic sprinkler systems; NFPA 14 is the design standard to use for FDCs serving standpipe systems. Threads for FDCs to sprinkler systems, standpipes, yard hydrants or any other fire hose connection must be approved (NFPA 1963 may be utilized as part of the approval or as otherwise approved) and be compatible with the connections used by the local fire department (see commentary, Sections 903.3.6 and 905.1).

**912.2 Location.** With respect to hydrants, driveways, buildings and landscaping, fire department connections shall be so located that fire apparatus and hose connected to supply the system will not obstruct access to the buildings for other fire apparatus. The location of fire department connections shall be *approved* by the fire chief.

❖ This section specifies that the FDC must be located so that vehicles and hose lines will not interfere with access to the building for the use of other fire department apparatus. The location of potential connected hose lines to the FDC and hydrants must be pre-planned with the fire department. Many fire departments have a policy restricting the distance that a FDC may be from a fire hydrant. Some also have policies that indicate the maximum distance from the nearest point of fire department vehicle access (often, the curb). Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have approval authority over the location of and access to the FDC.

Landscaping can also be a hindrance to fire department operations. Even where the FDC is visible, the extensive use of landscaping may make access difficult. Landscaping also changes over time. What may not have been an obstruction when it was planted can sometimes grow into an obstruction over time.

**912.2.1 Visible location.** Fire department connections shall be located on the street side of buildings, fully visible and recognizable from the street or nearest point of fire department vehicle access or as otherwise *approved* by the fire chief.

❖ FDCs must be readily visible and easily accessed. A local policy constituting what is readily visible and accessible needs to be established. While the intent is clearly understandable, its application can vary widely. A precise policy is the best way to avoid ambiguous directives that result in inconsistent and

arbitrary enforcement. Usually, the policy will address issues such as location on the outside of the building and proximity to fire hydrants.

Landscaping is often used to hide the FDCs from the public. This can greatly hamper the efforts of the fire department in staging operations and supplying water to the fire protection systems. Landscaping must be designed so that it does not obstruct the visibility of the FDC. Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have final approval authority over the visibility of and access to the FDC.

**912.2.2 Existing buildings.** On existing buildings, wherever the fire department connection is not visible to approaching fire apparatus, the fire department connection shall be indicated by an *approved* sign mounted on the street front or on the side of the building. Such sign shall have the letters “FDC” not less than 6 inches (152 mm) high and words in letters not less than 2 inches (51 mm) high or an arrow to indicate the location. Such signs shall be subject to the approval of the *fire code official*.

- ❖ The section acknowledges that FDCs on existing buildings may not always be readily visible from the street or nearest point of fire department vehicle access. In those instances, the location of the connection must be clearly marked with signage. The FDC may be located on the side of the building or in an alley, not visible to arriving fire-fighting forces. A sign is necessary so that those driving the arriving apparatus know where to maneuver the vehicle to get close to the FDC.

**912.3 Fire hose threads.** Fire hose threads used in connection with standpipe systems shall be *approved* and shall be compatible with fire department hose threads.

- ❖ There are several sections in the code which contain requirements for fire department connections. This section simply correlates with those requirements by further clarifying that fire hose threads for standpipe systems must be approved.

**912.4 Access.** Immediate access to fire department connections shall be maintained at all times and without obstruction by fences, bushes, trees, walls or any other fixed or moveable object. Access to fire department connections shall be *approved* by the fire chief.

**Exception:** Fences, where provided with an access gate equipped with a sign complying with the legend requirements of Section 912.5 and a means of emergency operation. The gate and the means of emergency operation shall be *approved* by the fire chief and maintained operational at all times.

- ❖ The FDC must be readily accessible to fire fighters and allow fire-fighting personnel an adequate area to maneuver a hose for the connection. Landscaping design must not block a clear view of the FDC from arriving fire department vehicles. Depending on the type of landscaping materials, an active maintenance program may be necessary to maintain ready access

over time. This section also recognizes that the obstructing objects regulated here can be either fixed or movable (such as outdoor furnishings, shopping cart queue areas, etc.). Note that no specific dimension is given as was the case in previous editions of the code. This performance language avoids previous misinterpretations that the code intended to allow obstructions to FDC access as long as they were kept 3 feet (914 mm) away. Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have final approval authority over the access to the FDC.

The exception recognizes the practical fact that sometimes, security or other considerations make installation of a fence around a building necessary as long as the fence meets the stated criteria. The sign requirement intends to provide a visual location cue to approaching fire apparatus where the height of the fence may obscure the visibility of the FDC.

**912.4.1 Locking fire department connection caps.** The *fire code official* is authorized to require locking caps on fire department connections for water-based *fire protection systems* where the responding fire department carries appropriate key wrenches for removal.

- ❖ This section allows for the FDC caps to be equipped with locks as long as the fire departments that respond to that building or facility have the appropriate key wrenches. This avoids vandalism and affords a more functional FDC when needed. Locking caps, even more so than regular FDC caps, need proper maintenance so that they can be removed when required. Any time that an additional mechanical function is added to something that is exposed to the elements, it must be done with the understanding that the corrosive nature of the elements can place the FDC out of commission if the cap cannot be removed (see Commentary Figure 912.4.1).

**Figure 912.4.1**  
**LOCKING FDC CAPS**  
(Photo courtesy of Knox Company)

**912.4.2 Clear space around connections.** A working space of not less than 36 inches (914 mm) in width, 36 inches (914 mm) in depth and 78 inches (1981 mm) in height shall be provided and maintained in front of and to the sides of wall-mounted fire department connections and around the circumference of free-standing fire department connections, except as otherwise required or *approved* by the fire chief.

❖ Care must be taken so that fences, utility poles, barricades and other obstructions do not prevent access to and use of FDCs. A clear space of 3 feet (914 mm) must be maintained in front of and to either side of wall-mounted FDCs and around free-standing FDCs to allow easy hose connections to the fitting and efficient use of spanner wrenches and other tools needed by the apparatus engineer.

Though not specifically mentioned in this section, it is also important that FDCs be installed with the hose connections well above adjoining grade to accommodate the free turning of a spanner wrench when connecting hoses to the FDC.

**912.4.3 Physical protection.** Where fire department connections are subject to impact by a motor vehicle, vehicle impact protection shall be provided in accordance with Section 312.

❖ Section 312 requires vehicle impact protection by placing steel posts filled with concrete around the FDC. Section 312 gives the specifications for the posts.

**912.5 Signs.** A metal sign with raised letters not less than 1 inch (25 mm) in size shall be mounted on all fire department connections serving automatic sprinklers, standpipes or fire pump connections. Such signs shall read: AUTOMATIC SPRINKLERS or STANDPIPES or TEST CONNECTION or a combination thereof as applicable. Where the fire department connection does not serve the entire building, a sign shall be provided indicating the portions of the building served.

❖ The purpose of the sign is to provide the responding firefighters with the correct information on which portions of a building are served by the fire department connection. They identify the type of system or zone served by a given FDC. Many buildings include multiple sets of fire department connections which are not interconnected, such as separate connections for the building sprinkler system and the dry standpipe system in open parking structures. Some buildings may have only a partial sprinkler system, such as rehabilitated buildings where a sprinkler system is only installed on certain floors or a building that only has basement sprinklers in accordance with Section 903.2.11.

Signs may also distinguish FDCs from fire pump test headers. Usually, FDCs may be distinguished from fire pump test headers by the types of couplings provided. FDCs are customarily equipped with female couplings, while fire pump test headers usually have separately valved male couplings. Furthermore, fire pump test headers are equipped with one 2<sup>1</sup>/<sub>2</sub>-inch

(64 mm) outlet for each 250 gallon per minute (gpm) (16 L/s) of rated capacity.

Raised letters are required so that any repainting or fading of the colors on the sign will not affect its ability to be read. Each letter must be at least 1 inch (25 mm) in height so that the wording is clear. Often the wording may be abbreviated such that "AUTOMATIC SPRINKLERS" reads as "AUTO. SPKR." Existing signs may use language slightly different than that noted in the code. As long as the information is adequately communicated there should be no reason to require new signage to replace existing ones (see Commentary Figure 912.5).

**Figure 912.5**  
**FIRE DEPARTMENT CONNECTION WITH SIGN**

**912.6 Backflow protection.** The potable water supply to automatic sprinkler and standpipe systems shall be protected against backflow as required by the *International Plumbing Code*.

❖ Section 608.16.4 of the IPC requires all connections to automatic sprinkler systems and standpipe systems to be equipped with a means to protect the potable water supply. The means of backflow protection can be either a double check-valve assembly or a reduced pressure-principle backflow preventer. This, in general, assumes a FDC is required. For example, a limited-area sprinkler system off the domestic supply does not necessarily require a FDC and would not require backflow protection.

**912.7 Inspection, testing and maintenance.** Fire department connections shall be periodically inspected, tested and maintained in accordance with NFPA 25. Records of inspection, testing and maintenance shall be maintained.

❖ Because FDCs are components of a water-based extinguishing system, NFPA 25 is applicable. Inspections must determine that connections are unob-

structed, well-protected and in good working order. Plugs or covers must be installed to protect threads and pipe openings, and must be easily removed to permit connection of a fire hose.

Caps or plugs must be kept in place whenever the connection is not in use to discourage the insertion of objects into the connection openings. The interior of piping behind connection clappers must be checked for foreign material and obstructions.

Threads must be compatible with local fire service hose couplings and free of burrs, depressions and other flaws. Couplings must spin freely. Clappers, if installed in the pipe openings, must open easily and automatically return to the closed position.

Exposed piping, fittings, valves and couplings must be free of water where subject to freezing. Defects must be corrected without delay. These and other maintenance features are addressed in NFPA 25. This section also requires that written inspection and maintenance records be kept. Such records should indicate the date and time and the name of the person conducting the inspection or maintenance. These records must be maintained by the owner and should be made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

### SECTION 913 FIRE PUMPS

**913.1 General.** Where provided, fire pumps shall be installed in accordance with this section and NFPA 20.

❖ This section contains specific installation requirements for fire pumps supplying water to fire protection systems. Inspection, testing and maintenance requirements comply with NFPA 20 unless noted otherwise. Applicable maintenance standards are also identified.

Fire pumps are installed in sprinkler and standpipe systems to pressurize the water supply for the minimum required sprinkler and standpipe operation. They are considered a design feature or component of the system. Fire pumps can improve only the pressure of the incoming water supply, not the volume of water available.

When the volume from a water supply is not adequate to supply sprinkler or standpipe demand, water tanks for private fire protection, improvements in the size and capacity of fire mains or water distribution systems or all of these for the installation of a fire pump are needed.

When fire pumps are required to meet the pressure requirements of sprinkler and standpipe systems, they must be installed and tested in accordance with NFPA 20.

**913.2 Protection against interruption of service.** The fire pump, driver and controller shall be protected in accordance with NFPA 20 against possible interruption of service through damage caused by explosion, fire, flood, earthquake, rodents, insects, windstorm, freezing, vandalism and other adverse conditions.

❖ This section lists hazards that must be taken into account when determining the extent of protection required for the fire pump and its auxiliary equipment. A pump room in a building that is protected against the listed hazards in compliance with the IBC would be considered in compliance. Because fire pumps are also typically located in separate detached structures, geographical and security issues must also be considered.

**913.2.1 Protection of fire pump rooms.** Rooms where fire pumps are located shall be separated from all other areas of the building in accordance with Section 913.2.1 of the *International Building Code*.

❖ The purpose of this section is to require indoor fire pump room separation by fire barriers and horizontal assemblies in accordance with the requirements in the IBC. See the commentary to Section 913.2.1 of the IBC for a complete discussion of the requirements.

**913.2.2 Circuits supplying fire pumps.** Cables used for survivability of circuits supplying fire pumps shall be *listed* in accordance with UL 2196. Electrical circuit protective systems shall be installed in accordance with their listing requirements.

❖ This section is provided to better protect cables used for survivability of circuits associated with fire pumps by referencing the appropriate standard. UL 2196 is the ANSI approved standard for tests of fire resistive cables. NFPA 20 includes selective survivability requirements to assure integrity of certain critical circuits. NFPA 70 does not specify the applicable standard within its mandatory provisions, but recognizes electrical circuit protective systems as an alternate to listed cables. An electrical circuit protective system is a field assembly of components that must be installed according to the listing requirements and manufacturer's instructions in order to maintain the listing for the system. There are more than two dozen electrical circuit protective systems listed in the *UL Fire Resistance Directory*.

**913.3 Temperature of pump room.** Suitable means shall be provided for maintaining the temperature of a pump room or pump house, where required, above 40°F (5°C).

❖ As previously noted for sprinkler systems, standpipe systems and other water-based fire protection systems, pump rooms or pump houses must be maintained at a temperature of 40°F (4°C) or above to prevent the system from freezing.

**913.3.1 Engine manufacturer's recommendation.** Temperature of the pump room, pump house or area where engines are installed shall never be less than the minimum recommended by the engine manufacturer. The engine manufacturer's recommendations for oil heaters shall be followed.

❖ The engine manufacturer's recommendation must be compiled with where the temperature is higher than the minimum established in Section 913.3. Maintaining the desired engine temperature enhances the startability of the engine. Maintaining water heaters and oil heaters as required for diesel engines, for example, will improve the starting capabilities of the fire pump and reduce engine wear and the drain on batteries.

**913.4 Valve supervision.** Where provided, the fire pump suction, discharge and bypass valves, and isolation valves on the backflow prevention device or assembly shall be supervised open by one of the following methods:

1. Central-station, proprietary or remote-station signaling service.
2. Local signaling service that will cause the sounding of an audible signal at a constantly attended location.
3. Locking valves open.
4. Sealing of valves and *approved* weekly recorded inspection where valves are located within fenced enclosures under the control of the *owner*.

❖ As was the case with sprinkler systems, water control valves that are a part of the fire pump installation must be supervised in the open position so that the system is operational when needed and also to reduce the chance of a system failure (see commentary, Section 903.4). In most cases the required water-based extinguishing system, of which the fire pump is an integral component, will be electrically supervised. Locking or sealing valves open as the only means of supervision may not be permitted, depending on the type of valve. Section 903.4, for example, specifically exempts jockey pump control valves from being electrically supervised if they are sealed or locked in the open position.

**913.4.1 Test outlet valve supervision.** Fire pump test outlet valves shall be supervised in the closed position.

❖ Fire pump test outlet valves are for performance testing of the fire pump and do not control the available water supply to either a sprinkler system or a standpipe system. These valves are normally in a closed position and are supervised accordingly.

**913.5 Testing and maintenance.** Fire pumps shall be inspected, tested and maintained in accordance with the requirements of this section and NFPA 25. Records of inspection, testing and maintenance shall be maintained.

❖ Fire pumps require periodic maintenance so that they will perform as required. Monthly maintenance includes running the pump at churn to exercise the pump and driver. Pump packings and relief valve settings must be adjusted as needed.

Annually, the pump must be retested to verify its proper performance. Pressure, flow, revolutions per minute, voltage and, for electric motor-driven pumps, voltage and amperage readings must be recorded, plotted and compared with original design criteria. Upon completion of testing and maintenance, the pump must be left in the automatic-start condition, ready for service. Because a fire pump is a component of a water-based extinguishing system, NFPA 25 is applicable. If the fire pump is powered by a liquid fuel, such as diesel, it is important that the fuel supply be replenished as soon as possible after the test.

**913.5.1 Acceptance test.** Acceptance testing shall be done in accordance with the requirements of NFPA 20.

❖ Chapter 14 of NFPA 20 details the procedure for conducting a fire pump acceptance test. This test is run to determine that the installation matches the sprinkler or standpipe system design criteria, the approved shop drawings and the pump manufacturer's performance specifications. The test is to be conducted in the presence of the building official in accordance with Section 901.5 by the installing contractor and representatives of the pump manufacturer and the controller manufacturer. Where the pump engine and/or transfer switch are separately supplied components, their manufacturer representative must also be present

**913.5.2 Generator sets.** Engine generator sets supplying emergency or standby power to fire pump assemblies shall be periodically tested in accordance with NFPA 110. Records of testing shall be maintained.

❖ This section does not require emergency or standby power for all fire pump installations, but rather requires the testing of on-site generator sets that are used for emergency or standby power to fire pump assemblies. The need for emergency or standby power is typically based on occupancy conditions as indicated in the IBC. Section 403.4.8 of the IBC, for example, requires standby power for all electrically powered fire pumps in high-rise buildings. A generator set is recognized as a permissible standby power source. NFPA 110 prescribes the operational testing requirements, including load tests, as well as the periodic inspection and maintenance for generator sets.

**913.5.3 Transfer switches.** Automatic transfer switches shall be periodically tested in accordance with NFPA 110. Records of testing shall be maintained.

❖ Automatic transfer switches are self-acting equipment that is used to transfer power from a normal source of electrical supply to an alternative supply, such as an engine generator set. NFPA 110 requires a test on each automatic transfer switch that simulates failure of the normal power source. Upon failure, the automatic transfer switch must then automatically transfer the load to the emergency power supply. Manual transfer switches are not permitted as the only means to transfer power between the normal

supply and the alternative supply to the fire pump controller.

**913.5.4 Pump room environmental conditions.** Tests of pump room environmental conditions, including heating, ventilation and illumination, shall be made to ensure proper manual or automatic operation of the associated equipment.

❖ Maintaining suitable environmental conditions is essential to the proper starting capability, performance and safe operation of fire pumps and associated emergency power supplies, where required. Adequate ventilation, for example, is needed to maintain the ambient temperature in the pump room within the range recommended by the manufacturer for the emergency power supply equipment.

### SECTION 914

#### FIRE PROTECTION BASED ON SPECIAL DETAILED REQUIREMENTS OF USE AND OCCUPANCY

**914.1 General.** This section shall specify where *fire protection systems* are required based on the detailed requirements of use and occupancy of the *International Building Code*.

❖ This section is intended to be a duplication of the fire protection system requirements included in Chapter 4 of the IBC located here in a single section of the code for ease of access by the user. It is organized based on the type of facility rather than the type of fire protection system required. Frequently, reference is made to other sections of the code where the requirements are to be found. Occasionally, administrative requirements are noted that do not appear in other sections. In all cases, the referenced section must be reviewed carefully since this section is intended to be subordinate to the main requirements found elsewhere in the code.

**914.2 Covered and open mall buildings.** Covered and open mall buildings shall comply with Sections 914.2.1 through 914.2.4.

❖ Various fire protection-related code sections from Section 402 of the IBC are included in the code so that the fire code official has convenient access to the necessary tools to address conditions and monitor new construction requirements related to fire protection systems in covered and open mall buildings. Not all covered and open mall provisions are included here. Specific information regarding kiosk placement, types of signage and other concerns are located in the IBC and can be consulted when the fire code official reviews the covered or open mall building. Although those provisions are not included here, they address issues that can have an adverse effect on the safety of occupants in the covered or open mall building.

**914.2.1 Automatic sprinkler system.** Covered and open mall buildings and buildings connected shall be equipped

throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, which shall comply with the all of the following:

1. The automatic sprinkler system shall be complete and operative throughout occupied space in the mall building prior to occupancy of any of the tenant spaces. Unoccupied tenant spaces shall be similarly protected unless provided with approved alternative protection.
2. Sprinkler protection for the mall of a covered mall building shall be independent from that provided for tenant spaces or anchor buildings.
3. Sprinkler protection for the tenant spaces of an open mall building shall be independent from that provided for anchor buildings.
4. Sprinkler protection shall be provided beneath exterior circulation balconies located adjacent to an open mall.
5. Where tenant spaces are supplied by the same system, they shall be independently controlled.

**Exception:** An *automatic sprinkler system* shall not be required in spaces or areas of open parking garages separated from the covered or open mall in accordance with Section 402.4.2.3 of the *International Building Code* and constructed in accordance with Section 406.5 of the *International Building Code*.

❖ The requirement for an automatic sprinkler system is found in Section 402.5 of the IBC. This reference provides the fire code official with the information and tools in order to work jointly with the building official in applying the sprinkler requirement for a covered and open mall building.

The covered or open mall building and connected buildings, such as anchor buildings, must be protected with an automatic sprinkler system to protect life and property effectively. As has been discussed throughout the section, numerous allowances (such as reduced tenant separations and elimination of area limitations) are based on the effectiveness of the automatic sprinkler system.

The sprinkler system is to be designed, installed, tested and maintained in accordance with Chapter 9 and NFPA 13. Additionally, the system must be installed such that any portion serving tenant spaces in a covered mall building may be shut down independently without affecting the operation of the systems protecting the mall area. This special feature is in recognition of the frequent need to shut down the system so that changes can be made to it as a result of tenant improvements and modifications.

In an open mall building, the sprinkler systems for the tenant spaces are to be separate from those provided for the anchor buildings. It is necessary that sprinkler protection for open mall buildings be extended to the underneath side of pedestrian walkways and exterior balconies used for circulation and egress purposes. Although the open mall itself

requires no sprinkler protection, it is important that those areas below overhead walkways be provided with sprinklers.

Section 909.12.4 requires operation of the sprinkler system to activate automatically the mechanical smoke control system (where an automatic control system is utilized). It is imperative that the zoning of the sprinkler system match the zoning of the smoke control system. This is necessary so that the area where water flow has occurred will also be the area from which smoke is removed.

The exception clarifies that sprinkler protection need not be extended to complying open parking garages that are adequately separated from the covered mall building, open mall building or anchor store. The allowance is consistent with the automatic sprinkler provisions of Section 903.2 where no sprinkler protection is required in open parking garages based on a Group S-2 occupancy classification.

**914.2.2 Standpipe system.** The covered and open mall building shall be equipped throughout with a standpipe system as required by Section 905.3.3.

❖ The standpipe requirements for covered and open mall buildings exist in the code, as well as in Section 402.7.1 of the IBC, which refers to Section 905 for the requirements. For additional information regarding the requirements, see the commentary for Section 905.3.3.

**914.2.3 Emergency voice/alarm communication system.** Where the total floor area exceeds 50,000 square feet (4645 m<sup>2</sup>) within either a covered mall building or within the perimeter line of an open mall building, an emergency voice/alarm communication system shall be provided. Emergency voice/alarm communication systems serving a mall, required or otherwise, shall be accessible to the fire department. The system shall be provided in accordance with Section 907.5.2.2.

❖ This section is identical to Section 402.7.4 of the IBC. In covered and open mall buildings, there is a need to be able to control the large number of people that may be present. This can best be done when specific instructions are conveyed. Covered and open malls that are less than 50,000 square feet (4645 m<sup>2</sup>) in area are not required to be provided with an emergency voice alarm system. If a public address system is provided in a smaller mall, it can serve the same purpose. See the commentary to Section 907.5.2.2 for additional information.

**914.2.4 Fire department access to equipment.** Rooms or areas containing controls for air-conditioning systems, automatic fire-extinguishing systems, *automatic sprinkler systems* or other detection, suppression or control elements shall be identified for use by the fire department.

❖ Section 402.7.5 of the IBC also states this requirement. The intent is that the fire department be able to access those systems that are critical to fire protection as well as those parts of the mechanical system that can aid in control of the ventilation system to use

as conditions warrant. The text is included here so that the fire code official has a means for applying the requirement and approving the means by which identification of the rooms or areas will be provided.

**914.3 High-rise buildings.** High-rise buildings shall comply with Sections 914.3.1 through 914.3.7.

❖ High-rise buildings have unique challenges that set them apart from other buildings. Section 403 of the IBC establishes multiple fire protection requirements for such buildings.

**914.3.1 Automatic sprinkler system.** Buildings and structures shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 and a secondary water supply where required by Section 914.3.3.

**Exception:** An *automatic sprinkler system* shall not be required in spaces or areas of:

1. Open parking garages in accordance with Section 406.5 of the *International Building Code*.
2. Telecommunications equipment buildings used exclusively for telecommunications equipment, associated electrical power distribution equipment, batteries and standby engines, provided that those spaces or areas are equipped throughout with an automatic fire detection system in accordance with Section 907.2 and are separated from the remainder of the building by not less than 1-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or not less than 2-hour *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both.

❖ In order to provide protection for occupants and fire fighters, high-rise buildings are required to be equipped with an automatic sprinkler system. There are two exceptions that allow sprinkler protection to be omitted. Exception 1 is for an open parking garage that is a part of the high-rise building. This exception recognizes the relatively low life safety threat posed by fires in open parking garages. Additional information on open parking garages can be obtained in the commentary for Section 406 of the IBC.

Exception 2 acknowledges the water sensitivity of telecommunications systems. See commentary to the same exception in Section 903.2.

**914.3.1.1 Number of sprinkler risers and system design.** Each sprinkler system zone in buildings that are more than 420 feet (128 m) in height shall be supplied by no fewer than two risers. Each riser shall supply sprinklers on alternate floors. If more than two risers are provided for a zone, sprinklers on adjacent floors shall not be supplied from the same riser.

❖ The intent of this section is to increase the reliability of automatic sprinkler systems in very tall buildings, i.e., those that exceed 420 feet in height, by requiring a minimum of two risers for each sprinkler system zone. The difficulty of fighting fires in very tall buildings ranges from difficult to virtually impossible with

the sprinkler system impaired. Accordingly, the reliable functioning of sprinkler systems is critical. Various events could cause a sprinkler riser to be impaired, thereby leaving the structure vulnerable to fire. The NIST World Trade Center (WTC) Report documented that the proximate cause of the buildings collapse was a building contents fire that raged out of control, in part at least, because the building's automatic sprinkler systems were nonfunctional due to the initial aircraft attack. Events far less dramatic could knock out or make a sprinkler riser inoperative, thereby leaving the structure highly vulnerable to fire.

Recommendation 12 of the NIST WTC report calls for the redundancy of active fire suppression systems to be increased to accommodate the greater risks associated with increased building height and population. This section seeks to do that by requiring two risers designed such that, if one riser is taken out of service, the other will be able to supply sprinklers on the floors above and below. This will impede any fire spread and allow the fire department time to respond and extinguish the fire. At the Meridian Plaza fire in Philadelphia, the further spread of an out of control fire occurring on floors not protected by sprinklers was prevented by the operation of ten sprinklers when the fire reached a floor which had been retrofitted with sprinklers.

**914.3.1.1.1 Riser location.** Sprinkler risers shall be placed in interior exit stairways and ramps that are remotely located in accordance with Section 1015.2.

❖ This section requires the sprinkler risers to be located in protected interior exit stairways and ramps and specifies a separation distance to reduce the possibility that one incident could incapacitate both risers which is consistent with the approach used in the code for interior exit stairway separation. See commentary to Section 1007.

**914.3.1.2 Water supply to required fire pumps.** In buildings that are more than 420 feet (128 m) in *building height*, required fire pumps shall be supplied by connections to no fewer than two water mains located in different streets. Separate supply piping shall be provided between each connection to the water main and the pumps. Each connection and the supply piping between the connection and the pumps shall be sized to supply the flow and pressure required for the pumps to operate.

**Exception:** Two connections to the same main shall be permitted provided the main is valved such that an interruption can be isolated so that the water supply will continue without interruption through no fewer than one of the connections.

❖ Fire pumps are installed in sprinkler and standpipe systems to pressurize the water supply for the minimum required sprinkler and standpipe operation. Fire pumps are only "required" to meet the system needs. Therefore, whether a particular high-rise building includes fire pumps will depend on interaction of the height of the building, the local water system and the

designs of the sprinkler and standpipe systems in the building (see Section 913 for more information on fire pumps).

The difficulty of fighting fires in very tall buildings ranges from hard to virtually impossible. Accordingly, the reliable functioning of required sprinkler and standpipe systems is critically important.

Recommendation 12 of the NIST WTC report called for the redundancy of active fire suppression systems to be increased to accommodate the greater risks associated with increasing building height and population. Where the systems require a fire pump and the building is more than 420 feet (128 m) in height, this section requires the fire pumps to be supplied by two water mains located in separate streets. The purpose of this is to increase the reliability of fire suppression systems in very tall buildings by requiring independent street-level water feeds such that the system will function as intended if one of those feeds is damaged or otherwise interrupted. Having two connections will greatly reduce the possibility of the loss of water due to a main break, given the valving which is a feature of a public water system. Each connection must be adequate to provide the flow and pressure needed for the fire pumps to operate. The exception is a performance-based provision that is not tied to any specific configuration.

**914.3.2 Secondary water supply.** An automatic secondary on-site water supply having a capacity not less than the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings assigned to Seismic Design Category C, D, E or F as determined by the *International Building Code*. An additional fire pump shall not be required for the secondary water supply unless needed to provide the minimum design intake pressure at the suction side of the fire pump supplying the *automatic sprinkler system*. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

**Exception:** Existing buildings.

❖ The intent of this section is that a secondary water supply be provided on the high-rise building site in order to provide a high level of functional reliability for the fire protection systems if a seismic event disables the primary water supply for high-rise buildings assigned these Seismic Design categories. The categories are described in Section 1613 of the IBC.

The text's specific wording that the secondary supply be "on-site" rather than "to the site" would preclude the use, for example, of a secondary connection to the municipal supply to achieve compliance with this requirement.

The required amount of water is equal to the hydraulically calculated sprinkler demand plus hose stream demand for a minimum 30 minute period dependent on the appropriate occupancy hazard classification in NFPA 13.

Note that the beginning of Section 914.3.2 requires that the secondary water supply be automatic; in other words, switchover to the secondary water source cannot occur manually. This is consistent with the definitions of "Automatic sprinkler system" and "Classes of standpipe systems;" in that both systems are required to be connected to a reliable water supply.

Generally, this section does not automatically require a second fire pump, but, if necessary, an additional pump may be required. A second pump would be necessary if the secondary water supply does not provide the necessary water pressure for intake into the primary fire pump.

**914.3.3 Fire alarm system.** A fire alarm system shall be provided in accordance with Section 907.2.13.

❖ See the commentary to Section 907.2.13.

**914.3.4 Automatic smoke detection.** Smoke detection shall be provided in accordance with Section 907.2.13.1.

❖ Section 907.2.13 indicates specific locations where smoke detection is required for a high-rise building. These requirements are due to the fact that the building is a high rise and not necessarily dependent upon the occupancy within. There may be additional requirements in other sections of the code that require specific detection due to the occupancy.

**914.3.5 Emergency voice/alarm communication system.** An emergency voice/alarm communication system shall be provided in accordance with Section 907.5.2.2.

❖ Due to the size of high-rise buildings, an emergency voice/alarm communication is required so that specific commands can be given as necessary. See the commentary to Sections 907.2.13 and 907.5.2.2 for additional information.

**914.3.6 Emergency responder radio coverage.** Emergency responder radio coverage shall be provided in accordance with Section 510.

❖ The provisions of Section 510 are concerned with the reliability of portable radios used by emergency responders inside of buildings. This is in keeping with the philosophy inherent in the I-Codes that, when a facility grows too large or complex for effective fire response, fire protection features must be provided within the building. See the commentary to Section 510 for complete information on this topic.

**914.3.7 Fire command.** A *fire command center* complying with Section 508 shall be provided in a location *approved* by the fire department.

❖ Section 508 of the code contains the same information as Section 911 of the IBC on this subject. The fire command center must always be accessible to the fire service. See the commentary to Section 508 for additional information.

**914.4 Atriums.** Atriums shall comply with Sections 914.4.1 and 914.4.2.

❖ Atriums are addressed in Section 404 of the IBC, which identifies several fire protection systems that must be included in atriums. It is important to remember that these are requirements that are unique to the specific condition noted and the fire protection systems are a result of those conditions. These requirements are only partially related to the occupancies that may be present.

**914.4.1 Automatic sprinkler system.** An *approved automatic sprinkler system* shall be installed throughout the entire building.

**Exceptions:**

1. That area of a building adjacent to or above the atrium need not be sprinklered, provided that portion of the building is separated from the atrium portion by not less than a 2-hour *fire barrier* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both.
2. Where the ceiling of the atrium is more than 55 feet (16 764 mm) above the floor, sprinkler protection at the ceiling of the atrium is not required.

❖ Due to the possibility that smoke and fire could spread through an unprotected vertical opening, an automatic sprinkler system is required when an atrium is present in a building and must be installed throughout the building as a preventive measure. If, however, the atrium is treated more like a shaft and provided with a 2-hour enclosure, only the atrium itself must be sprinklered.

The assumption in Exception 1 is that the passive protection systems that isolate the atrium would be sufficient to compensate for the limited sprinkler coverage and be an acceptable alternative to sprinklers throughout the building.

Exception 2 allows for the omission of sprinklers in tall spaces for two reasons. First, due to the entrainment of cooler ambient air in the flame plume, the likelihood that sprinklers will activate diminishes greatly with increased atrium ceiling height. Secondly, the effectiveness of the sprinkler water discharging from such heights is also substantially diminished.

**914.4.2 Fire alarm system.** A fire alarm system shall be provided where required by Section 907.2.14.

❖ See the commentary for Section 907.2.14.

**914.5 Underground buildings.** Underground buildings shall comply with Sections 914.5.1 through 914.5.5.

❖ Section 405 of the IBC contains requirements for underground buildings. The fire protection features

necessary for this type of building are also found elsewhere in this chapter but are reiterated in the following sections. Underground buildings present unique hazards in that the path of egress is upward, in the same direction as vertical fire movement. Fires in such buildings are also more challenging for fire fighters since there is no opportunity for an exterior fire attack. See the commentary for Section 405 of the IBC for additional information.

**914.5.1 Automatic sprinkler system.** The highest *level of exit discharge* serving the underground portions of the building and all levels below shall be equipped with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1. Water-flow switches and control valves shall be supervised in accordance with Section 903.4.

❖ Underground buildings have occupiable levels that are more than 30 feet (9144 mm) below the lowest level of exit discharge. This requirement from the IBC indicates that sprinklers are required for the portions of the building that are below ground and the story at the highest level of exit discharge. The provision does not require sprinklers for any stories that may be above the highest level of exit discharge. If sprinklers were required for those areas, it would be due to provisions in other sections of the code. In some respects, this is an expansion of the general provisions for windowless stories in Section 903.2.11.1.

**914.5.2 Smoke control system.** A smoke control system is required to control the migration of products of combustion in accordance with Section 909 and provisions of this section. Smoke control shall restrict movement of smoke to the general area of fire origin and maintain *means of egress* in a usable condition.

❖ One common application for an underground building is to use excavated caverns for storage. In such a condition, there is no roof from which the fire service can attempt to vent the “building.” Because occupants must egress in the same direction that smoke will vent itself, and because there are few, if any, openings by which to vent smoke to the exterior, the need for smoke control is greater than for traditional buildings. This section adds a degree of clarity to the design requirements of Section 909 in that the intent is to contain smoke to the general area of origin. Any method identified in Section 909 can be used, given that the intent is to allow for egress and limit smoke spread to areas of the building that are not involved in the fire event. See Section 909 for additional commentary on smoke control.

**914.5.3 Compartment smoke control system.** Where compartmentation is required by Section 405.4 of the *International Building Code*, each compartment shall have an independent smoke control system. The system shall be automatically activated and capable of manual operation in accordance with Section 907.2.18.

❖ When buildings contain levels that are more than 60 feet below the lowest level of exit discharge, Section

405.4.1 of the IBC requires that there be at least two fire-resistance-rated compartments per floor and of approximately the same size. Because compartmentation exists, there is a need for additional safety with the smoke control system. Consequently, each compartment must have a smoke control system that is independent of that in the adjoining compartment. The word “independent” means that there can be no sharing of ductwork, mechanical equipment or power distribution. Connection to the standby system can be shared since that is consistent with the general intent of the smoke control system provisions in Section 909 and the IMC. See the commentary to Section 405.4 of the IBC.

**914.5.4 Fire alarm system.** A fire alarm system shall be provided where required by Sections 907.2.18 and 907.2.19.

❖ The threshold for requiring the fire alarm system is the same as that for compartmentation—an occupied floor level more than 60 feet (18 288 mm) below the level of exit discharge. The fire alarm requirements include the requirements for an emergency voice/ alarm communication system. See the commentary to Sections 907.2.18 and 907.2.19 for additional information.

**914.5.5 Standpipe system.** The underground building shall be provided throughout with a standpipe system in accordance with Section 905.

❖ Section 905.3.1 requires a standpipe system when the building’s lowest level is more than 30 feet (9144 mm) below the lowest level of fire department access. By definition, an underground building is one in which the lowest level is more than 30 feet (9144 mm) below the lowest level of exit discharge. One condition uses fire department vehicle access as the benchmark while the other uses the level of exit discharge. Care must be taken so that both conditions are addressed when determining standpipe system requirements for buildings that have levels below ground.

**914.6 Stages.** Stages shall comply with Sections 914.6.1 and 914.6.2.

❖ Section 410 of the IBC contains definitions and requirements for both stages and platforms. A stage, however, is a special condition according to the IBC. It does not mean, for example, that an elevated platform in the front of the banquet hall is intended to be regulated the same as a stage. The term “stage,” as used here, is traditionally considered a “legitimate stage”—one with scenery drops and a gridiron above. See the commentary to Section 410 of the IBC for further information.

**914.6.1 Automatic sprinkler system.** Stages shall be equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1. Sprinklers shall be installed under the roof and gridiron and under all catwalks and galleries over the stage. Sprinklers shall be installed in dressing rooms, per-

former lounges, shops and storerooms accessory to such stages.

**Exceptions:**

1. Sprinklers are not required under stage areas less than 4 feet (1219 mm) in clear height utilized exclusively for storage of tables and chairs, provided the concealed space is separated from the adjacent spaces by Type X gypsum board not less than  $\frac{5}{8}$  inch (15.9 mm) in thickness.
  2. Sprinklers are not required for stages 1,000 square feet (93 m<sup>2</sup>) or less in area and 50 feet (15 240 mm) or less in height where curtains, scenery or other combustible hangings are not retractable vertically. Combustible hangings shall be limited to a single main curtain, borders, legs and a single backdrop.
  3. Sprinklers are not required within portable orchestra enclosures on stages.
- ❖ Stages contain significant quantities of combustible materials stored in, around and above the stage that are located in close proximity to large quantities of lighting equipment (i.e., scenery and lighting above the stage). There also is scenery on the sides and rear of the stage; shops located along the back and sides of the stage and storage, props, trap doors and lifts under the stage floor. This combination of fuel load and ignition sources increases the potential for a fire. As such, stages and accessory areas, such as dressing rooms, workshops and storerooms, are required to be protected with an automatic sprinkler system (see commentary, IBC Section 410.7).

Both of the exceptions are intended to be applied where the building would not otherwise be required to be provided with sprinklers. If the building must be sprinklered throughout then the two exceptions are moot. Sprinkler installations must be in accordance with NFPA 13 and placed as required by that standard.

Exception 1 allows simple storage in the space below the stage, a space traditionally used for table and chair storage. The space must be compartmentalized so that a minimal thermal barrier is provided between the stored material and the areas outside the space. If the height of the space exceeds 4 feet (1219 mm) or the materials stored are other than those associated with table and chair storage, then sprinklers must be provided.

Exception 2 recognizes that small stage settings do not pose the same risk as larger stages. In schools where the stage may only be an elevated portion at the end of the cafeteria, for example, the exception gives a basis for determining whether sprinkler protection is required or not. If scenery is simply manually set in place or moved horizontally, the large fuel loads associated with stages is not present.

**914.6.2 Standpipe system.** Standpipe systems shall be provided in accordance with Section 905.

- ❖ Due to the historic fires on stages of theaters, the code requires that a standpipe system be provided

for all stages greater than 1,000 square feet (93 m<sup>2</sup>) in area. The design requirements are dependent on the extent of sprinkler protection. See the commentary to Section 905.3.4 for additional information about the standpipe requirements.

**914.7 Special amusement buildings.** Special amusement buildings shall comply with Sections 914.7.1 and 914.7.2.

- ❖ A special amusement building is one in which the egress is not readily apparent, is intentionally confounded or is not readily available. Due to those characteristics, special fire protection features are required. See the commentary to Section 411 of the IBC for additional information about these types of facilities.

**914.7.1 Automatic sprinkler system.** Special amusement buildings shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1. Where the special amusement building is temporary, the sprinkler water supply shall be of an *approved* temporary means.

**Exception:** Automatic sprinklers are not required where the total floor area of a temporary special amusement building is less than 1,000 square feet (93 m<sup>2</sup>) and the *exit access* travel distance from any point to an *exit* is less than 50 feet (15 240 mm).

- ❖ Special amusement buildings do not normally have a readily identifiable means of egress. Consequently additional time for safe egress may be necessary. A sprinkler system will minimize the potential hazard to occupants by controlling fire development (see commentary, IBC Section 411).

**914.7.2 Automatic smoke detection.** Special amusement buildings shall be equipped with an automatic smoke detection system in accordance with Section 907.2.12.

- ❖ Section 907.2.12 indicates that a smoke detection system is required for special amusement buildings. See the commentary to Section 907.2.12 for additional information.

**914.8 Aircraft-related occupancies.** Aircraft-related occupancies shall comply with Sections 914.8.1 through 914.8.6.

- ❖ Aircraft related occupancies include air traffic control towers, residential and commercial hangars and heliports and helistops. Hangars can be those for storage and “parking” of the aircraft or for repair and painting. All of these are addressed in Section 412 of the IBC.

While the following provisions do not identify fire protection requirements for heliports and helistops, Section 412.8 of the IBC requires that these facilities be designed in accordance with NFPA 418. That standard contains various provisions for fire protection including a foam fire-extinguishing system for rooftop landing pads and portable fire extinguishers. Section 2007 of the code contains fire protection requirements for helistops and heliports. Section 905.3.6 requires a standpipe system for helistops and heliports. Additional requirements for portable fire extinguishers in aviation facilities can be found in Section 2005 of the code.

**914.8.1 Automatic smoke detection systems.** Airport traffic control towers shall be provided with an automatic smoke detection system installed in accordance with Section 907.2.22.

❖ Airport traffic control towers are required to have an automatic fire detection system. Because the tower is designed so that people are elevated in the air, the vertical supports generally are narrow and contain little room for separated stairways. An early notification of a fire hazard is important in alerting the occupants so that fire safety operations can be begun as quickly as possible. An automatic detection system is therefore required. Section 907.2.22.1 applies specifically to towers where sprinklers are provided and there are at least two means of egress. Where there is only a single means of egress, Section 907.2.22.2 specifies the coverage of the fire detection systems. Section 907.2.22.2 also applies to towers which are not sprinkler protected although only towers of a height of less than 35 feet would be without sprinklers (see IBC Section 412.3.6). Where suppression is not required by the code, the detection system is vital for the safety of the occupants. No requirements are included in Chapter 11 of the code to address existing airport traffic control towers.

**914.8.2 Automatic sprinkler system for new airport traffic control towers.** Where an occupied floor is located more than 35 feet (10 668 mm) above the lowest level of fire department vehicle access, new airport traffic control towers shall be equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ Sprinkler systems are required for all towers being constructed under Section 412.3.6 of the IBC once there is an occupied floor above 35 feet. This height was selected because shorter towers should be reachable by ladders typically found at rural fire stations and smaller airports. These are also the types of airports that would have the shorter control towers. Due to the absence of aerial ladders or means to reach higher elevations at these locations, additional levels of fire protection are required. As such, life safety is positively affected by limiting the chance of smoke/fire spread and flashover in the facility where delayed evacuation of the cab may be required. In addition, property protection to allow sooner reuse of the structure would be provided.

**914.8.3 Fire suppression for aircraft hangars.** Aircraft hangars shall be provided with a fire suppression system designed in accordance with NFPA 409, based upon the classification for the hangar given in Table 914.8.3.

**Exception:** Where a fixed base operator has separate repair facilities on site, Group II hangars operated by a fixed base operator used for storage of transient aircraft only shall have a fire suppression system, but the system shall be exempt from foam requirements.

❖ To minimize the fire hazards associated with aircraft hangars, most hangars are required to be protected with a fire suppression system. Where required, the

fire suppression system must be designed and installed in accordance with the referenced standard, NFPA 409 which requires fire suppression based on the type and construction and the activities in a given hangar.

In the standard, the suppression requirements are broken down based on three categories: Group I, Group II and Group III hangars. Table 914.8.2 designates which Group designation applies to various sizes of fire areas within a hangar and the type of construction. For example a hangar which is 28,000 square feet (2601 m<sup>2</sup>) in Type IIB construction would be a Group II hangar. Groups I and II hangars are required to have fire suppression as specified the NFPA 409. In general Group III hangars are exempt from providing fire suppression unless one (or more) of the hazardous operations listed in Section 914.8.3.1 occurs within the hangar. In these situations fire suppression based on the appropriate portion of the standard for either Group I or Group II is required.

The exception allows for Group II hangars that the foam requirements for fire suppression do not need to be provided if the hangar is essentially a parking garage for transient aircraft. The exception is only applicable where a larger airport facility has multiple hangars and separate hangars for repair operations.

**TABLE 914.8.3.** See page 9-149.

❖ This table is a correlation of the NFPA 409 construction and area limits with the IBC construction type requirements. It combines several tables in NFPA 409 into a single table that allows determination of the group type for aircraft hangars based on construction type and area before proceeding to the standard for the suppression requirements. Note a indicates that, regardless of size or construction type, any hangar with a door opening greater than 28 feet high (8534 mm) is required to have a fire suppression system as required for a Group I hangar. Note c provides a Group IV designation for any hangar located in a membrane structure.

**914.8.3.1 Hazardous operations.** Any Group III aircraft hangar in accordance with Table 914.8.3 that contains hazardous operations including, but not limited to, the following shall be provided with a Group I or II fire suppression system in accordance with NFPA 409 as applicable:

1. Doping.
2. Hot work including, but not limited to, welding, torch cutting and torch soldering.
3. Fuel transfer.
4. Fuel tank repair or maintenance not including defueled tanks in accordance with NFPA 409, inerted tanks or tanks that have never been fueled.
5. Spray finishing operations.
6. Total fuel capacity of all aircraft within the unsprinklered single *fire area* in excess of 1,600 gallons (6057 L).

7. Total fuel capacity of all aircraft within the maximum single *fire area* in excess of 7,500 gallons (28 390 L) for a hangar equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.

❖ Any of the operations listed in this section where they occur in a Group III hangar will require some level of fire suppression under NFPA 409. The hazardous operations on the list are straight forward. Additional information may be found as follows: Item 1 is discussed further in Section 914.8.4; Item 2 is regulated by Chapter 35; Items 3 and 4 are regulated by Chapter 57; Item 5 is regulated by Chapter 24.

**914.8.3.2 Separation of maximum single fire areas.** Maximum single *fire areas* established in accordance with hangar classification and construction type in Table 914.8.3 shall be separated by 2-hour *fire walls* constructed in accordance with Section 706 of the *International Building Code*. In determining the maximum single fire area as set forth in Table 914.8.3, ancillary uses that are separated from aircraft servicing areas by not less than a 1-hour *fire barrier* constructed in accordance with Section 707 of the *International Building Code* shall not be included in the area.

❖ Table 914.8.3 places a maximum size limit on hangars based on type of construction. For a hangar structure to exceed these sizes requires the construction of fire walls to establish fire areas than stay within the limits. This section is more stringent than the definition of “Fire areas” which allows fire barriers to establish a fire area. For hangars, the fire areas must be created by exterior walls of a building or a combination of exterior walls and fire walls. Note that there is some allowance for the use of fire barriers to create fire areas when separating ancillary uses such as business offices, maintenance shops and storage areas. The fire suppression requirements contained within NFPA 409 are primarily focused on the protection of aircraft within the servicing and storage area.

The fire protection requirements in the ancillary areas are not as extensive as those required for the aircraft servicing and storage areas and less restrictive separations are considered appropriate. This allowance is consistent with NFPA 409 requirements.

**914.8.4 Finishing.** The process of “doping,” involving the use of a volatile flammable solvent, or of painting shall be carried on in a separate detached building equipped with automatic fire-extinguishing equipment in accordance with Section 903.

❖ Doping is a type of lacquer used to protect, waterproof and make taut cloth surfaces of airplane wings. It is used on lighter-than-air, ultra-light and some light aircraft. It is essentially painting on fabric. Doping is not used on metallic surfaces; however, the use of flammable paints is also addressed in this section. When flammable finishes are applied, the process must occur in a separate building not attached to the hangar. Because the code text refers to Section 903 the intent is for an automatic sprinkler system to be installed, unless otherwise approved (see commentary, IBC Section 412.4.5).

**914.8.5 Residential aircraft hangar smoke alarms.** Smoke alarms shall be provided within residential aircraft hangars in accordance with Section 907.2.21.

❖ A residential aircraft hangar, as defined in Section 202 of the IBC, is “. . . an accessory building less than 2,000 square feet (186 m<sup>2</sup>) and 20 feet (6096 mm) in height, constructed on a one- or two-family residential property where aircraft are stored. . .” The requirements for the residential hangar are very similar to that for a residential garage. The hangar can be either detached or attached. If attached, it must be separated from the dwelling by construction with not less than a 1-hour fire-resistance rating. Section 907.2.21 requires a minimum of one smoke alarm in a residential aircraft hangar. See the commentary to Section 907.2.21 for additional information.

**TABLE 914.8.3  
HANGAR FIRE SUPPRESSION REQUIREMENTS<sup>a,b,c</sup>**

MAXIMUM SINGLE FIRE AREA (square feet)	INTERNATIONAL BUILDING CODE TYPE OF CONSTRUCTION								
	IA	IB	IIA	IIB	IIIA	IIIB	IV	VA	VB
> 40,001	Group I	Group I	Group I	Group I	Group I	Group I	Group I	Group I	Group I
40,000	Group II	Group II	Group II	Group II	Group II	Group II	Group II	Group II	Group II
30,000	Group III	Group II	Group II	Group II	Group II	Group II	Group II	Group II	Group II
20,000	Group III	Group III	Group II	Group II	Group II	Group II	Group II	Group II	Group II
15,000	Group III	Group III	Group III	Group II	Group III	Group II	Group III	Group II	Group II
12,000	Group III	Group III	Group III	Group III	Group III	Group III	Group III	Group II	Group II
8,000	Group III	Group III	Group III	Group III	Group III	Group III	Group III	Group III	Group II
5,000	Group III	Group III	Group III	Group III	Group III	Group III	Group III	Group III	Group III

For SI: 1 square foot = 0.0929 m<sup>2</sup>, 1 foot = 304.8 mm.

a. Aircraft hangars with a door height greater than 28 feet shall be provided with fire suppression for a Group I hangar regardless of maximum fire area.

b. Groups shall be as classified in accordance with NFPA 409.

c. Membrane structures complying with Section 3102 of the *International Building Code* shall be classified as a Group IV hangar.

**914.8.6 Aircraft paint hangar fire suppression.** Aircraft paint hangars shall be provided with fire suppression as required by NFPA 409.

❖ To minimize the fire hazards associated with aircraft paint hangars, all such buildings are required to be protected with a fire suppression system. This requirement is applicable regardless of the size of the hangar in terms of height or area or the types and quantities of aircraft that are being cleaned or painted. The fire suppression system must be designed and installed in accordance with NFPA 409.

This section assumes the primary function of the hangar is as a paint hangar. Minor painting may constitute finishing in accordance with Section 914.8.4. While not referenced in the code, NFPA 410 provides additional guidance on aircraft maintenance, including the painting of aircraft.

**914.9 Application of flammable finishes.** An *automatic sprinkler system* or fire-extinguishing system shall be provided in all spray, dip and immersing spaces and storage rooms, and shall be installed in accordance with Chapter 9.

❖ Chapter 24 provides detailed information about spaces and rooms involved in the application of flammable finishes. This section references Chapter 9 for the appropriate type of fire-extinguishing system.

**914.10 Drying rooms.** Drying rooms designed for high-hazard materials and processes, including special occupancies as provided for in Chapter 4 of the *International Building Code*, shall be protected by an *approved* automatic fire-extinguishing system complying with the provisions of Chapter 9.

❖ This section reiterates the requirements from Section 417.4 of the IBC. See the commentary to Section 417.4 of the IBC for additional information.

**914.11 Ambulatory care facilities.** Occupancies classified as ambulatory care facilities shall comply with Sections 914.11.1 through 914.11.3.

❖ This section simply introduces the fire protection requirements for ambulatory care facilities. See also the commentary to Section 422 of the IBC.

**914.11.1 Automatic sprinkler systems.** An *automatic sprinkler system* shall be provided for ambulatory care facilities in accordance with Section 903.2.2.

❖ See the commentary to Section 903.2.2.

**914.11.2 Manual fire alarm systems.** A manual fire alarm system shall be provided for ambulatory care facilities in accordance with Section 907.2.2.

❖ See the commentary to Section 907.2.2.

**914.11.3 Fire alarm systems.** An automatic smoke detection system shall be provided for ambulatory care facilities in accordance with Section 907.2.2.1.

❖ See the commentary to Section 907.2.2.1.

## SECTION 915 CARBON MONOXIDE DETECTION

**915.1 General.** Carbon monoxide detection shall be installed in new buildings in accordance with Sections 915.1.1 through 915.6. Carbon monoxide detection shall be installed in existing buildings in accordance with Section 1103.9.

❖ These provisions were added to this code and the IBC to be consistent with the requirements for carbon monoxide (CO) detectors in all new construction of one- and two-family dwellings that had been added to the IRC in the 2009 edition. Another reason for its approval was technical data in a 1998 article published by the *Journal of the American Medical Association* that stated that approximately 2,100 deaths occur annually as a result of CO poisoning. That annual number is based on the findings of a paper prepared by the U.S. Department of Health Centers for Disease Control (CDC). That paper documented epidemiological research by two CDC physicians who examined 56,133 death certificates over a 10-year period. Excluding suicides, homicides, structure fires and deaths resulting from CO poisoning in motor vehicles, the death rate steadily decreased for the sample period, from a value of 1513 people in 1979 to 878 in 1988. The highest death rates occurred in winter and among males, African Americans, the elderly and residents in northern states.

CO is a colorless, tasteless, odorless gas that interrupts the attachment of oxygen molecules to hemoglobin in blood cells and can cause headaches, confusion and dizziness. At higher concentrations, CO can cause loss of consciousness and eventual death. Exposures above 100 parts/million are dangerous to human health. It is not a toxic or highly toxic gas as defined in Chapter 2 but is classified as a flammable gas.

The provisions of Section 915 detail what occupancies require CO detection and where that detection is specifically to be located within the building. Also flexibility on the use of single- and multiple-station alarms versus CO detection systems is provided.

Retroactive requirements are found in Chapter 11. These requirements are essentially the same except that Group E classrooms are not addressed and the CO alarms can be battery powered.

**915.1.1 Where required.** Carbon monoxide detection shall be provided in Group I-1, I-2, I-4 and R occupancies and in classrooms in Group E occupancies in the locations specified in Section 915.2 where any of the conditions in Sections 915.1.2 through 915.1.6 exist.

❖ CO detection is provided to protect occupants of dwelling units and sleeping units within Group I-1, I-4, and R occupancies and classrooms in Group E occupancies. These are locations where occupants are

likely to be sleeping or that young children may be at risk. Sections 915.1.2 through 915.1.5 address the different scenarios that warrant CO detection and are more specific than past editions of the code and the IBC.

**915.1.2 Fuel-burning appliances and fuel-burning fireplaces.** Carbon monoxide detection shall be provided in *dwelling units, sleeping units* and classrooms that contain a fuel-burning appliance or a fuel-burning fireplace.

❖ This section clarifies that CO detection is required where the dwelling or sleeping unit or the classroom actually contains a fuel burning appliance or fuel burning fireplace. Section 915.1.3 discusses dwelling and sleeping units and classrooms that are served by fuel burning, forced-air furnaces.

**915.1.3 Forced-air furnaces.** Carbon monoxide detection shall be provided in *dwelling units, sleeping units* and classrooms served by a fuel-burning, forced-air furnace.

**Exception:** Carbon monoxide detection shall not be required in *dwelling units, sleeping units* and classrooms where carbon monoxide detection is provided in the first room or area served by each main duct leaving the furnace, and the carbon monoxide alarm signals are automatically transmitted to an approved location.

❖ This section addresses forced-air furnaces that physically move air. This source is more indirect than having the fuel-burning appliance or fuel-burning fireplace within the space itself but still creates a potential hazard.

The exception addresses the fact that if detection is provided more closely to the source, then further detection within dwelling units, sleeping units and Group E classrooms is not necessary provided that a CO alarm signal is transmitted to an approved location from which emergency actions can be initiated and occupants in the portions of the building more remote from the initial detection can be notified. The CO will continue to be generated until action is taken.

**915.1.4 Fuel-burning appliances outside of dwelling units, sleeping units and classrooms.** Carbon monoxide detection shall be provided in *dwelling units, sleeping units* and classrooms located in buildings that contain fuel-burning appliances or fuel-burning fireplaces.

**Exceptions:**

1. Carbon monoxide detection shall not be required in *dwelling units, sleeping units* and classrooms where there are no communicating openings between the fuel-burning appliance or fuel-burning fireplace and the *dwelling unit, sleeping unit* or classroom.
2. Carbon monoxide detection shall not be required in *dwelling units, sleeping units* and classrooms where carbon monoxide detection is provided in one of the following locations:
  - 2.1. In an approved location between the fuel-burning appliance or fuel-burning fireplace and the *dwelling unit, sleeping unit* or classroom.

- 2.2. On the ceiling of the room containing the fuel-burning appliance or fuel-burning fireplace.

❖ This section focuses on the presence of fuel burning equipment in buildings containing dwelling units, sleeping units and classrooms but with the fuel burning equipment located outside of those areas. CO detection is required in every dwelling unit, sleeping unit and classroom, even if that equipment does not serve those spaces. A good example of this is a multi-story hotel that has all electric HVAC in the sleeping units, but perhaps a fireplace in the lobby, forced air heating in the common area, and a boiler in an equipment room.

There are two exceptions provided that recognize, based upon several factors, that the CO is a very low risk to the spaces required to be protected by Section 915.

Exception 1 addresses buildings where there are no communicating openings between the location of the fuel burning appliance and dwelling units, sleeping units and classrooms. The intent is that if the appliance is not serving the space and has no communication with the space, CO should not enter those spaces. This covers situations where CO emanating from the fuel burning appliance has no direct path to a dwelling unit or sleeping unit, such as a water heater in an equipment room that only has access from the exterior of the building, and no openings through which the CO can get to dwelling units or sleeping units. An interior door, between the equipment room and a dwelling unit, even if it is self-closing, would not allow this exception to be used.

Exception 2 is similar to the exception to Section 915.1.3. This exception requires the installation of one or more CO alarms in approved locations between fuel burning appliances and the nearest dwelling unit, sleeping unit or classroom or on the ceiling of the room in which a fuel-burning appliance is located. CO alarms are only required where there are communicating openings including ducts, concealed spaces, interior hallways, stairs and spaces between the fuel-burning appliance or fuel burning fireplace and the dwelling unit or sleeping unit where air can flow from the appliance to the dwelling unit or sleeping unit.

**915.1.5 Private garages.** Carbon monoxide detection shall be provided in *dwelling units, sleeping units* and classrooms in buildings with attached private garages.

**Exceptions:**

1. Carbon monoxide detection shall not be required where there are no communicating openings between the private garage and the *dwelling unit, sleeping unit* or classroom.
2. Carbon monoxide detection shall not be required in *dwelling units, sleeping units* and classrooms located more than one story above or below a private garage.

3. Carbon monoxide detection shall not be required where the private garage connects to the building through an open-ended corridor.
4. Where carbon monoxide detection is provided in an approved location between openings to a private garage and *dwelling units*, *sleeping units* or classrooms, carbon monoxide detection shall not be required in the *dwelling units*, *sleeping units* or classrooms.

❖ This section addresses attached private garages. Private garages, a term defined in Chapter 2 of the code, are often sources of CO generation. When attached to a building containing dwelling units, sleeping units or classrooms in Group E, CO detection is required.

There are several exceptions to the requirement for CO detection. These are similar to those found in Sections 915.1.3 and 915.1.4.

Exception 1 is similar to Exception 1 in Section 915.1.4. If there are no communicating openings, then CO detection is not required. The likelihood of CO entering the dwelling units, sleeping units or classrooms is greatly reduced.

Exception 2 addresses buildings where the dwelling units, sleeping units and classrooms are two stories above or below the location of the fuel-burning appliance. The CO would need to travel through an entire story before reaching the areas of concern.

Exception 3 does not require CO alarms to be provided when the private garage is attached to the building by an open ended corridor (a term defined in Chapter 2 of the code and the IFC, and commonly called a breezeway). This allows the CO concentration to dissipate before becoming a hazard to building occupants.

Exception 4 is similar to the exception to Section 915.1.3 and recognizes that the detection can be located closer to the source of the hazard versus requiring detection in every dwelling unit, sleeping unit or classroom.

**915.1.6 Exempt garages.** For determining compliance with Section 915.1.5, an open parking garage complying with Section 406.5 of the *International Building Code* or an enclosed parking garage complying with Section 406.6 of the *International Building Code* shall not be considered a private garage.

❖ This section is only provided to distinguish open parking garages and enclosed parking garages from private garages. "Open parking garage" is a defined term in Section 202 of the code. "Private garage" is a defined term in Chapter 2 of the IBC.

**915.2 Locations.** Where required by Section 915.1.1, carbon monoxide detection shall be installed in the locations specified in Sections 915.2.1 through 915.2.3.

❖ Sections 915.2.1 through 915.2.3 provide more detail on where detection is specifically required to be installed. This is a clarification from previous editions. NFPA 720 does not provide detailed enough information as to where detection should be located so spe-

cific direction is provided in the code. In some cases, the locations differ from that provided in NFPA 720.

**915.2.1 Dwelling units.** Carbon monoxide detection shall be installed in *dwelling units* outside of each separate sleeping area in the immediate vicinity of the bedrooms. Where a fuel-burning appliance is located within a bedroom or its attached bathroom, carbon monoxide detection shall be installed within the bedroom.

❖ The language is similar to that required for smoke alarms but the detection is only required outside of each sleeping area. If the fuel-burning appliance is within the bedroom or the attached bathroom, detection is required within the bedroom itself. Commentary Figure 915.2.1 shows the layout of carbon monoxide alarms versus smoke alarms. Note that if they are combined (smoke and CO alarms) the smoke alarm placement would be more restrictive.

**915.2.2 Sleeping units.** Carbon monoxide detection shall be installed in *sleeping units*.

**Exception:** Carbon monoxide detection shall be allowed to be installed outside of each separate sleeping area in the immediate vicinity of the *sleeping unit* where the *sleeping unit* or its attached bathroom does not contain a fuel-burning appliance and is not served by a forced air furnace.

❖ The intent of this section is the same as Section 915.2.1, except that it is applicable to sleeping units. Sleeping units can be as simple as a hotel room or a suite-type layout. This allows the detection to be either in the sleeping area itself, as with a simple hotel room, or outside the sleeping area, as is the case for dwelling units.

**915.2.3 Group E occupancies.** Carbon monoxide detection shall be installed in classrooms in Group E occupancies. Carbon monoxide alarm signals shall be automatically transmitted to an on-site location that is staffed by school personnel.

**Exception:** Carbon monoxide alarm signals shall not be required to be automatically transmitted to an on-site location that is staffed by school personnel in Group E occupancies with an occupant load of 30 or less.

❖ This section clarifies that the detection is to be located within the classroom and that a signal from the CO detection be automatically transmitted to a location on-site where school personnel can react to the situation, such as the school office. The exception provides relief to small schools where it is very easy to communicate a hazardous situation throughout the building.

**915.3 Detection equipment.** Carbon monoxide detection required by Sections 915.1 through 915.2.3 shall be provided by carbon monoxide alarms complying with Section 915.4 or carbon monoxide detection systems complying with Section 915.5.

❖ This section provides the option of providing the CO detection through single- or multiple-station CO alarms or through a CO detection system. This is a similar concept to smoke alarms and smoke detec-

tion systems. Each type of CO detector is listed to a different UL standard depending on whether it is to be used as a stand-alone or interconnected detector (UL 2034) or a detector that is part of a CO detection system (UL 2075). Section 915.4 addresses CO alarms and Section 915.5 addresses CO detection systems.

**915.4 Carbon monoxide alarms.** Carbon monoxide alarms shall comply with Sections 915.4.1 through 915.4.3.

❖ If the option of using CO alarms is chosen, compliance is required with Sections 915.4.1 through 915.4.3. CO alarms can be stand-alone or interconnected (single- or multiple-station). Section 915 does not address whether such alarms are required to be interconnected.

CO alarms are designed to initiate an audible alarm when the level of CO is below that which can cause a loss of the ability to react to the dangers of CO exposure. UL specifies that CO alarms activate at a level where the CO concentration over a given period of time can achieve 10-percent carboxyhemoglobin (COHb) in the body. Ten-percent COHb will not cause physiological injury, but is a level at which increases in the CO concentration will begin to affect the human body.

**915.4.1 Power source.** Carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source, and when primary power is interrupted, shall receive power from a bat-

tery. Wiring shall be permanent and without a disconnecting switch other than that required for overcurrent protection.

**Exception:** Where installed in buildings without commercial power, battery-powered carbon monoxide alarms shall be an acceptable alternative.

❖ This section is very similar to that required for smoke alarms (i.e., Section 907.2.11.6). The power supply must be provided by the building with battery backup. As with smoke alarms, if commercial power is not available, battery power is acceptable.

**915.4.2 Listings.** Carbon monoxide alarms shall be listed in accordance with UL 2034.

❖ Single- or multiple-station CO alarms are required to be listed in accordance with UL 2034. This standard is specific to CO alarms that provide both detection and notification.

**915.4.3 Combination alarms.** Combination carbon monoxide/smoke alarms shall be an acceptable alternative to carbon monoxide alarms. Combination carbon monoxide/smoke alarms shall be listed in accordance with UL 2034 and UL 217.

❖ Since smoke alarms are required in many occupancies, often a single combination alarm is desired. In fact, in some jurisdictions the CO alarms are required to be combined with smoke alarms. To meet this requirement, the combination CO and smoke alarm must be listed to both UL 2034 and UL 217. See

Commentary Figure 915.4.3 for an example of a combination CO and smoke alarm.

**Figure 915.4.3  
COMBINATION CARBON  
MONOXIDE AND SMOKE ALARM**

**915.5 Carbon monoxide detection systems.** Carbon monoxide detection systems shall be an acceptable alternative to carbon monoxide alarms and shall comply with Sections 915.5.1 through 915.5.3.

❖ If a CO detection system is preferred over CO alarms, compliance with Sections 915.5.1 through 915.5.3 is required.

**915.5.1 General.** Carbon monoxide detection systems shall comply with NFPA 720. Carbon monoxide detectors shall be listed in accordance with UL 2075.

❖ There are two standards applicable to CO detection systems. The systems are required to comply with NFPA 720 and the detectors themselves are required to comply with UL 2075.

**915.5.2 Locations.** Carbon monoxide detectors shall be installed in the locations specified in Section 915.2. These locations supersede the locations specified in NFPA 720.

❖ This section is provided to clarify that the locations required for CO detectors in Section 915.2 differ from NFPA 720 and that those locations will supersede the standard. This simply reaffirms the provisions of Section 1027.1 regarding conflicts between the code and a referenced standard.

**915.5.3 Combination detectors.** Combination carbon monoxide/smoke detectors installed in carbon monoxide detection systems shall be an acceptable alternative to carbon monoxide detectors, provided they are listed in accordance with UL 2075 and UL 268.

❖ Similar to CO alarms, there is often a desire or a requirement to combine smoke detection and CO

detection systems. If the detectors themselves are combined, they need to be listed in accordance with both UL 2075 and UL 268. NFPA 720 requires the CO alarm be capable of transmitting a distinct audible signal that is different than the smoke alarm signal.

**915.6 Maintenance.** Carbon monoxide alarms and carbon monoxide detection systems shall be maintained in accordance with NFPA 720. Carbon monoxide alarms and carbon monoxide detectors that become inoperable or begin producing end-of-life signals shall be replaced.

❖ This section is simply a reference to the maintenance requirements of NFPA 720. In addition, when detectors become inoperable or start producing end-of-life signals, they are required to be replaced.

# Chapter 10: Means of Egress

## General Comments

The general criteria set forth in Chapter 10 regulating the design of the means of egress are established as the primary method for protection of people in buildings. Chapter 10 provides the minimum requirements for means of egress in all buildings and structures. Both prescriptive and performance language is utilized in this chapter to provide for a basic approach in determining a safe exiting system for all occupancies. Chapter 10 addresses all portions of the egress system and includes design requirements as well as provisions regulating individual components. The requirements detail the size, arrangement, number and protection of means of egress components. Functional and operational characteristics also are specified, permitting safe use of components without special knowledge or effort.

This chapter provides a zonal approach to egress through regulation of an egress system's three parts: exit access, exit and exit discharge. Section 1001 includes administrative provisions. Section 1002 shows a list of defined terms that are primarily associated with Chapter 10. For commentary on these definitions, see Chapter 2.

Sections 1003 through 1015 include general provisions that apply to all three components. This includes general means of egress requirements; occupant loads; means of egress sizing; the number of exits and exit access doorways and their configuration; illumination for the means of egress; specific requirements for accessible means of egress; doors, gates and turnstiles; provisions for stairways and ramps along with their associated handrail and guard requirements; and exit signage (see commentary to Section 1003).

The exit access requirements are in Sections 1016 through 1021. This includes general exit access requirements, exit access travel distance; aisles (for other than assembly spaces); specific requirements for stairways and ramps that serve as part of the exit access; corridors; and egress balconies (see commentary, Section 1016).

The exit requirements are in Sections 1022 through 1027. Exit information includes provisions for exits; interior and exterior stairways and ramps that serve as an exit element; exit passageways; luminous egress path markings that are required on the exit stairways in high-rise buildings (see Section 403); and horizontal exits (see commentary, Section 1022).

The exit discharge requirements are in Section 1028. Section 1029 includes those means of egress

requirements that are unique to spaces used for assembly purposes.

Emergency escape and rescue opening requirements are in Section 1030.

Section 1002 through 1030 are duplicated text from Chapter 10 of the *International Building Code*® (IBC®) and are fully applicable to new buildings constructed after adoption of the code. The code has one additional section at the end of the chapter dealing with maintenance of the means of egress (see commentary, Section 1031). For means of egress requirements in existing buildings, refer to the *International Existing Building Code*® (IEBC®) or Chapter 11.

The evolution of means of egress requirements has been influenced by lessons learned from real fire incidents. While contemporary fires may reinforce some of these lessons, one must view each incident as an opportunity to assess critically the safety and reasonability of current regulations.

Cooperation among the developers of model codes and standards has resulted in agreement on many basic terms and concepts. The text of the code, including this chapter, is consistent with these national uniformity efforts.

National uniformity in an area such as means of egress has many benefits for the fire code official and other code users. At the top of the list are the lessons to be learned from experiences throughout the nation and the world, which can be reported in commonly used terminology and conditions that we can all relate to and clearly understand.

## Purpose

A primary purpose of codes in general, and building and fire codes in particular, is to safeguard life in the presence of a fire. Integral to this purpose is the path of egress travel for occupants to escape and avoid a fire. Means of egress can be considered the lifeline of a building. The principles on which means of egress are based and that form the fundamental criteria for requirements are to provide a system:

1. That will give occupants alternative paths of travel to a place of safety to avoid fire.
2. That will shelter occupants from fire and the products of combustion.
3. That will accommodate all occupants of a structure.

4. That is clear, unobstructed, well marked and illuminated and in which all components are under the control of the user without requiring any tools, keys or special knowledge or effort.

History is marked with the loss of life from fire. Early as well as contemporary multiple fire fatalities can be traced to a compromise of one or more of the above principles.

Life safety from fire is a matter of successfully evacuating or relocating the occupants of a building to a place

of safety. As a result, life safety is a function of time: time for detection, time for notification and time for safe egress. The fire growth rate over a period of time is also a critical factor in addressing life safety. Other sections of the code, such as protection of vertical openings (Chapter 7), interior finish (Chapter 8), fire suppression and detection systems (Chapter 9), also have an impact on life safety. Chapter 10 addresses the issues related to the means available to relocate or evacuate building occupants.

## SECTION 1001 ADMINISTRATION

**1001.1 General.** Buildings or portions thereof shall be provided with a means of egress system as required by this chapter. The provisions of this chapter shall control the design, construction and arrangement of means of egress components required to provide an approved means of egress from structures and portions thereof. Sections 1003 through 1029 shall apply to new construction. Section 1030 shall apply to existing buildings.

**Exception:** Detached one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories above grade plane in height with a separate means of egress and their accessory structures shall comply with the *International Residential Code*.

- ❖ The minimum requirements for means of egress are to be incorporated in all structures as specified in this chapter. Application would be effective on the date the code is adopted and placed into effect.

The means of egress in an existing building that experiences a change of occupancy, such as from Group S-2 (storage) to A-3 (assembly), would require reevaluation for code compliance based on the new occupancy, as stated in *International Existing Building Code*® (IEBC)®. Similarly, the means of egress in an existing occupancy of Group A-3 in which additional seating is to be provided, thereby increasing the occupant load, would require reevaluation for code compliance based on the increased occupant load.

Fundamental to the level of life safety in any building, whether it is new or many years old, is the provision for an adequate egress system. It is for that reason that Section 1104 is retroactively applicable to existing buildings that are not undergoing changes, as regulated by the IEBC. The means of egress in existing buildings must also be properly maintained in accordance with Section 1031 if the intended level of safety is to remain for the life of the building.

Reflecting the correlation and compatibility that is a hallmark of the *International Codes*® (I-Codes)®, the

exception makes it clear that the means of egress in buildings that are within the scope of the *International Residential Code*® (IRC)® are to comply with those requirements instead of Chapter 10.

**1001.2 Minimum requirements.** It shall be unlawful to alter a building or structure in a manner that will reduce the number of *exits* or the capacity of the *means of egress* to less than required by this code.

- ❖ A fundamental concept in life safety design is that the means of egress system is to be constantly available throughout the life of a building. Any change in the building or its contents, by physical reconstruction, alteration or a change of occupancy, is cause to review the resulting egress system. As a minimum, a building's means of egress is to be continued as initially approved. If a building or portion thereof has a change of occupancy, the complete egress system is to be evaluated and approved for compliance with the current code requirements for new occupancies (see IEBC).

The means of egress in an existing building that experiences a change of occupancy, such as from Group S-2 (storage) to A-3 (assembly), requires reevaluation for code compliance based on the new occupancy. Similarly, the means of egress in an existing occupancy of Group A-3 in which additional seating is to be provided, thereby increasing the occupant load, requires reevaluation for code compliance based on the increased load.

The temptation is to temporarily remove egress components or other fire protection or life safety features from service during an alteration or repair to or temporary occupancy of a building. During such times, a building is frequently more vulnerable to fire and the rapid spread of products of combustion. Either the occupants should not occupy those spaces where the means of egress has been compromised by the construction, or compensating fire safety features, providing equivalent safety for the occupants, should be considered. Occupants in adjacent areas may also require access to the egress facilities in the area under construction.

## SECTION 1002 DEFINITIONS

**1002.1 Definitions.** The following terms are defined in Chapter 2:

ACCESSIBLE MEANS OF EGRESS.  
AISLE.  
AISLE ACCESSWAY.  
ALTERNATING TREAD DEVICE.  
AREA OF REFUGE.  
BLEACHERS.  
BREAKOUT.  
COMMON PATH OF EGRESS TRAVEL.  
CORRIDOR.  
DOOR, BALANCED.  
EGRESS COURT.  
EMERGENCY ESCAPE AND RESCUE OPENING.  
EXIT.  
EXIT ACCESS.  
EXIT ACCESS DOORWAY.  
EXIT ACCESS RAMP.  
EXIT ACCESS STAIRWAY.  
EXIT DISCHARGE.  
EXIT DISCHARGE, LEVEL OF.  
EXIT, HORIZONTAL.  
EXIT PASSAGEWAY.  
EXTERIOR EXIT RAMP.  
EXTERIOR EXIT STAIRWAY.  
FIRE EXIT HARDWARE.  
FIXED SEATING.  
FLIGHT.  
FLOOR AREA, GROSS.  
FLOOR AREA, NET.  
FOLDING AND TELESCOPIC SEATING.  
GRANDSTAND.  
GUARD.  
HANDRAIL.  
INTERIOR EXIT RAMP.  
INTERIOR EXIT STAIRWAY.  
LOW ENERGY POWER-OPERATED DOOR.  
MEANS OF EGRESS.  
MERCHANDISE PAD.  
NOSING.  
OCCUPANT LOAD.  
OPEN-ENDED CORRIDOR.  
PANIC HARDWARE.

PHOTOLUMINESCENT.  
POWER-ASSISTED DOOR.  
POWER-OPERATED DOOR.  
PUBLIC WAY.  
RAMP.  
SCISSOR STAIRWAY.  
SELF-LUMINOUS.  
SMOKE-PROTECTED ASSEMBLY SEATING.  
STAIR.  
STAIRWAY.  
STAIRWAY, SPIRAL.  
WINDER.

❖ This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter, but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms that may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

## SECTION 1003 GENERAL MEANS OF EGRESS

**1003.1 Applicability.** The general requirements specified in Sections 1003 through 1015 shall apply to all three elements of the *means of egress* system, in addition to those specific requirements for the *exit access*, the *exit* and the *exit discharge* detailed elsewhere in this chapter.

❖ The requirements in the chapter address the three parts of a means of egress system: the exit access, the exit and the exit discharge. This section specifies that the requirements of Sections 1003 through 1015 apply to the components of all three parts of the system. For example, the stair tread and riser dimensions in Section 1009 apply to interior exit access stairways, such as those leading from a mezzanine, and also apply to enclosed exit stairways per Section 1022, exterior exit stairways per Section 1026 and steps in the exit discharge per Section 1027.

The following sections are applicable for all parts of the means of egress:

- Section 1003 deals with the path for means of egress to remain free of obstructions and tripping hazards.

- Section 1004 provides criteria for determining occupant loads for a space. These numbers are used for determining means of egress, as a threshold for some suppression requirements and to determine the required plumbing fixture count.
- Section 1005 deals with the required size (i.e., width) of the path of travel for emergency evacuation. It is important not to create a “bottleneck” that could increase the amount of time necessary for occupants to exit the buildings.
- Section 1006 deals with the number of ways out of a space or off a floor, either by exit elements or exit access elements.
- Section 1007 provides placement and remoteness requirements for the exit and exit access elements prescribed in Section 1006.
- Section 1008 deals with illumination for the path of travel for the means of egress. Both general lighting and emergency backup lighting are addressed.
- Section 1009 – Chapter 11 indicates how to get people with mobility impairments into a building. Section 1009 explains the options to allow people with mobility impairments to self-evacuate or how to arrange for assisted rescue. The accessible means of egress is an important part of the fire and safety evacuation plans (see Section 1001.4).
- Section 1010 includes requirements for doors, gates and turnstiles that are part of the path of travel from any occupied spaces. For example, doors that lead to a walk-in closet must comply with this section, but doors for reach-in closets are exempted.
- Section 1011 provides information on all types of stairways: interior and exterior and from one riser to stairways with multiple flights and landings. Stepped aisles for areas within assembly seating are specifically addressed in Section 1029. For protection of the stairways between stories, see Sections 1019, 1023 and 1027.
- Section 1012 deals with ramps. Ramped aisles serving assembly seating areas are specifically addressed in Section 1029. The ramp provisions are coordinated with ICC A117.1 and the 2010 Standard for Accessible Design [formerly the Americans with Disabilities Act Accessibility Guidelines (ADAAG), now referred to as the 2010 ADA Standard]. For protection of the ramp between stories, see Sections 1019, 1023 and 1027.
- Section 1013 describes where exit signs are required and what criteria they need to meet to be readily visible.

- Section 1014 describes handrail requirements for stairways and ramps. Handrails are important for guidance and to arrest a possible fall.
- Section 1015 provides criteria for the vertical portions of barriers that serve to protect people from possible falls at dropoffs greater than 30 inches (762 mm).

**1003.2 Ceiling height.** The *means of egress* shall have a ceiling height of not less than 7 feet 6 inches (2286 mm).

**Exceptions:**

1. Sloped ceilings in accordance with Section 1208.2.
2. Ceilings of *dwelling units* and *sleeping units* within residential occupancies in accordance with Section 1208.2.
3. Allowable projections in accordance with Section 1003.3.
4. *Stair* headroom in accordance with Section 1011.3.
5. Door height in accordance with Section 1010.1.1.
6. *Ramp* headroom in accordance with Section 1012.5.2.
7. The clear height of floor levels in vehicular and pedestrian traffic areas of public and private parking garages in accordance with Section 406.4.1.
8. Areas above and below *mezzanine* floors in accordance with Section 505.2.

❖ Generally, the specified ceiling height is the minimum allowed in any part of the egress path. The exceptions are intended to address conditions where the code allows the ceiling height to be lower than specified in this section.

This section is consistent with the minimum ceiling height for other areas as specified in Section 1208. The exceptions are pointers to the lower headroom areas permitted in the code. For example, the headroom above and below a mezzanine is 7 feet (2134 mm) minimum.

**1003.3 Protruding objects.** Protruding objects on *circulation paths* shall comply with the requirements of Sections 1003.3.1 through 1003.3.4.

❖ This section begins the provisions that apply to protruding objects and helps to improve awareness of these safety and accessibility-related provisions. The intent of the phrase “on circulation paths” is intended to allow for judgment determining where people walk versus all floor surfaces. For example, a drinking fountain in an alcove is over a floor, but it is not over a circulation path; therefore, it typically it would not be considered a protruding object.

**1003.3.1 Headroom.** Protruding objects are permitted to extend below the minimum ceiling height required by Section 1003.2 where a minimum headroom of 80 inches (2032 mm) is provided over any walking surface, including walks, corri-

dors, aisles and passageways. Not more than 50 percent of the ceiling area of a means of egress shall be reduced in height by protruding objects.

**Exception:** Door closers and stops shall not reduce headroom to less than 78 inches (1981 mm).

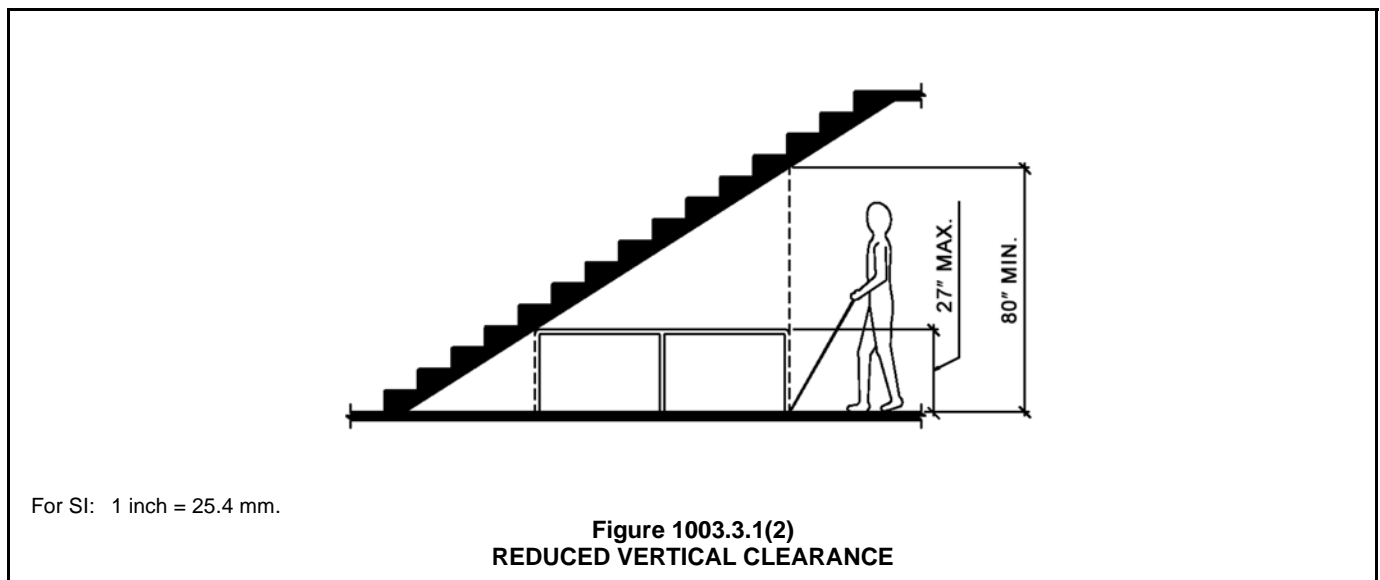

A barrier shall be provided where the vertical clearance is less than 80 inches (2032 mm) high. The leading edge of such a barrier shall be located 27 inches (686 mm) maximum above the floor.

❖ This provision is applicable to all routes that make up components of the means of egress. Specifically, the limitations in this section and those in Sections 1003.3.2 and 1003.3.3 provide a reasonable level of safety for people with vision impairments as well as during emergency events when vision may be obscured by smoke or low lighting.

Minimum dimensions for headroom clearance are specified in this section. The minimum headroom clearance over all walking surfaces or circulation paths is required to be maintained at 80 inches (2032 mm). This minimum headroom clearance is consistent with the requirements in Section 1011.3 for stairs and Section 1012.5.2 for ramps. Allowance must be made for door closers and stops, since their design and function necessitates placement within the door opening. The minimum headroom clearance for door closers and stops is allowed to be 78 inches (1981 mm) [see Commentary Figure 1003.3.1(1)]. The 2-inch (51 mm) projection into the doorway height is reasonable since these devices are normally mounted away from the center of the door opening, thus minimizing the potential for contact with a person moving through the opening. This is consistent with the exception to Section 1010.1.1.1.

The limitation on overhangs is of primary importance to individuals with visual impairments. When vertical clearance along a walking surface is less than 80 inches (2032 mm), such as underneath the stairway on the ground floor, some sort of barrier that is

detectable by a person using a cane must be provided. This can be a full-height wall, a rail at or below 27 inches (686 mm), a planter, fixed seating, etc. A low curb is not effective as a barrier. A person with visual impairments might mistake it for a stair tread, step up onto it and strike their head. A rail at handrail height would not be detectable by a person using a cane, and he or she could possibly walk into the rail before detecting it. Also, when making decisions on the choice of type of barrier, keep in mind that persons of shorter stature and children have a detectable range that may be below 27 inches (686 mm) [see Commentary Figure 1003.3.1(2)].

## MEANS OF EGRESS

**1003.3.2 Post-mounted objects.** A free-standing object mounted on a post or pylon shall not overhang that post or pylon more than 4 inches (102 mm) where the lowest point of the leading edge is more than 27 inches (686 mm) and less than 80 inches (2032 mm) above the walking surface. Where a sign or other obstruction is mounted between posts or pylons and the clear distance between the posts or pylons is greater than 12 inches (305 mm), the lowest edge of such sign or obstruction shall be 27 inches (686 mm) maximum or 80 inches (2032 mm) minimum above the finished floor or ground.

**Exception:** These requirements shall not apply to sloping portions of *handrails* between the top and bottom riser of *stairs* and above the *ramp* run.

- ❖ Post-mounted objects, such as signs or some types of drinking fountains or phone boxes, are not permitted to overhang more than 4 inches (102 mm) past the post where the bottom edge is located higher than 27 inches (686 mm) above the walking surface [see Commentary Figure 1003.3.2(1)]. Since the minimum required height of doorways, stairways and ramps in the means of egress is 80 inches (2032 mm), protruding objects located higher than 80 inches (2032 mm) above the walking surface are not regulated. Protrusions that are located lower than 27 inches (686 mm) above the walking surface are also permitted since they are more readily detected by a person using a long cane, provided that the minimum required width of the egress element is maintained. This is consistent with the post-mounted objects requirements in Section 307.3 of ICC A117.1, *Accessible and Usable Buildings and Facilities*. The intent is to reduce the potential for accidental impact for a person who is visually impaired.

When signs are provided on multiple posts, the posts must be located closer than 12 inches (305 mm) apart, or the bottom edge of the sign must be

lower than 27 inches (686 mm) so it is within detectable cane range or above 80 inches (2032 mm) so that it is above headroom clearances [see Commentary Figure 1003.3.2(2)].

The exception is intended for handrails that are located along the run of a stairway flight or ramp run. The extensions at the top and bottom of stairways and ramps must meet the requirements for protruding objects where people walk perpendicular to the stair or ramp.

**1003.3.3 Horizontal projections.** Objects with leading edges more than 27 inches (685 mm) and not more than 80 inches (2030 mm) above the floor shall not project horizontally more than 4 inches (102 mm) into the *circulation path*.

**Exception:** *Handrails* are permitted to protrude 4½ inches (114 mm) from the wall.

- ❖ Protruding objects could slow the egress flow through a corridor or passageway and injure someone hurriedly passing by or someone with a visual impairment. Persons with a visual impairment who use a long cane for guidance must have sufficient warning of a protruding object. Where protrusions are located higher than 27 inches (686 mm) above the walking surface, the cane will most likely not encounter the protrusion before the person collides with the object.

Additionally, people with poor visual acuity or poor depth perception may have difficulty identifying protruding objects higher than 27 inches (686 mm). Therefore, objects such as lights, signs and door hardware, located between 27 inches (686 mm) and 80 inches (2032 mm) above the walking surface, are not permitted to extend more than 4 inches (102 mm) from each wall (see Commentary Figure 1003.3.3). The requirement for protrusions into the door clear width in Section 1010.1.1.1 is different because it deals with allowances for panic hardware on a door.

For SI: 1 inch = 25.4 mm.

**Figure 1003.3.2(1)**  
**POST-MOUNTED OBJECTS**

It is not the intent of this section to prohibit columns, pilasters or wing walls to project into a corridor as long as adequate egress width is maintained. These types of structural elements are detectable by persons using a long cane.

The exception is an allowance for handrails when they are provided along a wall, such as in some hospitals or nursing homes. The 4½-inch (114 mm) measurement is intended to be consistent with projections by handrails into the required width of stairways and ramps in Section 1014.8. There are additional requirements when talking about the required width (see Section 1005.2).

**1003.3.4 Clear width.** Protruding objects shall not reduce the minimum clear width of *accessible routes*.

❖ The intent of this section is to limit the projections into an accessible route so that a minimum clear width of 36 inches (914 mm) is maintained along the route. ICC A117.1 is referenced by Chapter 11 for technical requirements for accessibility. ICC A117.1, Section 403.5, allows the accessible route to be reduced in width to 32 inches (813 mm) for segments not to exceed 24 inches (610 mm) in length and spaced a minimum of 48 inches (1219 mm) apart. This allows for movement through a doorway or through a gap in planters or counters.

## MEANS OF EGRESS

**1003.4 Floor surface.** Walking surfaces of the *means of egress* shall have a slip-resistant surface and be securely attached.

❖ As the pace of exit travel becomes hurried during emergency situations, the probability of slipping on smooth or slick floor surfaces increases. To minimize the hazard, all floor surfaces in the means of egress are required to be slip resistant. The use of hard floor materials with highly polished, glazed, glossy or finely finished surfaces should be avoided.

Field testing and uniform enforcement of the concept of slip resistance are not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification KK-L-165C] and the floor surface is greater than 0.5. Laboratory test procedures, such as ASTM D2047, can determine the static coefficient of resistance. Bulletin No. 4, "Surfaces," issued by the U.S. Architectural and Transportation Barriers Compliance Board (ATBCB or Access Board) contains further information regarding slip resistance.

**1003.5 Elevation change.** Where changes in elevation of less than 12 inches (305 mm) exist in the *means of egress*, sloped surfaces shall be used. Where the slope is greater than one unit vertical in 20 units horizontal (5-percent slope), *ramps* complying with Section 1012 shall be used. Where the difference in elevation is 6 inches (152 mm) or less, the *ramp* shall be equipped with either *handrails* or floor finish materials that contrast with adjacent floor finish materials.

### Exceptions:

1. A single step with a maximum riser height of 7 inches (178 mm) is permitted for buildings with occupancies in Groups F, H, R-2, R-3, S and U at exterior doors not required to be *accessible* by Chapter 11.
2. A *stair* with a single riser or with two risers and a tread is permitted at locations not required to be *accessible* by Chapter 11 where the risers and treads comply with Section 1011.5, the minimum depth of the tread is 13 inches (330 mm) and not less than one *handrail* complying with Section 1014 is provided within 30 inches (762 mm) of the centerline of the normal path of egress travel on the *stair*.
3. A step is permitted in *aisles* serving seating that has a difference in elevation less than 12 inches (305 mm) at locations not required to be *accessible* by Chapter 11, provided that the risers and treads comply with Section 1029.13 and the *aisle* is provided with a *handrail* complying with Section 1029.15.

Throughout a story in a Group I-2 occupancy, any change in elevation in portions of the *means of egress* that serve non-ambulatory persons shall be by means of a *ramp* or sloped walkway.

❖ Minor changes in elevation, such as a single step that is located in any portion of the means of egress (i.e., exit access, exit or exit discharge), may not be readily

apparent during normal use or emergency egress and are considered to present a potential tripping hazard. Where the elevation change is less than 12 inches (305 mm), a ramp or sloped surface is specified to make the transition from higher to lower levels. This is intended to reduce accidental falls associated with the tripping hazard of an unseen step. Ramps must be constructed in accordance with Section 1012.1. Ramp provisions do not require handrails for ramps with a rise of 6 inches or less. However, the presence of the ramp must be readily apparent from the directions from which it is approached. Handrails are one method of identifying the change in elevation. In lieu of handrails, the surface of the ramp must be finished with materials that visually contrast with the surrounding floor surfaces. The walking surface of the ramp should contrast both visually and physically.

None of the exceptions are permitted along an accessible route required for either entry or egress from a space or building (see Section 1009 and Chapter 11).

Exception 1 allows up to a 7-inch (178 mm) step at exterior doors to avoid blocking the outward swing of the door by a buildup of snow or ice in locations that are not used by the public on a regular basis (see Commentary Figure 1003.5). This exception is coordinated with Exception 2 of Section 1010.1.5, and is only applicable in occupancies that have relatively low occupant densities, such as factory and industrial

structures. This exception is not applicable to exterior doors that are required to serve as an accessible entrance or that are part of a required accessible route. If this exception is utilized at a Group R-2 or R-3 occupancy, the designer may want to consider the issues of potential tripping hazards if this is a common entrance for a large number of occupants.

Exception 2 allows the transition from higher to lower elevations to be accomplished through the construction of stairs with one or two risers. The pitch of the stairway, however, must be shallower than that required for typical stairways (see Section 1011.5.2). Since the total elevation change is limited to 12 inches (305 mm), each riser must be approximately 6 inches (152 mm) in height. The elevation change must be readily apparent from the directions from which it is approached. At least one handrail is required. It must be constructed in accordance with Section 1014 and located so as to provide a graspable surface from the normal walking path.

Exception 3 is basically a cross reference to the assembly provisions for stepped aisles in Section 1029.

None of the exceptions are permitted in a Group I-2 occupancy (e.g., nursing home, hospital) in areas where nonambulatory persons may need access. The mobility impairments of these individuals require additional consideration.

**1003.6 Means of egress continuity.** The path of egress travel along a *means of egress* shall not be interrupted by a building element other than a *means of egress* component as specified in this chapter. Obstructions shall not be placed in the minimum width or required capacity of a *means of egress* component except projections permitted by this chapter. The minimum width or required capacity of a *means of egress* system shall not be diminished along the path of egress travel.

❖ This section requires that the entire means of egress path be clear of obstructions that could reduce the egress path to below the minimum width at any point. The egress path is also not allowed to be reduced in width such that the design occupant load (required capacity) would not be served. Note, however, that the egress path could be reduced in width in situations where it is wider than required by the code based on the occupant load. For example, if the required width of a corridor was 52 inches (1321 mm) based on the number of occupants using the corridor and the corridor provided was 96 inches (2438 mm) in width, the corridor would be allowed to be reduced to the minimum required width of 52 inches (1321 mm) since that width would still serve the number of occupants required by the code. In the context of this section, a “means of egress component” would most likely be a door or doorway.

**1003.7 Elevators, escalators and moving walks.** Elevators, escalators and moving walks shall not be used as a compo-

nent of a required *means of egress* from any other part of the building.

**Exception:** Elevators used as an accessible *means of egress* in accordance with Section 1009.4.

❖ Generally, the code does not allow elevators, escalators and moving sidewalks to be used as a required means of egress. The concern is that, because of possible power outages, escalators and moving sidewalks may not provide a safe and reliable means of egress that is available for use at all times.

Elevators are not typically used for unassisted evacuation during fire emergencies. However, in taller buildings, fire fighters use the elevators for both staging to fight the fire and assisted evacuation. They can verify that the shaft is not full of smoke, that the elevators will remain operational and, since they know the fire location, at which floors the elevator can be safely accessed. In accordance with the exception, elevators are allowed to be part of an accessible means of egress (i.e., assisted evacuation), provided they comply with the requirements of Section 1009.4. Where elevators are required to serve as part of the accessible means of egress is addressed in Section 1009.2.1. There are new provisions for fire service elevators and occupant evacuation elevators for high rises in Sections 403, 3007 and 3008. These specific provisions will provide a level of safety that would meet the intent of the means of egress provisions in Chapter 10.

## SECTION 1004 OCCUPANT LOAD

**1004.1 Design occupant load.** In determining *means of egress* requirements, the number of occupants for whom *means of egress* facilities are provided shall be determined in accordance with this section.

❖ The design occupant load is the number of people intended to occupy a building or portion thereof at any one time; essentially the number for which the means of egress is to be designed. It is the largest number derived by the application of Sections 1004.1 through 1004.6. Occupant density is limited to ensure a reasonable amount of freedom of movement (see Section 1004.2). The design occupant load is also utilized to determine the required plumbing fixture count (see commentary, Chapter 29) and other building requirements, such as automatic sprinkler systems and fire alarm and detection systems (see Chapter 9).

The intent of this section is to indicate the procedure by which design occupant loads are determined. This is particularly important because accurate determination of design occupant load is fundamental to the proper design of any means of egress system.

## MEANS OF EGRESS

**1004.1.1 Cumulative occupant loads.** Where the path of egress travel includes intervening rooms, areas or spaces, cumulative *occupant loads* shall be determined in accordance with this section.

❖ When occupants from an accessory area move through another area to exit, the combined number of occupants must be utilized to determine the capacity that the egress components must be designed to accommodate. It is not the intent of this section to “double count” occupants. For example, the means of egress from a lobby must be sized for the cumulative occupant load of the adjacent office spaces if the occupants must travel through the lobby to reach an exit. Likewise, if an adjacent room has an egress route independent of the lobby, the occupant load of that room would not be combined with the occupant loads of the other rooms that pass through the lobby. If a portion of the adjacent room’s occupant load is to travel through the lobby, only that portion would be combined with the lobby occupant load for determining lobby egress (see Commentary Figure 1004.1.1). This is particularly important in determining the number of ways out of a space or off a story and the required capacity of those elements.

**1004.1.1.1 Intervening spaces or accessory areas.** Where occupants egress from one or more rooms, areas or spaces through others, the design *occupant load* shall be the combined *occupant load* of interconnected accessory or intervening spaces. Design of egress path capacity shall be based on

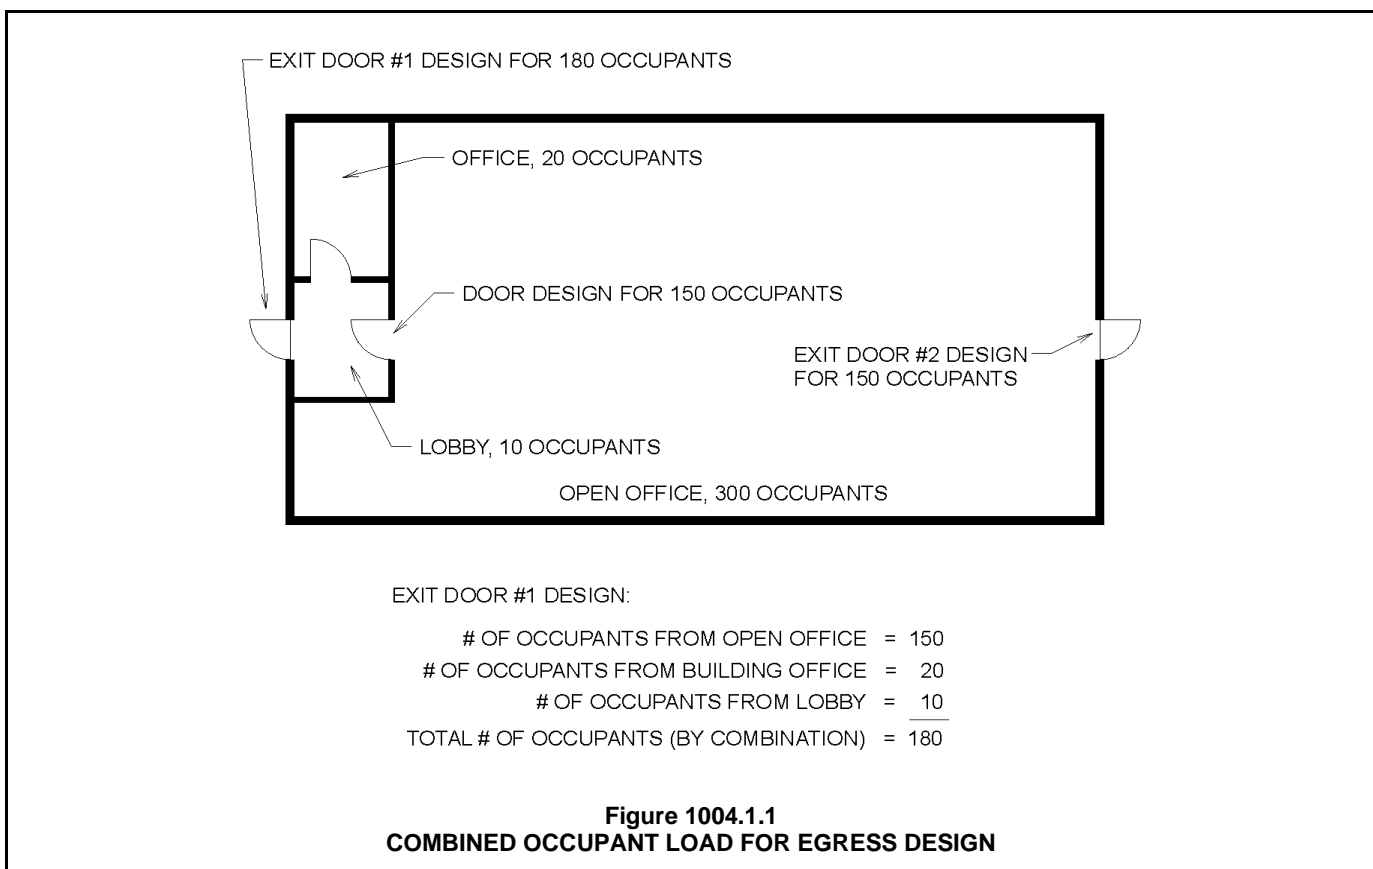

the cumulative portion of *occupant loads* of all rooms, areas or spaces to that point along the path of egress travel.

❖ An example of intervening spaces could be small tenant spaces within a large mercantile. It is common for banks or coffee shops to be located within large grocery stores. Another example would be a dentist’s office where people in the staff and exam room areas would egress through the reception area.

**1004.1.1.2 Adjacent levels for mezzanines.** That portion of the *occupant load* of a *mezzanine* with required egress through a room, area or space on an adjacent level shall be added to the *occupant load* of that room, area or space.

❖ The egress requirements for mezzanines that use exit access stairways to move to the ground level are handled similarly to those spaces with accessory areas addressed in Section 1004.1.1.1, versus the requirements for exiting from multiple stories in Sections 1004.1.1.3, 1005.4.1 and 1006. That is, that portion of the mezzanine occupant load that travels through the space below to get to the exit is to be added to the occupant load of the space on the floor below. The sizing and number of the egress components must reflect this combined occupant load. Section 505.2.3 contains additional criteria for the means of egress from mezzanines or a portion of it is enclosed.

**1004.1.1.3 Adjacent stories.** Other than for the egress components designed for convergence in accordance with Section

1005.6, the *occupant load* from separate stories shall not be added.

- ❖ Second-floor egress requirements that use exit access stairways to move to the ground level are coordinated with the requirements for exiting from multiple stories found in Sections 1005.3.1, 1005.4.1 and 1006. That is, the portion of the second floor occupant load that travels through the floor below to the exit is not to be added to the occupant load of the space on the floor below as you would for a mezzanine. The sizing and number of the egress components do not have to reflect this combined occupant load. The exception to the rule is where there would be egress convergence of two stories at a level between the two stories (see Section 1005.6).

**1004.1.2 Areas without fixed seating.** The number of occupants shall be computed at the rate of one occupant per unit of area as prescribed in Table 1004.1.2. For areas without *fixed seating*, the occupant load shall be not less than that number determined by dividing the floor area under consideration by the *occupant load* factor assigned to the function of the space as set forth in Table 1004.1.2. Where an intended function is not listed in Table 1004.1.2, the *building official* shall establish a function based on a listed function that most nearly resembles the intended function.

**Exception:** Where *approved* by the *building official*, the actual number of occupants for whom each occupied space, floor or building is designed, although less than those determined by calculation, shall be permitted to be used in the determination of the design *occupant load*.

- ❖ The numbers for floor area per occupant load factor in Table 1004.1.2 reflect common and traditional occupant density based on empirical data for the density of similar spaces. The number determined using the occupant load factors in Table 1004.1.2 generally establishes the minimum occupant load for which the egress facilities of the rooms, spaces and building must be designed. The design occupant load is also utilized for other code requirements, such as determining the required plumbing fixture count (see commentary, Chapter 29) and other building requirements, including automatic sprinkler systems and alarm and detection systems (see Chapter 9).

It is difficult to predict the many conditions by which a space within a building will be occupied over time. An assembly banquet room in a hotel, for example, could be arranged with rows of chairs to host a business seminar one day and with mixed tables and chairs to host a dinner reception the next day. In some instances, the room will be arranged with no tables and very few chairs to accommodate primarily standing occupants. In such a situation, the egress facilities must safely accommodate the maximum number of persons permitted to occupy the space. When determining the occupant load of this type of occupancy, the various arrangements (e.g., tables and chairs, chairs only, standing space) should be recognized. The worst-case scenario should be utilized to determine the requirements for the means of

egress elements. This is consistent with the requirements for multiple-use spaces addressed in Section 302.1.

While some of the values in the table utilize the net floor area, most utilize the gross floor area. See the commentary to Table 1004.1.2 and the definitions for "Floor area, gross" and "Floor area, net" in Chapter 2 for additional discussion and examples.

The occupant load determined in accordance with this section is typically the minimum occupant load on which means of egress requirements are to be based. Some occupancies may not typically contain an occupant load totally consistent with the occupant load density factors of Table 1004.1.2. The exception is intended to address the limited circumstances where the actual occupant load is less than the calculated occupant load. Previously, designing for a reduced occupant load was permitted only through the variance process. With this exception, the building official can make a determination if a design that would use the actual occupant load was permissible. The building official may want to create specific conditions for approval. For example, the building official could choose to permit the actual occupant load to be utilized to determine the plumbing fixture count, but not the means of egress or sprinkler design; the determination could be that the reduced occupant load may be utilized in a specific area, such as in the storage warehouse, but not in the factory or office areas. Another point to consider would be the potential of the space being utilized for different purposes at different times, or the potential of a future change of tenancy without knowledge of the building department. Any special considerations for such unique uses must be documented and justified. Additionally, the owner must be aware that such special considerations will impact the future use of the building with respect to the means of egress and other protection features.

**TABLE 1004.1.2.** See page 10-12.

- ❖ Table 1004.1.2 establishes minimum occupant densities based on the function or actual use of the space (not group classification). The table presents the maximum floor area allowance per occupant (i.e., occupant load factor) based on studies and counts of the number of occupants in typical buildings. The use of this table, then, results in the minimum occupant load for which rooms, spaces and the building must be designed. While an assumed normal occupancy may be viewed as somewhat less than that determined by the use of the table factors, such a normal occupant load is not necessarily an appropriate design criterion. The greatest hazard to the occupants occurs when an unusually large crowd is present. The code does not limit the occupant load density of an area, except as provided for in Section 1004.2, but once the occupant load is established, the means of egress must be designed for at least that capacity. If it is intended that the occupant load will exceed that calculated in accordance with the table, then the occupant load is to be

based on the estimated actual number of people, but not to exceed the maximum allowance in accordance with Section 1004.2. Therefore, the occupant load of the office or business areas in a storage warehouse or nightclub is to be determined using the occupant load factor most appropriate to that space—one person for each 100 square feet (9 m<sup>2</sup>) of gross floor area.

The use of net and gross floor areas as defined in Chapter 2 is intended to provide a refinement in the occupant load determination. The gross floor area technique applied to a building only allows the deduction of the plan area of the exterior walls, vent shafts and interior courts from the plan area of the building.

The net floor area permits the exclusion of certain spaces that would be included in the gross floor area. The net floor area is intended to apply to the actual occupied floor areas. The area used for permanent building components, such as shafts, fixed equipment, thicknesses of walls, corridors, stairways, toilet rooms, mechanical rooms and closets, is not included in net floor area. For example, consider a restaurant dining area with dimensions measured from the inside of the enclosing walls of 80 feet by 60 feet (24 384 mm by 18 288 mm) (see Commentary Figure 1004.1.2). Within the restaurant area is a 6-inch (152 mm) privacy wall running the length of the room [80 feet by 0.5 feet = 40 square feet (3.7 m<sup>2</sup>)], a fireplace [40 square feet (3.7 m<sup>2</sup>)] and a cloak room [60 square feet (5.6 m<sup>2</sup>)]. Each of these areas is deducted from the restaurant area, resulting in a net floor area of 4,660 square feet (433 m<sup>2</sup>). Since the restaurant intends to have unconcentrated seating that involves loose tables and chairs, the resulting occupant load is 311 persons (4,660 divided by 15). As the definition of “Floor area, net” indicates, certain spaces are to be excluded from the gross floor area to derive the net floor area. The key point in this definition is that the net floor area is to include the actual occupied area and does not include spaces uncharacteristic of that occupancy.

In determining the occupant load of a building with mixed groups, each floor area of a single occupancy must be separately analyzed, such as required by Section 1004.6. The occupant load of the business portion of an office/warehouse building is determined at a rate of one person for each 100 square feet (9 m<sup>2</sup>) of office space, whereas the occupant load of the warehouse portion is determined at the rate of one person for each 300 square feet (28 m<sup>2</sup>). There may even be different uses within the same room. For example, a restaurant dining room would have seating but may also have a waiting area with standing room, a take-out window with a queue line or employee areas behind a bar or reception desk.

If a specific type of facility is not found in the table, the occupancy it most closely resembles should be utilized. For example, a training room in a business office may utilize the 20-square-foot (1.86 m<sup>2</sup>) net established for educational classroom areas, or a dance or karate studio may use the occupant load for rinks and pools for the studio areas.

Table 1004.1.2 presents a method of determining

**TABLE 1004.1.2  
MAXIMUM FLOOR AREA ALLOWANCES PER OCCUPANT**

FUNCTION OF SPACE	OCCUPANT LOAD FACTOR <sup>a</sup>
Accessory storage areas, mechanical equipment room	300 gross
Agricultural building	300 gross
Aircraft hangars	500 gross
Airport terminal	
Baggage claim	20 gross
Baggage handling	300 gross
Concourse	100 gross
Waiting areas	15 gross
Assembly	
Gaming floors (keno, slots, etc.)	11 gross
Exhibit Gallery and Museum	30 net
Assembly with fixed seats	See Section 1004.4
Assembly without fixed seats	
Concentrated (chairs only-not fixed)	7 net
Standing space	5 net
Unconcentrated (tables and chairs)	15 net
Bowling centers, allow 5 persons for each lane including 15 feet of runway, and for additional areas	7 net
Business areas	100 gross
Courtrooms—other than fixed seating areas	40 net
Day care	35 net
Dormitories	50 gross
Educational	
Classroom area	20 net
Shops and other vocational room areas	50 net
Exercise rooms	50 gross
H-5 Fabrication and manufacturing areas	200 gross
Industrial areas	
Inpatient treatment areas	240 gross
Outpatient areas	100 gross
Sleeping areas	120 gross
Kitchens, commercial	200 gross
Library	
Reading rooms	50 net
Stack area	100 gross
Mall buildings—covered and open	See Section 402.8.2
Mercantile	
Areas on other floors	60 gross
Basement and grade floor areas	30 gross
Storage, stock, shipping areas	300 gross
Parking garages	200 gross
Residential	200 gross
Skating rinks, swimming pools	
Rink and pool	50 gross
Decks	15 gross
Stages and platforms	15 net
Warehouses	500 gross

For SI: 1 square foot = 0.0929 m<sup>2</sup>.

a. Floor area in square feet per occupant.

the absolute base minimum occupant load of a space that the means of egress is to accommodate.

The table occupant loads are based on the stereotypical configuration of spaces. For example, the dorm requirements were written based on dormitories with sleeping rooms with two to four students, a gang bathroom and a meeting/study lounge on each floor. Dormitory buildings that operate like army barracks may have a heavier occupant load, while facilities with groups of rooms with private bathrooms, living and even kitchenette areas may have a lower occupant load. Industrial facilities are based on typical fabricating plants. Warehouses are based on consistent in and out movement of product by employees. Factories with largely mechanized operations or warehouses that contain long-term storage are other examples where discussion with the building official and the application of the exception in Section 1004.1.2 might be considered.

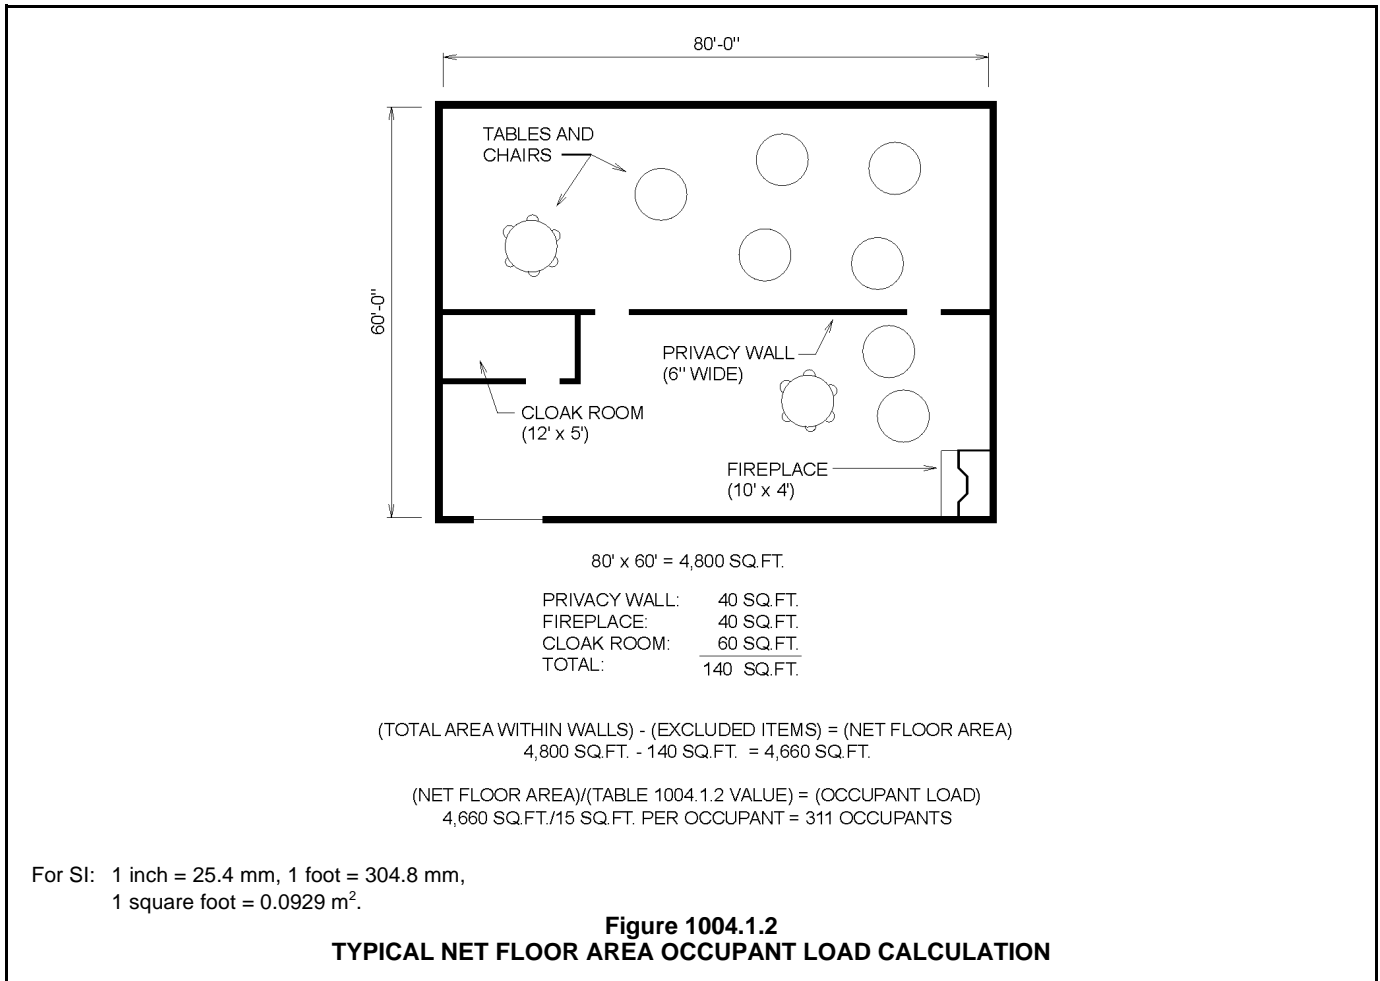

In addition to the table, Section 402 contains the basis for calculating the occupant load of a covered mall building; however, Table 1004.1.2 should be used for determining the occupant load of each anchor store.

**1004.2 Increased occupant load.** The *occupant load* permitted in any building, or portion thereof, is permitted to be

increased from that number established for the occupancies in Table 1004.1.2, provided that all other requirements of the code are met based on such modified number and the *occupant load* does not exceed one occupant per 7 square feet (0.65 m<sup>2</sup>) of occupiable floor space. Where required by the *building official*, an *approved aisle*, seating or fixed equipment diagram substantiating any increase in *occupant load* shall be submitted. Where required by the *building official*, such diagram shall be posted.

❖ An increased occupant load is permitted above that developed by using Table 1004.1.2, for example, by utilizing the actual occupant load. However, if the occupant load exceeds that which is determined in accordance with Section 1004.1.2, the building official has the authority to require aisle, seating and equipment diagrams to confirm that all occupants have access to an exit, the exits provide sufficient capacity for all occupants and compliance with this section is attained.

The maximum area of 7 square feet (0.65 m<sup>2</sup>) per occupant should allow for sufficient occupant movement in actual fire situations. This is not a conflict with the standing space provisions of 5 square feet (0.46 m<sup>2</sup>) net in accordance with Table 1004.1.2. Standing space is typically limited to a portion of a larger area, such as the area immediately in front of the bar or the

waiting area in a restaurant, while the rest of the dining area would use 15 square feet (1.4 m<sup>2</sup>) net per occupant.

**1004.3 Posting of occupant load.** Every room or space that is an assembly occupancy shall have the *occupant load* of the room or space posted in a conspicuous place, near the main *exit* or *exit access doorway* from the room or space. Posted signs shall be of an approved legible permanent design and shall be maintained by the owner or the owner’s authorized agent.

❖ Each room or space used for an assembly occupancy is required to display the approved occupant load. The placard must be posted in a visible location (near the main entrance) (see Commentary Figure 1004.3 for an example of an occupant load limit sign).

The posting is required to provide a means by which to determine that the maximum approved occupant load is not exceeded. This permanent and readily visible sign provides a constant reminder to building personnel and is a reference for building officials during periodic inspections. The posted occupant load could also be an indication that the room was designed for a layout of just tables and chairs, not a layout of chairs only (see Section 302.1).

While the composition and organization of information in the sign are not specified, information must be recorded in a permanent manner. This means that a sign with changeable numbers would not be acceptable.

**Figure 1004.3**  
**EXAMPLE OF OCCUPANT LOAD LIMIT SIGN**

**1004.4 Fixed seating.** For areas having *fixed seats* and *aisles*, the *occupant load* shall be determined by the number of *fixed seats* installed therein. The *occupant load* for areas in which *fixed seating* is not installed, such as waiting spaces, shall be

determined in accordance with Section 1004.1.2 and added to the number of *fixed seats*.

The *occupant load* of *wheelchair spaces* and the associated companion seat shall be based on one occupant for each *wheelchair space* and one occupant for the associated companion seat provided in accordance with Section 1108.2.3.

For areas having *fixed seating* without dividing arms, the *occupant load* shall be not less than the number of seats based on one person for each 18 inches (457 mm) of seating length.

The *occupant load* of seating booths shall be based on one person for each 24 inches (610 mm) of booth seat length measured at the backrest of the seating booth.

❖ The occupant load in an area with fixed seats is readily determined. In spaces with a combination of fixed and loose seating, the occupant load is determined by a combination of the occupant density number from Table 1004.1.2 and a count of the fixed seats.

For bleachers, booths and other seating facilities without dividing arms, the occupant load is simply based on the number of people that can be accommodated in the length of the seat. Measured at the hips, an average person occupies about 18 inches (457 mm) on a bench. In a booth, additional space is necessary for “elbow room” while eating. In a circular or curved booth or bench, the measurement should be taken just a few inches from the back of the seat, which is where a person’s hips would be located (see Commentary Figure 1004.4).

Some assembly spaces may have areas for standing or waiting. For example, some large sports stadiums have “standing room only” areas used for sell-out games. The Globe Theater in England has standing room in an area at the front of the theater. This section is not intended to assign an occupant load to the typical circulation aisles in an assembly space. Occupant load for wheelchair spaces should be based on the number of wheelchairs and companion seats that the space was designed for. As specified in Section 1004.6, if the wheelchair spaces may also be utilized for standing space or removable seating, the occupant load must be determined by the worst-case scenario.

**1004.5 Outdoor areas.** *Yards, patios, courts* and similar outdoor areas accessible to and usable by the building occupants shall be provided with *means of egress* as required by this chapter. The *occupant load* of such outdoor areas shall be assigned by the *building official* in accordance with the anticipated use. Where outdoor areas are to be used by persons in addition to the occupants of the building, and the path of egress travel from the outdoor areas passes through the building, *means of egress* requirements for the building shall be based on the sum of the *occupant loads* of the building plus the outdoor areas.

**Exceptions:**

1. Outdoor areas used exclusively for service of the building need only have one *means of egress*.

2. Both outdoor areas associated with Group R-3 and individual dwelling units of Group R-2.

❖ This section addresses the means of egress of outdoor areas such as yards, patios and courts. The primary concern is for those outdoor areas, used for functions that may include occupants other than the building occupants or the building occupants alone, where egress from the outdoor area is back through the building to reach the exit discharge. An example is an interior court of an office building where assembly functions are held during normal business hours for persons other than the building occupants. When court occupants must egress from the interior court back through the building, the building's egress system is to be designed for the building occupants, plus the assembly occupants from the interior court. Another example would be an outdoor dining area that exited back through the restaurant.

The occupant load is to be assigned by the building official based on use. It is suggested that the design occupant load be determined in accordance with Section 1004.1.2.

Exception 1 describes conditions where the occupant load is very limited, such as areas where an interior courtyard had strictly plants or mechanical equipment. If the courtyard was open for building occupants, other than maintenance personnel, to use the space, the space must be designed with the occupant loads in Table 1004.1.2. Balconies or patios associated with individual dwelling units, in Exception

2, would typically be used by the occupants of the unit. Means of egress can be back through the building in accordance with Section 1016.2.

**1004.6 Multiple occupancies.** Where a building contains two or more occupancies, the *means of egress* requirements shall apply to each portion of the building based on the occupancy of that space. Where two or more occupancies utilize portions of the same *means of egress* system, those egress components shall meet the more stringent requirements of all occupancies that are served.

❖ Since the means of egress systems are designed for the specific occupancy of a space, the provisions of this chapter are to be applied based on the actual occupancy conditions of the space served.

For example, a hospital is classified as Group I-2 and normally includes the associated administrative or business functions found in the same building. Chapter 3 would permit the entire building to be constructed to the more restrictive provisions for Group I-2; however, each area of the building need only have the means of egress designed in accordance with the actual occupancy conditions, such as Groups I-2 and B. If the corridor serves only the occupants in the business use (i.e., administrative staff), and is not intended to serve as a required means of egress for patients, the corridor need only be 36 or 44 inches (914 or 1118 mm) in width, depending on the occupant load.

Where the corridor is used by both Group I-2 and B occupancies, it must meet the most stringent require-

**Figure 1004.4**  
**TYPICAL FIXED SEATING**

ment. For example, if a corridor in the business area is also used for the movement of beds (i.e., exit access from a patient care area), it would need to be a minimum of 96 inches (2438 mm) in clear width.

## SECTION 1005 MEANS OF EGRESS SIZING

**1005.1 General.** All portions of the *means of egress* system shall be sized in accordance with this section.

**Exception:** *Aisles* and *aisle accessways* in rooms or spaces used for assembly purposes complying with Section 1029.

❖ This section is a charging paragraph for sizing for the means of egress system in a tenant space, floor or building. The exception is based on the understanding that means of egress paths within assembly areas have unique criteria based on the high occupant load and possibility of stepped or sloped aisles.

**1005.2 Minimum width based on component.** The minimum width, in inches (mm), of any *means of egress* components shall be not less than that specified for such component, elsewhere in this code.

❖ The code requires the utilization of two methods to determine the minimum width of egress components. While this section provides a methodology for determining required widths based on the design occupant load calculated in accordance with Section 1004.1, other sections provide minimum widths of various components. The actual width that is provided is to be the larger of the two widths.

**1005.3 Required capacity based on occupant load.** The required capacity, in inches (mm), of the *means of egress* for any room, area, space or story shall be not less than that determined in accordance with Sections 1005.3.1 and 1005.3.2.

❖ For this section, the sum of the capacities of the means of egress components that serve each space must equal or exceed the occupant load of that space. For example, the combined width of all of the exit stairways from a floor needs to be considered to determine if the stairways have adequate capacity for everyone to evacuate the building. All elements must meet the minimum width requirements specified in other sections (e.g., Section 1010.1.1 for doors; Sections 1009.3 and 1011.2 for stairs).

This section establishes the necessary width of each egress component on a “per-occupant” basis. Means of egress components are separated between “stairs” and “other;” “other” being doors, doorways, corridors, ramps, aisles, etc.

The traditional unit of measurement of egress capacity was based on a “unit exit width” that was to simulate the body ellipse with a basic dimensional width of 22 inches (559 mm)—approximately the shoulder width of an average adult male. This unit exit width was combined with assumed egress movement (such as single file or staggered file) to result in

an egress capacity per unit exit width for various occupancies. This assumption simplifies the dynamic egress process since contemporary studies have indicated that people do not egress in such precise and predictable movements. As traditionally used in the codes, the method of determining capacity per unit of clear width implies a higher level of accuracy than can realistically be achieved. The resulting factors preserve the features of the past practices that can be documented, while providing a more straightforward method of determining egress capacity.

**1005.3.1 Stairways.** The capacity, in inches, of *means of egress stairways* shall be calculated by multiplying the *occupant load* served by such *stairways* by a means of egress capacity factor of 0.3 inch (7.6 mm) per occupant. Where *stairways* serve more than one story, only the occupant load of each story considered individually shall be used in calculating the required capacity of the *stairways* serving that story.

### Exceptions:

1. For other than Group H and I-2 occupancies, the capacity, in inches, of *means of egress stairways* shall be calculated by multiplying the *occupant load* served by such *stairways* by a means of egress capacity factor of 0.2 inch (5.1 mm) per occupant in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 and an *emergency voice/ alarm communication* system in accordance with Section 907.5.2.2.
  2. Facilities with *smoke-protected assembly seating* shall be permitted to use the capacity factors in Table 1029.6.2 indicated for stepped aisles for *exit access* or *exit stairways* where the entire path for *means of egress* from the seating to the *exit discharge* is provided with a smoke control system complying with Section 909.
  3. Facilities with outdoor *smoke-protected assembly seating* shall be permitted to the capacity factors in Section 1029.6.3 indicated for stepped aisles for *exit access* or *exit stairways* where the entire path for *means of egress* from the seating to the *exit discharge* is open to the outdoors.
- ❖ The capacity factor for stairways is larger than “other egress components” because of the slowdown of travel to negotiate the steps. When the required occupant capacity of an egress component is determined, multiplication by the appropriate factor results in the required clear width of the component in inches, based on capacity. Similarly, if the clear width of a component is known, division by the appropriate factor results in the permitted capacity of that component.

Per Exception 1, other than in Group H or I-2, if the building is sprinklered and has an emergency voice/ alarm communication system, the capacity factor for stairways is permitted to be reduced to 0.2 inches (5.1 mm) per occupant.

Smoke-protected seating is permitted to use a lower capacity number to determine the width of the egress components within the seating bowl. When designing the stepped aisles within the seating bowl, the provisions for Section 1029 are applicable. When designing components outside of the seating bowl, Section 1005.3 is applicable. Per Exceptions 2 and 3, if both the seating bowl and the entire route out of the building is smoke protected, the entire route can use the lower capacity numbers specified in Section 1029. For example, if an outdoor stadium has an enclosed concourse that spectators use to enter and exit the stadium seating, the smoke-protected capacity numbers can be used to design the stepped aisles in the stadium, but the higher numbers for stairways must be used to size the stairways in the concourse. Only if the concourse is also open to the outside air can the smoke-protected seating capacity numbers be used for the entire means of egress route. See the definition of "Smoke-protected assembly seating." See also Sections 1029.6.2 and 1029.6.3.

The following illustrate typical calculations for stairways from a nonsprinklered, two-story, two-exit office building:

1. Determine the minimum required stairway width with a second-floor occupant load of 350:
  - 350 occupants divided by 0.3 inch = 105 inches (2667 mm) minimum;
  - 105 inches divided by two stairways is 52½ inches (1334 mm) minimum per stairway; or
  - Section 1009.1 prescribes that the width of an interior stairway cannot be less than 44 inches (1118 mm).

The capacity criteria are more restrictive and, therefore, the minimum required width for each stairway is 52½ inches (1334 mm).

2. Determine the minimum required stairway width with a second-floor occupant load of 90:
  - 90 occupants divided by 0.3 inches (7.62 mm) = 27 inches (686 mm) minimum;
  - 27 inches (686 mm) divided by two stairways is 13½ inches (343 mm); or
  - Section 1011.1 prescribes that the width of an interior stairway cannot be less than 44 inches (1118 mm). Note that the stair width reduction in Section 1011.2, Exception 1, is applicable only when the entire occupant load of a story is less than 50.

The minimum clear width requirements are more restrictive and, therefore, the minimum required width for each stairway is 44 inches (1118 mm).

The maximum capacity of a 44-inch (1118 mm) stairway is 44 inches divided by 0.3 inches (7.62 mm) per occupant = 146 occupants. Therefore, a floor level with two exit stairways could have 292 occu-

pants before the capacity would control the stairway egress width.

Using the exception for sprinklered buildings, a 44-inch (1118 mm) stairway divided by 0.2 inches (5.08 mm) per occupant = 220 occupants. Therefore, a floor level with two exit stairways could have 440 occupants before the capacity would control the stairway egress width.

Keep in mind that accessible means of egress stairways in nonsprinklered buildings require a minimum clear width of 48 inches (1219 mm) between handrails.

**1005.3.2 Other egress components.** The capacity, in inches, of *means of egress* components other than *stairways* shall be calculated by multiplying the *occupant load* served by such component by a means of egress capacity factor of 0.2 inch (5.1 mm) per occupant.

**Exceptions:**

1. For other than Group H and I-2 occupancies, the capacity, in inches, of *means of egress* components other than *stairways* shall be calculated by multiplying the *occupant load* served by such component by a means of egress capacity factor of 0.15 inch (3.8 mm) per occupant in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 and an *emergency voice/alarm communication* system in accordance with Section 907.5.2.2.
  2. Facilities with *smoke-protected assembly seating* shall be permitted to use the capacity factors in Table 1029.6.2 indicated for level or ramped *aisles* for *means of egress* components other than *stairways* where the entire path for *means of egress* from the seating to the *exit discharge* is provided with a smoke control system complying with Section 909.
  3. Facilities with outdoor *smoke-protected assembly seating* shall be permitted to the capacity factors in Section 1029.6.3 indicated for level or ramped *aisles* for *means of egress* components other than *stairways* where the entire path for *means of egress* from the seating to the *exit discharge* is open to the outdoors.
- ❖ The capacity factor for "other egress components" (e.g., doors, gates, corridors, aisles, ramps) is less than stairways because of the slowdown of travel to negotiate the steps. When the required occupant capacity of an egress component is determined, multiplication by the appropriate factor results in the required clear width of the component in inches, based on capacity. Similarly, if the clear width of a component is known, division by the appropriate factor results in the permitted capacity of that component.
- Per Exception 1, other than in Group H or I-2, if the building is sprinklered and has an emergency voice/alarm communication system, the capacity factor for doors, corridors, aisles, etc., is permitted to be reduced to 0.15 inches (3.8 mm) per occupant.

Smoke-protected seating is permitted to use a lower capacity number to determine the width of the egress components. When designing the ramped or level aisles and aisle accessways within the seating bowl, the provisions for Section 1029 are applicable. When designing components outside of the seating bowl, Section 1005.3 is applicable. Per Exceptions 2 and 3, if both the seating bowl and the entire route out of the building is smoke protected, the entire route can use the lower capacity numbers. For example, if an outdoor stadium has an enclosed concourse that spectators use to enter and exit the stadium seating, the smoke-protected capacity numbers can be used to design the ramped or level aisles in the stadium, but the higher numbers for other egress components must be used to size the corridors or ramps in the concourse. Only if the concourse is also open to the outside air can the smoke-protected seating capacity numbers be used for the entire means of egress route. See the definition of "Smoke-protected assembly seating." See also Sections 1029.6.2 and 1029.6.3.

For example, two exit access doorways from a room with an occupant load of 300 would each have a required capacity of not less than 150. Based on the minimum required clear door width [32-inch (813 mm) clear width per door divided by 0.2 inch (5.08 mm) per occupant = 160 occupants], two 32-inch (813 mm) clear width doors would meet both the minimum clear width (Section 1010.1.1) and the capacity requirements. Two exits from a space with an occupant load of 450 would each have a required capacity of not less than 225, necessitating more doors or larger door leaves.

Using the exception, the door capacity would increase [32-inch (813 mm) clear width per door divided by 0.15 inch (3.08 mm) per occupant = 213 occupants].

**1005.4 Continuity.** The minimum width or required capacity of the *means of egress* required from any story of a building shall not be reduced along the path of egress travel until arrival at the public way.

❖ The requirement that both the minimum widths and required capacity from any floor are to be provided all the way along the exit to the termination, typically down the stairway to the exterior exit door at the level of exit discharge, results in an egress width that is adequate for the exit discharge.

The sum total capacity of the exits that serve a floor is not to be less than the occupant load of the floor as determined by Section 1004.1. If an exit, such as a stairway, also serves a second floor and the required capacity of the exit serving the occupants of the second floor is greater than the first floor, the greater capacity would govern the egress components that the occupants of the floors share. For example, if an exit stairway serves two floors, with occupant loads of 300 on the lower floor and 500 on the upper floor, assuming that two stairways serve each floor, the two stairways would be designed for a capacity of 250

people each, using the upper-floor occupant load of 500 as the basis of determination. Note that the doors to the stairways on the lower floor would be designed for a capacity of 150 and the doors to the stairways on the upper floor would be designed for a capacity of 250. Reversing these two floors would result in the portion of the stairways that serves the upper floor to be designed for a capacity of 150 and the stairways that serve the lower floor to be designed for 250. Requiring the egress component to be designed for the largest tributary occupant load accommodates the worst-case situation.

Also note that the capacity of the exits is based on the occupant load of one floor. The occupant loads are not combined with other floors for the exit design. It is assumed that the peak demand or flow of occupants from more than one floor level at a common point in the means of egress will not occur simultaneously, except as provided for in Sections 1005.6 (Egress convergence) and 1004.1.1.2 (Adjacent levels for mezzanines).

**1005.5 Distribution of minimum width and required capacity.** Where more than one *exit*, or access to more than one *exit*, is required, the *means of egress* shall be configured such that the loss of any one *exit*, or access to one *exit*, shall not reduce the available capacity or width to less than 50 percent of the required capacity or width.

❖ It is critical that the distribution of both egress capacity and minimum width are examined. Where multiple means of egress are required, the loss of any one path cannot reduce the available capacity or width to less than 50 percent. The 50-percent minimum of the required egress capacity and width results in a fairly uniform distribution of egress paths. This requirement does not, however, require that the capacities be equally distributed when *more* than two means of egress are provided. An egress design with a dramatic imbalance of egress component capacities relative to occupant load distribution should be reviewed closely to avoid a needless delay in egressing a story or area. The balancing of the means of egress components, in accordance with the distribution of the occupant load, is reasonable and, in some cases, necessary for facilities having mixed occupancies with dramatically different occupant loads.

**1005.6 Egress convergence.** Where the *means of egress* from stories above and below converge at an intermediate level, the capacity of the *means of egress* from the point of convergence shall be not less than the largest minimum width or the sum of the required capacities for the *stairways* or *ramps* serving the two adjacent stories, whichever is larger.

❖ Convergence of occupants can occur whenever the occupants of an upper floor travel down and occupants of a lower floor travel up and meet at a common, intermediate egress component on the route to the exit discharge. The intermediate component may or may not be another occupiable floor and, most often, is an exit door [see Commentary Figures 1005.6(1) and 1005.6(2)].

The entire premise of egress convergence is based on the assumption of simultaneous notification (i.e., all occupants of all floors begin moving toward the exits at the same time). As illustrated in Commentary Figure 1005.6(3), the occupants of the first floor will have exited the building by the time most of the occupants of the second floor have reached the exit discharge door. However, as illustrated in Commentary

Figure 1005.6(1), the occupants of a basement will reach the discharge door simultaneously with the second-floor occupants, thereby creating a bottleneck and the need for sizing the affected component for a larger combined occupant load.

An egress convergence situation can also be created when an intermediate floor level is not present, as illustrated in Commentary Figure 1005.6(2). Again,

## MEANS OF EGRESS

under the assumption of simultaneous notification, occupants of both floors would reach the exit discharge door at approximately the same time, invoking the requirements for increased egress capacity.

**1005.7 Encroachment.** Encroachments into the required *means of egress* width shall be in accordance with the provisions of this section.

❖ This section addresses maximum encroachment into the required width along the path of travel for means of egress. Types of encroachment are door leaves, door hardware, handrails, trim and protruding objects. These requirements are referenced for aisles (Section 1018.1), corridors (Section 1020.3), exit passageways (Section 1024.2) and exit courts (Section 1028.4.1). Along stairways, handrail projections are permitted per Section 1014.8.

**1005.7.1 Doors.** Doors, when fully opened, shall not reduce the required width by more than 7 inches (178 mm). Doors in any position shall not reduce the required width by more than one-half.

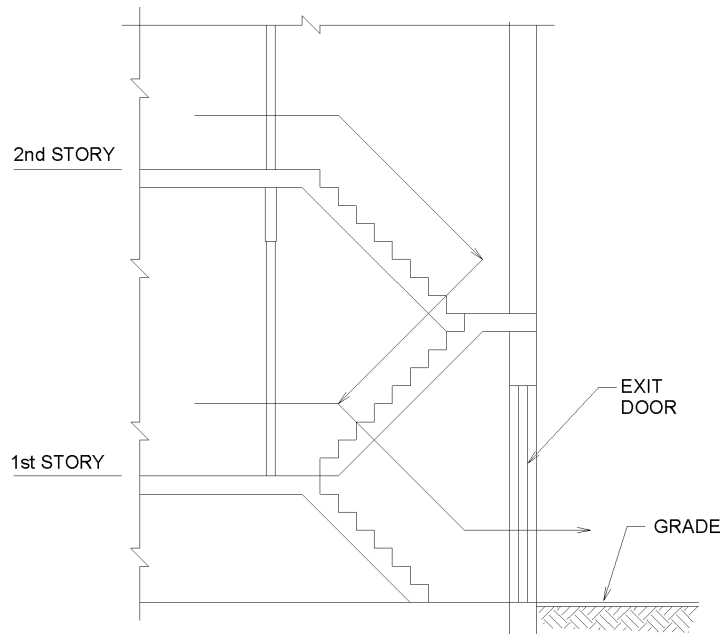

### Exceptions:

1. Surface-mounted latch release hardware shall be exempt from inclusion in the 7-inch maximum (178 mm) encroachment where both of the following conditions exist:
  - 1.1. The hardware is mounted to the side of the door facing away from the adjacent wall where the door is in the open position.
  - 1.2. The hardware is mounted not less than 34 inches (865 mm) nor more than 48 inches (1219 mm) above the finished floor.

2. The restrictions on door swing shall not apply to doors within individual *dwelling units* and *sleeping units* of Group R-2 occupancies and *dwelling units* of Group R-3 occupancies.

❖ Projections or restrictions in the required width can impede and restrict occupant travel, causing egress to occur less efficiently than expected. The swinging of a door, such as from a room into a corridor, and any handrails along the route are permitted projections.

Historically, this section has looked at doors on one wall at a time. Doors located across the hall from one another are not considered additive when considering protrusion limits. Doors would not typically be opened to the full extent at exactly the same moment, nor can they remain open at 90 degrees and totally blocking the hall because of the maximum limitation of 7 inches (178 mm) when fully open (typically approaching 180 degrees). Regarding door encroachment, there are two tests. The arc created by the door's outside edge cannot project into more than one-half of the required corridor width. When opened to its fullest extent, the door cannot project more than 7 inches (178 mm) into the required width, which is the dimension of the leaf thickness excluding the hardware as shown in Commentary Figure 1005.7.1. Door hardware encroachment is addressed separately in Exception 1. These projections are permitted because they are considered to be temporary and do not significantly impede the flow. Occupants will compensate for the projection by a reduction in the natural cushion they retain between themselves and a boundary, known as the edge effect.

**Figure 1005.6(3)**  
**NO EGRESS CONVERGENCE**

Per Exception 2, the door swing restrictions do not apply within dwelling units since the occupant load is very low. Based on the intent of this section, other situations that could be approved by the official having jurisdiction would be situations where the opening door would not block the egress, such as the door at the end of a corridor, or the room was not typically occupied, such as a janitor's closet.

The provision in Exception 1 indicates that hardware facing the corridor when the door is fully open need not be considered when determining the allowable door encroachment into a corridor of 7 inches (178 mm) maximum. The allowance is applicable provided the hardware is mounted within a height range of 34 inches to 48 inches (865 to 1220 mm), which is consistent with the range for means of egress door hardware height as established in Section 1010.1.9.2. Where hardware extends across a door, such as panic hardware, the 4-inch (102 mm) projection in the door opening is addressed in Section 1010.1.1.1.

**1005.7.2 Other projections.** *Handrail* projections shall be in accordance with the provisions of Section 1014.8. Other nonstructural projections such as trim and similar decorative features shall be permitted to project into the required width not more than 1½ inches (38 mm) on each side.

**Exception:** Projections are permitted in corridors within Group I-2 Condition 1 in accordance with Section 407.4.3.

❖ Handrails are not required along corridors, level aisles, exit passageways and exit corridors; however, if provided, Section 1014.8 would be applicable. Handrails are sometimes provided along the hallways in hospitals or nursing homes to aid the residents. Bumper guards along the walls are not handrails.

Items such as baseboards, chair rails, pilasters, etc., are limited to protruding over the *required* width of the corridor a maximum of 1½ inches (38 mm); however, once again, Section 1003.3.3 would be applicable

when the corridor was wider than required.

The exception is in recognition of a situation unique to nursing homes (Group I-2, Condition 1). IBC Section 407.4.3 includes allowances for furniture in corridors to address the need of patients needing a place to sit to rest as well as the new style of design that emphasizes the residential aspects of the environment.

**1005.7.3 Protruding objects.** Protruding objects shall comply with the applicable requirements of Section 1003.3.

❖ This section is a reminder that protruding objects are applicable when looking at encroachments into a confined path of travel. The difference, however, is that door and other projections are applied to the required minimum width, while protruding object provisions apply to paths of travel even when wider than required.

### SECTION 1006 NUMBER OF EXITS AND EXIT ACCESS DOORWAYS

**1006.1 General.** The number of *exits* or *exit access doorways* required within the *means of egress* system shall comply with the provisions of Section 1006.2 for spaces, including *mezzanines*, and Section 1006.3 for *stories*.

❖ The criteria in this section to determine the number of ways to leave rooms or spaces (including mezzanines) and stories are based on an empirical judgment of the associated risks.

**1006.2 Egress from spaces.** Rooms, areas or spaces, including *mezzanines*, within a *story* or *basement* shall be provided with the number of *exits* or access to *exits* in accordance with this section.

❖ This section dictates the minimum number of paths of travel an occupant is to have available to avoid a fire incident in the occupied room or space. While providing multiple egress doorways from every room is

## MEANS OF EGRESS

unrealistic, a point does exist where alternative egress paths must be provided based on the number of occupants at risk, the distance any one occupant must travel to reach a doorway and the relative hazards associated with the occupancy of the space. Generally, the number of egress doorways required from any room or space coincides with the occupant load threshold criteria set forth for the minimum number of exits required from a story (see Section 1006.3).

**1006.2.1 Egress based on occupant load and common path of egress travel distance.** Two exits or exit access doorways from any space shall be provided where the design occupant load or the common path of egress travel distance exceeds the values listed in Table 1006.2.1.

### Exceptions:

1. In Group R-2 and R-3 occupancies, one means of egress is permitted within and from individual dwelling units with a maximum occupant load of 20 where the dwelling unit is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 and the common path of egress travel does not exceed 125 feet (38 100 mm).
  2. Care suites in Group I-2 occupancies complying with Section 407.4.
- ❖ This section dictates the minimum number of paths of travel an occupant is to have available to avoid a fire incident in the occupied room or space. While providing multiple egress doorways from every room is unrealistic, a point does exist where alternative egress paths must be provided based on the number of occupants at risk, the distance any one occupant must travel to reach a doorway and the relative hazards associated with the occupancy of the space.

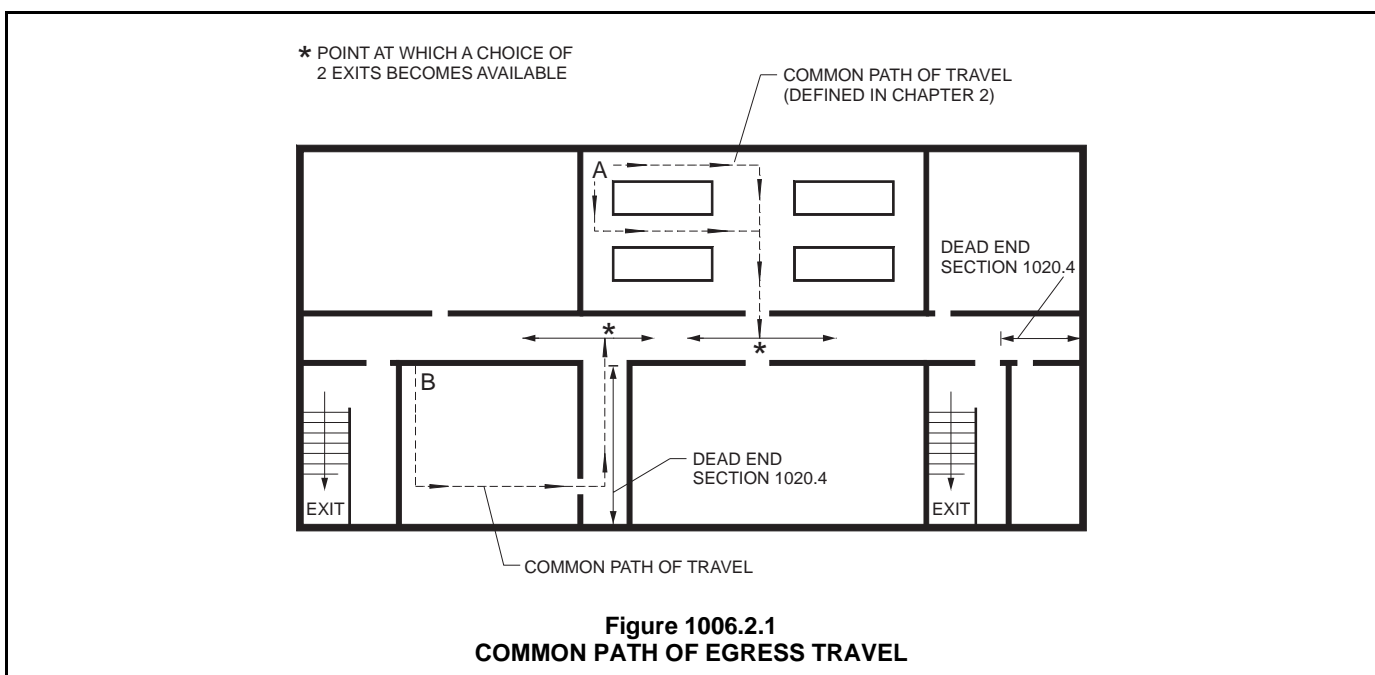

Generally, the number of egress doorways required from any room or space coincides with the occupant load threshold criteria set forth for determining the minimum number of exits required from a story (see Section 1006.3).

The limiting criteria in Table 1006.2.1 for rooms or spaces permitted to have a single exit access doorway are based on an empirical judgment of the associated risks.

If the occupants of a room are required to egress through another room, as permitted in Sections 1004.1.1.1 and 1016.2, the rooms are to be combined to determine if multiple doorways are required from the combined rooms. For example, if a suite of offices shares a common reception area, the entire suite with the reception area must meet both the occupant load and the travel distance criteria. The same logic would hold true for a space with a mezzanine (see Section 1004.1.1.2).

It should be noted that where two doorways are required, the remoteness requirement of Section 1007.1 is applicable.

The common path of travel is the distance measured from the most remote point in a space to the point in the exit path where the occupant has access to two required exits in separate directions. The distance limitations are applicable to all paths of travel that lead out of a space or building where two exits are required. An illustration of this distance is found in Commentary Figure 1006.2.1. The illustration reflects two examples of a common path of travel where the occupants at points A and B are able to travel in only one direction before they reach a point at which they have a choice of two paths of travel to the required exits from the building. Note that from point A, the occupants have two available paths, but these merge to form a single path out of the space. This is also

considered a common path of travel. The common path of travel is considered part of the overall travel distance limitations in Section 1017.2.

While a Group R-3 occupancy is typically a single-exit space, it is included in the table to address mixed-use buildings.

Exception 1 allows for individual dwelling units to be considered a space with one means of egress, provided they meet the same common path of travel requirements in Table 1006.2.1. If the building is sprinklered with an NFPA 13 or 13R system, the occupant load for the unit can be 20 (4,000-square-foot apartment/200 square feet per occupant = 20 occupants), whereas if the unit complies with the table, the occupant load is limited to 10 people per unit (2,000-square-foot apartment/200 square feet per occupant = 10 occupants).

Exception 2 allows for hospital patient rooms and care suites to egress in accordance with the specific criteria in IBC Section 407.4, including the common path of egress travel provisions (Table 1006.2.1, Note d). Other areas in Group I-2 occupancies are addressed in Table 1006.2.1.

**TABLE 1006.2.1.** See below.

❖ The table represents an empirical judgment of the risks associated with a single means of egress from a room or space based on the occupant load in the

room, the travel distance to the exit access door and the inherent risks associated with the occupancy (such as occupant mobility, occupant familiarity with the building, occupant response and the fire growth rate). The number 49 is for consistency with other occupant load thresholds, such as panic hardware (see Section 1010.1.10).

Since the occupants of Groups I and R may be sleeping and, therefore, not able to detect a fire in its early stages without staff supervision or room detectors, the number of occupants in a single egress room or space is limited to 10. See the exceptions to Section 1006.2.1 for Group R-2 and R-3 individual units and Group I-2 patient rooms and care suites.

Because of the potential for rapidly developing hazardous conditions, the single egress condition in Groups H-1, H-2 and H-3 is limited to a maximum of three persons. Because the materials contained in Groups H-4 and H-5 do not represent the same fire hazard potential as those found in Groups H-1, H-2 and H-3, the occupant load for spaces with one means of egress is increased.

Because of the reduced occupant density in Group S and the occupants' normal familiarity with the building, the single egress condition is permitted with an occupant load of 29.

In nonsprinklered business, storage and utility buildings, the length of the common path of egress

**TABLE 1006.2.1  
SPACES WITH ONE EXIT OR EXIT ACCESS DOORWAY**

OCCUPANCY	MAXIMUM OCCUPANT LOAD OF SPACE	MAXIMUM COMMON PATH OF EGRESS TRAVEL DISTANCE (feet)		
		Without Sprinkler System (feet)		With Sprinkler System (feet)
		Occupant Load		
		OL ≤ 30	OL > 30	
A <sup>c</sup> , E, M	49	75	75	75 <sup>a</sup>
B	49	100	75	100 <sup>a</sup>
F	49	75	75	100 <sup>a</sup>
H-1, H-2, H-3	3	NP	NP	25 <sup>b</sup>
H-4, H-5	10	NP	NP	75 <sup>b</sup>
I-1, I-2 <sup>d</sup> , I-4	10	NP	NP	75 <sup>a</sup>
I-3	10	NP	NP	100 <sup>a</sup>
R-1	10	NP	NP	75 <sup>a</sup>
R-2	10	NP	NP	125 <sup>a</sup>

R-4 <sup>e</sup>	10	75	75	125 <sup>a</sup>
S <sup>f</sup>	29	100	75	100 <sup>a</sup>
U	49	100	75	75 <sup>a</sup>

For SI: 1 foot = 304.8 mm.

NP = Not Permitted.

- a. Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2. See Section 903 for occupancies where *automatic sprinkler systems* are permitted in accordance with Section 903.3.1.2.
- b. Group H occupancies equipped throughout with an *automatic sprinkler system* in accordance with Section 903.2.5.
- c. For a room or space used for assembly purposes having *fixed seating*, see Section 1029.8.
- d. For the travel distance limitations in Group I-2, see Section 407.4.
- e. The length of *common path of egress travel* distance in a Group R-3 occupancy located in a mixed occupancy building or within a Group R-3 or R-4 *congregate living facility*.
- f. The length of *common path of egress travel* distance in a Group S-2 *open parking garage* shall be not more than 100 feet.

travel is greater for single-exit spaces when the occupant load for that space is 30 or less. Business, factories and nontransient residential buildings get an increase in the common path of travel in recognition of the additional fire safety offered by a fully sprinklered building. While a Group R-4 is required to be sprinklered, the additional travel distance is not granted where they choose to use an NFPA 13D system as permitted in Section 903.3.1.3. Common path of egress travel does not apply to stories or buildings with one exit. The definition for "Common path" indicates the provisions are only applicable when access to two or more exits is required. See Section 1021.2 for travel limitations for single-exit one-, two- and three-story buildings and Section 1015.1 for spaces with one exit.

Note a indicates if the travel distance increase is based on an NFPA 13 or NFPA 13R sprinkler system being provided throughout the building, whichever is applicable to that occupancy. Where a Group R-4 occupancy can use an NFPA 13D system, the travel distance is indicated in the "without sprinkler system" column. The table does not currently provide information for a Group R-3 occupancy with an NFPA 13D system. Note b is a general reminder for special requirements for sprinklers in Group H.

The reference in Note c to Section 1029.8 is to allow for the unique common path of travel requirements in spaces with assembly seating, such as in a lecture room or sports facility.

Note d is a reference to the common path of travel provisions specific to Group I-2 care rooms and suites that are specifically addressed in IBC Section 407.4.

As indicated in Note e, while Group R-3 dwellings are typically only required to have one exit (see Section 1006.2.1 Exception 1 and Section 1006.3.2, Exception 5), there can be a situation where a Group R-3 unit is included in a mixed-use building. In these situations, the travel distance limitations for common path of travel in the table are applicable.

Note f is an allowance for the common path of travel in an open parking garage to be 100 feet (30 480 mm) when the occupant load is greater than 30 and there is no sprinkler system provided. This is in recognition of the minimal possibility of smoke accumulation due to the openness requirements and the low fuel loads for open parking garages.

**1006.2.1.1 Three or more exits or exit access doorways.** Three *exits* or *exit access doorways* shall be provided from any space with an occupant load of 501 to 1,000. Four *exits* or *exit access doorways* shall be provided from any space with an occupant load greater than 1,000.

❖ Large facilities with high occupant loads are required to have more than two exits leading from each story. This is so that at least one exit will be available in case of a fire emergency and to increase the likelihood that a large number of occupants can be accommodated by the remaining exits when one exit is not available. Section 1005.5 specifies that the loss

of one exit must not reduce the available exit capacity by more than 50 percent. This is reiterated in Sections 1029.2 and 1029.3 for spaces with assembly seating with more than 300 occupants. Exits should be separated in accordance with Section 1007.1.2. While an equal distribution of exit capacity among all the exits is not required, a proper design would consider occupant load distribution as well as reasonable capacity distribution so as to avoid a severe dependence on one exit or bottlenecks in anticipated high-use areas.

**1006.2.2 Egress based on use.** The numbers of *exits* or access to *exits* shall be provided in the uses described in Sections 1006.2.2.1 through 1006.2.2.5.

❖ Five types of spaces, because of their levels of hazard, have egress requirements based on use rather than occupant load and travel distance.

**1006.2.2.1 Boiler, incinerator and furnace rooms.** Two *exit access doorways* are required in boiler, incinerator and furnace rooms where the area is over 500 square feet (46 m<sup>2</sup>) and any fuel-fired equipment exceeds 400,000 British thermal units (Btu) (422 000 KJ) input capacity. Where two *exit access doorways* are required, one is permitted to be a fixed ladder or an *alternating tread device*. *Exit access doorways* shall be separated by a horizontal distance equal to one-half the length of the maximum overall diagonal dimension of the room.

❖ This section requires two exit access doorways for the specified mechanical equipment spaces because of the level of hazards in this type of space. A fixed ladder or an alternating tread device is permitted for service personnel to egress where two doorways are required. The remoteness of the exit access doorways specified in this section provides two paths of travel to exit the room so that if one doorway is not available, the alternate path can be used.

**1006.2.2.2 Refrigeration machinery rooms.** Machinery rooms larger than 1,000 square feet (93 m<sup>2</sup>) shall have not less than two *exits* or *exit access doorways*. Where two *exit access doorways* are required, one such doorway is permitted to be served by a fixed ladder or an *alternating tread device*. *Exit access doorways* shall be separated by a horizontal distance equal to one-half the maximum horizontal dimension of the room.

All portions of machinery rooms shall be within 150 feet (45 720 mm) of an *exit* or *exit access doorway*. An increase in *exit access* travel distance is permitted in accordance with Section 1017.1.

Doors shall swing in the direction of egress travel, regardless of the *occupant load* served. Doors shall be tight fitting and self-closing.

❖ The reasons for these requirements are the same as for Section 1006.2.2.1. Travel distance is to be limited in accordance with Section 1017.2. For example, the travel distance limit for a large refrigeration machinery room classified as Group F-1 that has a sprinkler system throughout the entire building in accordance

with NFPA 13 would be 250 feet (76 200 mm) based on Table 1017.2. The 150-foot (45 720 mm) maximum distance to an exit or exit access doorway that is specified in this section would not apply in this example. The 150-foot (45 720 mm) travel distance is intended to be applied where a sprinkler system is not installed and to shorten the time that occupants would be exposed to the hazards within the machinery room.

**1006.2.2.3 Refrigerated rooms or spaces.** Rooms or spaces having a floor area larger than 1,000 square feet (93 m<sup>2</sup>), containing a refrigerant evaporator and maintained at a temperature below 68°F (20°C), shall have access to not less than two *exits* or *exit access doorways*.

*Exit access* travel distance shall be determined as specified in Section 1017.1, but all portions of a refrigerated room or space shall be within 150 feet (45 720 mm) of an *exit* or *exit access doorway* where such rooms are not protected by an approved *automatic sprinkler system*. Egress is allowed through adjoining refrigerated rooms or spaces.

**Exception:** Where using refrigerants in quantities limited to the amounts based on the volume set forth in the *International Mechanical Code*.

❖ Refrigeration rooms also have a higher hazard level. The exception is intended to apply if Chapter 11 of the *International Mechanical Code*® (IMC®) does not require a separate refrigeration machinery room due to the small amount of refrigerant used (see the commentary to Section 1104 of the IMC for further explanation of the machinery room requirements).

**1006.2.2.4 Day care means of egress.** Day care facilities, rooms or spaces where care is provided for more than 10 children that are 2½ years of age or less, shall have access to not less than two *exits* or *exit access doorways*.

❖ Day care occupancies are limited to a maximum of 10 occupants for rooms or spaces with infants and toddlers before two exits are required from a room. This limit is in consideration of needing a quick means of egress for children who would need to be carried or led for evacuation (i.e., children under 2½ years of age).

There is an exception for the Group I-4 classification in IBC Section 308.6.1 that allows day care facilities with up to 100 children 2½ years of age or less with care rooms having direct access to the exterior to be classified as Group E. An exterior door to the outside from infant and toddler rooms can serve as the second exit to meet this section. It is not the intent that a day care classified as Group E, with children 2½ years of age or less, could use the means of egress requirements for Group E for these rooms.

**1006.2.2.5 Vehicular ramps.** Vehicular ramps shall not be considered as an *exit access ramp* unless pedestrian facilities are provided.

❖ A vehicle-only ramp may be considered as one of the required exit access ramps if pedestrian walkways

are provided along the ramp. The low-slope ramps that are lined with parking spaces are not considered vehicle ramps. In open parking garages, according to Section 1019.3, Exception 6, the exit access stairways and ramps are not required to be enclosed since an open parking structure is designed to permit the ready ventilation of the products of combustion to the outside by exterior wall openings (see IBC Section 406.5.2). Also, parking structures are characterized by open floor areas that allow the occupants to observe a fire condition and choose a travel path that would avoid the fire threat.

**1006.3 Egress from stories or occupied roofs.** The *means of egress* system serving any *story* or occupied roof shall be provided with the number of *exits* or access to *exits* based on the aggregate *occupant load* served in accordance with this section. The *path of egress travel* to an *exit* shall not pass through more than one adjacent *story*.

❖ Emergency evacuation from a multistory building will typically involve stairways or ramps as the vertical element for the means of egress route. The number of required ways off the story (via exit or exit access elements) is based on the occupant loads shown in Table 1006.3.1. These stairways and ramps must comply with the general provisions (Sections 1011 and 1012 respectively), and can be exit access (Section 1019) or exits (Section 1023 and 1027). When exit access stairways or ramps are part of that route, the measurement of the exit access travel distance will include travel from the most remote point on the floor, to and down the exit access stairway or ramp and from the bottom of the stairway or ramp to an enclosure for an exit stairway or ramp or exterior exit door (see Section 1017.3). Vertical travel is slower than horizontal travel, so the exit access stairway or ramp in a building with two or more exits should not be used for more than one story before an exit is reached.

**1006.3.1 Egress based on occupant load.** Each *story* and occupied roof shall have the minimum number of independent *exits*, or access to *exits*, as specified in Table 1006.3.1. A single *exit* or access to a single *exit* shall be permitted in accordance with Section 1006.3.2. The required number of *exits*, or *exit access stairways* or *ramps* providing access to *exits*, from any *story* or occupied roof shall be maintained until arrival at the *exit discharge* or a *public way*.

❖ This section starts out saying that every occupant on a story must have access to the required number of means of egress as specified:

- Per Table 1006.3.1—at least two means of egress per floor;
- Three means of egress for floors with greater than 500 occupants and four means of egress for floors with greater than 1,000 occupants;
- Per Sections 1006.3.2.1 and 1006.3.2.2—limited allowance for a single means of egress from a floor.

Saying “means of egress” instead of “exits” acknowledges that direct entrances to exits on each story are not always mandatory since access to exits (i.e., exit access stairways or ramps) on some stories is permissible within certain limitations. This allows some freedom of design when, for instance, required exit stairways may not be available without passing through other tenant spaces. The intent is to allow for a balance of security concerns providing adequate safety for emergency evacuation.

If a designer chooses to use horizontal exits instead of exit stairways or exit ramps, those specific provisions are addressed in Section 1026. For buildings built into a hillside, an exit door directly to the outside would also provide the same or better level of protection as an interior exit element. It is not the intent of this provision to prohibit horizontal exits or direct exterior exit doors as an option.

Once the number of means of egress is determined, those paths must remain available until occupants leave the building (see Commentary Figure 1006.3.1). The need for exits to be independent of each other cannot be overstated. Each occupant of each floor must be provided with the required number of exits without having to pass through one exit to gain access to another. Each exit is required to be independent of other exits to prohibit such areas from merging downstream and becoming, in effect, one exit.

**TABLE 1006.3.1  
MINIMUM NUMBER OF EXITS OR  
ACCESS TO EXITS PER STORY**

OCCUPANT LOAD PER STORY	MINIMUM NUMBER OF EXITS OR ACCESS TO EXITS FROM STORY
1-500	2
501-1,000	3
More than 1,000	4

❖ Table 1006.3.1 specifies that the minimum number of exits available to each occupant of a floor is based on the total occupant load of that floor. This is so that at least one exit will be available in case of a fire emergency and to increase the likelihood that a larger number of occupants can be accommodated by the remaining exits when one exit is not available. While an equal distribution of exit capacity among all of the exits is not required, a proper design would not only balance capacity with the occupant load distribution, but also consider a reasoned distribution of capacity to avoid a severe dependence on one exit.

**1006.3.2 Single exits.** A single *exit* or access to a single *exit* shall be permitted from any *story* or occupied roof where one of the following conditions exists:

1. The *occupant load*, number of *dwelling units* and *exit access* travel distance do not exceed the values in Table 1006.3.2(1) or 1006.3.2(2).
2. Rooms, areas and spaces complying with Section 1006.2.1 with *exits* that discharge directly to the exte-

**Figure 1006.3.1  
NUMBER OF EXITS**

rior at the *level of exit discharge*, are permitted to have one *exit* or access to a single *exit*.

3. Parking garages where vehicles are mechanically parked shall be permitted to have one *exit* or access to a single *exit*.
4. Group R-3 and R-4 occupancies shall be permitted to have one *exit* or access to a single *exit*.
5. Individual single-story or multistory *dwelling units* shall be permitted to have a single *exit* or access to a single *exit* from the *dwelling unit* provided that both of the following criteria are met:
  - 5.1. The *dwelling unit* complies with Section 1006.2.1 as a space with one *means of egress*.
  - 5.2. Either the *exit* from the *dwelling unit* discharges directly to the exterior at the *level of exit discharge*, or the *exit access* outside the *dwelling unit*'s entrance door provides access to not less than two approved independent *exits*.

❖ The base assumption is that all stories of a building shall have access to at least two separate ways out for emergencies.

Single-exit stories can have access to an exit from any floor, therefore, single-exit stories can use an open exit access stairway for as many stories as permitted by Sections 1006.3.2 and 1019.3.3 provided they meet the exit access of travel distance limitations for that use in Sections 1006.2.1 and 1006.3.2 and Tables 1006.2.1, 1006.3.2(1) and 1006.3.2(2).

A story can have a single exit if the design meets one of the five items listed.

Item 1 states what situations permit one exit by a reference to Tables 1006.3.2(1) and 1006.3.2(2). If a story can meet the provisions for occupant load, number of units and travel distance in Table 1006.3.2(1) or 1006.3.2(2), then that story can have one means of egress. See the commentary for Tables 1006.3.2(1) and 1006.3.2(2) for information on single-exit buildings.

Item 2 references Table 1006.2.1 for single-exit spaces. Table 1006.2.1 is intended to be applicable to rooms and spaces on a floor, but not to an entire floor level. One of the main concerns has been that vertical travel takes longer than horizontal travel in emergency exiting situations. However, if the single-exit space can exit directly to the exterior rather than egress into an interior corridor, a higher level of safety is provided. While the term "building" limits the area addressed to that bordered by exterior walls or fire walls, a common application of Item 2 is on a tenant-by-tenant basis. For example, a single-story strip mall may not meet the provisions for a building with one means of egress but each tenant area meets the provisions for a space with one means of egress in accordance with Section 1006.1. This tenant could exist as either a stand-alone single-exit building or as a single-exit tenant space that exits into an interior corridor. Is it not just as safe to permit this tenant to exist as part of a larger building with the door exiting

directly to the exterior? See also the commentary to Tables 1006.3.2(1) and 1006.3.2(2).

While not specifically stated in this section, there is a situation where the single means of egress can be used from a multilevel tenant space. When the combined occupant load of the space and a mezzanine meets the occupant load in Table 1006.2.1 and the common path of travel distance measured from the most remote point down the exit access stairway and to the exterior exit doorway, the ground floor space and its mezzanine can be considered a space with one means of egress.

Item 3 allows for one exit from all stories in a parking garage where the cars are mechanically parked. This is in recognition of the extremely low occupant load in this unique type of building. The single exit would be for maintenance and service personnel who could be on the different levels. Exit access travel would still have to meet Table 1017.2. If this facility is an open parking garage, it could have one exit access stairway compliant with Sections 1017.2, Exception 1, and 1006.3.2, Exception 1.

Group R-3 is limited to no more than two dwelling units per building. Often these units are townhouse style with direct exits at grade or one unit on top of another. Residents in Group R-3 and R-4 congregate residences typically operate as a single-family home. The Fair Housing Act includes no discrimination based on familial status (i.e., family cannot be determined by blood or marriage). Many court cases have been filed under the Fair Housing Act (FHA) requiring that group homes be permitted to operate similar to a single-family home as a point of nondiscrimination. For additional information on the FHA, see the commentaries at the beginning of Chapter 11 and under IBC Section 1107. In either configuration, per Item 4, each unit is required to have only one exit leading from the building. In a multistory unit, any interior stairway would be considered an exit access stairway (Section 1019.3, Exception 2) and would be part of the exit access travel distance in Table 1017.2.

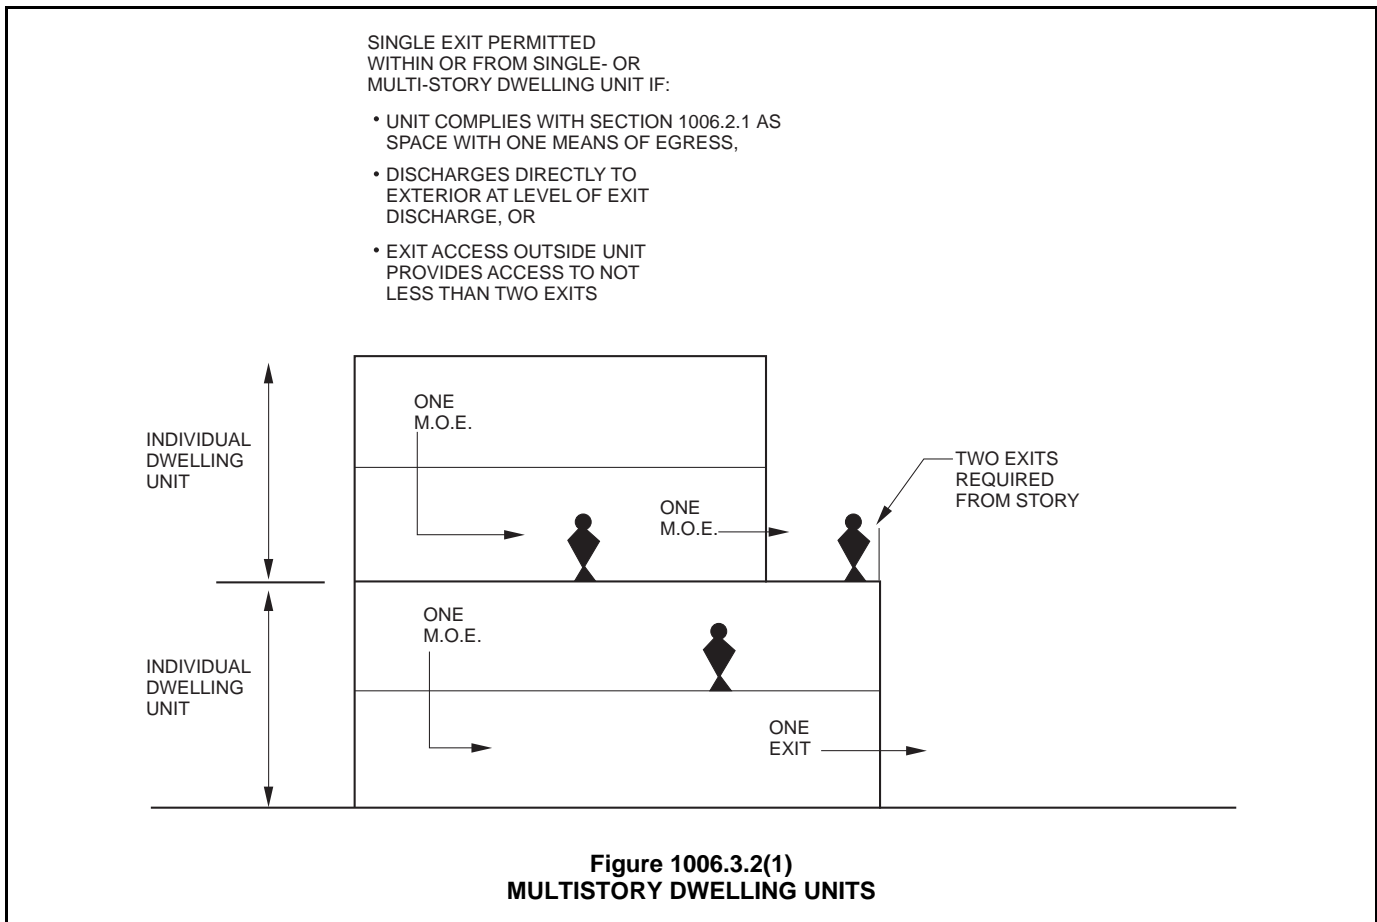

Item 5 is based on decades of practice within an individual dwelling. Item 4 addresses single exits for a Group R-3 building; one or two apartments could be provided in a mixed-use building and still be considered Group R-3. This exception could be used within the unit. Multistory apartments may also be provided within Group R-2 high-rise residential buildings.

In Group R-2, R-3 and R-4 facilities with multistory dwelling units, the means of egress from a dwelling or sleeping unit is typically permitted to be from one level only. In a Group R-2 apartment- or townhouse-style building, if the building is sprinklered with an NFPA 13 or 13R system and the common path of travel from the most remote point on any level to the exit door from the unit itself is 125 feet (22 860 mm) maximum (see Section 1006.2.1), that unit may have only one means of egress. Section 1006.2.1, Exception 1, provides for an occupant load of 20, rather than the 10 occupants allowed in Table 1006.3(2).

**MEANS OF EGRESS**

Therefore, this could allow apartments of up to 4,000 square feet (185.81 m<sup>2</sup>). An exit access stairway would be permitted within the unit as part of the exit access travel distance (Section 1019.3, Exception 2). Once the occupants exit the unit itself, however, they must be outside at grade or the floor level must have access to two or more means of egress for all tenants, depending on the number required for the building as a whole [see Commentary Figures 1006.3.2(1)

and 1006.3.2(3)]. The common path of egress within the unit would be part of the overall exit access travel distance of 250 feet (45 720 mm) required in Table 1017.2). It is not the intent to allow this exception for apartment-style dwelling units in conjunction with the allowances for a single-exit building. The emergency escape and rescue opening addressed in Section 1029 does not count toward the required number of exits.

**TABLE 1006.3.2(1).** See below.

❖ Per Note b, this table addresses when single exits can be provided from stories in Group R-2 occupancies having dwelling units only, such as apartments and condominiums. For Group R-2 occupancies with sleeping units, such as dormitories, sororities, fraternities, convents, monasteries or boarding houses, see Table 1006.3.2(2). The second row is to clarify that buildings containing Group R-2 single-exit buildings cannot be four stories or taller. In addition to meeting the number of dwelling units per floor and exit access travel distance, these buildings must be equipped throughout with an NFPA 13 or 13R sprinkler system and an emergency escape and rescue opening must be provided in every bedroom (Note a). The exit access travel distance would be measured from the most remote point in the unit to the exit from the floor. This is different from the travel distance in Section 1006.2.1, Exception 1 where the travel distance is measured to the door of the unit. However, in order to be able to use the single-exit building provisions, each unit must also meet the single-exit space requirements, so the occupant load of each apartment is limited. See Commentary Figures 1006.3.2(2) and 1006.3.2(3) for examples of the differences. Formal committee interpretation 21-14 states that this table allows for groups of four units on a story to have access to a single exit. These units would have to be separated in accordance with IBC Section 420, but

would not have to be separated by fire barriers or fire walls.

See the commentary to Table 1006.3.2(2) for additional discussion on single-exit building options.

This table is not intended to work in combination with Section 1006.3.2, Exception 5. That section requires a minimum of two exits from the floor.

**TABLE 1006.3.2(2).** See page 10-30.

❖ Buildings with one exit are permitted where the configuration and occupancy meet certain characteristics so as not to present an unacceptable fire risk to the occupants. Buildings that are relatively small in size have a shorter travel distance and fewer occupants; thus, having access to a single exit does not significantly compromise the safety of the occupants since they will also be alerted to and get away from the fire more quickly. It is important to note that the provisions in Section 1006.3.2 apply to individual stories. Multiple single-exit spaces or units may exist in the same building, including those cases where differing occupancies exist. Therefore, Tables 1006.3.2(1) and 1006.3.2(2) can address mixed occupancy buildings (see Section 1006.3.2.1).

Occupants of a story of limited size and configuration may have access to a single exit, provided that the building does not have more than one level below the first story above the grade plane. The limitation on the number of levels above and below the first story is intended to limit the vertical travel an occu-

SINGLE EXIT WITHIN AND FROM UNIT

- 250 FT. MAX. EXIT TRAVEL DISTANCE
- NO LIMIT ON NUMBER OF UNITS
- 125 FT. MAX. COMMON PATH OF TRAVEL (TO APARTMENT DOOR)
- 20 OCCUPANT MAX. PER UNIT PER SECTION 1006.3.2, ITEM 5

For SI: 1 foot = 304.8 mm.

**Figure 1006.3.2(3)**  
**EXAMPLE OF SINGLE-EXIT APARTMENT WITHIN A TWO-EXIT BUILDING**

**TABLE 1006.3.2(1)**  
**STORIES WITH ONE EXIT OR ACCESS TO ONE EXIT FOR R-2 OCCUPANCIES**

STORY	OCCUPANCY	MAXIMUM NUMBER OF DWELLING UNITS	MAXIMUM COMMON PATH OF EGRESS TRAVEL DISTANCE
Basement, first, second or third story above grade plane	R-2 <sup>a, b</sup>	4 dwelling units	125 feet
Fourth story above grade plane and higher	NP	NA	NA

For SI: 1 foot = 3048 mm.

NP = Not Permitted.

NA = Not Applicable.

a. Buildings classified as Group R-2 equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 and provided with *emergency escape and rescue openings* in accordance with Section 1030.

b. This table is used for R-2 occupancies consisting of *dwelling units*. For R-2 occupancies consisting of *sleeping units*, use Table 1006.3.2(2).

**MEANS OF EGRESS**

pant must accomplish to reach the exit discharge in a single-exit building (see Section 1006.3.2.2).

Only one exit is required from a story where permitted by Table 1006.3.2(1) or 1006.3.2(2) regardless of the number of exits required from other stories in the building. For example, a Group B occupancy on the second floor of a two-story building is only required to have one exit from the story, provided its occupant load does not exceed 29 and the maximum exit access travel distance to the exit stairway does not exceed 75 feet (22 860 mm). The number of occupants and travel distances on the first floor do not affect the determination of the second story as a single-exit story. Other stories are also regulated independently as to number of exits. For mixed-occupancy floors or floors where tenant spaces have separate exits, see Section 1006.3.2.1.

Tables 1006.3.2(1) and 1006.3.2(2) list the characteristics a building must have to be of single-exit construction, including occupancy, maximum height of building above grade plane, maximum occupants or dwelling units per floor and exit access travel distance per floor. The occupant load of each floor is determined in accordance with the provisions of Section 1004.1. The exit access travel distance is measured along the natural and unobstructed path to the exit, as described in Section 1017.3. If the occupant load or common path of travel is exceeded, two exits are required from each floor in the building.

The enclosure required for the exit in a two- or three-story, single-exit building is identical to any other complying exit (e.g., interior stairs, exterior stairs, etc.). Similarly, the fire-resistance rating required for opening protectives is identical to that required by IBC Section 716. Exit access stairways could be used in two-story buildings, with or without basements, where permitted by Sections 1019.3 and 1006.3.1.

Per Note c, Group R-2 sleeping units, such as con-

gregate residences, fraternities, sororities, dormitories, convents or monasteries, use Table 1021.2(2). Table 1006.3.2(1) addresses dwelling units in Group R-2 occupancies. Effectively, this section allows for one-story congregate residences to have a single exit where there are 10 or fewer occupants on that first floor or basement. The travel distance from the most remote part of a unit to the exit must be less than 75 feet (22 860 mm). The maximum occupant load would limit the congregate residence to 2,000 square feet (185.81 m<sup>2</sup>) maximum per floor. Per Note a, the congregate residence must be sprinklered throughout with an NFPA 13 or 13R system and all bedrooms must have an emergency escape and rescue opening (Section 1029.1). Alternatively, a congregate residence could use Section 1006.3.2, Item 4. Emergency escape windows would be required, but a single exit for upper floors would be allowed as well as an NFPA 13D sprinkler system where permitted by Section 903.2.8.

Table 1006.3.2(2) allows for two-story business, factory, mercantile and storage facilities to have a single-exit stairway or exit access stairway (see Section 1019.3) from the second floor if the space meets the maximums of 29 occupants and a 75-foot (22 860 mm) travel distance. The increased travel distance in Note b is not permitted for the second floor. However, there is an increase for travel distance permitted for Group S-2 open parking garages in Note d.

Table 1006.3.2(2) allows for a variety of single-story buildings, with or without basements, which meet the maximum occupant load and exit access travel distance specified. Exit access stairways from the basement would be a viable option where permitted by Section 1019.3.

Again, these tables are based on per-story criteria. These tables would also allow for mixed occupancies, such as four apartments over a restaurant or a business over a day care, as long as occupant loads

**TABLE 1006.3.2(2)  
STORIES WITH ONE EXIT OR ACCESS TO ONE EXIT FOR OTHER OCCUPANCIES**

STORY	OCCUPANCY	MAXIMUM OCCUPANT LOAD PER STORY	MAXIMUM COMMON PATH OF EGRESS TRAVEL DISTANCE (feet)
First story above or below grade plane	A, B <sup>b</sup> , E F <sup>b</sup> , M, U	49	75
	H-2, H-3	3	25
	H-4, H-5, I, R-1, R-2 <sup>a,c</sup> , R-4	10	75
	S <sup>b,d</sup>	29	75
Second story above grade plane	B, F, M, S <sup>d</sup>	29	75
Third story above grade plane and higher	NP	NA	NA

For SI: 1 foot = 304.8 mm.

NP = Not Permitted.

NA = Not Applicable.

- a. Buildings classified as Group R-2 equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 and provided with *emergency escape and rescue openings* in accordance with Section 1030.
- b. Group B, F and S occupancies in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 shall have a maximum *exit access* travel distance of 100 feet.
- c. This table is used for R-2 occupancies consisting of *sleeping units*. For R-2 occupancies consisting of *dwelling units*, use Table 1006.3.2(1).
- d. The length of *exit access* travel distance in a Group S-2 *open parking garage* shall be not more than 100 feet.

and travel distances are met. Means of egress could be by a stairway through the floor below or a separate exterior stairway from the upper level. For additional information on a mixed-use floor, see Section 1006.3.2.1.

Formal code interpretation 21-14 states that this table allows for an exit configuration for multiple single-exit spaces for Groups B, M, F and S on the second floor where each group meets Table 1006.3.2(2).

**1006.3.2.1 Mixed occupancies.** Where one *exit*, or *exit access stairway* or *ramp* providing access to *exits* at other *stories*, is permitted to serve individual *stories*, mixed occupancies shall be permitted to be served by single *exits* provided each individual occupancy complies with the applicable requirements of Table 1006.3.2(1) or 1006.3.2(2) for that occupancy. Where applicable, cumulative *occupant loads* from adjacent occupancies shall be considered in accordance with the provisions of Section 1004.1. In each *story* of a mixed occupancy building, the maximum number of occupants served by a single *exit* shall be such that the sum of the ratios of the calculated number of occupants of the space divided by the allowable number of occupants indicated in Table 1006.3.2(2) for each occupancy does not exceed one. Where *dwelling units* are located on a story with other occupancies, the actual number of *dwelling units* divided by four plus the ratio from the other occupancy does not exceed one.

❖ Where multiple tenants or occupancies are located on a specific story, they are to be regulated by a “unity” formula if they want to use the same exit. If they have separate exits, they will be evaluated separately. This would allow for a second floor of a mixed-use occupancy to be evaluated similarly to Section 1016.2, which applies where multiple spaces combine. For example, the second story of a building houses two tenants, one business and one mercantile. Each tenant would be permitted a single, but separate, exit, provided each had an occupant load of less than 30 and a travel distance not exceeding 75 feet (22.860 m) (see Commentary Figure 1006.3.2, Option 2). However, if the tenants wanted to share the same single exit, the combined occupant load would have to be less than 30 (see Commentary Figure 1006.3.2.1, Option 3).

Where the mixed-use stories includes dwelling units, since four dwelling units are allowed per floor in a single-exit building, for the unity formula use 0.25 for one unit, 0.50 for two units and 0.75 for three units.

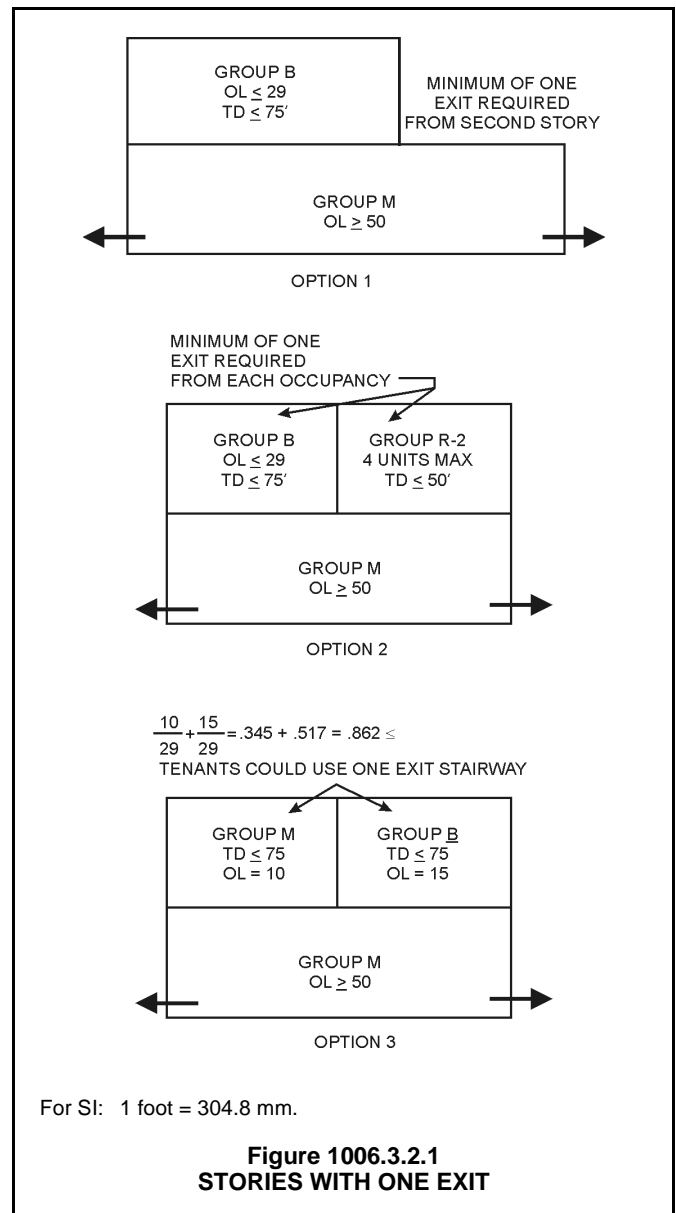

**SECTION 1007  
EXIT AND EXIT ACCESS  
DOORWAY CONFIGURATION**

**1007.1 General.** *Exits*, *exit access doorways*, and *exit access stairways* and *ramps* serving spaces, including individual building *stories*, shall be separated in accordance with the provisions of this section.

❖ The final exits, as well as the doors, stairways and ramps that get occupants to those exits (exit access

elements), need to be unobstructed and obvious at all times for occupants to evacuate the building safely in an emergency situation. This is consistent with the requirements in Section 1010.1 that exit or exit access doors are not to be concealed by curtains, drapes, decorations or mirrors. Whether the doors from the space are exit access doors leading to a hallway or actual exit doors leading to an exit enclosure or directly to the outside, they must be located in accordance with this section.

The need for exits from a space or story to be independent of each other cannot be overstated. Each occupant of each floor must be provided with the required number of exits without having to pass through one exit to gain access to another. Each exit is required to be independent of other exits to prohibit such areas from merging downstream and becoming, in effect, one exit.

The requirement for exits to be continuous is consistent with the exit termination requirements in Section 1023.3 and the exit discharge termination requirements in Section 1024.4. The intent is to provide safety in all portions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway or ramp. Exit passageways (see Section 1024) are a continuation of an exit enclosure. This would include, but not be limited to, the fire-resistance rating of the exit enclosure walls and the opening protection rating of the doors.

Section 1028.1, Exceptions 1 and 2, allows for an alternative for direct access to the outside via an intervening lobby or vestibule. Horizontal exits (see Section 1026), while not providing direct access to the outside of the structure, do move occupants to another “building” by moving through a fire wall (see Section 1026 and Section 1028.1, Exception 3) or into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

**1007.1.1 Two exits or exit access doorways.** Where two exits, exit access doorways, exit access stairways or ramps, or any combination thereof, are required from any portion of the exit access, they shall be placed a distance apart equal to not less than one-half of the length of the maximum overall diagonal dimension of the building or area to be served measured in a straight line between them. Interlocking or scissor stairways shall be counted as one exit stairway.

**Exceptions:**

1. Where interior exit stairways or ramps are interconnected by a 1-hour fire-resistance-rated corridor conforming to the requirements of Section 1020, the required exit separation shall be measured along the shortest direct line of travel within the corridor.
  2. Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, the separation distance shall be not less than one-third of the length of the maximum overall diagonal dimension of the area served.
- ❖ This section provides a method to determine, quantitatively, remoteness between exits and exit access doors based on the dimensional characteristics of the space served. This measure has been common practice for some years with significant success. Very simply, the method involves determining the maximum dimension between any two points in a floor or a room (e.g., a diagonal between opposite corners in a rectangular room or building or the diameter in a circular room or building). If two doors or exits are required from the room or building (see Sections 1006.2 and 1006.3), the straight-line distance between the center of the thresholds of the doors must be at least one-half of the maximum dimension [see Commentary Figure 1007.1.1(1)].

While technical proof is not available to substantiate this method of determining remoteness, it has been found to be realistic and practical for most building designs. Buildings with exits in a center core and occupied spaces around the perimeter are addressed in Exception 1.

If a scissor stairway is utilized, regardless of the separation of the two entrances, the scissor stair may only be counted as one exit. Two independent stairways within the same enclosure could result in both stairways being usable in an emergency where smoke penetrates the single enclosure (see the definition for “Scissor stairways” in Chapter 2). Interlocking stairways that occur over the same building footprint but within separate enclosures are not “scissor stairways” and can count as two independent exits. Due to concern about smoke migration, careful review of the construction details and verification that they meet all the provisions for fire barriers and horizontal assemblies must be made. Of special concern would be the provisions for continuity, penetrations and joints.

The entrance to the enclosures for exit stairways or ramps shall meet the same arrangement as exit and exit access doorways. The need for exits to be independent of each other cannot be overstated.

In Exception 1, a method of permitting the distance between exits to be measured along a complying corridor connecting the enclosure for the exit stairway or ramp has served to mitigate the disruption to this design concept [see Commentary Figure 1007.1.1(2)].

As reflected in Exception 2, the protection provided by an automatic sprinkler system can reduce the threat of fire buildup so that the reduction in remoteness to one-third of the diagonal dimension is not unreasonable, based on the presumption that it provides the occupants with an acceptable level of safety from fire [see Commentary Figure 1007.1.1(3)]. The automatic sprinkler system must be installed throughout the building in accordance with NFPA 13 or 13R. This reduced separation (one-third diagonal) may also be used when applying the requirements of Exception 1.

In applying the provisions of this section, it is important to recognize any convergence of egress paths that may exist. Commentary Figure 1007.1.1(4) illustrates an assembly room with remotely located exit access doors, but the doors from the entire space are not considered remote in accordance with this section.

**1007.1.1.1 Measurement point.** The separation distance required in Section 1007.1.1 shall be measured in accordance with the following:

1. The separation distance to exit or exit access doorways shall be measured to any point along the width of the doorway.

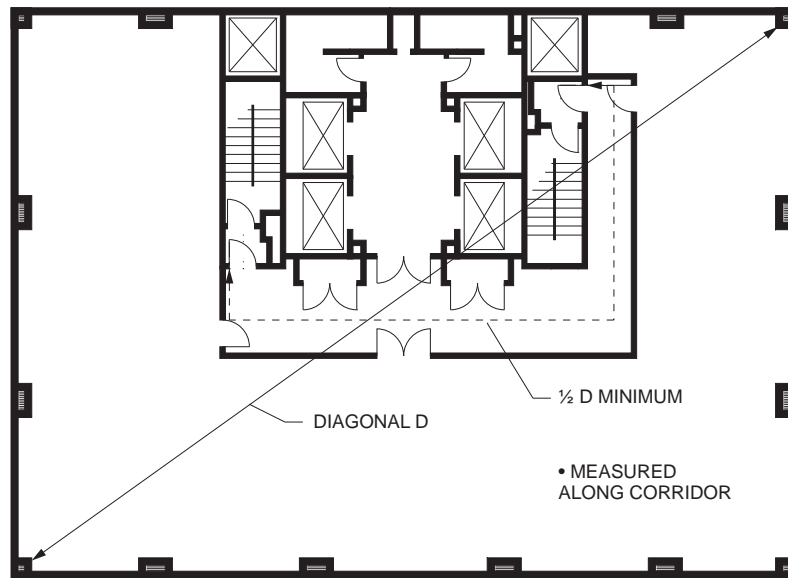

2. The separation distance to *exit access stairways* shall be measured to the closest riser.
3. The separation distance to *exit access ramps* shall be measured to the start of the ramp run.

❖ Where exit access stairways are permitted to be unenclosed, the remoteness measurement for doorways shall begin at the center of the top riser of the unenclosed stairways; this is consistent with the exit access travel distance measurement in Section

1017.3. When enclosure is provided, distances are measured to the door of the enclosure. Typically, travel distance is measured to the center of the door, ramp or stairway; however, there is an allowance for that point to be at any location along the door, stairway or ramp. The intent is to reduce subjectivity in the determination of exit/exit access configuration. The result is that a designer could literally measure to the far extreme edge of the two doorways leading out of a room to meet the separation requirements.

**Figure 1007.1.1(1)**  
**EXAMPLES OF REMOTENESS BETWEEN EXITS OR EXIT ACCESS DOORS FROM A ROOM OR BUILDING**

EXAMPLE:

DIAGONAL DIMENSION = 134'-0"

MIN. SEPARATION OF EXITS =  $134' \div 2 = 67'-0'$

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**Figure 1007.1.1(2)**  
**REMOVEDNESS OF INTERCONNECTING BY A 1-HOUR FIRE-RESISTANCE-RATED CORRIDOR**

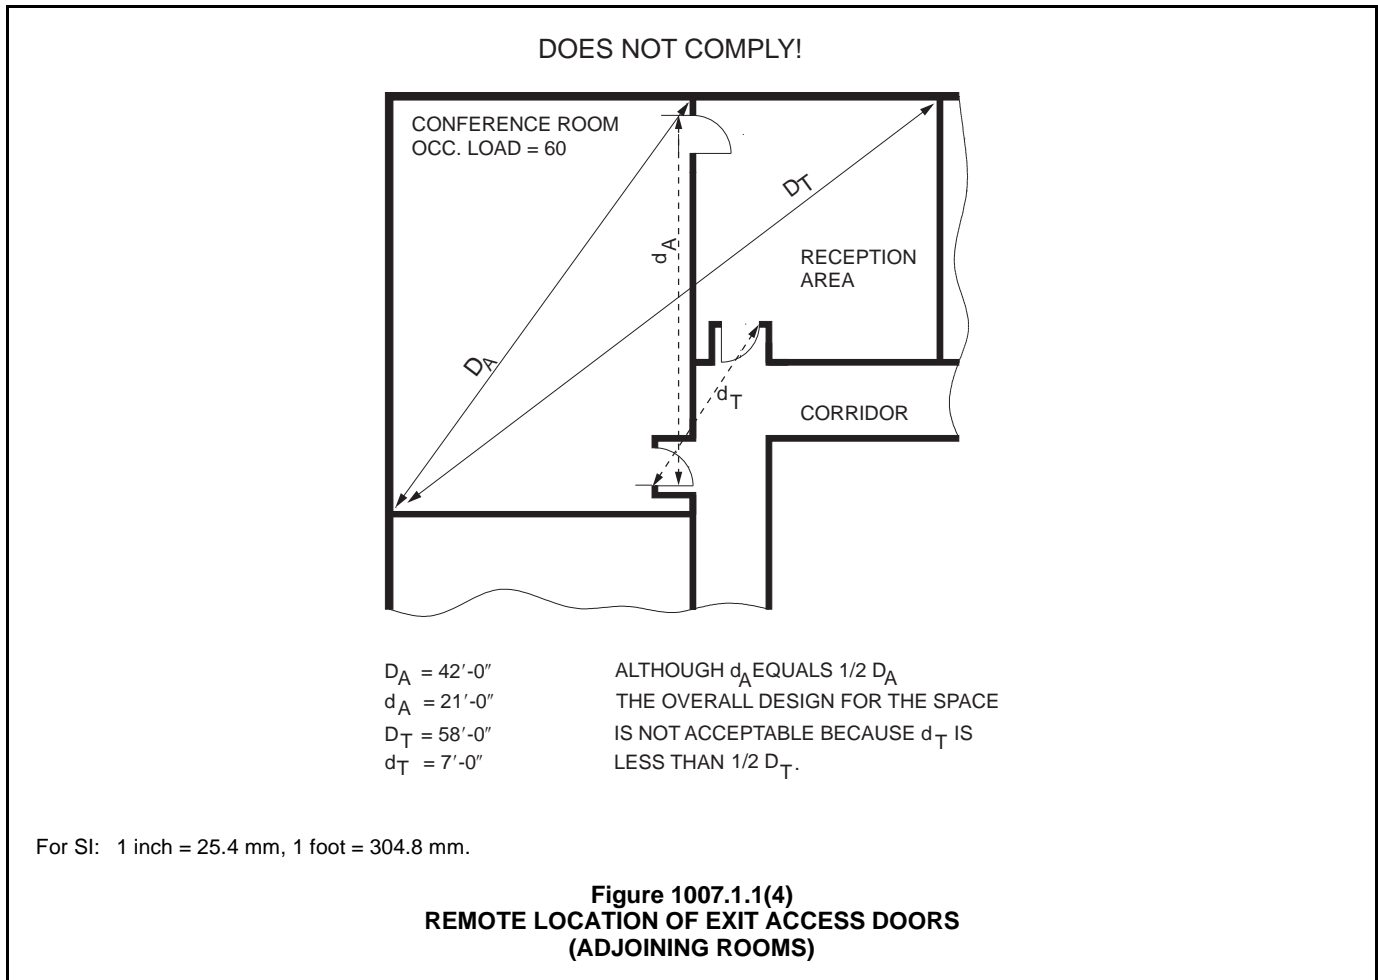

EXAMPLE:

DIAGONAL DIMENSION = 134'-0"

MIN. SEPARATION OF EXITS =  $134' \div 3 = 44'-8"$

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**Figure 1007.1.1(3)**  
**REMOVEDNESS OF EXITS IN A BUILDING WITH AN AUTOMATIC SPRINKLER SYSTEM**

### 1007.1.2 Three or more exits or exit access doorways.

Where access to three or more *exits* is required, not less than two *exit* or *exit access doorways* shall be arranged in accordance with the provisions of Section 1007.1.1. Additional required *exit* or *exit access doorways* shall be arranged a reasonable distance apart so that if one becomes blocked, the others will be available.

❖ When there are three or more required exits from a building or exit access doors from a room, they are to be analyzed identically to the method described in Section 1007.1.1. Two of the exits or exit access doors must meet the remoteness test. Any additional exits or doors can be located anywhere within the floor plan that meets the code requirements, including independence, accessibility, capacity and continuity.

There is no specific separation requirement provided in Section 1007.1.2 for the third exit, but the exits must be located so that one fire event will not block two exits; thus, two doors immediately adjacent would not be acceptable. The appropriate separation is subjective and would be partially dependent on the layout of the space. Using some other provisions in the code for guidance can help. Section 1005.5 states that multiple means of egress need to be sized such that the loss of any one will not reduce the

capacity below 50 percent. This intent is repeated for an assembly space with more than 300 occupants. Sections 1029.2 and 1029.3 can require this space to have a main exit that accommodates one-half of the total occupant load and then require the balance of the exits (means of egress) to provide for the remaining one-half of the occupant load. The “main exit” is typically the result of a single “main entrance” for fee or ticket entry. If there is not a main exit, the exceptions to both Sections 1029.2 and 1029.3 require the means of egress to be “distributed around the perimeter of the building.”

### 1007.1.3 Remoteness of exit access stairways or ramps.

Where two *exit access stairways* or *ramps* provide the required *means of egress* to *exits* at another *story*, the required separation distance shall be maintained for all portions of such *exit access stairways* or *ramps*.

❖ The intent of these provisions are to prohibit open stairways and ramps that meet the separation distance at the first riser or start of the ramp run from converging toward one another such that the separation distance is reduced as the occupants follow the egress path to the lower level. Exit access stairways and ramps have to maintain the separation distance until the travel to the lower floor is complete (see Commentary Figure 1007.1.3).

**1007.1.3.1 Three or more exit access stairways or ramps.** Where more than two *exit access stairways* or *ramps* provide the required *means of egress*, not less than two shall be arranged in accordance with Section 1007.1.3.

❖ See the commentary to Section 1007.1.3, Remoteness of exit access stairways and ramps.

### SECTION 1008 MEANS OF EGRESS ILLUMINATION

**1008.1 Means of egress illumination.** Illumination shall be provided in the *means of egress* in accordance with Section 1008.2. Under emergency power, means of egress illumination shall comply with Section 1008.3.

❖ This section is split into two distinct requirements: Section 1008.2 for egress lighting during typical lighting situations and Section 1008.3 for egress lighting for emergencies when the building has lost normal power.

**1008.2 Illumination required.** The *means of egress* serving a room or space shall be illuminated at all times that the room or space is occupied.

**Exceptions:**

1. Occupancies in Group U.
2. *Aisle accessways* in Group A.
3. *Dwelling units* and *sleeping units* in Groups R-1, R-2 and R-3.
4. *Sleeping units* of Group I occupancies.

❖ All portions of the means of egress serving a space must be illuminated by artificial lighting when that space is occupied, so that the paths of exit travel are always visible and available for evacuation of the occupants during emergencies. The intent is to allow

portions of a building to have the lights turned off when that portion is unoccupied.

Three of the exceptions are for occupancies where the constant illumination of the means of egress would interfere with the use of space, such as sleeping areas or theater seating during a performance.

Bear in mind that means of egress lighting is not emergency lighting. For emergency lighting requirements, see Section 1008.3.

The high-rise provisions in IBC Section 403 utilize the means of egress lighting and emergency lighting in this section. High-rise buildings also require a secondary backup system of luminous egress path markings within enclosed exit stairways (Section 1025). Section 1025.5 requires the enclosed exit stairways to be illuminated for 60 minutes prior to the daily occupancy and during the entire time the building is occupied so that the self-luminous stripes can charge. In a building that is always occupied, such as a hospital or hotel, this would require at least some of the lights in the stairway to be on 24 hours per day.

**1008.2.1 Illumination level under normal power.** The *means of egress* illumination level shall be not less than 1 footcandle (11 lux) at the walking surface.

**Exception:** For auditoriums, theaters, concert or opera halls and similar assembly occupancies, the illumination at the walking surface is permitted to be reduced during performances by one of the following methods provided that the required illumination is automatically restored upon activation of a premises' fire alarm system:

1. Externally illuminated walking surfaces shall be permitted to be illuminated to not less than 0.2 footcandle (2.15 lux).
2. Steps, landings and the sides of ramps shall be permitted to be marked with self-luminous materials in

accordance with Sections 1025.2.1, 1025.2.2 and 1025.2.4 by systems listed in accordance with UL 1994.

- ❖ The intensity of lighting along the entire means of egress, including open plan spaces, aisles, corridors and passageways, exit stairways, exit doors and places of exit discharge at the walking surface or floor level must not be less than 1 footcandle (11 lux). One footcandle (11 lux) is approximately the same lighting level as found outdoors at twilight. It has been found that even this relatively low level of lighting renders enough visibility for occupants to evacuate a building safely.

It is important to note that this lighting level is measured at the floor in order to make the floor surface visible. Levels of illumination above the floor may be higher or lower, thus allowing lights along steps to be used rather than general area lighting.

The exception addresses assembly occupancies where low light level is needed for the function of the space. It is not the intent of the exception to require a fire alarm system but to require a connection to the egress lighting where a fire alarm system is provided. There are two options for that path lighting. Per Exception 1, the level of intensity of aisle lighting in such spaces may be reduced to 0.2 footcandle (2.15 lux), but only during the time of a performance. This intensity of illumination is sufficient to distinguish the aisles and stairs leading to the egress doors and not be a source of distraction during a performance. The option in Exception 2 allows for internally illuminated luminous path stripes (see Section 1025). Since the illumination in the space between shows and the duration of the shows may not be compatible with luminous path markings that charge from a light source, this option is currently not permitted.

**1008.2.2 Exit discharge.** In Group I-2 occupancies where two or more exits are required, on the exterior landings required by Section 1010.6.1, means of egress illumination levels for the exit discharge shall be provided such that failure of any single lighting unit shall not reduce the illumination level on that landing to less than 1 footcandle (11 lux).

- ❖ Section 1006.1, by requiring the means of egress to be illuminated, would include the exit discharge. Often, when moving to the outside of the building, the lighting from the parking lot or street lights will sufficiently light the exit discharge without additional lighting from the building itself. The transition moving from a lighted space to the outside may be an issue at the exit door, therefore, many facilities do provide a light over the exit door on the outside. For hospitals, the fixture provided must have at least two light bulbs, so that if one burns out, the other will still provide sufficient light for this transition.

This proposal was submitted by the Adhoc Health Care Committee, so it is limited to their scope of work. To reduce potential hazards at this important juncture, this could be considered best practice for other occupancies.

**1008.3 Emergency power for illumination.** The power supply for means of egress illumination shall normally be provided by the premises' electrical supply.

- ❖ The main routes for means of egress must be illuminated in times of emergency when the occupants must have a lighted path of exit travel in order to evacuate the building safely. The code is very specific in the description of the areas that are required to be illuminated by the emergency, not the standby power system (see Section 604.2.12).

**1008.3.1 General.** In the event of power supply failure in rooms and spaces that require two or more means of egress, an emergency electrical system shall automatically illuminate all of the following areas:

1. *Aisles.*
2. *Corridors.*
3. *Exit access stairways and ramps.*

- ❖ Where two means of egress are required from a room or space, emergency lighting must be provided along aisle corridors, exit access stairways and ramps. It is not the intent to require the entire space to be lit as during normal use situations addressed in Section 1008.2. However, the main egress paths out of the two exit spaces must be illuminated. This would always include the main corridor in a story with two exits required, and could include paths off that main corridor. For example, an aisle in an open office plan must be illuminated, but not the path within individual offices that egress through the open area. Exit access stairways from a mezzanine or from a second floor (as permitted by Section 1019.3) and the route from the bottom of the stairway to the exit must also be illuminated.

**1008.3.2 Buildings.** In the event of power supply failure in buildings that require two or more *means of egress*, an emergency electrical system shall automatically illuminate all of the following areas:

1. *Interior exit access stairways and ramps.*
2. *Interior and exterior exit stairways and ramps.*
3. *Exit passageways.*
4. Vestibules and areas on the level of discharge used for *exit discharge* in accordance with Section 1028.1.
5. Exterior landings as required by Section 1010.1.6 for *exit doorways* that lead directly to the *exit discharge*.

- ❖ Where two or more exits are required from a story, essential portions of the interior egress system must be illuminated. This includes:

- Exit access stairways from a second floor (as permitted by Section 1019.3) as well as the route from the bottom of the stairway to the exit (see Section 1008.3.1).
- All exit stairways and ramps along their entire length.

## MEANS OF EGRESS

- Exit passageways used in facilities with long travel distances, such as malls, or as an extension of the exit stairway enclosure.
- Means of egress systems that use exit balconies (see Section 1021) or open exterior exit stairways or ramps (see Section 1028).
- Interior exit discharge elements, such as lobbies and vestibules (see Section 1028.1), where stairways discharge into these elements instead of directly to the exterior of a building.
- Exterior portions of the exit discharge. Note that only the portion of the exterior discharge that is immediately adjacent to the building exit discharge door is required to have emergency illumination and not the entire exterior discharge path to the public way.

**1008.3.3 Rooms and spaces.** In the event of power supply failure, an emergency electrical system shall automatically illuminate all of the following areas:

1. Electrical equipment rooms.
  2. Fire command centers.
  3. Fire pump rooms.
  4. Generator rooms.
  5. Public restrooms with an area greater than 300 square feet (27.87 m<sup>2</sup>).
- ❖ The intent of Items 1 through 4 is to have emergency lighting in areas significant for emergency responders or maintenance personnel who may be trying to locate and fix the loss of power issue for the building. Item 5 requires an emergency light in large restrooms. Given the activity, people may need some illumination to quickly get themselves ready to be able to evacuate.

**1008.3.4 Duration.** The emergency power system shall provide power for a duration of not less than 90 minutes and shall consist of storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Section 2702.

- ❖ So that there will be a continuing source of electrical energy for maintaining the illumination of the means of egress when there is a loss of the main power supply, the means of egress lighting system must be connected to an emergency electrical system that consists of storage batteries, unit equipment or an on-site generator. This emergency power-generating facility must be capable of supplying electricity for at least 90 minutes, thereby giving the occupants sufficient time to leave the premises. In most cases, where the loss of the main electrical supply is attributed to a malfunction in the distribution system of the electric power company, experience has shown that such power outages do not usually last as long as 90 minutes.

The IFC requirements for emergency power for emergency egress lighting and exit signage in existing buildings only require a 60-minute time duration.

This is not a conflict, but rather recognition of the loss of battery storage capability over a length of time.

**1008.3.5 Illumination level under emergency power.** Emergency lighting facilities shall be arranged to provide initial illumination that is not less than an average of 1 footcandle (11 lux) and a minimum at any point of 0.1 footcandle (1 lux) measured along the path of egress at floor level. Illumination levels shall be permitted to decline to 0.6 footcandle (6 lux) average and a minimum at any point of 0.06 footcandle (0.6 lux) at the end of the emergency lighting time duration. A maximum-to-minimum illumination uniformity ratio of 40 to 1 shall not be exceeded. In Group I-2 occupancies, failure of any single lighting unit shall not reduce the illumination level to less than 0.2 footcandle (2.2 lux).

- ❖ This section provides the criteria of the illumination levels of the emergency lighting system. The initial average level for the main egress paths is the same as for the overall means of egress illumination in Section 1008.2.1. The reduction of illumination recognizes the performance characteristics over time of some types of power supplies, such as batteries. The minimum levels are sufficient for the occupants to egress from the building. In addition, the emergency lighting system is a secondary system that is spaced along the main egress routes. It will not provide the same level of general lighting over the route as what can be provided by the building lighting system.

The maximum illumination uniformity ratio of 40 means that the variation in the illumination levels is not to exceed that number. For example, a minimum of 0.06 footcandle (0.6 lux) would establish a maximum illumination of 2.4 footcandles (24 lux) in an adjacent area. This is to establish a variation limit such that the means of egress can be seen as a person walks from bright to darker areas along the egress path.

Group I-2 nursing homes and hospitals typically use a defend-in-place strategy for patients and residents who require assistance from a staff trained in the fire and safety evacuation plans. Given the possible critical nature of some of the patients and the need to move some people with life-sustaining equipment, there is an additional requirement that the lighting in the main corridors and along the exit path will always have some redundancy in the fixtures providing that illumination. This could be done with either two bulb fixtures, or locating emergency lighting fixtures close enough that if one burned out, light from fixtures on each side would overlap enough to not result in a dark spot.

## SECTION 1009 ACCESSIBLE MEANS OF EGRESS

**1009.1 Accessible means of egress required.** Accessible means of egress shall comply with this section. Accessible spaces shall be provided with not less than one accessible means of egress. Where more than one means of egress are required by Section 1006.2 or 1006.3 from any accessible

space, each *accessible* portion of the space shall be served by not less than two accessible *means of egress*.

**Exceptions:**

1. Accessible *means of egress* are not required to be provided in existing buildings.
  2. One accessible *means of egress* is required from an *accessible mezzanine* level in accordance with Section 1009.3, 1009.4 or 1009.5.
  3. In assembly areas with ramped *aisles* or stepped *aisles*, one accessible *means of egress* is permitted where the *common path of egress travel* is *accessible* and meets the requirements in Section 1029.8.
- ❖ The Access Board has revised and updated its accessibility guidelines for buildings and facilities covered by the Americans with Disabilities Act of 1990 (ADA) and the Architectural Barriers Act of 1968 (ABA). The final ADA/ABA Guidelines, published by the Access Board in July 2004, serve as the basis for the minimum standards when adopted by other federal agencies responsible for issuing enforceable standards. The plan is to eventually use this new document in place of the Uniform Federal Accessibility Standard (UFAS) and ADAAG. The U.S. Department of Justice officially adopted the new federal requirements on September 15, 2010. The new name is the *2010 Standard for Accessible Design*, otherwise known as the 2010 ADA Standard. The 2010 ADA Standard, Section 207/F207, references the 2000 edition of the IBC with 2001 Supplement, as well as the 2003 edition of the IBC, for accessible means of egress requirements. The International Code Council® (ICC®) is very proud to be recognized for its work regarding accessible means of egress in this manner. Refer to the Access Board website ([www.access-board.gov](http://www.access-board.gov)) for more specific information and the current status of this adoption process. Based on the date of the publication and the adoption process, later editions of the IBC are not specifically referenced; however, none of the later editions reduced the accessible means of egress requirements found in the referenced IBC editions, so they should be able to be considered as providing equivalent or better accessibility.

The accessible means of egress locations may not be near the accessible route used for ingress into the building (see Sections 1104 and 1105). For example, a two-story building requires one accessible route to connect all accessible spaces within the building. The accessible route to the second level is typically by an elevator. During a fire emergency, persons with mobility impairments on the second level should move to the exit stairways for assisted rescue, not back the way they came in via the elevator. Signage at the elevator will direct occupants to an exit stairway.

This section establishes the minimum requirements for means of egress facilities serving all spaces that are required to be accessible to people

with physical disabilities. Previously, attention had been focused on response to the civil-rights-based issue of providing adequate access for people with physical disabilities into and throughout buildings. Concerns about life safety and evacuation of people with mobility impairments were frequently cited as reasons for not embracing widespread building accessibility, in the best interests of the disabled community.

The provisions for accessible means of egress are predominantly, though not exclusively, intended to address the safety of persons with a mobility impairment. These requirements reflect the balanced philosophy that accessible means of egress are to be provided for occupants who have gained access into the building but are incapable of independently utilizing the typical means of egress facilities, such as the exit stairways. By making such provisions, the code now addresses means of egress for all building occupants, with and without physical disabilities.

Any space that is not required by the code to be accessible in accordance with Chapter 11 is not required to be provided with accessible means of egress. This may include an entire story, a portion of a story, a mezzanine or an individual room. For example, a mechanical penthouse is not required to be accessible in accordance with Section 1103.2.9; therefore, the mechanical penthouse is not required to have an accessible means of egress.

In new construction and additions, at least two accessible means of egress are required. For example, in buildings, stories or spaces required by Section 1006.3.1 to have three or more exits or exit access doors, a minimum of two accessible means of egress is required. The accessibility requirements are based on the required means of egress from both individual spaces and the building as a whole. Therefore, facilities with multiple large assembly rooms, such as banquet halls or multiplex theaters where the second exit from the space is often a door directly to the outside, may require additional accessible means of egress from the building because of space requirements.

While there are no dispersment requirements specific to accessible means of egress or travel distance limitations where there is no area of refuge requirement (see Sections 1009.3, 1009.4 and 1009.6), the code requires all exits to be distinct, separated and independent. The main intent is that a person with mobility impairments will always have options. If not all exits are accessible, possible entrapment should be a consideration in determining which exits are to be made accessible. In most buildings, the upper floors will already have an accessible route to all stairways. On the first floor, if the issue is accessible exit discharge, see Section 1009.7.

An accessible means of egress is required to provide a continuous path of travel to a public way. This principle is consistent with the general requirements for all means of egress, as reflected in Section

1003.1 and in the definition of “Means of egress” in Chapter 2. This section also emphasizes the intent that accessible means of egress must be available to a person with a mobility impairment, such as a person using a wheelchair, scooter or walker. Some mobility impairments do not allow for self-evacuation along a stairway; therefore, utilization of the exit and exit discharge may require assistance. The safety and fire evacuation plans (see Sections 404 and 1001.4) require planning for all occupants of a building. This assistance is typically with the fire department or other trained personnel, either along the exit stairways or in buildings five stories or taller, with the elevator system or a combination of both (see commentary, Section 1009.2.1). It is required that accessible routes, areas of refuge and exterior areas of rescue assistance are indicated on these plans. These plans must be approved by the local fire official and reviewed annually.

The exceptions address special situations where accessible means of egress requirements need special consideration. Note that these are exceptions for accessible means of egress; not exceptions for accessible entrance requirements (see IBC Section 1105).

Exception 1 indicates that existing buildings undergoing alterations are not required to be provided with accessible means of egress as part of that alteration. In many cases, meeting the requirements for accessible means of egress, especially the 48-inch (1219 mm) clear stair width required in nonsprinklered buildings, would be considered technically infeasible. However, if an accessible means of egress was part of the original construction, it must be maintained in accordance with IEBC Section 410.2 or 705.1.

Exception 2 is a special consideration for mezzanines. The size of mezzanines is limited to a portion of the space below (see IBC Section 505). Most are open to the space below; thus, with the same atmosphere and line of sight, fire recognition is quicker than in a two-story situation. If the elevator used for ingress has not gone into fire department recall, that system could be used for self-evacuation. There are three different scenarios:

1. If the mezzanine is exempted from accessibility, such as a mechanical mezzanine (see Section 1103.2.9), or small enough not to be required to be accessed by an accessible route (see Section 1104.4, Exception 1), no accessible means of egress is required.
2. If a mezzanine is required to be accessible (see IBC Section 1104.4) and meets the provisions for spaces with one means of egress (see Section 1006.2), the exit access stairway must meet the provisions of Section 1009.3. Per Section 1009.3, Exception 1, this can be an open exit access stairway. Per Exception 4, in a nonsprinklered building, a designer would have the option of either an area of refuge or two-way communication at the elevator. Per Exception 5, in sprinklered buildings, the area of refuge would not be required.
3. If a mezzanine is required to be accessible (see IBC Section 1104.4) and is required to have two means of egress, at least one of the means of egress stairways must meet the provisions of Section 1009.3. Per Section 1009.3, Exception 1, this can be an open exit access stairway. Per Exception 4, in a nonsprinklered building, a designer would have the option of either an area of refuge or two-way communication at the elevator. Per Exception 5, in sprinklered buildings, the area of refuge would not be required. Practically speaking, in a sprinklered building, both stairways from the mezzanine will meet Section 1009.3.

While under Scenarios 2 and 3 it is optional to have the elevator meet the requirements of Section 1009.4, the provisions for standby power at elevators are based on fire department assisted rescue. This is an expensive option that would likely never be used during a fire event. Where platform lifts can be used in new construction (see IBC Section 1109.8), they are so limited that it is not likely that they will provide the accessible route to a mezzanine. If the platform lift serves as part of the route to the space, Section 1009.5 allows for platform lifts to serve as part of the accessible route for accessible means of egress when they have standby power.

Exception 3 is in consideration of the practical difficulties of providing accessible routes in assembly areas with sloped floors and stepped aisles. Rooms with more than 50 persons are required to have two means of egress; therefore, each accessible seating location is required to have access to two accessible means of egress. Depending on the slope of the seating arrangement, providing an accessible route to both distinct exits can be difficult to achieve, especially in small theaters. A maximum travel distance of 30 feet (9144 mm) for ambulatory persons moving from the last seat in dead-end aisles or from box-type seating arrangements to where they have access to a choice of means of egress routes has been established in Section 1029.8. In accordance with Exception 3, persons using wheelchair seating spaces have the same maximum 30-foot (9144 mm) travel distance from the accessible seating locations to a cross aisle or out of the room to an adjacent corridor or space where two choices for accessible means of egress are provided. Note that there are increases in travel distance for smoke-protected seating and small spaces, such as boxes, galleries or balconies. For additional information, see Section 1029.8.

**1009.2 Continuity and components.** Each required accessible *means of egress* shall be continuous to a *public way* and shall consist of one or more of the following components:

1. *Accessible routes* complying with Section 1104.

2. *Interior exit stairways* complying with Sections 1009.3 and 1023.
3. *Exit access stairways* complying with Sections 1009.3 and 1019.3 or 1019.4.
4. *Exterior exit stairways* complying with Sections 1009.3 and 1027 and serving levels other than the *level of exit discharge*.
5. Elevators complying with Section 1009.4.
6. Platform lifts complying with Section 1009.5.
7. *Horizontal exits* complying with Section 1026.
8. *Ramps* complying with Section 1012.
9. *Areas of refuge* complying with Section 1009.6.
10. Exterior areas for assisted rescue complying with Section 1009.7 serving exits at the *level of exit discharge*.

❖ This section identifies the various building features that can serve as elements of an accessible means of egress. Accessible routes are readily recognizable as to how they can provide accessible means of egress; however, some nontraditional principles have been established for the total concept of accessible means of egress. This is evident in that stairways and elevators are also identified as elements that can be part of an accessible means of egress. For example, elevators are generally not available for egress during a fire, while stairways are not independently usable by a person using a wheelchair. The concept of accessible means of egress includes the idea that evacuating people with a mobility impairment may require the assistance of others. In some situations, provisions are also included for creating an area of refuge or exterior areas of rescue assistance wherein people can safely await either further instructions or evacuation assistance. Larger refuge areas can also be established by utilizing horizontal exits. All of these elements can be arranged in the manner prescribed in this section to provide accessible means of egress.

It is important to note that the subjects of Item 10, exterior areas for assisted rescue, are intended to be used only at the level of exit discharge (see commentary in Chapter 2 for the defined term, "Level of exit discharge"). Exterior exit stairways that are from other floors are addressed by Item 4.

**1009.2.1 Elevators required.** In buildings where a required *accessible* floor is four or more *stories* above or below a *level of exit discharge*, not less than one required *accessible means of egress* shall be an elevator complying with Section 1009.4.

**Exceptions:**

1. In buildings equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, the elevator shall not be required on floors provided with a *horizontal exit* and located at or above the *levels of exit discharge*.
2. In buildings equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, the elevator shall not be

required on floors provided with a *ramp* conforming to the provisions of Section 1012.

❖ Elevators are the most common and convenient means of providing access to the upper floors in multistory buildings. As such, elevators represent a prime candidate for accessible means of egress from such buildings, especially in light of the difficulties involved in carrying a person up or down a stairway for multiple levels. The primary consideration for elevators as an accessible means of egress is that the elevator will be available and protected during a fire event to allow for fire department assisted rescue. Typically it is not the intent that people use the elevator for self-evacuation due to the hazards associated with smoke in the elevator shaft or the elevator taking people to the floor with a direct fire hazard. There are some new technological advances for "fire service access elevators" and "occupant evacuation elevators" that are discussed in Sections 403, 3007 and 3008.

This section addresses where an elevator must serve as part of an accessible means of egress. See IBC Section 1104 for when elevators are required for the accessible route into a building. By a reference to Section 1009.4, both an area of refuge and a standby source of power for the elevator are required. The standby power requirement establishes a higher degree of reliability that the elevator will be available and usable by reducing the likelihood of power loss caused by fire or other conditions of power failure.

The code defines "Exit Discharge, Level of" as the story at which an exit terminates. In buildings having four or more stories above or below the level of exit discharge, it is unreasonable to rely solely on exit stairways for all of the required accessible means of egress. This is the point at which complete reliance on assisted evacuation down the stairs will not be effective or adequate because of the limited availability of either experienced personnel who are trained to carry people safely (e.g., fire fighters) or the availability of special devices (i.e., self-braking stairway descent equipment or evacuation chairs). In this case, the code requires that at least one elevator, serving all floors of the building, is to serve as one of the required accessible means of egress. This should not represent a hardship, since elevators are typically provided in such buildings for the convenience of the occupants.

On a flat site, "buildings with four or more stories above the level of exit discharge" would typically be a five-story building. The level of exit discharge is the entire first story level (not merely the plane or level of the first floor); therefore, the fifth floor is the fourth story above the level of exit discharge. In a building with multiple basements, a story four stories below the level of exit discharge would be the fourth basement level. The actual vertical distance is the same from the fifth floor above grade down to discharge, as it is from the fourth floor below grade up to discharge. The verbiage is such that a building built on a sloped site

## MEANS OF EGRESS

can take into consideration that people may be exiting the building from different levels on different sides of the building (see Commentary Figure 1009.2.1).

Exception 1 establishes that accessible egress elevator service to floor levels at or above the level of exit discharge is not necessary under specified conditions. The conditions are that the building is equipped throughout with an automatic sprinkler system in accordance with NFPA 13 or NFPA 13R (see Section 903.3.1.1 or 903.3.1.2) and that floors not serviced by an accessible egress elevator are provided with a horizontal exit. The presence of an automatic sprinkler system significantly reduces the potential fire hazard and provides for increased evacuation time. The combination of automatic sprinklers and a horizontal exit provides adequate protection for the occupants despite their distance to the level of exit discharge. This exception does not apply to floor levels below the level of exit discharge, since such lev-

els are typically below grade and do not have the added advantage of exterior openings that are available for fire-fighting or rescue purposes. This option is most often utilized when a defend-in-place approach to occupant protection is utilized, such as in a hospital, nursing home or jail. Keep in mind that the horizontal exit (see Section 1026) creates large refuge areas that have separation requirements and capacity requirements that exceed area of refuge requirements.

Exception 2 specifies that a building sprinklered throughout in accordance with NFPA 13 or NFPA 13R (see Section 903.3.1.1 or 903.3.1.2), with ramp access to each level, such as in a sports stadium, is not required to also have an elevator for accessible means of egress. The reasoning behind this is that the issue of carrying people down stairways does not occur because the ramps may be utilized instead.

**Figure 1009.2.1**  
**ELEVATOR REQUIRED FOR ACCESSIBLE MEANS OF EGRESS**

**1009.3 Stairways.** In order to be considered part of an accessible *means of egress*, a *stairway* between *stories* shall have a clear width of 48 inches (1219 mm) minimum between *handrails* and shall either incorporate an *area of refuge* within an enlarged floor-level landing or shall be accessed from an *area of refuge* complying with Section 1009.6. *Exit access stairways* that connect levels in the same *story* are not permitted as part of an accessible *means of egress*.

**Exceptions:**

1. *Exit access stairways* providing *means of egress* from *mezzanines* are permitted as part of an accessible *means of egress*.
  2. The clear width of 48 inches (1219 mm) between *handrails* is not required in buildings equipped throughout with an *automatic sprinkler* system installed in accordance with Section 903.3.1.1 or 903.3.1.2.
  3. The clear width of 48 inches (1219 mm) between *handrails* is not required for *stairways* accessed from a refuge area in conjunction with a *horizontal exit*.
  4. *Areas of refuge* are not required at *exit access stairways* where two-way communication is provided at the elevator landing in accordance with Section 1009.8.
  5. *Areas of refuge* are not required at *stairways* in buildings equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2.
  6. *Areas of refuge* are not required at *stairways* serving *open parking garages*.
  7. *Areas of refuge* are not required for *smoke-protected assembly seating* areas complying with Section 1029.6.2.
  8. *Areas of refuge* are not required at *stairways* in Group R-2 occupancies.
  9. *Areas of refuge* are not required for *stairways* accessed from a refuge area in conjunction with a *horizontal exit*.
- ❖ This section addresses stairways between floor levels or to a mezzanine level (see Exception 1). The last sentence indicates that steps that connect raised or lowered areas on the same level are not permitted to be part of an accessible means of egress. People with mobility impairments cannot be asked to wait at the top of steps that may be anywhere in the building; they must be able to get to the stairways where the fire department will be coming into the building.

Stairways (exit or exit access) between floor levels, while not part of an accessible route, can serve as part of the accessible means of egress when they are used as part of an assisted evacuation route. The starting point for these requirements is that the stairways must be 48 inches (1219 mm) clear width between handrails; and either include or be accessed directly by a location where people can wait for

assisted evacuation. This place to wait can be either an “area of refuge” (see Section 1009.6) or a “refuge area” created by a horizontal exit (see Exception 9 and Section 1026).

There are many mobility impairments that can limit or negate a person’s ability to walk up and down the stairs. The taller the building, the higher the percentage of the population that will be affected. For example, an elderly person or a person with a broken foot may be able to get down a couple of flights, but not from an upper floor in a high-rise.

Note that this section is for exit stairways as addressed in Sections 1023 and 1027 and exit access stairways as addressed in Section 1019. Therefore, exit access stairways between stories can be considered part of an accessible means of egress, but exit access steps within the same level, such as steps in a corridor or room leading to an exit or exit access doorway, cannot. Stairways that lead from the level of exit discharge (see the commentary to Chapter 2 for the defined term, “Exit discharge, level of”) to grade are considered part of the exit discharge. When the exit discharge is not accessible, the options are an interior area of refuge complying with Section 1009.6 or an exterior area of assisted rescue in accordance with Section 1009.7. Do not use the provisions in this section.

The dimension of 48 inches (1219 mm) clear width between handrails is sufficient to enable two or three persons to carry a person up or down to the level of exit discharge where access to a public way is afforded.

The enclosed exit stairway, in combination with an area of refuge, can provide for safety from fire in one of two ways. One approach is for the fire-resistance-rated stairway enclosure to afford the necessary safety. To accomplish this, the landing within the stairway enclosure must be able to contain the wheelchair. The concept is that the person in the wheelchair will remain on the stairway landing for a period of time awaiting further instructions or evacuation assistance; therefore, the stairway landing must be able to accommodate the wheelchair without obstructing the use of the stairway by other egressing occupants. An enlarged, story-level landing is required within the stairway enclosure and must be of sufficient size to accommodate the number of wheelchairs [see Section 1009.6 and Commentary Figure 1009.3(1)].

The other approach is to utilize an enclosed exit stairway that is accessed from an area of refuge complying with Section 1009.6. Under this approach, the stairway is made safe by virtue of its access being in an area that is separated and protected from the point of fire origin. An area of refuge can be created by constructing a vestibule adjacent and with direct access to the stair enclosure [see Section 1009.6 and Commentary Figure 1009.3(2)]. This is similar in theory to the approach of an enlarged landing within the stairway enclosure. Again, the general means of

## MEANS OF EGRESS

egress path must be available past the wheelchair spaces.

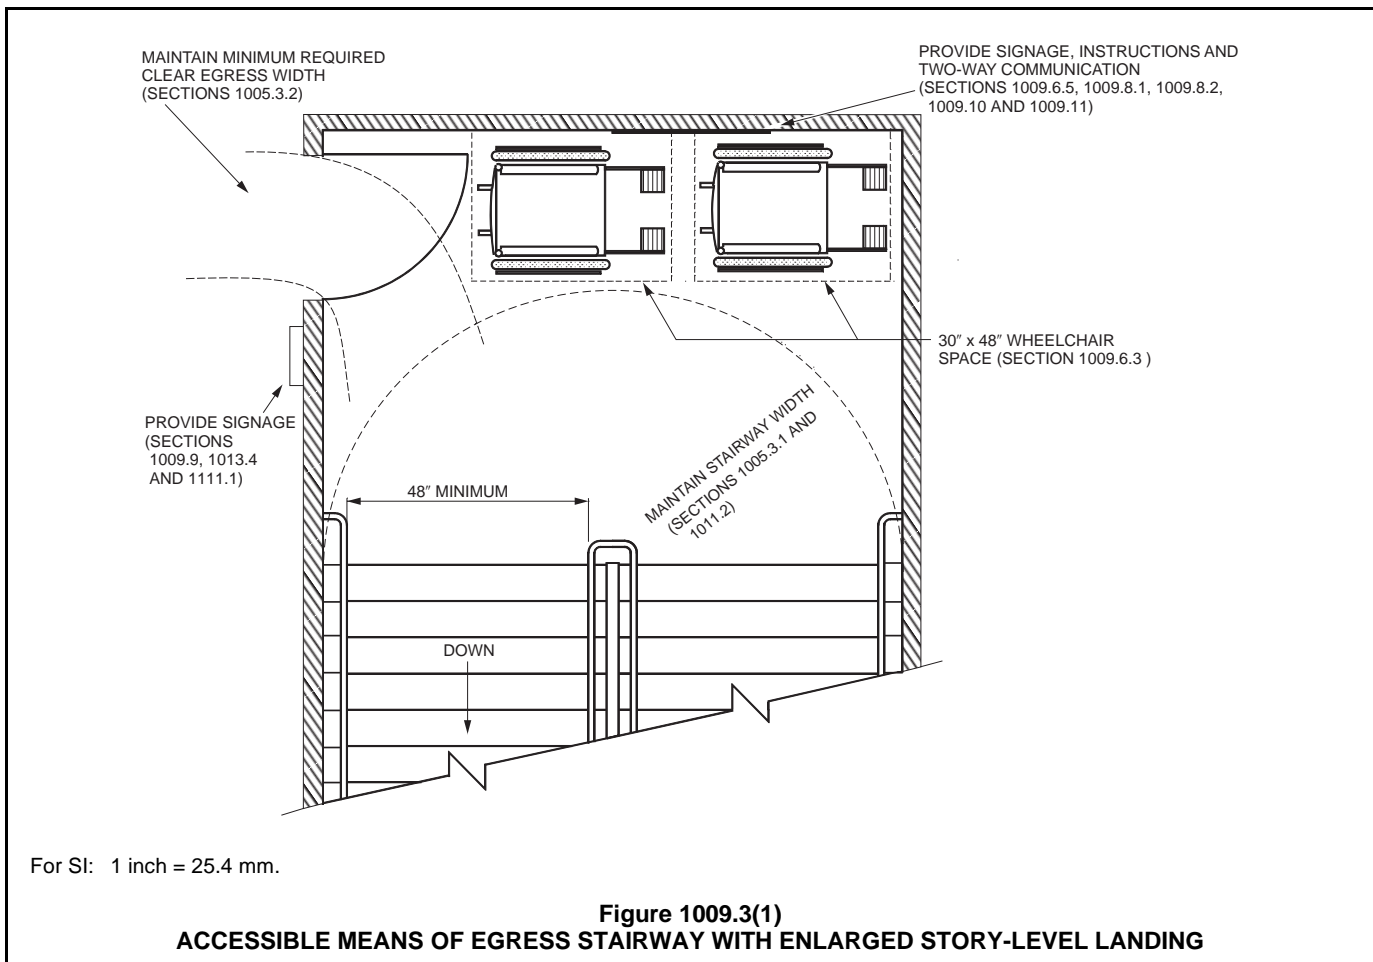

Exceptions may be combined. Exceptions 2 through 9 are either the area of refuge or the 48-inch (1219 mm) stairway width requirement. It is very important to note that an exception for the area of refuge in Section 1009.3 or 1009.4 is not an exception for the accessible means of egress. The accessible route must be available to the stairway or elevator so that people with mobility impairments and emergency responders can meet up as soon as possible.

The exceptions are applicable to all stairways between stories (i.e., exit access, interior exit and exterior exit). The same stairway that serves the ambulatory population for between floor levels can also serve as part of the accessible means of egress. Open exit access stairway requirements for mezzanines and in assembly seating arrangements are addressed in Exceptions 2 and 3 to Section 1009.1.

While the last sentence of Section 1009.3 says that exit access stairways between levels cannot serve as part of an accessible means of egress, Exception 1 allows for exit access stairways between a floor level and a mezzanine. IBC Section 505.1 requires at least a 7-foot clearance below and above a mezzanine. Thus, while it is considered part of the floor below for other parts of the code, there are allowances for the

height difference being similar to a story change in level and the difficulty of providing a ramp for that height. Therefore, the open exit access stairway from the mezzanine can serve as part of an accessible means of egress. In a sprinklered building, Exceptions 2 and 5 would allow for a narrower stairway and no area of refuge. In a nonsprinklered building, Exception 4 would allow for two-way communication at the elevator as an alternative to providing an area of refuge at the top of the open stairway.

Exceptions 2 and 5 are in recognition of the increased level of safety and evacuation time that are afforded in a sprinklered occupancy. The expectation is that a supervised system will reduce the threat of fire by reliably controlling and confining the fire to the immediate area of origin. There is also additional safety afforded by sprinkler system requirements for automatic notification when the system is activated. This has been substantiated by a study of accessible means of egress conducted for the General Services Administration (GSA). A report issued by the National Institute for Standards and Technology (NIST), NIST IR 4770, *Staging Areas for Persons with Mobility Limitations*, concluded that the operation of a properly designed sprinkler system eliminates the life threat to all building occupants, regardless of their individual physical abilities, and is a superior form of protection

as compared to areas of refuge. It was deemed that the ability of a properly designed and operational automatic sprinkler system to control a fire at its point of origin and to limit production of toxic products to a level that is not life-threatening to all occupants of the building, including persons with disabilities, eliminates the need for areas of refuge.

Exceptions 2 and 3 deal with stairway width. Exceptions 4 through 9 are exceptions for the area of refuge. These are not exceptions for the accessible route to the exit, just the area of refuge at the exit.

Exception 2 allows the stairway width to go back to the base requirements in Section 1011.2 in buildings sprinklered in accordance with NFPA 13 or NFPA 13R for both unenclosed and enclosed exit and exit access stairways (see Sections 1011, 1022 and 1027). Exception 2 is often used in conjunction with Exception 5. With the sprinkler system in place, there is more opportunity for the fire department to bring in evacuation chairs or possibly bring people to the elevator for evacuation, thus the extra width for carrying someone down the stairway is not needed. This is safer for both emergency responders and the evacuees.

Exception 5 is for the area of refuge for all exit access stairways (see Section 1011) and exit stairways, interior and exterior (see Sections 1023 and

1027), where the building is sprinklered throughout with an NFPA 13 or 13R system. Again, this is not an exception for the accessible route to the exit, just the area of refuge at the exit.

Exception 3 allows the stairway width to go back to the base requirements in Section 1011.2 when the stairway is within the refuge area created by a horizontal exit. This exception considers that the extra exiting time will permit the egress down the stairway to be more deliberate. Horizontal exits are often used in hospitals or jails when the defense scenario is defend in place rather than evacuation.

Exception 5 can be used in conjunction with Exception 9. In the case of a horizontal exit [see Commentary Figure 1009.3(3)], each floor area on either side of the exit is considered a refuge area (see commentary, Section 1026.1) by virtue of the construction and separation requirements for horizontal exits. The discharge area is always assumed to be the nonfire side and, therefore, is protected from fire. Therefore, per Exception 9, stairways within this refuge area are not required to have areas of refuge.

Exceptions 6 and 7 are for structures where the natural ventilation of the products of combustion will be afforded by the exterior openings or smoke protection required of such structures (see IBC Section 406.3 and Sections 909 and 1029.6.2 of the code).

**Figure 1009.3(2)**  
**ACCESSIBLE MEANS OF EGRESS STAIRWAY ACCESSED FROM AN AREA OF REFUGE**

## MEANS OF EGRESS

The most immediate hazard for occupants in a fire incident is exposure to smoke and fumes. Floor areas in open parking structures communicate sufficiently with the outdoors such that the need for protection from smoke is not necessary; therefore, open parking garages are exempted from the requirements for an area of refuge (see also the exception to Section 1009.6.4). Because of this level of natural ventilation, parking garage exit stairways are not required to be enclosed (see Section 1019.3, Exception 6). The logic for exterior sports facilities and smoke-protected seating is the same: if there is no accumulation of smoke, there is no need for areas of refuge, even when a sprinkler system is not included (see Section 1019.3, Exception 7).

Exception 8 is in recognition of the dwelling unit separation and fire-resistance-rated corridors in Group R-2 facilities (see IBC Section 420 and Section 1020 of the code). Effectively, each dwelling unit can serve as a protected area. Since the current text requires all Group R structures to be sprinklered (see Section 903.2.8), Exceptions 2 and 5 could also be utilized.

**1009.4 Elevators.** In order to be considered part of an accessible *means of egress*, an elevator shall comply with the emergency operation and signaling device requirements of Section 2.27 of ASME/CSA B44 A17.1. Standby power shall be provided in accordance with Chapter 27 and Section 3003. The elevator shall be accessed from an *area of refuge* complying with Section 1009.6.

### Exceptions:

1. *Areas of refuge* are not required at the elevator in *open parking garages*.
2. *Areas of refuge* are not required in buildings and facilities equipped throughout with an *automatic*

*sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

3. *Areas of refuge* are not required at elevators not required to be located in a shaft in accordance with Section 712.
4. *Areas of refuge* are not required at elevators serving *smoke-protected assembly seating* areas complying with Section 1029.6.2.
5. *Areas of refuge* are not required for elevators accessed from a refuge area in conjunction with a *horizontal exit*.

❖ Elevators are the most common and convenient means of providing access to upper and lower floors in multistory buildings. As such, elevators represent a prime candidate for accessible means of egress from such buildings, especially in light of the difficulties involved in carrying a person in a wheelchair up or down a stairway. The primary consideration for elevators as an accessible means of egress is that the elevator will be available and protected during a fire event. See IBC Sections 403, 3007 and 3008 for new provisions in high-rise buildings for “fire service access elevators” and “occupant evacuation elevators.”

This section addresses the use of an elevator as part of an accessible means of egress by requiring both a backup source of power for the elevator and access to the elevator from an area of refuge. For situations where elevators are required to be part of one of the accessible means of egress, see Section 1009.2.1. Note that an elevator lobby that is off a fire-resistance-rated corridor must also comply with Section 713.14 and IBC Chapter 30. The backup power requirement establishes a higher degree of reliability

**Figure 1009.3(3)**  
**ACCESSIBLE MEANS OF EGRESS STAIRWAY ACCESSED FROM A HORIZONTAL EXIT**

that the elevator will be available and usable by reducing the likelihood of power loss caused by fire or other conditions. Requiring access from an area of refuge affords the same degree of fire safety as described for stairways (see commentary, Section 1009.3). Additionally, the reference to Section 604.2 and IBC Section 3003 clarifies that the elevator will comply with the emergency operation features that relate to operating an elevator under fire conditions (see commentary, Section 604.2.1 and IBC Section 3003). Elevators on an accessible route are also required to meet the accessibility provisions of ICC A117.1 (see commentary, IBC Sections 1109.7 and 3001.3).

Exception 2 is for the area of refuge for all elevators where the building is sprinklered throughout with an NFPA 13 or 13R system. Again, this is not an exception for the accessible route to the exit, just the area of refuge at the elevator with standby power. Exception 2 is in recognition of the increased level of safety and evacuation time that is afforded in a sprinklered occupancy. The expectation is that a supervised system will reduce the threat of fire by reliably controlling and confining the fire to the immediate area of origin. There is also additional safety afforded by sprinkler system requirements for automatic notification when the system is activated. This has been substantiated by a study of accessible means of egress conducted for the GSA. NIST IR 4770 concluded that the operation of a properly designed sprinkler system eliminates the life threat to all building occupants, regardless of their individual physical abilities, and is a superior form of protection as compared to areas of refuge. It was deemed that the ability of a properly designed and operational automatic sprinkler system to control a fire at its point of origin and to limit production of toxic products to a level that is not life threatening to all occupants of the building, including persons with disabilities, eliminates the need for areas of refuge.

If a level in an open parking garage contains accessible parking spaces or is part of the route to and from those spaces, that level is required to have accessible means of egress. Exception 1, for open parking structures, is in recognition of the natural ventilation of the products of combustion that will be afforded by the exterior openings required of such structures (see IBC Section 406.5.2). The most immediate hazard for occupants in a fire incident is exposure to smoke and fumes. Floor areas in open parking structures are sufficiently exposed to the outdoors; thus, the need for protection from smoke is not necessary. Therefore, open parking garages are exempt from the requirements for an area of refuge to access an elevator that is utilized as part of the accessible means of egress. The same idea holds true for smoke-protected seating areas, in accordance with Exception 4. The protection offered by the smoke control system allows for adequate evacuation time before there is danger from smoke and fume accumulation.

Exception 3 allows elevators not required to be enclosed by IBC Section 712 to not have an area of refuge or be accessed by a horizontal exit. If there is no shaft enclosure around the elevator, construction of a smoke-tight compartment immediately in front of the elevator doors would be very difficult. While there are many items listed under IBC Section 712, combined with the height requirements in Section 1009.2.1, typically this would be elevators in atriums or in open and enclosed parking garages. Again, the nature of the location adjacent to an atrium or with the open ramps in parking garages would minimize the chances of smoke accumulation at the elevators.

In the case of a horizontal exit [see Commentary Figure 1009.3(3)], each floor area on either side of the exit is considered a refuge area (see commentary, Section 1026.1) by virtue of the construction and separation requirements for horizontal exits. The discharge area is always assumed to be the nonfire side and, therefore, is protected from fire. Therefore, per Exception 5, any elevator within this refuge area is not required to have areas of refuge.

**1009.5 Platform lifts.** Platform lifts shall be permitted to serve as part of an accessible *means of egress* where allowed as part of a required *accessible route* in Section 1109.8 except for Item 10. Standby power for the platform lift shall be provided in accordance with Chapter 27.

❖ Previously, there have been concerns about whether a platform lift will be reliably available at all times. However, ASME A18.1, the standard for platform lifts, no longer requires key operation. It is important to note that platform lifts are not prohibited by the code. They simply cannot be counted as a required accessible means of egress in other than locations where they are allowed as part of the accessible route into a space (see commentary, IBC Section 1109.8). When platform lifts are utilized as part of an accessible means of egress, they must come equipped with standby power. Per ASME A18.1, the standby power needs to be sufficient to run the platform lift for at least five round trips. Note that platform lifts cannot be used to meet accessible means of egress requirements for a situation that utilizes Section 1109.8, Item 10. Accessible means of egress must be provided at other locations.

IBC Section 1109.8, Item 10, recognizes that existing site constraints may make installation of a ramp or elevator infeasible. An example would be the situation of dealing with existing public sidewalks, easements and public ways in downtown urban areas. This situation would be most common in hilly areas where the street and sidewalk follow grade and the building's floor is level, resulting in steps up or down at entrances. The concern for allowing this as part of the accessible means of egress is due to standby power requiring only five cycles. If a platform lift was utilized to provide entry for a large building, or for a building with a large number of occupants that may use mobility devices, such as a hospital, it was

deemed that there might not be sufficient time or power for everyone to evacuate safely.

In existing buildings undergoing alterations, platform lifts are allowed as part of an accessible route into a building (see commentary, IEBC Sections 410.8.3 and 705.1.3) at any location as long as they are compliant with ASME A18.1. Note that accessible means of egress are not required in existing buildings undergoing an alteration or a change of occupancy (see Section 1007.1 and IEBC Sections 410.6 and 705.1).

**1009.6 Areas of refuge.** Every required *area of refuge* shall be accessible from the space it serves by an accessible *means of egress*.

❖ Areas of refuge, when provided, are an important component of fire and safety evacuation plans for buildings. These areas must be included in the plans required by Section 404 and IBC Section 1001.4.

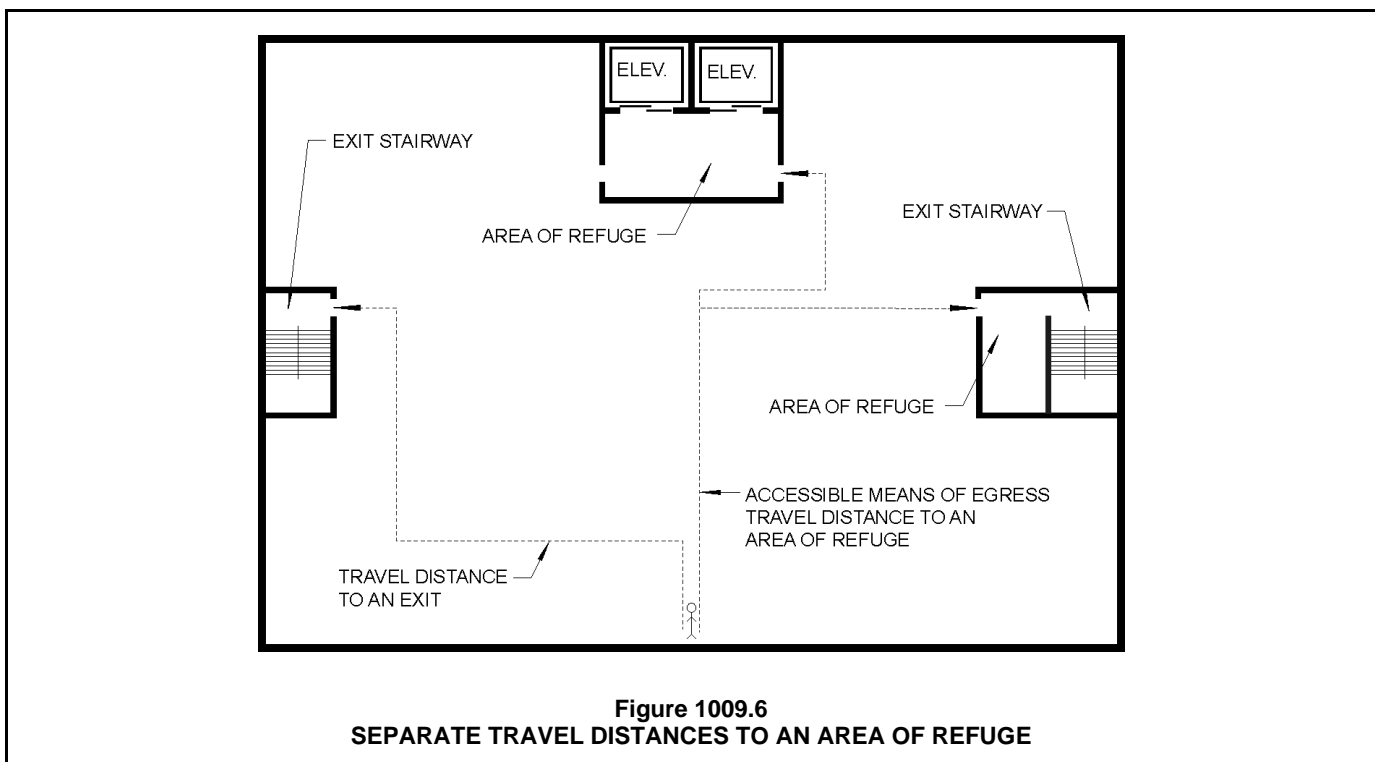

An area of refuge is of no value as part of an accessible means of egress if it is not accessible. The code states an obvious but essential requirement: the path that leads to an area of refuge must qualify as an accessible means of egress. This provision is required so that there will be an accessible route leading from every accessible space to each required area of refuge. See Commentary Figure 1009.6.

**1009.6.1 Travel distance.** The maximum travel distance from any *accessible space* to an *area of refuge* shall not exceed the *exit access* travel distance permitted for the occupancy in accordance with Section 1017.1.

❖ For consistency in principle with the general means of egress design concepts, the code also limits the

travel distance to the area of refuge. The limitation is the same distance as specified in Section 1017.2 for maximum exit access travel distance. This equates the maximum travel distance required to reach an exit with the maximum distance required to reach an area of refuge. It should be noted that an area of refuge is not necessarily an exit in the classic sense. For example, when the area of refuge is an enlarged, story-level landing within an exit stairway, the area of refuge is within the exit and the maximum travel distance for both the conventional exit and the accessible area of refuge is measured to the same point (the entrance to the exit stairway). If the area of refuge is a vestibule immediately adjacent to an enclosed exit stairway, the maximum travel distance for the required accessible means of egress is measured to the entrance of the area of refuge and, for the travel distance to the exit, to the entrance of the exit stairway (see Commentary Figure 1009.6). In the case of accessible means of egress with an elevator, the maximum travel distance may end up being measured along two different paths, with the only consistency between the conventional means of egress and the accessible means of egress being the maximum travel distance (see Commentary Figure 1009.6). The travel distance within an area of refuge is not directly regulated, but will be limited by the general provisions for maximum exit access travel distance, which are always applicable.

In summary, the code takes a reasonably consistent approach for both conventional and accessible means of egress by limiting the distance one must travel to reach a safe area from which further egress to a public way is available.

**Figure 1009.6**  
**SEPARATE TRAVEL DISTANCES TO AN AREA OF REFUGE**

**1009.6.2 Stairway or elevator access.** Every required *area of refuge* shall have direct access to a *stairway* complying with Sections 1009.3 and 1023 or an elevator complying with Section 1009.4.

❖ To ensure that there is continuity in an accessible means of egress, the code requires that every area of refuge have direct access to either an exit stairway (see Section 1009.3) or an elevator (see Section 1009.4). This, again, may be viewed as stating the obvious, but it is necessary so that the egress layout does not involve entering an area of refuge and then having to leave that protected area before gaining access to a stairway or elevator. Once an occupant reaches the safety of an area of refuge, that level of protection must be continuous until the vertical transportation element (the stairway or elevator) is reached.

If one chooses to comply with accessible means of egress requirements by providing an accessible elevator with an area of refuge in the form of an elevator lobby, the elevator shaft and the lobby are required to be constructed in accordance with IBC Section 713.14 and IBC Chapter 30. The requirements provide additional assurance that the elevator will not be rendered unavailable because of smoke movement into the elevator shaft. If the elevator is in a refuge area that is formed by the use of a horizontal exit (i.e., fire walls or fire barriers in accordance with Section 1026.2) or smoke compartments formed by smoke barriers (see IBC Sections 407.5 and 408.6), it is presumed that the refuge area is relatively free from smoke; therefore, the extra protection of IBC Section 713.14 and IBC Chapter 30 may not be needed.

**1009.6.3 Size.** Each *area of refuge* shall be sized to accommodate one *wheelchair space* of 30 inches by 48 inches (762 mm by 1219 mm) for each 200 occupants or portion thereof, based on the *occupant load* of the *area of refuge* and areas served by the *area of refuge*. Such *wheelchair spaces* shall not reduce the *means of egress* minimum width or required capacity. Access to any of the required *wheelchair spaces* in an *area of refuge* shall not be obstructed by more than one adjoining *wheelchair space*.

❖ The number of wheelchair spaces that are required to be provided in an area of refuge is intended to represent broadly the expected population of the average building. As one point of measurement, a 1977 survey conducted by the National Center for Health indicated that one in 333 civilian, noninstitutionalized persons uses a wheelchair. The 1990 ADA currently utilizes the criterion of one space for each 200 occupants, based on the space served by the area of refuge. Given the variations and difficulties involved in accurately predicting a representative ratio for application to all occupancies, it was concluded that a requirement for one space for each 200 occupants based on the area of refuge itself, plus the areas served by the area of refuge, represents a reasonable criterion. Very few buildings would ever require

more than four wheelchair spaces on a floor, since nearly all buildings with an occupant load greater than 400 per floor would be sprinklered and using Exception 5 in Section 1009.3.

Arrangement of the required wheelchair spaces is critical so as not to interfere with the means of egress for ambulatory occupants (see Section 1011.6). Since the design concept is that wheelchair occupants will move to the area of refuge and await further instructions or evacuation assistance, the spaces must be located so as not to reduce the required means of egress width of the stairway, door, corridor or other egress path through the exterior area of egress.

In order to provide for orderly maneuvering of wheelchairs, this section states that access to any of the required wheelchair spaces cannot be obstructed by more than one adjoining wheelchair space. For example, this precludes an arrangement that three or more wheelchairs could be stacked down a dead-end corridor. This also effectively limits the difficulty any given wheelchair occupant would have in reaching or leaving a given wheelchair space, as well as providing easier access to all wheelchair spaces by persons providing evacuation assistance.

**1009.6.4 Separation.** Each *area of refuge* shall be separated from the remainder of the story by a *smoke barrier* complying with Section 709 or a *horizontal exit* complying with Section 1026. Each *area of refuge* shall be designed to minimize the intrusion of smoke.

**Exceptions:**

1. *Areas of refuge* located within an enclosure for *interior exit stairways* complying with Section 1023.
2. *Areas of refuge* in outdoor facilities where *exit access* is essentially open to the outside.

❖ The minimum standard for construction of an area of refuge is a smoke barrier, in accordance with Section 709. This establishes a minimum degree of performance by means of a 1-hour fire-resistance rating, including opening protectives and a minimum degree of performance against the intrusion of smoke into an enclosed area of refuge, as specified in Sections 709.4 and 709.5. By the nature of the connection to the stair enclosure or elevator shaft, the normal smoke barrier requirement for extension from exterior wall to exterior wall is replaced by connection to the shaft enclosure.

An alternative is to provide a refuge area created by a horizontal exit complying with Section 1026. Horizontal exits are formed by fire walls or fire barriers with a minimum fire-resistance rating of 2 hours. The horizontal exit separation must extend vertically through all levels of the building, unless floor assemblies have a fire-resistance rating of not less than 2 hours with no unprotected openings (see Section 1026.2). The other provisions for horizontal exits for additional egress elements, opening protection and capacity must also be complied with.

This section does not require an area of refuge within an exit stairway to be designed to prevent the intrusion of smoke. This was based on a study of areas of refuge conducted by the NIST for the GSA, which concluded that a story-level landing within a fire-resistance-rated exit stairway would provide a satisfactory staging area for evacuation assistance (see Exception 1).

Exception 2 is in recognition that, despite not being a sprinklered venue, where the entire facility is protected from smoke and fumes by the nature of being open to the outside a separation for areas of refuge is not required.

**1009.6.5 Two-way communication.** *Areas of refuge* shall be provided with a two-way communication system complying with Sections 1009.8.1 and 1009.8.2.

❖ If a building includes areas of refuge at the stairway or elevators, each area of refuge must include a two-way communication system. If the building uses one of the exceptions for areas of refuge, Section 1007.8 would still require a two-way communication system at the elevator. This way anyone needing assistance can communicate with a person at a constantly attended location to request evacuation assistance. This system is an important part of the fire and safety evacuation plans required by Section 404 and IBC Section 1001.4. See Sections 1009.8.1 and 1009.8.2 for specific requirements for this system.

**1009.7 Exterior areas for assisted rescue.** Exterior areas for assisted rescue shall be accessed by an *accessible route* from the area served.

Where the *exit discharge* does not include an *accessible route* from an *exit* located on the *level of exit discharge* to a *public way*, an exterior area of assisted rescue shall be provided on the exterior landing in accordance with Sections 1009.7.1 through 1009.7.4.

❖ Section 1009.2 requires the accessible means of egress to have an accessible route along the path for exit access, exit and exit discharge. Stairways that lead from the level of exit discharge (see the commentary to Chapter 2 for the defined term, “Exit discharge, level of”) to grade are considered part of the exit discharge. When the exit discharge is not accessible, the options are an interior area of refuge complying with Section 1009.6 or an exterior area of assisted rescue in accordance with Section 1009.7. The provisions for stairways in Section 1009.3, including the exceptions for sprinklered buildings, are not an option to address nonaccessible exit discharge.

Exterior areas of assisted rescue are intended to be open-air locations for persons with physical disabilities to wait for assisted rescue. There must be an interior or exterior accessible route along the path of travel for access to this location. This allows a person unable to negotiate the exit discharge to get to a location where they can be quickly discovered by the fire department or other emergency responders.

In most situations, interior areas of refuge are not a positive alternative. Tenants tend to use such areas as convenient storage areas. Where persons with mobility impairments can wait for assisted rescue outside of the building, they are effectively protected from interior smoke and fumes—the deadliest of the fire hazards. Being immediately visible at an exit should also result in a shorter period of time before assisted rescue is achieved.

Exterior areas for assisted rescue, when provided, are an important component of the fire and safety evacuation plans for the buildings. These areas must be included in the plans required by Section 404 and IBC Section 1001.4.

The option under Section 1009.7 is commonly used only at the level of exit discharge for the second exit out the back of a building or tenant space. This will be either a single-story building, or the first level of a multistory building, where the secondary exit discharge is not accessible due to changes in elevation around the perimeter. If this is an exterior exit stairway (i.e., more than one story of vertical travel), the provisions in Section 1009.3 would be applicable.

Examples of this issue are:

**Example 1:**

A strip mall would have accessible entrances to each tenant in the front (Section 1105.6). Many have service entrances or loading bays across the back, so the second exit door leads to steps. A ramp installed for accessible exit discharge could: be a prohibitively large structure due to the elevation change; block access to the loading docks; get damaged by the maneuvering trucks; or, be impossible because of space restrictions in a narrow alley.

**Example 2:**

An office building has a second exit that leads to a concrete stoop and the exit discharge is sloped, is uneven or may be blocked by snow. This is just as impassible for a person using a wheelchair as a series of steps. Providing a sidewalk all the way to the front of the building may not be practical because of adjacent buildings or because someone could be travelling adjacent to a burning building.

Sections 1009.7.1 through 1009.7.4 provide criteria for a safe place to wait temporarily for assistance. These address size, separation/protection, openness and any steps leading from the exterior area for assisted rescue.

**1009.7.1 Size.** Each exterior area for assisted rescue shall be sized to accommodate *wheelchair spaces* in accordance with Section 1009.6.3.

❖ The exterior area for assisted rescue must have an enlarged landing area with space for at least one wheelchair for every 200 occupants that will be using that exit. The wheelchair spaces must be located so that they do not obstruct the general means of egress. If these spaces are confined by walls, guards

or edges, they must also meet the alcove provisions in ICC A117.1 so that persons using wheelchairs can maneuver into the space [see Commentary Figure 1009.7.1].

**1009.7.2 Separation.** Exterior walls separating the exterior area of assisted rescue from the interior of the building shall have a minimum *fire-resistance rating* of 1 hour, rated for exposure to fire from the inside. The fire-resistance-rated exterior wall construction shall extend horizontally 10 feet (3048 mm) beyond the landing on either side of the landing or equivalent fire-resistance-rated construction is permitted to extend out perpendicular to the exterior wall 4 feet (1220 mm) minimum on the side of the landing. The *fire-resistance-rated* construction shall extend vertically from the ground to a point 10 feet (3048 mm) above the floor level of the area for assisted rescue or to the roof line, whichever is lower. Openings within such *fire-resistance-rated* exterior walls shall be protected in accordance with Section 716.

❖ The protection provided by an exterior area for assisted rescue would be equivalent to that required for an interior area of refuge. Note that there is no exception for the exterior area of assisted rescue for buildings that contain sprinkler systems. The separation requirements are similar to exterior exit stairways, rated walls and protected openings for 10 feet (3048 mm) above, below and to the sides of the landing (see Sections 1023.7 and 1027.6). The exceptions for exterior exit stairway protection in Section 1027.6 would not be applicable where the area

includes an exterior area for assisted rescue (see Commentary Figure 1009.7.2).

The current separation requirements address typical rear exit situations. Other locations may require alternative protection measures to “shield” an exterior area for assisted rescue. The principle of “wing” walls (as used at a fire wall extension) suggests an alternative to  $\frac{3}{4}$ -hour opening protectives at dock doors adjacent to an exterior area for assisted rescue.

Note that providing a rescue location 10 feet (3048 mm) away from an exterior wall does not serve as a viable alternative to a fire-resistance-rated exterior wall. Persons waiting for assistance must have a minimum level of shielding from a fire in the building.

A common situation is for the path of egress travel from the first floor to move through the bottom level of an enclosed exit stairway. If there are steps outside the exit door of the stairway, there is no accessible path for exit discharge. Where approved by the code official (see Section 104.9), the stairway enclosure could be considered equivalent to a protected exterior wall. It is assumed that the fire is in the building somewhere, not in the stairway. A person with a mobility impairment could be provided with a place to wait either inside the stairway enclosure, or outside the building with the stairway enclosure as the separation between them and the fire – as an alternative to Section 1009.7.2. The exterior wall of an interior exit stairway can be nonfire-resistance rated where permitted by Section 1023.7.

**1009.7.3 Openness.** The exterior area for assisted rescue shall be open to the outside air. The sides other than the separation walls shall be not less than 50 percent open, and the open area shall be distributed so as to minimize the accumulation of smoke or toxic gases.

❖ The openness criteria for exterior areas of assisted rescue are similar to the requirements for exterior balconies. The purpose is to ensure that a person at an exterior area of rescue assistance is not in danger from smoke and fumes. The criteria are to address the situation where the rescue area is open to outside air, but a combination of roof overhangs and perimeter walls or guards could still trap enough smoke that the safety of the occupants would be jeopardized.

**1009.7.4 Stairways.** Stairways that are part of the means of egress for the exterior area for assisted rescue shall provide a clear width of 48 inches (1220 mm) between handrails.

**Exception:** The clear width of 48 inches (1220 mm) between handrails is not required at stairways serving buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

❖ Any steps that lead from an exterior area for assisted rescue to grade must have a clear width of 48 inches (1219 mm) between handrails. The additional width is to permit adequate room to assist a mobility-impaired person down the steps and to a safe location.

If the building is sprinklered, the exception allows for the stairway to utilize the minimum widths required in Section 1011.2. This is consistent with Section 1009.3, Exceptions 2 and 3.

**1009.8 Two-way communication.** A two-way communication system complying with Sections 1009.8.1 and 1009.8.2 shall be provided at the landing serving each elevator or bank

of elevators on each accessible floor that is one or more stories above or below the level of exit discharge.

**Exceptions:**

1. Two-way communication systems are not required at the landing serving each elevator or bank of elevators where the two-way communication system is provided within areas of refuge in accordance with Section 1009.6.5.
2. Two-way communication systems are not required on floors provided with ramps conforming to the provisions of Section 1012.
3. Two-way communication systems are not required at the landings serving only service elevators that are not designated as part of the accessible means of egress or serve as part of the required accessible route into a facility.
4. Two-way communication systems are not required at the landings serving only freight elevators.
5. Two-way communication systems are not required at the landing serving a private residence elevator.

❖ Unless provided in areas of refuge, in multistory buildings a two-way communication system must be located at the elevator landing of each accessible floor level other than the level of exit discharge. The system is intended to offer a means of communication to individuals with mobility impairment, either permanent or temporary, who need assistance during an emergency situation. Such a system can be useful not only in the event of a fire, but also in the case of a natural or technological disaster by providing emergency responders with the location of individuals who will require assistance in being evacuated from floor levels above or below the discharge level. The ability

of emergency responders to locate persons needing assistance quickly is an important part of the fire and safety plan. The two-way communication system is a critical element in that plan.

Exception 1 exempts the requirement for locating the communication systems at the elevator landings where the building is provided with complying areas of refuge. Since areas of refuge are required by Section 1009.6.5 to be equipped with two-way communication systems, there is limited need to provide such additional systems at the elevator landings. However, where multistory buildings are not provided with areas of refuge, such as is the case with most sprinklered buildings, the installation of communications systems at the elevator landings is important to those individuals unable to negotiate egress stairways during an emergency. As a result, both sprinklered and nonsprinklered multistory buildings will be provided with the means for two-way communication at all accessible floor levels other than the level of exit discharge.

Exception 2 applies to floor levels that utilize ramps as vertical accessible means of egress elements. Where complying ramps are available for independent evacuation, such as occurs in a sports stadium, the two-way communication system is not required at the elevator landings.

Because persons at an exterior area of rescue assistance provided at ground level (i.e., level of exit discharge) are immediately visible and such locations are at high risk for vandalism, two-way communication systems are not required for exterior areas of assisted rescue.

If the option of horizontal exits is utilized, the code does not currently address whether a two-way communication system should be provided within a refuge area without an elevator. Since the horizontal exit is not typically recognizable by a person not familiar with the building plan, the most logical location for the two-way communication, if provided, would seem to be adjacent to the exit stairway that was located within the refuge area.

Exceptions 3, 4 and 5 address types of elevators where two way communications are not required. The two-way communication is intended for anyone to be able to communicate with emergency responders. If it is located in the lobby of the public elevator, a system at a back of house service elevator would be redundant and not easy for most occupants to find. A freight elevator cannot be part of an accessible route, so again, this is not the elevator that occupants would typically use. The ASME A17.1 limits the use of private residence elevators to within or serving individual dwelling units. If a person lives in a unit with an elevator, it is not unreasonable to expect them to address communication needs that may arise on their own, such as carrying a portable or cell phone with them.

**1009.8.1 System requirements.** Two-way communication systems shall provide communication between each required

location and the *fire command center* or a central control point location *approved* by the fire department. Where the central control point is not a *constantly attended location*, a two-way communication system shall have a timed automatic telephone dial-out capability to a monitoring location or 9-1-1. The two-way communication system shall include both audible and visible signals.

- ❖ Use of an elevator, stair enclosure or other area of refuge as part of an accessible means of egress requires a person to wait for evacuation assistance or relevant instructions. The two-way communication system allows this person to inform emergency personnel of his or her location and to receive additional instructions or assistance as needed.

The arrangement and design of the two-way communication system is specified in Section 1009.8.1. In addition to the required locations specified in Section 1009.6.5 for areas of refuge or Section 1009.8 for elevator landings, a communication device is also required to be located in a high-rise building's fire command center or at a central control point whose location is approved by the fire department (see IBC Section 403.4.4 and Section 907.2.13.2 of the code). "Central control point" is not a defined term. However, given the intent and function of the two-way communication system, a central control point is a location where an individual answers the call for assistance and either provides or requests aid for a person who needs help. A suitable central control point is often not available in low-rise buildings or in a high-rise building where the central control point may not be manned on a 24-hour basis. In order that a caller may reach an appropriate emergency location, the fire department must approve the configuration of the system. A central control point could be the lobby of a building constantly staffed by a security officer, an alarm company, a public safety answering point such as a 9-1-1 center or a central supervising station in a Group I occupancy. There could be a combination solution—such as a system configured to automatically call 9-1-1 when the central control point within the building is not manned. The communication system provides visual signals for the hearing impaired and audible signals to assist the vision impaired.

**1009.8.2 Directions.** Directions for the use of the two-way communication system, instructions for summoning assistance via the two-way communication system and written identification of the location shall be posted adjacent to the two-way communication system. Signage shall comply with the ICC A117.1 requirements for visual characters.

- ❖ Guidance to the users of a two-way communication system is also specified. Operating instructions for the two-way communication system must be posted and the instructions are to include a means of identifying the physical location of the communication device. If a signal from a two-way communication system terminates to a public safety answering point, such as a fire department communication center, current 9-1-1 telephone technology only reports the

address of the location of the emergency—it does not report a floor or area from the address reporting the emergency. The “identification of the location” posted adjacent to the communication system should ensure that most discrete location information can be provided to the central control point. This will aid emergency responders, especially in high-rise buildings or corporate campuses with multiple multistory structures. The signage is not required to be raised letters or braille, but is required to meet the style, size and contrast requirements for visual signage in A117.1.

**1009.9 Signage.** Signage indicating special accessibility provisions shall be provided as shown:

1. Each door providing access to an *area of refuge* from an adjacent floor area shall be identified by a sign stating: AREA OF REFUGE.
2. Each door providing access to an exterior area for assisted rescue shall be identified by a sign stating: EXTERIOR AREA FOR ASSISTED RESCUE.

Signage shall comply with the *ICC A117.1* requirements for visual characters and include the International Symbol of Accessibility. Where exit sign illumination is required by Section 1013.3, the signs shall be illuminated. Additionally, visual characters, raised character and braille signage complying with ICC A117.1 shall be located at each door to an *area of refuge* and exterior area for assisted rescue in accordance with Section 1013.4.

❖ Signage enables an occupant to become aware of an area of refuge and/or the exterior area for rescue assistance. The assistance areas must provide signage on or above the door stating either “AREA OF REFUGE” or “EXTERIOR AREA FOR ASSISTED RESCUE” and includes the International Symbol of Accessibility. The approach that the code takes for identification of the area of refuge is comparable to the general provisions for identification of exits, including the requirement for lighted signage. Raised letters and braille stating “EXIT” are also required adjacent to the door for the benefit of persons with a visual impairment.

The current text does not clearly indicate how to identify a refuge area formed by a horizontal exit. In hospitals and jails, where this option is typically utilized, the location of the horizontal exits must be part of the staff training for the fire safety and evacuation plans.

**1009.10 Directional signage.** Directional signage indicating the location of all other *means of egress* and which of those are accessible *means of egress* shall be provided at the following:

1. At *exits* serving a required *accessible* space but not providing an approved accessible *means of egress*.
2. At elevator landings.
3. Within *areas of refuge*.

❖ The additional signage required by this section is intended to advise persons of the locations of all means of egress and which of those also serve as

accessible means of egress. Since not all of the exits will necessarily be accessible means of egress, it is appropriate to provide this information at exit stairways and, particularly, at all elevators, regardless of whether they are part of an accessible means of egress. Directional signage is not required to meet raised character or braille signage requirements. Depending on the facility, this could be as simple as a basic block plan of the main corridors and stairways in the building in relation to the elevator.

**1009.11 Instructions.** In *areas of refuge* and exterior areas for assisted rescue, instructions on the use of the area under emergency conditions shall be posted. Signage shall comply with the ICC A117.1 requirements for visual characters. The instructions shall include all of the following:

1. Persons able to use the *exit stairway* do so as soon as possible, unless they are assisting others.
2. Information on planned availability of assistance in the use of *stairs* or supervised operation of elevators and how to summon such assistance.
3. Directions for use of the two-way communication system where provided.

❖ The instructions provided at the exterior area of rescue assistance and the areas of refuge will differ. The required instructions on the proper use of the area of refuge and the communication system provide a greater likelihood that the communication system will accomplish its intended function and occupants will behave as expected. A two-way communication system will not be of much value if a person in that area does not know how to operate it. Also, since the area of refuge is required by Section 1009.9 to be identified as such, ambulatory occupants may mistakenly conclude that they should remain in that area. The instructions remind ambulatory occupants that they should continue to egress as soon as possible.

For an exterior area of assisted rescue at grade level, a two-way communication system is not required so this portion of the instructions is not needed. However, instructions for any ambulatory persons to move to the exit discharge are still required, as well as information on how assistance will be provided at this location.

Since each building’s means of egress and fire and safety evacuation plans are unique, specific requirements for verbiage are not indicated, but will depend on the situation. The signage is not required to be raised letters or braille, but is required to meet the style, size and contrast requirements for visual signage in A117.1.

## SECTION 1010 DOORS, GATES AND TURNSTILES

**1010.1 Doors.** *Means of egress* doors shall meet the requirements of this section. Doors serving a *means of egress* system shall meet the requirements of this section and Section 1022.2. Doors provided for egress purposes in numbers

greater than required by this code shall meet the requirements of this section.

*Means of egress* doors shall be readily distinguishable from the adjacent construction and finishes such that the doors are easily recognizable as doors. Mirrors or similar reflecting materials shall not be used on *means of egress* doors. *Means of egress* doors shall not be concealed by curtains, drapes, decorations or similar materials.

❖ The general requirements for doors are in this section and the following subsections. The reference to Section 1022.2 is intended to emphasize that exterior exit doors must lead to a route that will allow a path to a public street or alley (see definition for “Public way”). A door that is intended to be used for egress purposes, even though that door may not be required by the code, is also required to meet the requirements of this section. An example may be an assembly occupancy where four doors would be required to meet the required capacity of the occupant load. But assume the designer elects to provide six doors for aesthetic reasons or occupant convenience. All six doors must comply with the requirements of this section.

Doors need to be easily recognizable for immediate use in an emergency condition. Thus, the code specifies that doors are not to be hidden in such a manner that a person would have trouble seeing where to egress.

**1010.1.1 Size of doors.** The required capacity of each door opening shall be sufficient for the *occupant load* thereof and shall provide a minimum clear width of 32 inches (813 mm). Clear openings of doorways with swinging doors shall be measured between the face of the door and the stop, with the door open 90 degrees (1.57 rad). Where this section requires a minimum clear width of 32 inches (813 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 32 inches (813 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. *Means of egress* doors in a Group I-2 occupancy used for the movement of beds shall provide a clear width not less than 41½ inches (1054 mm). The height of door openings shall be not less than 80 inches (2032 mm).

**Exceptions:**

1. The minimum and maximum width shall not apply to door openings that are not part of the required *means of egress* in Group R-2 and R-3 occupancies.
2. Door openings to resident *sleeping units* in Group I-3 occupancies shall have a clear width of not less than 28 inches (711 mm).
3. Door openings to storage closets less than 10 square feet (0.93 m<sup>2</sup>) in area shall not be limited by the minimum width.
4. Width of door leaves in revolving doors that comply with Section 1010.1.4.1 shall not be limited.

5. Door openings within a *dwelling unit* or *sleeping unit* shall be not less than 78 inches (1981 mm) in height.
6. Exterior door openings in *dwelling units* and *sleeping units*, other than the required *exit* door, shall be not less than 76 inches (1930 mm) in height.
7. In other than Group R-1 occupancies, the minimum widths shall not apply to interior egress doors within a *dwelling unit* or *sleeping unit* that is not required to be an *Accessible unit*, *Type A unit* or *Type B unit*.
8. Door openings required to be *accessible* within *Type B units* shall have a minimum clear width of 31.75 inches (806 mm).
9. Doors to walk-in freezers and coolers less than 1,000 square feet (93 m<sup>2</sup>) in area shall have a maximum width of 60 inches (1524 mm).
10. In Group R-1 *dwelling units* or *sleeping units* not required to be *Accessible units*, the minimum width shall not apply to doors for showers or saunas.

❖ The size of a door opening determines its capacity as a component of egress and its ability to fulfill its function in normal use. A door opening must meet certain minimum criteria as to its width and height in order to be used safely and to provide accessibility to people with physical disabilities. Doorways that are not in the means of egress are not limited in size by this section. However, doors that are used for egress purposes, including additional doors over and above the number of means of egress required by the code, are required to meet the requirements of this section unless one of the exceptions applies.

The minimum clear width of an egress doorway for occupant capacity is based on the portion of the occupant load (see Section 1004.1) intended to utilize the doorway for egress purposes, multiplied by the egress width per occupant from Section 1005.1. The capacity of a 32-inch (813 mm) clear width door is  $32/0.2 = 160$  occupants. The 0.15-inch (3.81 mm) allowance for capacity is permitted in sprinklered buildings ( $32/0.15 = 213$  occupants). The clear width of a swinging door opening is the horizontal dimension measured between the face of the door and the door stops when the door is in the 90-degree (1.57 rad) position [see Commentary Figure 1010.1.1(1)].

Using the face of the door as the measurement point is consistent with the provisions of ICC A117.1 and the ADAAG Review Advisory Committee. Further, this measurement is not intended to prohibit other projections into the required clear width, such as latching or panic hardware [see the commentary to Section 1010.1.1.1 and Commentary Figure 1010.1.1(2) for further discussion on the specific projections allowed in the required clear width]. For non-swinging means of egress doors, such as a sliding

## MEANS OF EGRESS

door, the clear width is to be measured from the face of the door jambs.

The minimum clear width in a doorway of 32 inches (813 mm) is to allow passage of a wheelchair as well as persons utilizing walking devices or other support apparatus. Similarly, because of the difficulties that a person with physical disabilities would have in opening a pair of doors simultaneously, the 32-inch (813 mm) minimum must be provided by a single door leaf.

Note that in some cases, with standard door construction and hardware, a 36-inch-wide (914 mm) door is the narrowest door that can be used while still providing the minimum clear width of 32 inches (813 mm). A standard 34-inch-wide (864 mm) door has

less than a 32-inch (813 mm) clear opening depending on the thickness of the opposing doorstop, the door thickness and the type of hinge. The building designer must verify that the swinging door specified will in fact provide the required clear width.

A minimum clear width of 41<sup>1</sup>/<sub>2</sub> inches (1054 mm) is required for doors in any portion of Group I-2 where patients may need to be moved in beds. This is especially important for evacuating patients from the area in the event of a fire.

The maximum width for a means of egress door leaf in a swinging door is 48 inches (1219 mm) because larger doors are difficult to handle and are of sizes that typically are not fire tested. The maximum

For SI: 1 inch = 25.4 mm.

**Figure 1010.1.1(1)**  
**TYPICAL DOOR OPENING CLEARANCE**

For SI: 1 inch = 25.4 mm.

**Figure 1010.1.1(2)**  
**TYPICAL DOOR OPENING CLEARANCE WITH PANIC HARDWARE**

width only applies to swinging doors and not to horizontal sliding doors.

Minimum door heights are required to provide clear headroom for the users. A minimum height of 80 inches (2032 mm) has been empirically derived as sufficient for most users. Note that although the clear height of a doorway is not specified, typical door frame dimensions will render an opening very close to 80 inches (2032 mm) in clear height. The exception in Sections 1003.3.1 and 1010.1.1.1 allows for door closers and doorstops to be as low as 78 inches (1981 mm).

Exception 1 is very limited in scope and is primarily intended to permit decorative-type doors, e.g., café doors, in dwelling units. This exception addresses spaces that are provided with two or more doors when only one means of egress is required. These nonrequired doors are exempted from the minimum and maximum dimensions.

Exception 2 permits the continued use of doors to resident sleeping rooms (cells) in jails (Group I-3) to be a minimum of 28 inches (711 mm), according to current practices.

Exception 3 is for all occupancies. This exception permits doors to storage closets less than 10 square feet (0.9 m<sup>2</sup>) in area to be less than 32 inches (813 mm). This provision is intended to include those closets that can be reached in an arm's length and thus do not require full passage into the closet to be functional.

Exception 4 permits the door leaves in a revolving door assembly to comply with Section 1010.1.4.1, which provides for adequate egress width when the revolving door is collapsed into a breakout position.

Exception 5 permits the doorway within a dwelling or sleeping unit to be a minimum of 78 inches (1981 mm) in clear height. This is deemed acceptable because of the familiarity persons in a dwelling or sleeping unit usually have with the egress system and the lack of adverse injury statistics relating to such doors. Note that this exception does not apply to exterior doors of a townhouse or the main entrance doors leading to the hallway in hotels or apartment buildings. However, exterior doors could use the limited exception for doorstops and closers in Sections 1003.3.1 and 1010.1.1.1.

Exception 6 permits exterior doorways to a dwelling or sleeping unit, except for the required exit door, to be a minimum of 76 inches (1930 mm) in clear height. Accordingly, the required exterior exit door to a dwelling or sleeping unit must be 80 inches (2032 mm) in height (exterior doors are not within the scope of Exception 5), but other exterior doors are allowed to be a height of only 76 inches (1930 mm). This provision allows for the continued use of 76-inch-high (1930 mm) sliding patio doors and swinging doors sized to replace such doors.

Exception 7 allows interior means of egress doors within dwelling or sleeping units to have a clear width less than 32 inches (813 mm). If the dwelling or

sleeping unit is required to be an Accessible, Type A or Type B unit, this exception is not applicable. ICC A117.1 requires door openings within Accessible and Type A units to be 32 inches (813 mm) clear and doors within Type B units to be 31<sup>3</sup>/<sub>4</sub> inches (806 mm) clear. This exception is not applicable to Group R-1. The requirement for all doorways within a Group R-1 unit to be sized to provide access to persons with physical disabilities is applicable to both entrance doors to the units and all doors to rooms in the unit (e.g., bathroom doors). Because of the social interaction and visitation that often occur in lodging facilities, a door opening sized for accessibility (e.g., wheelchairs, walkers, canes, crutches) is deemed necessary to allow people with disabilities to visit a friend's, colleague's or relative's unit. In addition, wider doors provide an additional benefit to all persons handling luggage and bulky items, or for the situation when an Accessible unit is not available. This requirement for Group R-1 occupancies is consistent with the 2010 ADA Standard.

Exception 10 has put in an allowance for sauna and steam room doors in hotels rooms that are not Accessible units. The doors to the bathroom would still have to provide a 32-inch clear width.

Exception 8 addresses the clear width of doors within a Type B dwelling or sleeping unit. The 31<sup>3</sup>/<sub>4</sub>-inch (806 mm) dimension effectively allows for 2-foot, 10-inch (864 mm) doors to be used inside the unit. Again, note that the exterior door to the garden-style apartments or the main door to the hallway from units in an apartment building are not covered by this exception. ICC A117.1 requires the exterior doors of Type B dwelling units to provide a 32-inch (813 mm) clear width. This is consistent with the correlative text in ICC A117.1 for Type B units. Refer to Chapter 11 for additional information related to Type B dwelling and sleeping units.

Exception 9 allows for doors on walk-in freezers and coolers that would allow for the use of small carts to move supplies in and out. Such doors would still have to meet the force requirements in Section 1010.1.3.

**1010.1.1.1 Projections into clear width.** There shall not be projections into the required clear width lower than 34 inches (864 mm) above the floor or ground. Projections into the clear opening width between 34 inches (864 mm) and 80 inches (2032 mm) above the floor or ground shall not exceed 4 inches (102 mm).

**Exception:** Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the floor.

✦ This section of the code provides specific allowances for projection into the required clear widths of means of egress doors. These allowances directly correspond with the method of measuring the required clear width of the door as specified in Section 1010.1.1. A reasonable range of projections for door hardware and trim has been established by these requirements. The use of the means of egress door by a wheelchair occupant will not be significantly

impacted by small projections located in inconspicuous areas. The key to these allowances is their location. Projections are allowed at a height between 34 inches (864 mm) and 80 inches (2032 mm). Below the 34-inch (864 mm) height, the code does not permit any projections since they would decrease the available width for wheelchair operation. The full 32-inch (813 mm) width must be provided at this location. At 34 inches (864 mm) and higher, projections of up to and including 4 inches (102 mm) are permitted. The 4-inch (102 mm) projection is consistent with the allowances of Section 1003.3.3. This section permits door hardware, such as panic hardware, to extend into the clear width, yet maintain accessibility for persons with physical disabilities [see Commentary Figure 1010.1.1(2)].

Allowance must be made for door closers and stops, since their design and function necessitates placement within the door opening. The minimum headroom clearance for door closers and stops is allowed to be 78 inches (1981 mm) [see Commentary Figure 1003.3.1(1)]. The 2-inch (51 mm) projection into the doorway height is reasonable since these devices are normally mounted away from the center of the door opening, thus minimizing the potential for contact with a person moving through the opening. This is consistent with the exception in Section 1003.3.1. Other items that are mounted at the top of the door opening, such as an electromagnetic lock on a pair of doors, would still require an 80-inch (2032 mm) minimum headroom.

While this section deals with door hardware projection within the clear door opening width, door hardware projection into the required width of corridors, aisles, exit passageways and exit discharge is addressed in Section 1005.7.1.

**1010.1.2 Door swing.** Egress doors shall be of the pivoted or side-hinged swinging type.

**Exceptions:**

1. Private garages, office areas, factory and storage areas with an *occupant load* of 10 or less.
2. Group I-3 occupancies used as a place of detention.
3. Critical or intensive care patient rooms within suites of health care facilities.
4. Doors within or serving a single *dwelling unit* in Groups R-2 and R-3.
5. In other than Group H occupancies, revolving doors complying with Section 1010.1.4.1.
6. In other than Group H occupancies, special purpose horizontal sliding, accordion or folding door assemblies complying with Section 1010.1.4.3.
7. Power-operated doors in accordance with Section 1010.1.4.2.
8. Doors serving a bathroom within an individual *sleeping unit* in Group R-1.

9. In other than Group H occupancies, manually operated horizontal sliding doors are permitted in a *means of egress* from spaces with an *occupant load* of 10 or less.

❖ Generally, egress doors are required to be the side-swinging type. The swinging hardware can be either a hinge or a pivot type (see the definition for “Balanced door”). Side-swinging doors are familiar to all occupants in the method of operation. Door designs with pivots are permitted by this section since the door action itself has little difference between the side-hinged-type door.

The code has several conditions where it allows doors that are not side-hinged-swinging types.

Examples of the doors permitted in Exception 1 are overhead garage doors and horizontal sliding doors. Exception 1 allows doors other than the swinging type for the listed uses where the number of occupants is very low.

Exception 2 allows for the sliding-type doors that are commonly used in prisons and jails.

Exception 3 allows for sliding doors between nursing areas and patient rooms in critical care and intensive care suites. Patients are not typically moving around on their own in these areas, visitors are extremely limited, the glass doors allow a better view for nurse supervision and the sliding option allows for equipment locations unaffected by door swing. See also IBC Section 407 and Sections 1010.1.9.6 and 1010.1.9.8 of the code for these types of areas.

Exception 4 allows for sliding-type doors or pocket-type doors within or serving individual units in a non-transient residential occupancy. Residents are typically familiar with the door operation. The use of sliding doors on the interior of dwelling units is permitted by the Fair Housing Accessibility Guidelines (FHAG) and by ICC A117.1 for Accessible, Type A and Type B units.

Exception 5 allows for revolving doors that meet the requirements of Section 1010.1.4.1. Revolving doors are not permitted for egress from high-hazard spaces.

Exception 6 allows for special-purpose horizontal sliding, accordion or folding doors that meet the requirements of Section 1010.1.4.3 to be used in the means of egress. The doors addressed by Section 1010.1.4.3 are commonly in the normally-open position (hidden in their enclosure). In the event of fire or smoke, where these doors are installed in the means of egress, Section 1010.1.4.3 requires the doors to be power operated but also openable manually to the required minimum egress width. This exception is intended to allow wide span openings to be used in a means of egress.

Exception 7 allows for power-operated doors that meet the requirements of Section 1010.1.4.2. This is to enhance the movement of the general population as well as people with mobility impairments to areas

of safety without obstructions, since the specified doors afford simple operation by persons for both typical and emergency operation.

Exception 8 allows for pocket doors between the bathrooms and living or sleeping space within hotel rooms. Since the bathroom is most commonly placed immediately inside the entrance to the room, a side-swinging door could be an obstruction for a person entering carrying suitcases. Familiarity with these types of doors and minimal occupant loads makes this situation acceptable.

Exception 9 partially overlaps the allowances in Exception 1 for horizontal sliding doors by matching the 10 or less occupant load, but extends the use to all other groups except for high hazard. For example, some emergency rooms or clinics use glazed horizontal sliding doors to divide patient care rooms providing for increased privacy and infection control while still allowing visual supervision. Another example would be that a pocket door may be used for access to a bathroom within a private office. The allowance for such a manually operated horizontal sliding door provides greater design flexibility and efficiency, while at the same time maintaining an acceptable level of safety.

**1010.1.2.1 Direction of swing.** Pivot or side-hinged swinging doors shall swing in the direction of egress travel where serving a room or area containing an occupant load of 50 or more persons or a Group H occupancy.

❖ A side-hinged door must swing in the direction of egress travel where the required occupant capacity of the room is 50 or more. As such, a room with two doors and an occupant load of 99 would require both doors to swing in the direction of egress travel, even though each door has a calculated occupant usage of less than 50. At this level of occupant load, the possibility exists that, in an emergency situation, a compact line of people could form at a closed door that swings in a direction opposite the egress flow. This could delay or eliminate the first person's ability to open the door inward with the rest of the queue behind the person.

In a Group H occupancy, the threat of rapid fire buildup, or worse, is such that any delay in egress caused by door swing may jeopardize the opportunity for all occupants to evacuate the premises. For this reason, all egress doors in Group H occupancies are to swing in the direction of egress.

**1010.1.3 Door opening force.** The force for pushing or pulling open interior swinging egress doors, other than fire doors, shall not exceed 5 pounds (22 N). These forces do not apply to the force required to retract latch bolts or disengage other devices that hold the door in a closed position. For other swinging doors, as well as sliding and folding doors, the door latch shall release when subjected to a 15-pound (67 N) force.

The door shall be set in motion when subjected to a 30-pound (133 N) force. The door shall swing to a full-open position when subjected to a 15-pound (67 N) force.

❖ The ability of all potential users to be physically capable of opening an egress door is a function of the forces required to open the door. The 5-pound (22 N) maximum force for pushing and pulling interior swinging doors without closers that are part of the means of egress inside a building is based on that which has been deemed appropriate for people with a physical limitation due to size, age or disability. The operating force is permitted to be higher for all exterior doors, interior swinging doors that are not part of the means of egress, doors that are part of the means of egress but also serve as opening protectives in fire-resistance-rated walls (i.e., fire doors), sliding doors and folding doors. This recognizes that doors with closers, particularly fire doors, require greater operating forces in order to close fully in an emergency where combustion gases may be exerting pressure on the door assembly. Similarly, exterior doors are exempted because air pressure differentials and strong winds may prevent doors from being fully automatically closed.

The opening force is different than the force to retract bolts or operate other types of door hardware. A maximum force of 15 pounds (67 N) is required for operating the latching mechanism. Once unlatched, a maximum force of 30 pounds (133 N) is applied to the latch side of the leaf to start the door in motion by overcoming its stationary inertia. Once in motion, it must not take more than 15 pounds (67 N) of force to keep the door in motion until it reaches its full open position and the required clear width is available. To conform to this requirement on a continual basis, door closers must be adjusted periodically and door fits must also be checked and adjusted when necessary.

**1010.1.3.1 Location of applied forces.** Forces shall be applied to the latch side of the door.

❖ See the commentary for door opening forces in Section 1010.1.3.

**1010.1.4 Special doors.** Special doors and security grilles shall comply with the requirements of Sections 1010.1.4.1 through 1010.1.4.4.

❖ This section simply defines the scope of the code requirements for special doors such as revolving doors, power-operated swinging doors, power-operated horizontal sliding doors and security grilles

**1010.1.4.1 Revolving doors.** Revolving doors shall comply with the following:

1. Revolving doors shall comply with BHMA A156.27 and shall be installed in accordance with the manufacturer's instructions.

## MEANS OF EGRESS

- Each revolving door shall be capable of *breakout* in accordance with BHMA A156.27 and shall provide an aggregate width of not less than 36 inches (914 mm).
- A revolving door shall not be located within 10 feet (3048 mm) of the foot or top of *stairways* or escalators. A dispersal area shall be provided between the *stairways* or escalators and the revolving doors.
- The revolutions per minute (rpm) for a revolving door shall not exceed the maximum rpm as specified in BHMA A156.27. Manual revolving doors shall comply with Table 1010.1.4.1(1). Automatic or power-operated revolving doors shall comply with Table 1010.1.4.1(2).
- An emergency stop switch shall be provided near each entry point of power or automatic operated revolving doors within 48 inches (1220 mm) of the door and between 24 inches (610 mm) and 48 inches (1220 mm) above the floor. The activation area of the emergency stop switch button shall be not less than 1 inch (25 mm) in diameter and shall be red.
- Each revolving door shall have a side-hinged swinging door that complies with Section 1010.1 in the same wall and within 10 feet (3048 mm) of the revolving door.
- Revolving doors shall not be part of an *accessible route* required by Section 1009 and Chapter 11.

❖ Revolving doors must comply with all seven provisions.

Item 1: BHMA A156.27 is the revolving door industry standard and includes numerous safety-related requirements for revolving doors. For example, BHMA A156.27 requires manually operated revolving doors to contain governors to limit the rotational speed of the door. For automatic, or power-operated, revolving doors, BHMA A156.27 includes requirements for numerous sensors and switches, and complex motor controls to safely operate the door.

Item 2: One of the causes contributing to the loss of lives in the 1942 Coconut Grove fire in Boston was that the revolving doors at the club's entrance could not collapse (*breakout*) for emergency egress and there was not an alternative means of egress adjacent to the revolving doors. Thus, in the panic of the fire, the door became jammed and the club's occupants were trapped.

As a result of this fire experience, all revolving doors, including those for air structures, now are required to be equipped with a breakout feature. A breakout operation is where all leaves collapse parallel to each other and to the direction of egress [see Commentary Figure 1010.1.4.1(1)]. A breakout operation creates two openings of approximately equal width. The sum of the widths is not to be less than 36 inches (914 mm) so that a stream of pedestrians may use each side of the opening. BHMA A156.27 includes explicit breakout requirements for the wide range of sizes and configurations of manual and automatic revolving doors.

Item 3: If a stairway or escalator delivers users to a

landing in front of a revolving door at a greater rate than the capacity of the door, a compact line of people will develop. Lines of people formed on a stairway or escalator create an unsafe situation, since stairways and escalators are not intended to be used as standing space for persons who may be waiting to use the revolving doors. Therefore, to avoid congestion at a revolving door that under normal operation has a maximum delivery capacity of users, a dispersal area is required between the stairways or escalators and the revolving doors to allow for the queuing of people as they enter the door. Accordingly, to create a dispersal area for users of a revolving door, the door is not to be placed closer than 10 feet (3048 mm) from the foot or top of a stairway or escalator.

Item 4: Door speeds also directly relate to the capacity of a revolving door, which is calculated by multiplying the number of leaves (wings) by the revolutions per minute (rpm). For example, if you have a four-leaf door (four-bay door) moving at 10 rpm, the door will allow 40 people to move in either direction in 1 minute. The larger revolving doors are designed to allow more than one person in each bay, and this should be taken into account when calculating the capacity of a revolving door.

Item 5: An emergency stop switch near each entry point of automatic or power-operated revolving doors provides a method to stop the door's operation.

Item 6: In case a revolving door malfunctions or becomes obstructed, the adjacent area is to be equipped with a conventional side-hinged door to provide users with an immediate alternative way to exit a building. The side-hinged door is intended to be

used as a relief device for people lined up to use the revolving door or who desire to avoid it because of a physical disability or other reason. It also can be used when the revolving door is obstructed or out of service. The swinging door is to be immediately adjacent to the revolving door so that its availability is obvious [see Commentary Figure 1010.1.4.1(2)]. A single swinging door can be located between side-by-side revolving doors in order to comply with this provision.

Item 7: While some revolving doors may be considered part of a means of egress, they cannot be considered part of a required accessible route for either ingress or egress. This requirement is consistent with ICC A117.1, which also prohibits revolving gates and turnstiles along the only accessible route. The side-swinging door required by Item 6 can serve as the accessible entrance or exit required by Section 1009 and IBC Section 1105.

A route through a hinged or sliding door differs remarkably from that provided through a revolving door. For a revolving door, the route includes a turn into the doorway, an arcing path of travel as the door revolves, followed by a change of direction when leaving the door. Items that may cause difficulty for anyone with mobility impairments could involve the overall doorway diameter, the number of leaves and their relative angle, and the configuration of the return walls surrounding the revolving door. Additionally, the speed of the door movement if motorized, or the force required for movement if not motorized, would be a concern for anyone who needed to keep both hands on their device to move forward (e.g., walker or wheelchair).

Automatic revolving doors, if large enough, may be usable by many people who use wheelchairs. However, the intent of this section is that these types of doors not be the only means of passage at an entrance or exit. An alternative door in full compliance with this section is considered necessary because some people with disabilities may be uncertain of the usability, or may not have enough strength or speed to use them. Although manufacturers have developed safety criteria, certain questions remain, such as the appropriate maximum and minimum speeds that would work for persons trying to maneuver a wheelchair through a revolving door.

Revolving doors range from (smaller) manually operated revolving door systems to automatic (power operated) revolving doors of small (8-foot) to large (24-foot) diameter. Three configurations of revolving doors are illustrated in Commentary Figures 1010.1.4(3) through 1010.1.4(5).

**TABLE 1010.1.4.1(1)  
MAXIMUM DOOR SPEED MANUAL REVOLVING DOORS**

REVOLVING DOOR MAXIMUM NOMINAL DIAMETER (FT-IN)	MAXIMUM ALLOWABLE REVOLVING DOOR SPEED (RPM)
6-0	12
7-0	11
8-0	10
9-0	9
10-0	8

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

❖ See the commentary for Section 1010.1.4 and Table 1010.1.4.1(2).

MEANS OF EGRESS

**TABLE 1010.1.4.1(2)  
MAXIMUM DOOR SPEED AUTOMATIC OR  
POWER-OPERATED REVOLVING DOORS**

REVOLVING DOOR MAXIMUM NOMINAL DIAMETER (FT-IN)	MAXIMUM ALLOWABLE REVOLVING DOOR SPEED (RPM)
8-0	7.2
9-0	6.4
10-0	5.7
11-0	5.2
12-0	4.8
12-6	4.6
14-0	4.1
16-0	3.6
17-0	3.4
18-0	3.2
20-0	2.9
24-0	2.4

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

❖ Door speeds also directly relate to the capacity of a revolving door, which is calculated for smaller revolving doors by multiplying the number of leaves (wings) by the revolutions per minute (rpm). For example, if you have an 8-foot diameter four-leaf door (four-bay door) moving at 10 rpm, the door will allow 40 people to move in either direction in 1 minute. Larger revolving doors may be designed to allow for more than one person in each bay as the door rotates, which should be taken into account when determining maximum egress capacity of the revolving door.

**1010.1.4.1.1 Egress component.** A revolving door used as a component of a *means of egress* shall comply with Section 1010.1.4.1 and the following three conditions:

1. Revolving doors shall not be given credit for more than 50 percent of the minimum width or required capacity.
2. Each revolving door shall be credited with a capacity based on not more than a 50-person *occupant load*.

**Figure 1010.1.4.1(4)  
EXAMPLE OF AUTOMATIC REVOLVING DOOR  
(8-FOOT DIAMETER)**

**Figure 1010.1.4.1(3)  
EXAMPLE OF MANUAL REVOLVING DOOR  
(7-FOOT DIAMETER)**

**Figure 1010.1.4.1(5)  
EXAMPLE OF AUTOMATIC REVOLVING DOOR  
(20-FOOT DIAMETER)**

3. Each revolving door shall provide for egress in accordance with BHMA A156.27 with a *breakout* force of not more than 130 pounds (578 N).

❖ A revolving door can be incorporated, to a very limited extent, in a means of egress. Compliance with these three additional conditions is required.

Condition 1 limits the exit capacity that revolving doors can provide in a building. This is so that 50 percent of the capacity has conventional egress components and is not dependent on mechanical devices or fail-safe mechanisms.

Condition 2 limits the capacity of any one revolving door for the same reasons as stated in Condition 1. Each revolving door is therefore limited to a 50-person capacity.

Condition 3 limits the breakout force to 130 pounds (578 N), as opposed to the 180-pound (792 N) value listed in Section 1010.1.4.1.2. Revolving doors used as means of egress are not permitted to have the breakout force exceed 130 pounds (578 N) under any circumstances.

**1010.1.4.1.2 Other than egress component.** A revolving door used as other than a component of a *means of egress* shall comply with Section 1010.1.4.1. The *breakout* force of a revolving door not used as a component of a *means of egress* shall not be more than 180 pounds (801 N).

**Exception:** A *breakout* force in excess of 180 pounds (801 N) is permitted if the collapsing force is reduced to not more than 130 pounds (578 N) when not less than one of the following conditions is satisfied:

1. There is a power failure or power is removed to the device holding the door wings in position.
2. There is an actuation of the *automatic sprinkler system* where such system is provided.
3. There is an actuation of a smoke detection system that is installed in accordance with Section 907 to provide coverage in areas within the building that are within 75 feet (22 860 mm) of the revolving doors.
4. There is an actuation of a manual control switch, in an approved location and clearly identified, that reduces the *breakout* force to not more than 130 pounds (578 N).

❖ This section addresses revolving doors that are not used to serve any portion of the occupant egress capacity. For example, where adjacent side-hinged doors have more than the required egress capacity, the revolving door would not be part of the required means of egress.

The maximum breakout force of 180 pounds (792 N), applied within 3 inches (76 mm) of the outer edge of a wing, is based on industry standards to accommodate normal use conditions and other forces that may act on the leaves, such as those caused by wind or air pressure. An exception for revolving doors that are not a component of a required means of egress allows the breakout force to exceed 180 pounds (792

N) in normal operating conditions provided that a force of not more than 130 pounds (578 N) is required whenever any one of the listed conditions is satisfied.

**1010.1.4.2 Power-operated doors.** Where *means of egress* doors are operated or assisted by power, the design shall be such that in the event of power failure, the door is capable of being opened manually to permit *means of egress* travel or closed where necessary to safeguard *means of egress*. The forces required to open these doors manually shall not exceed those specified in Section 1010.1.3, except that the force to set the door in motion shall not exceed 50 pounds (220 N). The door shall be capable of swinging open from any position to the full width of the opening in which such door is installed when a force is applied to the door on the side from which egress is made. Power-operated swinging doors, power-operated sliding doors and power-operated folding doors shall comply with BHMA A156.10. Power-assisted swinging doors and low-energy power-operated swinging doors shall comply with BHMA A156.19.

**Exceptions:**

1. Occupancies in Group I-3.
2. Horizontal sliding doors complying with Section 1010.1.4.3.
3. For a biparting door in the emergency breakout mode, a door leaf located within a multiple-leaf opening shall be exempt from the minimum 32-inch (813 mm) single-leaf requirement of Section 1010.1.1, provided a minimum 32-inch (813 mm) clear opening is provided when the two biparting leaves meeting in the center are broken out.

❖ For convenience purposes, power-operated doors are intended to facilitate the normal nonemergency flow of persons through a doorway. Where a power-operated or power-assisted door is also required to be an egress door, the door must conform to the requirements of this section. The essential characteristic is that the door is to be manually openable from any position to its full open position at any time, with or without a power failure or a failure of a door mechanism. Hence, both swinging and horizontal sliding doors, complying with this section, may be used, provided the door can be operated manually from any position as a swinging door and that the minimum required clear width for egress capacity is not less than 32 inches (813 mm). Note that the opening forces of Section 1010.1.3 are applicable, except that the 30-pound (133 N) force needed to set the door in motion is increased to 50 pounds (220 N) as an operational tolerance in the design of the power-operated door.

Definitions for the different types of power-operated doors were added to the 2015 IBC to help clarify which standard (BHMA A156.10 or BHMA A156.19) is applicable to which type of power-operated door.

*Power-operated doors* are required to comply with BHMA A156.10. These doors open automatically when approached by a person or upon an action by a person, close automatically and include provisions

such as presence sensors to prevent entrapment. *Low-energy power-operated doors* are required to comply with BHMA A56.19. These doors are always swinging doors which open automatically upon an action by a person such as pressing a push plate or waving a hand in front of a sensor. Additionally, these doors close automatically and operate with decreased forces and decreased speeds (compared to *power-operated doors*). Least common are *power-assisted doors*, which are required to comply with BHMA A156.19. These doors are swinging doors which open by reduced pushing or pulling force on the door-operating hardware, close automatically after the pushing or pulling force is released and function with decreased forces.

In accordance with Exception 1, power-operated doors in detention and correctional occupancies (Group I-3) are not required to be manually operable by the occupants (inmates) for security reasons, but otherwise are required to conform to IBC Section 408.

Exception 2 states that power-operated, special-purpose horizontal sliding accordion or folding doors that meet the requirements of Section 1010.1.4.3 are not required to meet the requirements of Section 1010.1.4.2. This is consistent with the option offered in Section 1010.1.2 by Exception 6.

Exception 3 allows an individual leaf of a four-panel biparting door to be less than 32 inches (813 mm) wide, provided 32 inches (813 mm) of clear space is available when the two center biparting leaves are broken out as part of the emergency breakaway feature.

**1010.1.4.3 Special purpose horizontal sliding, accordion or folding doors.** In other than Group H occupancies, special purpose horizontal sliding, accordion or folding door assemblies permitted to be a component of a *means of egress* in accordance with Exception 6 to Section 1010.1.2 shall comply with all of the following criteria:

1. The doors shall be power operated and shall be capable of being operated manually in the event of power failure.
  2. The doors shall be openable by a simple method from both sides without special knowledge or effort.
  3. The force required to operate the door shall not exceed 30 pounds (133 N) to set the door in motion and 15 pounds (67 N) to close the door or open it to the minimum required width.
  4. The door shall be openable with a force not to exceed 15 pounds (67 N) when a force of 250 pounds (1100 N) is applied perpendicular to the door adjacent to the operating device.
  5. The door assembly shall comply with the applicable *fire protection rating* and, where rated, shall be self-closing or automatic closing by smoke detection in accordance with Section 716.5.9.3, shall be installed in accordance with NFPA 80 and shall comply with Section 716.
  6. The door assembly shall have an integrated standby power supply.
  7. The door assembly power supply shall be electrically supervised.
  8. The door shall open to the minimum required width within 10 seconds after activation of the operating device.
- ❖ Special purpose horizontal sliding, accordion or folding doors are permitted in the means of egress, in other than rooms or areas of Group H, under the conditions set forth in this section. Special purpose horizontal sliding, accordion or folding doors are not permitted to be used in Group H occupancies because of the potential for delaying or impeding egress from those areas and the additional risk to occupants in hazardous occupancies. Note that this section regulates doors that are part of the means of egress to meet a set of requirements different than Section 1010.1.4.2 (e.g., a power-operated horizontal sliding door that does not have “breakout” capabilities to allow the door panels to swing if power is lost). The doors addressed by Section 1010.1.4.3 are commonly in the normally open position (hidden in their enclosure).
- All eight of the criteria listed in this section must be met for a special purpose horizontal sliding, accordion or folding door since there is a concern that it must be able to be easily opened to the minimum required width under all conditions.
- Additionally, the door must be openable even if a force of 250 pounds (1100 N) is being applied perpendicular to it, as may occur if a group of people were pushing on it.
- Since the doors are manually operable, they need not automatically open or close during a loss of power; however, a standby power supply must be provided. The primary power supply must be supervised so that an alarm is received at a constantly attended location (such as a security desk) on loss of the primary power. If the doors are also serving as opening protective (i.e., fire doors), they must be automatic closing or self-closing in accordance with IBC Section 716.
- Since the maximum swinging door leaf width limitations of Section 1008.1.1 do not apply, a maximum opening time of 10 seconds is permitted. It should be noted, however, that the door need not open fully within the 10 seconds; rather, it must open to the minimum required width. For example, if the door is protecting an opening that is 10 feet (3048 mm) wide, but the minimum required width of the opening is 32 inches (813 mm) (as determined by Section 1008.1.1), the door need only open 32 inches (813 mm) within the 10-second criterion. In fact, the door may have controls such that the automatic opening feature only opens the door to a width of 32 inches (813 mm). If additional width is required, it can be accomplished by manual means and, possibly, by an additional activation of the operating device.

**1010.1.4.4 Security grilles.** In Groups B, F, M and S, horizontal sliding or vertical security grilles are permitted at the main *exit* and shall be openable from the inside without the use of a key or special knowledge or effort during periods that the space is occupied. The grilles shall remain secured in the full-open position during the period of occupancy by the general public. Where two or more *means of egress* are required, not more than one-half of the *exits* or *exit access doorways* shall be equipped with horizontal sliding or vertical security grilles.

❖ This section really functions as an exception to several sections, including Sections 1010.1.2 (Door swing) and 1010.1.9.3 (Locks and latches), and permits the use of these security grilles under conditions that are similar to those found in IBC Section 402 for covered mall buildings. These security grilles will be open when the space is occupied and will, therefore, not obstruct any egress path. Since the building may be partially used (e.g., team practice in a football stadium) when not fully occupied, no more than one-half of the exits from the building can be through security grilles.

**1010.1.5 Floor elevation.** There shall be a floor or landing on each side of a door. Such floor or landing shall be at the same elevation on each side of the door. Landings shall be level except for exterior landings, which are permitted to have a slope not to exceed 0.25 unit vertical in 12 units horizontal (2-percent slope).

**Exceptions:**

1. Doors serving individual *dwelling units* in Groups R-2 and R-3 where the following apply:
  - 1.1. A door is permitted to open at the top step of an interior *flight of stairs*, provided the door does not swing over the top step.
  - 1.2. Screen doors and storm doors are permitted to swing over *stairs* or landings.

2. Exterior doors as provided for in Section 1003.5, Exception 1, and Section 1022.2, which are not on an *accessible route*.
3. In Group R-3 occupancies not required to be *Accessible units, Type A units* or *Type B units*, the landing at an exterior doorway shall be not more than 7<sup>3</sup>/<sub>4</sub> inches (197 mm) below the top of the threshold, provided the door, other than an exterior storm or screen door, does not swing over the landing.
4. Variations in elevation due to differences in finish materials, but not more than 1/2 inch (12.7 mm).
5. Exterior decks, patios or balconies that are part of *Type B dwelling units*, have impervious surfaces and that are not more than 4 inches (102 mm) below the finished floor level of the adjacent interior space of the dwelling unit.
6. Doors serving equipment spaces not required to be *accessible* in accordance with Section 1103.2.9 and serving an occupant load of five or less shall be permitted to have a landing on one side to be not more than 7 inches (178 mm) above or below the landing on the egress side of the door.

❖ Changes in floor surface elevation at a door, however small, often are slip or trip hazards. This is because persons passing through a door, including those who may have some mobility impairments, usually do not expect changes in floor surface elevation or are not able to recognize them because of the intervening door leaf. Under emergency conditions, a fall in a doorway could result not only in injury to the falling occupant but also interruption of orderly egress by other occupants. The exterior landing is allowed to slope to drain.

The size of this landing is set by Section 1010.1.6. In accordance with Exception 4, the floor surface elevation of the landing is to be at the same elevation plus or minus 1/2 inch (12.7 mm) (see Commentary Figure 1010.1.5).

Note that some of the exceptions indicate which direction the door swings to allow the exceptions while others do not limit the door swing direction.

Exception 1, which applies to nontransient residential occupancies, recognizes that occupants are familiar with the stair and landing arrangements. In Exception 1.1, an interior stairway can start immediately at the door, provided the door leaf does not swing over the stairway. Exception 1.2 clarifies that a screen door or storm door would not be considered the main door prohibited from swinging over the stairway by Exception 1.1.

Exception 2 references two other locations. Section 1003.5, Exception 1, permits a 7-inch (178 mm) change in elevation at exterior doors in Groups F, H, R-2, R-3, S and U if they are not on an accessible route. The door could swing in either direction for this exception and may actually be required to swing out in accordance with Section 1010.1.2. A reference to Section 1022.2 does not address a change in elevation but does address exterior exit doors.

In accordance with Exception 3, for a residential unit, the step-down is limited to  $7\frac{3}{4}$  inches (197 mm) measured from the top of the threshold rather than the interior floor surface. In addition, the exterior door cannot swing over the exterior landing. A screen door or storm door could swing over the exterior landing. This is consistent with the exception to Section 1010.1.7.

Exception 4 addresses a change in floor finish material (see Commentary Figure 1010.1.5).

In accordance with Exception 5, Type B dwelling or sleeping units are not required to have level landings on both sides of some of the exterior doors. Please note that this exception is not applicable for the primary entrance door to the unit (see Section 1105.1.7). Exterior doors that open out onto an exterior deck, patio or balcony are allowed a 4-inch (102 mm) step down. Type B units are established by Chapter 11 for residential occupancies containing four or more dwelling or sleeping units. In order to use this exception, the exterior decks, patios or balconies must be of solid and impervious construction, such as concrete or wood. A 4-inch (102 mm) step from inside the unit down to the exterior surfaces is allowed for weather purposes. This allowance is consistent with the provisions of ICC A117.1 and Fair Housing Accessibility Guidelines (FHAG).

While Exception 2 would allow for exterior doors of Group F or S to have a step down, it would not have this same allowance for small equipment spaces within a building. Sometimes these rooms have a step down to allow for spills within the space to not leak out under the door. This space is not required to be accessible (see IBC Section 1103.2.9) and the space is only accessed by maintenance and service personnel, so a step down would not be a barrier.

**1010.1.6 Landings at doors.** Landings shall have a width not less than the width of the *stairway* or the door, whichever is greater. Doors in the fully open position shall not reduce a

required dimension by more than 7 inches (178 mm). Where a landing serves an *occupant load* of 50 or more, doors in any position shall not reduce the landing to less than one-half its required width. Landings shall have a length measured in the direction of travel of not less than 44 inches (1118 mm).

**Exception:** Landing length in the direction of travel in Groups R-3 and U and within individual units of Group R-2 need not exceed 36 inches (914 mm).

❖ Door landings are at either side of the door. Landings can overlap floor surfaces within a room or corridor, overlap an exterior porch or balcony, or share the landings for stairways. The 7-inch (178 mm) encroachment and one-half required width limitations are consistent with Section 1005.7 for door encroachment. Section 1005.7 deals with egress width and capacity and is referenced from aisles (see Section 1018.1), corridors (see Section 1020.3), exit passageways (see Section 1024.2) and egress courts (see Section 1028.4.1).

This section also is intended to address landings at the entrance door to enclosed stairways (also see Section 1011.6 for stairway landings). The width of a landing at a door in a stairway is to be not less than the width of the stairway or the door, whichever is greater [see Commentary Figure 1011.6(4) for an example of these provisions].

No matter what size the door or stair landing is, door landings are to have the floor elevation requirements of Section 1010.1.5 extending at least 44 inches (1118 mm) in the direction of egress travel.

The reduction in landing length from 44 inches minimum to 36 inches minimum for certain residential occupancies allowed by the exception is in recognition of their low occupant load.

**1010.1.7 Thresholds.** Thresholds at doorways shall not exceed  $\frac{3}{4}$  inch (19.1 mm) in height above the finished floor or landing for sliding doors serving *dwelling units* or  $\frac{1}{2}$  inch (12.7 mm) above the finished floor or landing for other doors. Raised thresholds and floor level changes greater than  $\frac{1}{4}$  inch (6.4 mm) at doorways shall be beveled with a slope not greater than one unit vertical in two units horizontal (50-percent slope).

**Exceptions:**

1. In occupancy Group R-2 or R-3, threshold heights for sliding and side-hinged exterior doors shall be permitted to be up to  $7\frac{3}{4}$  inches (197 mm) in height if all of the following apply:
  - 1.1. The door is not part of the required *means of egress*.
  - 1.2. The door is not part of an *accessible route* as required by Chapter 11.
  - 1.3. The door is not part of an *Accessible unit, Type A unit* or *Type B unit*.
2. In *Type B units*, where Exception 5 to Section 1010.1.5 permits a 4-inch (102 mm) elevation change at the door, the threshold height on the exterior side of the door shall not exceed  $4\frac{3}{4}$  inches (120

mm) in height above the exterior deck, patio or balcony for sliding doors or 4 1/2 inches (114 mm) above the exterior deck, patio or balcony for other doors.

- ❖ A threshold is a potential tripping hazard and a barrier to accessibility by people with mobility impairments. For these reasons, thresholds for all doorways, except exterior sliding doors serving dwelling units, are to be a maximum of 1/2 inch (12.7 mm) high. Exterior sliding doors serving dwelling units, however, are permitted to be 3/4 inch (19.1 mm) high because of practical design considerations, concern for deterioration of the doorway because of snow and ice buildup and lack of adequate drainage in severe climates. Raised threshold and floor level changes at doorways without beveled edge treatment [see Commentary Figure 1010.1.7(1)] are limited to 1/4 inch (6.3 mm) high vertically.

Commentary Figures 1010.1.7(2), 1010.1.7(3) and 1010.1.7(4) illustrate configurations where the change in elevation is between 1/4 inch (6.4 mm) and 1/2 inch (12.7 mm). The slope of required beveled edges cannot exceed one unit vertical in two units horizontal (1:2 or 50-percent slope) but lesser slopes are fully compliant. This kind of threshold treatment provides for minimum obstructions for wheelchair users and limits the trip hazard for those with other mobility disabilities.

The first exception permits a 7/4-inch (197 mm) threshold at both side-swinging and sliding exterior doors in Group R-2 and R-3 buildings. However, this door cannot be part of the required means of egress out of a building; cannot be part of an accessible route required into a building or unit (see IBC Sections 1104 and 1105) and cannot serve an Accessible, Type A or

Type B unit. The result would be that this exception would be permitted at the “back door,” stoop or patio in single-family homes (see IBC Section 1103.2.3) or upper floor balconies within individual apartments in buildings without elevators (see IBC Section 1107). This terminology is consistent with the 7 3/4-inch (197 mm) step down in Section 1010.1.5, Exception 3; however, this exception is to the threshold requirements, not the landing elevations.

The second exception is for doors where a 4-inch step down is permitted in Type B dwelling units between the interior finished floor surface and the exterior surface of exterior decks, patios and balconies (Section 1010.1.5 Exception 5). This section would permit the height of the threshold itself to exceed 1/2 or 3/4 inch in height, as long as the resultant profile from the interior floor to the exterior surface is maintained.

The threshold itself can be higher than 1/2 or 3/4 inch measured from the outside. The additional height, however, is contained within the 4-inch step down. The height of the threshold is limited to 1/2 inch or 3/4 inch above the interior floor and the total height must not be more than 4 1/2 or 4 3/4 inches above the exterior surface, depending upon the type of door. If the threshold is greater than 1/4 inch above the interior floor, it is to be beveled. See Commentary Figure 1010.1.7(5).

**MEANS OF EGRESS**

**1010.1.8 Door arrangement.** Space between two doors in a series shall be 48 inches (1219 mm) minimum plus the width of a door swinging into the space. Doors in a series shall swing either in the same direction or away from the space between the doors.

**Exceptions:**

1. The minimum distance between horizontal sliding power-operated doors in a series shall be 48 inches (1219 mm).
2. Storm and screen doors serving individual *dwelling units* in Groups R-2 and R-3 need not be spaced 48 inches (1219 mm) from the other door.
3. Doors within individual *dwelling units* in Groups R-2 and R-3 other than within *Type A dwelling units*.

❖ Door arrangement is required to be such that an occupant's use of a means of egress doorway is not hampered by the operation of a preceding door located in the same line of travel so that the occupant

flow can be smooth through the openings. Successive doors in a single egress path (i.e., in a series) can cause such interference. The 4-foot (1219 mm) clear distance between doors when the first door is open at 90 degrees allows an occupant, including a person using a wheelchair, to move past one door and its swing before beginning the operation of the next door [see Commentary Figure 1010.1.8(1)]. Note that where doors in a series are not arranged in a straight line, the intent of the code is to provide sufficient space to enable occupants to negotiate the second door without being encumbered by the first door's swing arc. To facilitate accessibility, the space between doors should provide sufficient clear space for a wheelchair [30 inches by 48 inches (762 mm by 1219 mm)] beyond the arc of the door swing [see Commentary Figure 1010.1.8(2)]. Additionally, the approach and access provisions of ICC A117.1 must be considered for all doors along an accessible route.

The exception is to permit horizontal sliding power-

operated doors (see Section 1010.1.4.2) to be designed with a lesser distance between them in a series arrangement because they are customarily designed to open simultaneously or in sequence such that movement through them is unhampered. Storm and screen doors on residential dwelling units need not be spaced at 48 inches (1219 mm) since it would be impractical, and they do not operate the same as doors in a series. Doors within dwelling units of Group R-2 or R-3 that are not Type A dwelling units (see IBC Section 1107) are also permitted to have a lesser distance between doors, because the accessibility provisions do not apply. There are requirements in Chapter 10 of the ICC A117.1 for door arrangements within Accessible and Type A dwelling and sleeping units.

**1010.1.9 Door operations.** Except as specifically permitted by this section, egress doors shall be readily openable from the egress side without the use of a key or special knowledge or effort.

❖ When installed for security purposes, locks and latches can intentionally prohibit the use of an egress door and thus interfere with or prevent the egress of occupants at the time of a fire. While the security of property is important, the life safety of occupants is essential. Where security and life safety objectives conflict, alternative measures, such as those permitted by each of the exceptions in Section 1010.1.9.3, may be applicable.

Egress doors are permitted to be locked, but must be capable of being unlocked and readily openable from the side from which egress is to be made. The outside of a door can be key locked as long as the inside—the side from which egress is to be made—can be unlocked without the use of tools, keys or special knowledge or effort. For example, an unlocking operation that is integral with an unlatching operation is acceptable.

Examples of special knowledge would be a combination lock or an unlocking device or deadbolt in an unknown, unexpected or hidden location. Special effort would dictate the need for unusual and unexpected physical ability to unlock or make the door fully available for egress.

Where a pair of egress door leaves is installed, with or without a center mullion, the general requirement is that each leaf must be provided with its own releasing or unlatching device so as to be readily openable. Door arrangements or devices that depend on the release of one door before the other can be opened are not to be used except as permitted by Section 1010.1.9.4.

**1010.1.9.1 Hardware.** Door handles, pulls, latches, locks and other operating devices on doors required to be *accessible* by Chapter 11 shall not require tight grasping, tight pinching or twisting of the wrist to operate.

❖ Any doors that are located along an accessible route for ingress or egress must have door hardware that is easy to operate by a person with limited mobility or

dexterity. This would include all elements of the door hardware used in typical door operation, such as door levers, locks, security changes, etc. This requirement is also an advantage for persons with arthritis in their hands. Items such as small, full-twist thumb turns or smooth circular knobs are examples of hardware that is not acceptable. There are many types latching or locking devices can be operated without tight grasping, tight pinching, or twisting of the wrist what would comply with the requirements of this section.

Some people with disabilities are unable to grasp objects with their hands or twist their wrists. Such people are unable to operate, or have great difficulty operating, door hardware other than lever-operated mechanisms, push-type mechanisms and U-shaped door pulls. Door hardware that can be operated with a closed fist or a loose grip accommodates the greatest range of users. Hardware operated by simultaneous hand and finger movement requires greater dexterity and coordination and should be avoided for doors along an accessible route (see Commentary Figure 1010.1.9.1).

**Figure 1010.1.9.1  
DOOR HARDWARE**

**1010.1.9.2 Hardware height.** Door handles, pulls, latches, locks and other operating devices shall be installed 34 inches (864 mm) minimum and 48 inches (1219 mm) maximum above the finished floor. Locks used only for security purposes and not used for normal operation are permitted at any height.

**Exception:** Access doors or gates in barrier walls and fences protecting pools, spas and hot tubs shall be permitted to have operable parts of the release of latch on self-latching devices at 54 inches (1370 mm) maximum above the finished floor or ground, provided the self-latching devices are not also self-locking devices operated by means of a key, electronic opener or integral combination lock.

❖ The requirements in this section place the door hardware at a level that is usable by most people, including a person using a wheelchair. The exception allows security locks to be placed at any height. An example would be an unframed glass door at the front door of a tenant space in a mall that has the lock near the floor level. The lock is only used when the store is not open for business. Such locks are not required for the normal operation of the door.

The exception permits a special allowance for security latches at pools, spas and hot tubs. The con-

cern is that the 48-inch (1219 mm) maximum height would place the security latch within reach of children. The 54-inch (1372 mm) maximum height is intended to override the maximum 48-inch (1219 mm) reach range in ICC A117.1. This compromise addresses concerns for children's safety and still maintains accessibility to a reasonable level. Based on the last phrase in the exception, if the gate hardware also had a locking function and a key or other similar device would be needed to unlock the hardware to allow unlatching the latch, then the exception to allow the hardware to be 54-inches (1372 mm) above the floor is not applicable. A reference to this exception is found in IBC Section 1109.13, Exception 7, for the accessibility requirements for operable parts. This is consistent with the 2010 Standard and ANSI/NSPI-8 1996, *Model Barrier Code for Residential Swimming Pools, Spas, and Hot Tubs*.

**1010.1.9.3 Locks and latches.** Locks and latches shall be permitted to prevent operation of doors where any of the following exist:

1. Places of detention or restraint.
  2. In buildings in occupancy Group A having an *occupant load* of 300 or less, Groups B, F, M and S, and in *places of religious worship*, the main door or doors are permitted to be equipped with key-operated locking devices from the egress side provided:
    - 2.1. The locking device is readily distinguishable as locked.
    - 2.2. A readily visible durable sign is posted on the egress side on or adjacent to the door stating: THIS DOOR TO REMAIN UNLOCKED WHEN THIS SPACE IS OCCUPIED. The sign shall be in letters 1 inch (25 mm) high on a contrasting background.
    - 2.3. The use of the key-operated locking device is revokable by the *building official* for due cause.
  3. Where egress doors are used in pairs, *approved* automatic flush bolts shall be permitted to be used, provided that the door leaf having the automatic flush bolts does not have a doorknob or surface-mounted hardware.
  4. Doors from individual *dwelling* or *sleeping units* of Group R occupancies having an *occupant load* of 10 or less are permitted to be equipped with a night latch, dead bolt or security chain, provided such devices are operable from the inside without the use of a key or tool.
  5. *Fire doors* after the minimum elevated temperature has disabled the unlatching mechanism in accordance with *listed fire door* test procedures.
- ❖ Where security and life safety objectives conflict, alternative measures, such as those permitted by each of the listed situations, may be applicable.
- Item 1 is needed for jails and prisons or locations where someone must be kept inside for their own safety (i.e., dementia wards, psychiatric wards).
- Item 2 permits a locking device, such as a double-

cylinder dead bolt, on the main entrance door to a building or space. It must be immediately apparent that these doors are locked. For example, such locking devices may have an integral indicator that automatically reflects the "locked" or "unlocked" status of the device. In addition, a sign must be provided that clearly states that the door is to be unlocked when the building or space is occupied. The sign on or adjacent to the door not only reminds employees to unlock the door, but also advises the public that an unacceptable arrangement exists if one finds the door locked. Ideally, the individual who encounters the locked door will notify management and possibly the building official. Note that the use of the key-locking device is revocable by the building official. The locking arrangement is not permitted on any door other than the main exit and, therefore, the employees, security and cleaning crews will have access to other exits without requiring the use of a key. This allowance is not limited just to multiple-exit buildings but also to small buildings with one exit. This option is an alternative to the panic hardware required by Section 1010.1.10.

In Item 3, an automatic flush bolt device is one that is internal to the inactive leaf of a pair of doors. The device has a small "knuckle" that extends from the inactive leaf into an opening in the active leaf. When the active leaf is opened, the bolt is automatically retracted. When the active leaf is closed, the knuckle is pressed into the inactive leaf by the active leaf, extending the flush bolt(s), in the head or sill of the inactive leaf (see Commentary Figure 1010.1.9.3).

Automatic flush bolts on one leaf of a pair of egress doors are acceptable, provided the leaf with the automatic flush bolts is not equipped with a doorknob or other hardware that would imply to the user that the door leaf is unlatched independently of the companion leaf.

Item 4 addresses the need for security in residential dwelling and sleeping units such as hotel rooms, apartments, dormitory rooms or townhouses. The occupants are familiar with the operation of the indicated devices, which are intended to be relatively simple to operate without the use of a key or tool. Note that this item only applies to the door leading from individual dwelling or sleeping units in a building. This item would not be applicable for doors locked as part of a security system in a multiunit building.

Item 5 is in recognition of required test procedures (UL 10B or UL 10C) for listed fire doors, which include the disabling of the locking mechanism when a fire door is exposed to the elevated temperatures of a fire.

**1010.1.9.4 Bolt locks.** Manually operated flush bolts or surface bolts are not permitted.

**Exceptions:**

1. On doors not required for egress in individual *dwelling units* or *sleeping units*.
2. Where a pair of doors serves a storage or equipment room, manually operated edge- or surface-mounted bolts are permitted on the inactive leaf.

3. Where a pair of doors serves an *occupant load* of less than 50 persons in a Group B, F or S occupancy, manually operated edge- or surface-mounted bolts are permitted on the inactive leaf. The inactive leaf shall not contain doorknobs, panic bars or similar operating hardware.
4. Where a pair of doors serves a Group B, F or S occupancy, manually operated edge- or surface-mounted bolts are permitted on the inactive leaf provided such inactive leaf is not needed to meet egress capacity requirements and the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1. The inactive leaf shall not contain doorknobs, panic bars or similar operating hardware.
5. Where a pair of doors serves patient care rooms in Group I-2 occupancies, self-latching edge- or surface-mounted bolts are permitted on the inactive leaf provided that the inactive leaf is not needed to meet egress capacity requirements and the inactive leaf shall not contain doorknobs, panic bars or similar operating hardware.

❖ This section is applicable to doors that are required to be for means of egress purposes or are identified as a means of egress, such as by an “Exit” sign or other device. Doors, as well as a second leaf in a doorway that is provided for a purpose other than means of egress, such as for convenience or building operations, should be arranged or identified so as not to be mistaken as a means of egress. The use of manually operated flush bolts or surface bolts on means of egress doors have traditionally been prohibited because of the inability of users to quickly identify and operate such devices under emergency conditions.

This section prohibits installation of manually operated flush and surface bolts except in limited situa-

tions. The exceptions allowing the use of such hardware are intended to expand the use of manually operated edge- or surface-mounted bolts under specified conditions while maintaining an appropriate degree of safety for the building occupants. Flush and surface bolts represent locking devices that may be difficult to operate because of their location and operation (see Commentary Figure 1010.1.9.4).

Where edge-mounted or surface-mounted manually operated bolts are installed on the inactive leaf of a pair of doors, per the exceptions below, the manually operated bolts must have no effect on the egress operation of the active leaf.

Exception 1 allows manual flush bolts and surface bolts at some doors within an individual dwelling or sleeping unit. Even then, such bolts may only be used on doors not required for egress (see Section 1010.1.9.3, Item 4, for security of doors from individual dwelling and sleeping units).

Exception 2 provides for edge-mounted or surface-mounted bolts on the inactive leaf of a pair of doors from storage or equipment areas. Double doors are often provided to allow for the easy removal or replacement of large pieces of equipment or bulk movement of goods.

Exceptions 3 and 4 offer two options for limited doors in Group B, F and S occupancies. Again, the wider door is sometimes needed for the movement of equipment. Automatic flush bolts and removable center posts can be easily damaged and difficult to maintain in areas of frequent door usage. Revisions to the requirements for door hardware on such pairs of doors will increase building functionality while maintaining a very high degree of occupant safety.

In Exception 3, the number of occupants within the space must be less than 50, the active leaf must meet means of egress requirements and the inactive leaf must not have any operating hardware so that it could be mistaken for an egress door.

In accordance with Exception 4, if the Group B, F or S building is sprinklered throughout with an NFPA 13 system, the room served by the double door can have any occupant load if the inactive leaf is not required for egress capacity and has no operating hardware.

Exception 5 is in recognition of the need to move equipment into some patient sleeping and treatment rooms in hospital and nursing home environments. Again, the inactive leaf must not be needed for means of egress or have any operating hardware. This is consistent with IBC Section 407.1.1, which allows for staff to operate patient sleeping and treatment room doors during emergency events. The doors would still have to meet smoke barrier opening protective requirements. The clear width requirement of 41<sup>1</sup>/<sub>2</sub> inches (1054 mm) in Section 1010.1.1 would still have to be met with the active door leaf.

**1010.1.9.5 Unlatching.** The unlatching of any door or leaf shall not require more than one operation.

**Exceptions:**

1. Places of detention or restraint.
2. Where manually operated bolt locks are permitted by Section 1010.1.9.4.
3. Doors with automatic flush bolts as permitted by Section 1010.1.9.3, Item 3.

4. Doors from individual *dwelling units* and *sleeping units* of Group R occupancies as permitted by Section 1010.1.9.3, Item 4.

❖ The code prohibits the use of locks or latching devices that require more than one operation on any door required or used for egress, which could be a safety hazard in an emergency situation. The exceptions address locations where multiple locks or latching devices which require more than one operation are acceptable. See the referenced sections for additional commentary.

**1010.1.9.5.1 Closet and bathroom doors in Group R-4 occupancies.** In Group R-4 occupancies, closet doors that latch in the closed position shall be openable from inside the closet, and bathroom doors that latch in the closed position shall be capable of being unlocked from the ingress side.

❖ The intent of this provision is to address possible entrapment concerns in group homes. If a closet door has a door latch, the closet door must be openable from both inside and outside. This will ensure that someone cannot get stuck inside a closet by accident. If a closet does not latch, no interior hardware is required. In case a resident needs assistance in a bathroom, the bathroom door must have a type of hardware that would allow the door to be unlocked from the outside by staff. This requirement is unique to Group R-4. There are not similar requirements for other Group R occupancies, Group I-1 assisted living facilities or Group I-2 nursing homes; however, some assisted living or nursing home facilities install such devices to increase patient safety. Section 403.3.6 in the *International Plumbing Code*<sup>®</sup> (IPC<sup>®</sup>) prohibits the doors leading from multistall bathrooms from being lockable from the inside.

**1010.1.9.6 Controlled egress doors in Groups I-1 and I-2.** Electric locking systems, including electro-mechanical locking systems and electromagnetic locking systems, shall be permitted to be locked in the means of egress in Group I-1 or I-2 occupancies where the clinical needs of persons receiving care require their containment. Controlled egress doors shall be permitted in such occupancies where the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or an *approved automatic smoke or heat detection system* installed in accordance with Section 907, provided that the doors are installed and operate in accordance with all of the following:

1. The door locks shall unlock on actuation of the *automatic sprinkler system* or *automatic fire detection system*.
2. The door locks shall unlock on loss of power controlling the lock or lock mechanism.
3. The door locking system shall be installed to have the capability of being unlocked by a switch located at the *fire command center*, a nursing station or other approved location. The switch shall directly break power to the lock.

4. A building occupant shall not be required to pass through more than one door equipped with a controlled egress locking system before entering an exit.
5. The procedures for unlocking the doors shall be described and approved as part of the emergency planning and preparedness required by Chapter 4 of the *International Fire Code*.
6. All clinical staff shall have the keys, codes or other means necessary to operate the locking systems.
7. Emergency lighting shall be provided at the door.
8. The door locking system units shall be listed in accordance with UL 294.

**Exceptions:**

1. Items 1 through 4 shall not apply to doors to areas occupied by persons who, because of clinical needs, require restraint or containment as part of the function of a psychiatric treatment area.
  2. Items 1 through 4 shall not apply to doors to areas where a *listed* egress control system is utilized to reduce the risk of child abduction from nursery and obstetric areas of a Group I-2 hospital.
- ❖ The intent of these provisions is to address the special safety needs for wards, units, or areas in assisted living facilities, nursing homes and hospitals where egress may need to be controlled for the safety of the occupants or where specialized protective measures are needed for patients. "Controlled egress" means simply that the ability of occupants, such as patients or residents, to leave a space is controlled by others, such as staff. The areas where controlled egress may be permitted include psychiatric areas, dementia units, Alzheimer's units, maternity units, and newborn nurseries. Code officials may also permit these provisions in other areas such as emergency departments or pediatric areas where the safety and/or security of the occupants are of primary concern. In all situations, there must be a balance between maintaining a safe and secure environment and providing for emergency egress.

The requirements of this section apply to locking systems controlling egress. The functions of an ingress control locking system are not addressed in the codes and are unrelated as long as egress is provided as required or permitted by this section and other applicable provisions of the code.

In areas where additional security may be a concern, a door hardware system may include an unlocking device, such as a keypad, card reader, eye scanner, thumbprint scanner or other credential device. Where these credential unlocking systems are only on the ingress side of a building or space, there are no limitations in the codes. Where these credential unlocking systems are on the egress side of a space (perhaps to monitor personnel movement), egress must be available through one of the locking systems addressed in Section 1010.1.9.7, 1010.1.9.8 or 1010.1.9.9. Such a credential unlocking device could

also be included in the controlled locking arrangements of IBC Section 408.4 and Section 1010.1.9.6, Item 6 of the code.

IBC Section 907.6 requires a fire alarm system to be installed in accordance with the requirements of that section and NFPA 72. NFPA 72 includes specific requirements for unlocking doors in the direction of egress that are consistent with the requirements in this section for controlled egress locking systems. Additionally, NFPA 72 includes specific requirements and guidance for backup power where the backup power is used to keep these doors in a locked condition in the direction of egress.

Items 1 through 3 address when the controlled egress locks would be required to automatically unlock allowing unrestricted egress.

Item 4 requires that no occupant shall have to pass through more than one controlled egress lock before entering an exit.

Item 5 requires the procedures for unlocking the doors to be described, approved by the code official, and included in the emergency planning and preparedness plan required by Chapter 4 of the *International Fire Code*.

Item 6 requires clinical staff to have the means necessary to operate the controlled egress locking system, such as keys, codes, etc.

Item 7 requires emergency lighting at the controlled egress door to ensure visibility for egress during a possible power outage.

Item 8 requires the units of the controlled egress locking system to be listed to UL 294. The UL 294 Access Control Systems standard applies to construction, performance, and operation of systems which control passage through a door, and electrical, electronic, or mechanical units of these systems.

The first exception allows for the automatic unlocking requirements to be omitted for doors in a psychiatric treatment area in hospitals or nursing homes due to additional safety concerns for the residents.

The second exception allows for automatic unlocking requirements to be omitted where a listed egress control system is installed for the specific purposes of reducing child abductions from nursery and obstetric areas of hospitals.

**1010.1.9.7 Delayed egress.** Delayed egress locking systems shall be permitted to be installed on doors serving any occupancy except Group A, E and H in buildings that are equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or an *approved automatic smoke or heat detection system* installed in accordance with Section 907. The locking system shall be installed and operated in accordance with all of the following:

1. The delay electronics of the delayed egress locking system shall deactivate upon actuation of the *automatic sprinkler system* or *automatic fire detection system*, allowing immediate, free egress.
2. The delay electronics of the delayed egress locking system shall deactivate upon loss of power controlling the

lock or lock mechanism, allowing immediate free egress.

3. The delayed egress locking system shall have the capability of being deactivated at the *fire command center* and other *approved* locations.
4. An attempt to egress shall initiate an irreversible process that shall allow such egress in not more than 15 seconds when a physical effort to exit is applied to the egress side door hardware for not more than 3 seconds. Initiation of the irreversible process shall activate an audible signal in the vicinity of the door. Once the delay electronics have been deactivated, rearming the delay electronics shall be by manual means only.

**Exception:** Where approved, a delay of not more than 30 seconds is permitted on a delayed egress door.

5. The egress path from any point shall not pass through more than one delayed egress locking system.

**Exception:** In Group I-2 or I-3 occupancies, the egress path from any point in the building shall pass through not more than two delayed egress locking systems provided the combined delay does not exceed 30 seconds.

6. A sign shall be provided on the door and shall be located above and within 12 inches (305 mm) of the door exit hardware:
  - 6.1. For doors that swing in the direction of egress, the sign shall read: PUSH UNTIL ALARM SOUNDS. DOOR CAN BE OPENED IN 15 [30] SECONDS.
  - 6.2. For doors that swing in the opposite direction of egress, the sign shall read: PULL UNTIL ALARM SOUNDS. DOOR CAN BE OPENED IN 15 [30] SECONDS.
  - 6.3. The sign shall comply with the visual character requirements in ICC A117.1.

**Exception:** Where approved, in Group I occupancies, the installation of a sign is not required where care recipients who because of clinical needs require restraint or containment as part of the function of the treatment area.

7. Emergency lighting shall be provided on the egress side of the door.
  8. The delayed egress locking system units shall be listed in accordance with UL 294.
- ❖ The intent of these provisions is to address special needs where there are concerns about internal security. Delays in egress, as allowed in this section, are not considered detrimental to occupant evacuation. The intent of these provisions is also to address special needs where occupants may need to be protected from harm because of their own actions. For example, residents or patients in some Group I-1 or Group I-2 occupancies may present a danger to themselves of elopement from the building into traffic, weather and other environmental hazards.

Delayed egress locking systems are permitted for doors in a means of egress serving occupancies other than those in Groups A, E and H. Delayed egress locking systems are not permitted in assembly or educational occupancies because the resulting delay in egress is not acceptable given the greater number of occupants who may be unfamiliar with the space or of a young age. Also, the delay from Group H would be unreasonable given the potential for rapid fire buildup in such areas.

This locking system is called “delayed egress” because of Item 4, which permits a fixed amount of time to pass prior to allowing egress.

The requirements of this section apply to locking systems which delay egress. The functions of an ingress control locking system are unrelated and are not addressed as long as egress is provided as required or permitted by this section and other applicable provisions of the code.

The requirements of this section apply to electromagnetic locking systems which open on hardware activation. The functions of an ingress control locking system are not addressed in the codes and are unrelated as long as egress is provided as required or permitted by this section and other applicable provisions of the code.

In areas where additional security may be a concern, a door hardware system may include an unlocking device, such as a keypad, card reader, eye scanner, thumbprint scanner or other credential device. Where these credential unlocking systems are only on the ingress side of a building or space, there are no limitations in the codes. Where these credential unlocking systems are on the egress side of a space (perhaps to monitor personnel movement), egress must be available through one of the locking systems addressed in Section 1010.1.9.7, 1010.1.9.8 or 1010.1.9.9. Such a credential unlocking device could also be included in the controlled locking arrangements of IBC Section 408.4 and Section 1010.1.9.6, Item 6 of the code.

IBC Section 907.6 requires a fire alarm system to be installed in accordance with the requirements of that section and NFPA 72. NFPA 72 includes specific requirements for unlocking doors in the direction of egress that are consistent with the requirements in this section for delayed egress locking systems. Additionally, NFPA 72 includes specific requirements and guidance for backup power where the backup power is used to keep these doors in a locked condition in the direction of egress.

Because of the egress delay caused by the system on the egress door, the building must be provided throughout with compensating fire protection features to promptly warn occupants of a fire condition. All listed conditions must be met in order to permit use of a delayed egress locking system.

Item 1 interconnects the locking system with an automatic sprinkler system in accordance with NFPA 13 or, alternatively, an automatic fire detection sys-

tem in accordance with Section 907, which is required to be installed throughout the building. Such systems are to provide occupants with an early warning of a fire event, and thus additional time for egress. Note that actuation of the automatic sprinkler system or actuation of the automatic fire detection system must eliminate the delay of the delayed egress locking system so the door immediately allows egress (without delay).

Item 2 specifies the delay is to be eliminated on loss of power. Since the operation of the delayed egress locking system is dependent on electrical power, in the event of electrical power loss to the lock or locking mechanism, the doors must immediately allow egress (without delay).

Item 3 specifies that the delay in the delayed egress locking system is capable of being eliminated by a signal sent from a fire command center or other approved locations. Personnel at the fire command center location would normally be the first alerted to an emergency event and would be expected to take appropriate action to allow immediate egress at all doors equipped with delayed egress locking systems. Other locations may be alternates to or back up the fire command center. Item 3 facilitates remotely eliminating the delay in the delayed egress locking system in the event of a fire or in the event of other nonfire emergencies.

Item 4 specifies the operational characteristics of the delayed egress locking system. The delay timer of the system and the audible signal (alarm) at the door may be configured one of two ways. In some occupancies, the delay timer is initiated and the alarm sounded immediately upon an attempt to open the door by pushing on the panic bar, or causing a slight movement of the door. In other occupancies, to prevent nuisance alarms from inadvertent bumps or accidental contact, the initiation of the delay timer and sounding of the alarm may be deferred by up to 3 seconds, requiring the occupant to attempt to operate the door hardware for up to, but not more than, 3 seconds.

Once the delay timer starts, the door is required to be openable from the egress side in not more than 15 seconds (or not more than 30 seconds where approved by the code official, per the exception). At the end of the delay, the door's locking system is required to allow the door to be opened by the occupant operating the egress side door hardware (i.e. pushing on the panic bar), allowing egress. The unlocking cycle is irreversible; once it is started, it does not stop. Once the door is openable from the egress side at the end of the delay, it remains openable allowing immediate egress until someone comes to the door and manually rearms the delay. The first user to the door may face a delay, but after that other users would be able to exit immediately. A method of automatically rearming the delayed egress locking system at the door from a remote location such as a central control station or security office is not permitted.

The exception to Item 4 permits the building official to allow the time delay prior to allowing egress to be increased beyond 15 seconds, but not in excess of 30 seconds. This exception is more often granted for the safety/security of occupants (e.g., to reduce or prevent elopement of patients) than for loss or theft prevention.

Item 5 limits the egress path to not more than one door with a delayed egress locking system. However, the exception to Item 5 allows not more than two doors with delayed egress locking systems in Groups I-2 and I-3 with the delay of the two systems to be not more than 30 seconds total.

Having multiple doors can help with preventing resident elopement and yet the overall delay does not exceed the previously accepted time period. An example of where the two-door arrangement may be helpful is a multistory facility where both the door from the story and the door from the building could be controlled.

Item 6 requires a sign to inform occupants how to operate the delayed egress locking system and when that door will become available for egress. An undesirable consequence of the door not unlocking immediately is if the user assumes it will never be available for egress and then proceeds to another exit door. In some occupancies, delayed egress locking systems may be utilized on doors not required to swing in the direction of egress travel. Options 6.1 and 6.2 allow for signs appropriate for the swing of the door. The required sign is typically supplied with the delayed egress locking system. The reference to ICC A117.1 visual requirements would not require raised letters or braille, but would require readable text, with good finish and contrast. The exception in Item 6 allows the sign to be omitted if the clinical needs of occupants require restraint or containment, as these patients may be capable of reading and following the sign's instructions then potentially putting themselves in harm's way. Based on the level of staff training within these facilities, the need to protect the patients by preventing elopement and the facts that these systems are required to be interconnected with the sprinkler or fire detection systems and unlock upon loss of power, it was determined that eliminating the sign in these facilities is reasonable.

Item 7 requires emergency lighting on the egress side of the door so that the user can read the sign required by Item 5.

Item 8 requires the units of the delayed egress locking system to be listed to UL 294. The UL 294 Access Control Systems standard applies to construction, performance and operation of systems which control passage through a door, and electrical, electronic or mechanical units of these systems.

**1010.1.9.8 Sensor release of electrically locked egress doors.** The electric locks on sensor released doors located in a *means of egress* in buildings with an occupancy in Group A,

## MEANS OF EGRESS

B, E, I-1, I-2, I-4, M, R-1 or R-2 and entrance doors to tenant spaces in occupancies in Group A, B, E, I-1, I-2, I-4, M, R-1 or R-2 are permitted where installed and operated in accordance with all of the following criteria:

1. The sensor shall be installed on the egress side, arranged to detect an occupant approaching the doors. The doors shall be arranged to unlock by a signal from or loss of power to the sensor.
  2. Loss of power to the lock or locking system shall automatically unlock the doors.
  3. The doors shall be arranged to unlock from a manual unlocking device located 40 inches to 48 inches (1016 mm to 1219 mm) vertically above the floor and within 5 feet (1524 mm) of the secured doors. Ready access shall be provided to the manual unlocking device and the device shall be clearly identified by a sign that reads "PUSH TO EXIT." When operated, the manual unlocking device shall result in direct interruption of power to the lock—*independent of other electronics*—and the doors shall remain unlocked for not less than 30 seconds.
  4. Activation of the building *fire alarm system*, where provided, shall automatically unlock the doors, and the doors shall remain unlocked until the fire alarm system has been reset.
  5. Activation of the building *automatic sprinkler system* or *fire detection system*, where provided, shall automatically unlock the doors. The doors shall remain unlocked until the *fire alarm system* has been reset.
  6. The door locking system units shall be listed in accordance with UL 294.
- ❖ The intent of this section is to provide consistent requirements where an electronically locked door is unlocked by activating devices mounted somewhere other than on the door itself. The unlocking activation is designed to be from a passive action by the occupant (e.g., walking to the door triggering a sensor), but the system includes a required nearby manual unlocking device (such as a push button) as a secondary electrical lock release device.

This section permits doors in a means of egress and entrance doors to tenant spaces in occupancies of Groups A, B, E, I-1, I-2, I-4, M, R-1 and R-2 to be electronically secured (locked) to control ingress while maintaining the doors as a means of egress. Typically these systems are used in high-security areas where a record of who has entered and left a space is desired. Or this system may be used where there is a concern for elopement or child abduction (Group I-1, I-2 or I-4).

This section of the IBC does not limit the number of doors in a means of egress that may be equipped with sensor-released electrically locked doors.

IBC Section 907.6 requires that a fire alarm system, where provided, is installed in accordance with the requirements of that section and NFPA 72. NFPA 72 includes specific requirements for unlocking doors

in the direction of egress, which are consistent with the requirements in this section for sensor release of electrically locked egress doors. Additionally, NFPA 72 includes specific requirements and guidance for backup power where the backup power is used to keep these doors in a locked condition.

The requirements of this section apply to locking systems with a sensor release. The functions of an ingress control locking system are not addressed in the codes and are unrelated as long as egress is provided as required or permitted by this section and other applicable provisions of the code.

In areas where additional security may be a concern, a door hardware system may include an unlocking device, such as a keypad, card reader, eye scanner, thumbprint scanner or other credential device. Where these credential unlocking systems are only on the ingress side of a building or space, there are no limitations in the codes. Where these credential unlocking systems are on the egress side of a space (perhaps to monitor personnel movement), egress must be available through one of the locking systems addressed in Section 1010.1.9.7, 1010.1.9.8 or 1010.1.9.9. Such a credential unlocking device could also be included in the controlled locking arrangements of IBC Section 408.4 and Section 1010.1.9.6, Item 6 of the code.

In areas where additional security may be a concern, a door hardware system may include a remote unlocking device, such as a keypad, card reader, eye scanner or thumbprint scanner. Where these systems are only on the ingress side of a building or space, there are no limitations in the codes. Where these systems are on the egress side of a space, free egress must still be available through one of the electromagnetic systems addressed in Section 11010.1.9.7, 1010.1.9.8 or 1010.1.9.9. Such a remote unlocking device could also be included in the controlled locking arrangements for IBC Section 408.4 and Section 1010.9.6 of the code.

Items 1 through 6 provide operational criteria to ensure egress during normal and emergency situations. Occupancies in Groups F, S and H are not included here because of their increased hazard caused by fuel load and other potentially life-threatening factors.

Item 1 requires that such doors be provided with an occupant sensor on the egress side of the door. These sensors typically operate on an infrared, microwave or sonic principle, but other technologies may be available. This sensor is required to automatically release the electrical lock on approach of an occupant from the egress side or when there is a loss of power to the sensor. This provision is written as "performance-based," where any means of sensor design can be utilized to cause the doors to unlock, allowing immediate egress. This section does not indicate at what distance the sensor should be set to operate. The sensor may be set to detect an approaching occupant in time to unlock the electrical

locks prior to the occupant reaching the door, to permit egress without the occupant realizing the doors were electrically locked. In other applications, the sensor may be set to require the occupant to be closer to the door prior to unlocking the electrical lock to allow egress.

Item 2 states that if there is a loss of power to the electrical lock or to the locking system, the electrical lock on the door must unlock. These doors are commonly secured with fail-safe devices which prioritize life safety over security (such as electromagnetic locks or fail-safe power bolts) so that the electrical locks on these doors will automatically unlock when power to the electrical locking device or locking system is interrupted. In some instances, the locking system controller may be powered from a different source than the electrical locking device itself. In these cases, a loss of power to the locking system controller (while power remains applied to the locking device) must also cause the electrical locking device on the egress door to automatically unlock.

Item 3 requires that there be a manual unlocking device (push button), within 5 feet of the door, mounted 40 to 48 inches above the floor, unobstructed and with a clearly identifiable sign that says "PUSH TO EXIT." When operated, the manual unlocking device is to directly interrupt, independent of other electronics, the power to the electrical lock and cause the doors to remain electrically unlocked for a minimum of 30 seconds. To achieve a minimum 30-second delay independent of other electronics, the push button unlocking device should be designed and installed to provide this delay. The 30-second minimum is to allow adequate time for an individual to operate the manual unlocking device and then to egress through the door.

Items 4 and 5 require the building fire alarm system, automatic fire detection system or sprinkler system, if provided, to be interfaced with the door's electric locking system to unlock automatically on activation. The electrical locks on the doors are to remain unlocked until the fire alarm system is reset, ensuring egress is not impeded by the electric locking system.

Item 6 requires the units of the locking system to be listed to UL 294. The UL 294 Access Control System standard applies to construction, performance, and operation of systems which control passage through a door, and electrical, electronic, or mechanical units of these systems.

To summarize, it is important to keep in mind that an egress door equipped with a sensor release system must always allow egress whether power is present or not. The egress door must be "fail-safe" and must assume this "fail-safe" condition when power is removed from any part of the sensor release system. In other words, if the sensor release system loses power, the egress door must be capable of being opened. People must be kept from being involuntarily locked inside buildings.

**1010.1.9.9 Electromagnetically locked egress doors.** Doors in the *means of egress* in buildings with an occupancy in Group A, B, E, I-1, I-2, I-4, M, R-1 or R-2 and doors to tenant spaces in Group A, B, E, I-1, I-2, I-4, M, R-1 or R-2 shall be permitted to be locked with an electromagnetic locking system where equipped with hardware that incorporates a built-in switch and where installed and operated in accordance with all of the following:

1. The hardware that is affixed to the door leaf has an obvious method of operation that is readily operated under all lighting conditions.
2. The hardware is capable of being operated with one hand.
3. Operation of the hardware directly interrupts the power to the electromagnetic lock and unlocks the door immediately.
4. Loss of power to the locking system automatically unlocks the door.
5. Where *panic or fire exit hardware* is required by Section 1010.1.10, operation of the *panic or fire exit hardware* also releases the electromagnetic lock.
6. The locking system units shall be listed in accordance with UL 294.

❖ The intent of this section is to provide consistent requirements where an electromagnetic lock is released by door-mounted hardware such as a panic bar, lockset/latchset, or touch-sense bar, all of which would be equipped with an integral switch that, when actuated by the normal actions of opening the door, causes the electromagnetic lock to release allowing immediate egress. In the identified occupancy groups, doors in the means of egress are permitted to be locked with an electromagnetic locking system where equipped with door hardware that incorporates a built-in switch, provided all the specified conditions are met. Additionally, doors to tenant spaces of the identified occupancy groups may be equipped with electromagnetic locks, provided all of the specified conditions are met. The use of this type of locking system may provide for a greater degree of security preventing or controlling access or ingress than that offered by a door with mechanical locking devices alone. The allowance for electromagnetically locked egress doors is limited to low- and moderate-hazard occupancies where security may be a concern.

It may be important to note other "shall be permitted" locking arrangements in the code may also use electromagnetic locks as part of their system. Controlled egress locking systems (Section 1010.1.9.6), delayed egress locking systems (Section 1010.1.9.7), and sensor release of electrically locked door systems (Section 1010.1.9.8) all frequently use electromagnetic locks.

The requirements of this section apply to electromagnetic locking systems which open on hardware activation. The functions of an ingress control locking system are not addressed in the codes and are unre-

lated as long as egress is provided as required or permitted by this section and other applicable provisions of the code.

In areas where additional security may be a concern, a door hardware system may include an unlocking device, such as a keypad, card reader, eye scanner, thumbprint scanner or other credential device. Where these credential unlocking systems are only on the ingress side of a building or space, there are no limitations in the codes. Where these credential unlocking systems are on the egress side of a space (perhaps to monitor personnel movement), egress must be available through one of the locking systems addressed in Section 1010.1.9.7, 1010.1.9.8 or 1010.1.9.9. Such a credential unlocking device could also be included in the controlled locking arrangements of IBC Section 408.4 and Section 1010.1.9.6, Item 6 of the code.

When the occupant prepares to egress through the door, the method of operating the door hardware must be obvious, even under poor lighting conditions. The operation shall be accomplished through the use of a single motion and meet the general requirement that the door be readily openable without the use of special knowledge or effort. The release of the electromagnetic lock on the door must occur immediately on the operation of the door hardware by interrupting the power supply to the electromagnetic lock. This requirement is the same regardless of the type of door hardware: panic hardware, fire exit hardware, a latchset/lockset, or a touch-sense bar. As an additional safeguard, the loss of power to the locking system is required to automatically release the electromagnetic lock on the door.

A properly designed and installed electromagnetic locking system complying with the requirements of this section of the IBC may not be obvious to the occupants, as the door unlatches/unlocks (electromagnetically and mechanically) allowing egress through the normal operation of the door hardware (panic or fire exit hardware, latchset/lockset, or touch-sense bar). Considering these performance requirements, this section of the IBC does not include a requirement that the electromagnetic lock be unlocked (released) on activation of the building fire alarm system. Also, this section of the IBC does not limit the number of doors in the means of egress which may be equipped with electromagnetic locking systems.

The units of the electromagnetic locking system are required to be listed in accordance with UL 294. The UL 294 Access Control Systems standard applies to construction, performance, and operation of systems which control passage through a door, and electrical, electronic, or mechanical units of these systems. Where these special provisions are utilized, the requirements of Section 1010.1.10 regarding panic hardware remain applicable. In Group A and E occupancies having occupant loads of 50 or

more, the door hardware must also comply with the requirements for panic hardware.

**1010.1.9.10 Locking arrangements in correctional facilities.** In occupancies in Groups A-2, A-3, A-4, B, E, F, I-2, I-3, M and S within correctional and detention facilities, doors in *means of egress* serving rooms or spaces occupied by persons whose movements are controlled for security reasons shall be permitted to be locked where equipped with egress control devices that shall unlock manually and by not less than one of the following means:

1. Activation of an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
2. Activation of an *approved manual fire alarm box*.
3. A signal from a *constantly attended location*.

❖ Correctional facilities can include a variety of uses where detainees may be gathered for eating, recreational activities, education, technical training, job training, etc. Correctional facilities can also contain types of support services, such as a store, storage areas or hospital area. Security is still a concern within these areas. This provision will allow the correctional facility to maintain security on all areas. Most commonly the doors would be opened by staff from a central control point under Item 3, but Items 1 and 2 allow for other alternatives in lower security facilities. This provision is not intended to apply to these groups when located outside of a detention or correctional facility.

**1010.1.9.11 Stairway doors.** Interior *stairway means of egress* doors shall be openable from both sides without the use of a key or special knowledge or effort.

**Exceptions:**

1. *Stairway* discharge doors shall be openable from the egress side and shall only be locked from the opposite side.
2. This section shall not apply to doors arranged in accordance with Section 403.5.3.
3. In *stairways* serving not more than four stories, doors are permitted to be locked from the side opposite the egress side, provided they are openable from the egress side and capable of being unlocked simultaneously without unlatching upon a signal from the *fire command center*, if present, or a signal by emergency personnel from a single location inside the main entrance to the building.
4. *Stairway exit* doors shall be openable from the egress side and shall only be locked from the opposite side in Group B, F, M and S occupancies where the only interior access to the tenant space is from a single *exit stairway* where permitted in Section 1006.3.2.
5. *Stairway exit* doors shall be openable from the egress side and shall only be locked from the opposite side in Group R-2 occupancies where the only

interior access to the *dwelling unit* is from a single *exit stairway* where permitted in Section 1006.3.2.

- ❖ Based on adverse fire experience where occupants have become trapped in smoke-filled stairway enclosures, stairway doors generally must be arranged to permit reentry into the building without the use of any tools, keys or special knowledge or effort. For security reasons, this restriction does not apply to the discharge door from the stairway enclosure to the outside or into an exit passageway (Exception 1). Section 403 for high-rise buildings permits locking doors from the stairway side, provided the doors are capable of being unlocked from a fire command station and there is a communication system within the stairway enclosure that allows contact with the fire command station (Exception 2).

Exception 3 addresses the need for security. The exception is limited to four-story buildings to provide a short travel distance to the stairway discharge door for the building occupants. In addition, to allow quick entrance for fire fighters and emergency responders, a means of simultaneously unlocking all of the doors by emergency personnel must be provided. This provision further requires that the stairway doors be unlocked without unlatching. Stairway doors will typically be fire door assemblies, and their continued latching is necessary to maintain the integrity of the fire-resistive separation for the exit enclosure. The remote unlocking signal shall be initiated from the fire command station, if provided, or a single point of signal initiation at an approved location inside the building's main entrance.

Exceptions 4 and 5 allow for stairways in single-exit buildings to have doorways that lead to multiple tenants and dwelling units. For security reasons, those doors can remain locked from the stairway side so no one can enter another tenant space or dwelling unit from the exit stairway.

**1010.1.10 Panic and fire exit hardware.** Doors serving a Group H occupancy and doors serving rooms or spaces with an *occupant load* of 50 or more in a Group A or E occupancy shall not be provided with a latch or lock other than *panic hardware* or *fire exit hardware*.

**Exceptions:**

1. A main *exit* of a Group A occupancy shall be permitted to be locking in accordance with Section 1010.1.9.3, Item 2.
2. Doors serving a Group A or E occupancy shall be permitted to be electromagnetically locked in accordance with Section 1010.1.9.9.

Electrical rooms with equipment rated 1,200 amperes or more and over 6 feet (1829 mm) wide, and that contain over-current devices, switching devices or control devices with *exit* or *exit access doors*, shall be equipped with *panic hardware* or *fire exit hardware*. The doors shall swing in the direction of egress travel.

- ❖ Doors that are part of a means of egress from the locations listed in this section shall not be provided

with a latch or lock other than panic hardware or fire exit hardware unless one of the two exceptions is met. Fire exit hardware is essentially panic hardware with internal modifications for use on fire-rated doors. Also see the commentaries to the definitions for "Fire exit hardware" or "Panic hardware" and Sections 1010.1.10.1 and 1010.1.10.2.

For all Group H occupancies, regardless of the occupant load, if latching (or locking) hardware is installed, it must be panic hardware or fire exit hardware because of the physical hazards of these spaces.

For all doors that provide means of egress for rooms and spaces of assembly and educational (Group A and E) occupancies with an occupant load of 50 or more, if latching (or locking) hardware is installed, it must be panic hardware or fire exit hardware. This would include large assembly spaces in mixed-use buildings. These uses are characterized by higher occupant load densities. Whereas doors from an assembly or educational room with an occupant load of less than 50 do not require panic hardware or fire exit hardware, a door that provides means of egress for two or more such rooms would require panic hardware or fire exit hardware when the combination of spaces has a total occupant load of 50 or more.

The first exception clarifies that the provisions for key-locking hardware at the main exit in Group A occupancies are permitted instead of panic hardware at those specific locations. (For the Group A exception, see the commentary to Section 1010.1.9.3, Item 2.)

The second exception resolves a potential conflict with Section 1010.1.9.9, and specifically Item 5, which allows an electromagnetic lock to be installed in addition to panic or fire exit hardware where panic or fire exit hardware would be required as long as the operation of the panic hardware or fire exit hardware releases the electromagnetic lock.

Certain electrical rooms are required to have panic hardware. Refer to IBC Chapter 27 and *NFPA 70: National Electrical Code*® (NEC) for specific requirements for when panic hardware or fire exit hardware is required. This requirement is applicable only where multiple conditions are present. The type of room regulated creates a potentially hazardous environment. In the event of an electrical accident, the more immediate egress provided by the panic hardware is desirable.

**1010.1.10.1 Installation.** Where *panic* or *fire exit hardware* is installed, it shall comply with the following:

1. *Panic hardware* shall be *listed* in accordance with UL 305.
2. *Fire exit hardware* shall be *listed* in accordance with UL 10C and UL 305.
3. The actuating portion of the releasing device shall extend not less than one-half of the door leaf width.

## MEANS OF EGRESS

4. The maximum unlatching force shall not exceed 15 pounds (67 N).
- ❖ As its name implies, panic hardware is special unlatching and unlocking hardware that is intended to simplify the unlatching and unlocking operation to a single, no more than 15-pound (67 N), force applied in the direction of egress [see Commentary Figures 1010.1.10.1(1) and (2)]. In a panic situation with a rush of persons trying to utilize a door, devices such as doorknobs or thumb turns may cause sufficient delay so as to create a crush at the door and prevent or slow the opening operation.

The locational specifications for the activating panel or bar are based on ready availability and access to the unlatching device. Note that the section requires the width of the actuating portion of the panic hardware or fire exit hardware to measure at least one-half the width of the door leaf. For example, on a 3-0 door (nominal 36 inches wide), the activating portion of the panic or fire hardware would measure at least 18 inches. Panic and fire exit hardware must be listed. UL 305, *Standard for Safety Panic Hardware*, includes construction and performance requirements dealing with endurance, emergency operation, elevated ambient exposure and low-temperature impact tests to ensure that the panic device operates properly (for panic hardware on a balanced door, see Section 1010.1.10.2). The activation device must be mounted between 34 inches and 48 inches (864 mm and 1219 mm) above the floor in accordance with Section 1010.1.9.2. Section 1010.1.1.1 allows the panic hardware to extend the full width of the door as long as it does not protrude more than 4 inches (102 mm) into the door's required minimum clear width.

Standard panic hardware or "listed panic hardware" is not approved for use on fire door assemblies. Panic hardware and fire exit hardware can be similar in appearance.

Where a fire door, such as to an exit stairway, is required to be equipped with panic hardware, the hardware must accomplish the dual objectives of panic hardware and continuity of the enclosure in which it is located—thus the reference to UL 10C, *Standard for Safety Positive Pressure Fire Tests of Door Assemblies*. In this case, fire exit hardware is to be provided that meets both objectives and requirements, since panic hardware is not tested for use on fire doors. There are standard test procedures designed to evaluate the performance of panic and fire exit hardware from the panic standpoint as well as from a fire protection standpoint. "Fire door assemblies" are defined in Section 716.5 as a combination of doors, frame, hardware and other accessories required to provide a specific degree of fire and smoke barrier protection to the opening in a fire wall, fire barrier, fire partition, smoke barrier or exterior wall required to have a fire-resistance rating.

Fire doors must close and positively latch in order to protect exit stairways, corridors and other areas of the building from the spread of smoke and fire. Additionally, fire doors are required to self-close and automatically latch after each use. Positive latching of fire doors is not related to the locking of the door and should never be confused with locking or security issues.

The requirement for positive latching means that dogging devices are not permitted on fire exit hardware. A dogging device is an option on the hardware

For SI: 1 pound = 4.4 N.

**Figure 1010.1.10.1(1)**  
**EXAMPLES OF TYPICAL PANIC HARDWARE**

that allows for the panic hardware to be locked in the fully depressed position. A dogging device mechanically defeats the latching feature of panic hardware preventing the door from positively latching when in the closed position. The dogging device is typically manually activated with a small wrench or tool and is activated through a hole adjacent to the activation bar. Dogging capability is often provided on exterior doors that are intended as building entrances.

Fire exit hardware must be labeled. Typical locations are on either end of the hardware. Information on the label must include the words “listed” and “fire exit hardware” and indicate a control or serial number. The label on the fire door itself should indicate that it is a fire door suitable for use with fire exit hardware.

**1010.1.10.2 Balanced doors.** If *balanced doors* are used and *panic hardware* is required, the *panic hardware* shall be the push-pad type and the pad shall not extend more than one-half the width of the door measured from the latch side.

- ❖ The provisions for balanced doors ensure that the occupants push only on the latch side of the door since the hinge side of a balanced door pivots “against” the direction of egress (see the commentary for the definition of “Door, balanced” in Chapter 2).

**1010.2 Gates.** Gates serving the *means of egress* system shall comply with the requirements of this section. Gates used as a

component in a *means of egress* shall conform to the applicable requirements for doors.

**Exception:** Horizontal sliding or swinging gates exceeding the 4-foot (1219 mm) maximum leaf width limitation are permitted in fences and walls surrounding a stadium.

- ❖ This section specifies that all requirements for doors also apply to gates, except that gates surrounding a stadium are allowed to exceed 4 feet (1219 mm) in width. Usually a large gate is required to adequately serve a stadium crowd for egress purposes.

**1010.2.1 Stadiums.** *Panic hardware* is not required on gates surrounding stadiums where such gates are under constant immediate supervision while the public is present, and where safe dispersal areas based on 3 square feet (0.28 m<sup>2</sup>) per occupant are located between the fence and enclosed space. Such required safe dispersal areas shall not be located less than 50 feet (15 240 mm) from the enclosed space. See Section 1028.5 for *means of egress* from safe dispersal areas.

- ❖ Panic hardware is impractical for large gates that surround stadiums. Normally, these gates are opened and closed by the stadium’s grounds crew, which is constantly in attendance during the use of such gates. The safe dispersal area requirement provides for the safety of the crowd if for some reason the gate is not open. The safe dispersal area is to be between the stadium enclosure and the surrounding fence and

Figure 1010.1.10.1(2)  
EXAMPLES OF TYPICAL PANIC HARDWARE

the area to be occupied is not to be closer than 50 feet (15 240 mm) to the stadium enclosure.

See the commentary for Section 1028.5 for access to a safe dispersal area when access to a public way is not available.

**1010.3 Turnstiles.** Turnstiles or similar devices that restrict travel to one direction shall not be placed so as to obstruct any required *means of egress*.

**Exception:** Each turnstile or similar device shall be credited with a capacity based on not more than a 50-person *occupant load* where all of the following provisions are met:

1. Each device shall turn free in the direction of egress travel when primary power is lost and on the manual release by an employee in the area.
2. Such devices are not given credit for more than 50 percent of the required egress capacity or width.
3. Each device is not more than 39 inches (991 mm) high.
4. Each device has not less than 16½ inches (419 mm) clear width at and below a height of 39 inches (991 mm) and not less than 22 inches (559 mm) clear width at heights above 39 inches (991 mm).

Where located as part of an *accessible route*, turnstiles shall have not less than 36 inches (914 mm) clear at and below a height of 34 inches (864 mm), not less than 32 inches (813 mm) clear width between 34 inches (864 mm) and 80 inches (2032 mm) and shall consist of a mechanism other than a revolving device.

❖ This section provides for a limited use of turnstiles to serve as a means of egress component. The exception to this section limits each turnstile to a maximum egress capacity of 50 persons. The turnstile must comply with all four listed items to be considered as serving any part of the occupant load for means of egress. The turnstiles must rotate freely both when there is a loss of power and when they are manually released. Note that the 50-person limit applies to each individual turnstile. These provisions are similar to the revolving door provisions in Section 1010.1.4.1.

If turnstiles are located along an accessible route, the route for persons using mobility devices must be something other than a revolving device, such as a swinging gate. A common example would be the turnstiles for automatic ticket taking, such as at the entrance to a mass transit platform.

**1010.3.1 High turnstile.** Turnstiles more than 39 inches (991 mm) high shall meet the requirements for revolving doors.

❖ Where a turnstile is higher than 39 inches (991 mm), the restriction to egress is much like a revolving door. Thus, the egress limitations for revolving doors in Section 1010.1.4.1 apply to this type of turnstile. If a high turnstile does not meet the revolving door requirements for doors that are an egress component, it is not to be included as serving a portion of the means of egress. It would be necessary to pro-

vide doors in these areas for egress. High turnstiles may not be part of an accessible route for ingress or egress.

**1010.3.2 Additional door.** Where serving an *occupant load* greater than 300, each turnstile that is not portable shall have a side-hinged swinging door that conforms to Section 1010.1 within 50 feet (15 240 mm).

❖ This section addresses a common egress condition for sports arenas where a number of turnstiles are installed for ticket taking. Portable turnstiles are moved from the egress path for proper exiting capacity. Permanent turnstiles are not considered as providing any of the required egress capacity when serving an occupant load greater than 300, no matter how many turnstiles are installed. Doors are required to provide occupants with a path of egress other than through the turnstiles. The doors are to be located within 50 feet (15 240 mm) of the turnstiles.

## SECTION 1011 STAIRWAYS

**1011.1 General.** *Stairways* serving occupied portions of a building shall comply with the requirements of Sections 1011.2 through 1011.13. *Alternating tread devices* shall comply with Section 1011.14. Ship's ladders shall comply with Section 1011.15. Ladders shall comply with Section 1011.16.

**Exception:** Within rooms or spaces used for assembly purposes, stepped aisles shall comply with Section 1029.

❖ It is important for stairway safety that all stairways meet the provisions in this section. This would include all elevation changes using stairways; everything from one riser to multiple flights and landings between stories (see the definitions for "Stair" and "Stairway" in Chapter 2). These provisions will be applicable for interior exit access stairways, interior exit stairways and exterior exit stairways, as well as any steps along the paths for exit access or exit discharge. It is intended that this section be applicable to required stairways as well as what can be called "convenience" stairways.

It is important to understand the terminology. Exit stairways are stairways that provide a protected path of travel between the exit access and the exit discharge. Interior exit stairways are required to be enclosed in accordance with Section 1022. Exterior exit stairways are protected by the exterior wall of the building and must comply with Section 1027. Exit access stairways are typically unenclosed interior stairways and comply with Section 1019 when they provide access between stories. Exit access travel distance stops at an exit stairway enclosure, but includes any travel down an exit access stairway. Stairways that are outside and provide a route from the level of exit discharge to grade are considered part of the exit discharge. See the commentary in Chapter 2 for the defined term, "Exit discharge, level of."

Sections 1011.2 through 1011.13 provide criteria for the typical stairway. Special provisions are pro-

vided for curved stairways (Section 1011.9), spiral stairways (Section 1011.10), and stairways to the roof for fire department access and for elevator equipment service (Sections 1011.12 and 1011.13).

Items that provide vertical access similar to stairways are also addressed in this section: alternating tread devices (Section 1011.14), ship's ladders (Section 1011.15) and ladders (Section 1011.16). These devices are only permitted to provide access to very limited spaces.

The exception indicates that stepped aisles (previously called aisle stairs) are addressed in Section 1029. Having this exception at the beginning of the stairway section negated the need for repeated exceptions throughout the stairway provisions. While both stairways and stepped aisles are a series of treads and risers, how occupants move on and off and configurations are very different. Occupants leave and join stepped aisles along the entire run, while occupants only enter the stairways at the top and bottom. Stepped aisles have center handrails with breaks to allow for access into the seating, while most stairways have handrails on both sides. Stepped aisles can be nonuniform in some locations to allow for parabolic seating bowls, while with stairways, uniform tread and riser configurations are required. Section 1029 should be used for stepped aisles between and immediately adjacent to seating or where the steps are a direct continuation of the stepped aisles and lead to a level cross aisle or floor. Section 1011 is used for stairways that lead from the balcony, concourse or cross aisle to a floor level above or below the seating areas (see Sections 1011.5.2, 1011.5.4 and 1011.6).

**1011.2 Width and capacity.** The required capacity of stairways shall be determined as specified in Section 1005.1, but the minimum width shall be not less than 44 inches (1118 mm). See Section 1009.3 for accessible means of egress stairways.

**Exceptions:**

1. Stairways serving an occupant load of less than 50 shall have a width of not less than 36 inches (914 mm).
2. Spiral stairways as provided for in Section 1011.10.
3. Where an incline platform lift or stairway chairlift is installed on stairways serving occupancies in Group R-3, or within dwelling units in occupancies in Group R-2, a clear passage width not less than 20 inches (508 mm) shall be provided. Where the seat and platform can be folded when not in use, the distance shall be measured from the folded position.

❖ To provide adequate space for occupants traveling in opposite directions and to permit the intended full egress capacity to be developed, minimum dimensions are dictated for means of egress stairways. A minimum width of 44 inches (1118 mm) is required for stairway construction to permit two columns of

users to travel in the same or opposite directions. The reference to Section 1005.1 is for the determination of stairway width based on the occupant load it will serve (i.e., capacity). The larger of the two widths is to be used.

Exception 1 recognizes the relatively small occupant loads of less than 50 that permit a staggered file of users when traveling in the same direction. When traveling in opposite directions, one column of users must stop their ascent (or descent) to permit the opposite column to continue. Again, considering the relatively small occupant loads, any disruption of orderly flow will be infrequent. The use of this exception is limited to buildings where the entire occupant load of each upper story and/or basement is less than 50.

Exception 2 permits a spiral stairway to have a minimum width of 26 inches (660 mm) when it conforms to Section 1011.10, on the basis that the configuration of a spiral stairway will allow nothing other than single-file travel.

Exception 3 addresses the use of inclined platform lifts or stairway chairlifts for individual dwelling units. For clarification on the types of lifts, see the commentary to IBC Section 1109.8. Both types of lifts may be installed to aid persons with mobility impairments in their homes. The code and ASME A18.1 allow for a reduction in the width of the stair to a minimum of 20 inches (508 mm) of clear passageway to be maintained on a stairway where a lift is located. If a portion of the lift, such as a platform or seat, can be folded, the minimum clear dimension is to be measured from the folded position. If the lift cannot be folded, then the 20 inches (508 mm) is measured from the fixed position. The track for these lifts typically extends 9 to 12 inches (229 to 305 mm) from the wall, making the 20-inch (508 mm) clear measurement actually 24 to 27 inches (610 to 686 mm) from the edge of the track.

The code does not have any specific provisions for where incline platform lifts are utilized along stairways in locations other than within dwelling units. IBC Section 1109.8 limits the use of platform lifts in new construction to mainly areas with minimal occupant loads or where elevators and ramps are impracticable. IEBC Section 410.8.3 and IBC Section 705.1.3 allow for platform lifts anywhere in existing buildings in order to gain accessibility for persons with mobility impairments. When in the closed and off position, the platform lifts should not block the clear width required for the stairway, or use of the handrails. The industry is currently working on different options to address the concern that the lift may be in operation during an event that requires evacuation.

**1011.3 Headroom.** Stairways shall have a headroom clearance of not less than 80 inches (2032 mm) measured vertically from a line connecting the edge of the nosings. Such headroom shall be continuous above the stairway to the point where the line intersects the landing below, one tread depth

## MEANS OF EGRESS

beyond the bottom riser. The minimum clearance shall be maintained the full width of the *stairway* and landing.

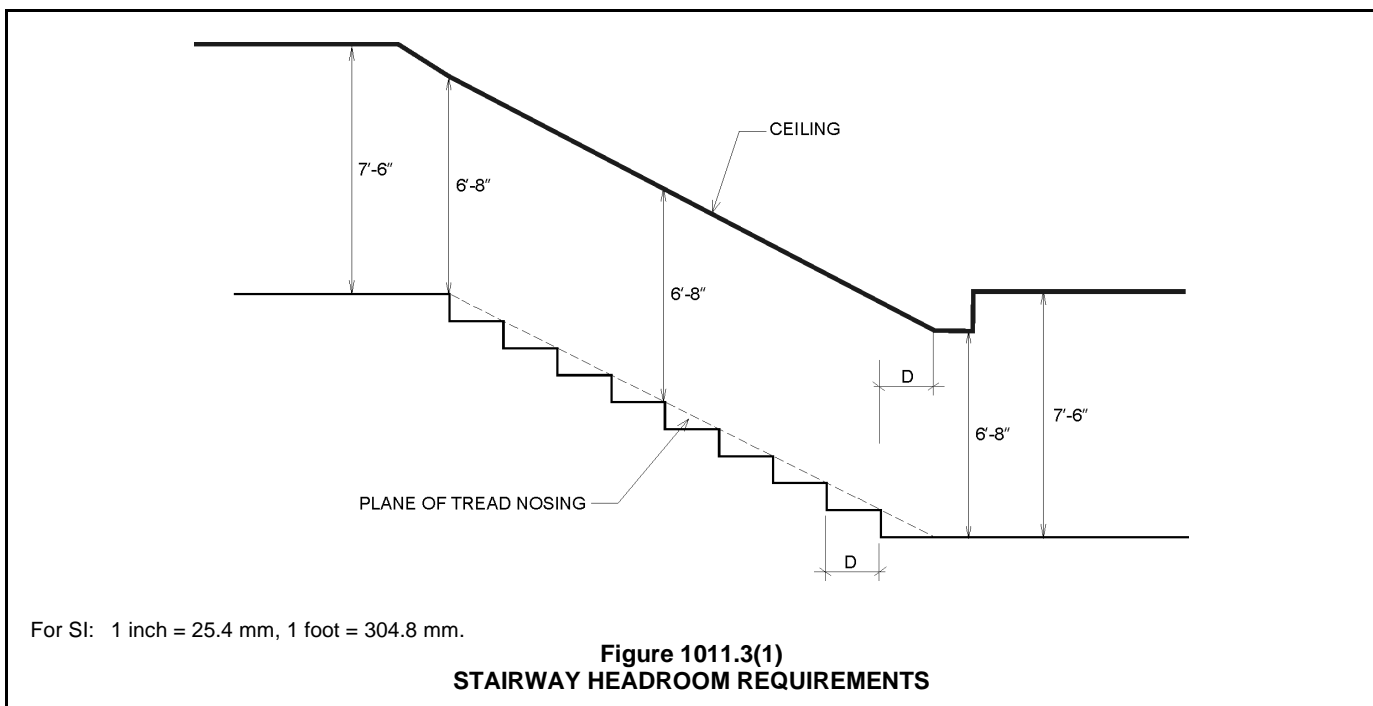

### Exceptions:

1. *Spiral stairways* complying with Section 1011.10 are permitted a 78-inch (1981 mm) headroom clearance.
  2. In Group R-3 occupancies; within *dwelling units* in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual *dwelling units* in Group R-2 occupancies; where the *nosings* of treads at the side of a *flight* extend under the edge of a floor opening through which the *stair* passes, the floor opening shall be allowed to project horizontally into the required headroom not more than 4<sup>3</sup>/<sub>4</sub> inches (121 mm).
- ❖ This headroom requirement is necessary to avoid an obstruction to orderly flow and to provide visibility to the users so that the desired path of travel can be planned and negotiated. Height is a vertical measurement above every point along the stairway stepping and walking surfaces, with minimum height measured vertically from the tread nosing or from the surface of a landing or platform up to the ceiling [see Commentary Figure 1011.3(1)].
- Section 1003.2 and IBC Section 1208.2 require a minimum ceiling height within a room of 7 feet, 6 inches (2307 mm). A bulkhead or doorway at the bottom of the stairway would be allowed to meet the minimum headroom height of 80 inches (2032 mm), as permitted in Section 1003.3.
- Exception 1, allowing for a clear headroom of 6 feet, 6 inches (1981 mm) for spiral stairs, correlates with the provisions of Section 1011.10.

Exception 2 recognizes a common method of stairwell construction in which the stringer on the open side of a stair is supported by the same floor joists or wall that supports the edge of the opening through which the stairway passes to the floor above, thus resulting in the stairway being wider at the lower portion than at the top portion. In this case, headroom is not required for a distance of up to 4<sup>3</sup>/<sub>4</sub> inches (121 mm) measured horizontally from the edge of the opening above to the handrail or guard system, which limits the clear width on the lower open sides of the stairway. The 4<sup>3</sup>/<sub>4</sub> inches (121 mm) maximum is derived from the finished width of a typical 2 by 4 supporting wall and is not critical to obstructing orderly flow or visibility in the desired path of travel [see Commentary Figure 1011.3(2)].

**1011.4 Walkline.** The walkline across *winder* treads shall be concentric to the direction of travel through the turn and located 12 inches (305 mm) from the side where the *winders* are narrower. The 12-inch (305 mm) dimension shall be measured from the widest point of the clear *stair* width at the walking surface of the *winder*. Where *winders* are adjacent within the *flight*, the point of the widest clear *stair* width of the adjacent *winders* shall be used.

❖ This requirement is essential for smooth, consistent travel on stairs that turn with winder treads. It provides a standard location for the regulation of the uniform tread depth of winders. Because of the wide range of anthropometrics of stairway users, there is no one line that all persons will travel on stairs; however, the code recognizes a standard location of a walkline is essential to design and enforcement. Each footfall of the user through the turn can be associated with an arc to describe the path traveled. As a user ascends or descends the flight, the turning at each

step should be consistent through the turn. The walkline is established concentric to, or having the same center (approximately parallel) as, the arc of travel of the user. The tread depth dimension at the walkline is one of two tread depths across the width of the stair at which winder tread depth is regulated, cited in Section 1011.5.2. The second is the minimum tread depth. Regulation at these two points controls the angularity of the turn and the configuration of the flight. In order to establish consistently shaped winders, tread depths must always be measured concentric to the arc of travel. The walkline is unique as the only line or path of travel where winder tread depth is controlled by the same minimum tread depth as rectangular treads. However, Exception 2 of Section 1011.5.4 recognizes that winder tread depth need not be compared to rectangular tread depths for dimensional uniformity in the same flight because the location of the walkline is chosen for the purpose of providing a standard and cannot be specific to the variety of actual paths followed by all users. This specific line location is determined by measuring along each nosing edge 12 inches (305 mm) from the extreme of the clear width of the stair at the surface of the winder tread or the limit of where the foot might be placed in use of the stair. If adjacent winders are present, the point of the widest clear stair width at the surface of the tread in the group of adjacent consecutive winders is used to provide the reference from which the 12-inch (305 mm) dimension will be measured along each nosing. The tread depth may be determined by measuring between adjacent nosings at these determined intersections of the nosings with

the walkline. It is important to note that the clear stair width is only that portion of the stair width that is clear for passage. Portions of the stair beyond the clear width are not consequential to use of the stair, consistent travel or location of the walkline.

**1011.5 Stair treads and risers.** *Stair* treads and risers shall comply with Sections 1011.5.1 through 1011.5.3.

❖ The provisions for treads and risers contribute to the efficient use of the stairway, facilitating smooth and consistent travel. This section provides dimensional ranges and tolerances for the component elements to allow the flexibility required to design and construct a stair or a flight of stairs that are elements of a stairway. The allowed proportion of maximum riser height and minimum tread depth provide for a maximum angle of ascent but there is no maximum tread depth to consider with the minimum riser height that would define a minimum angle for a stairway. Nor is the proportion of riser height to tread depth compared with the limitations of the length of the user's stride on stairways, which is significantly foreshortened from the user's stride on the level. For this reason, care should be taken when incorporating larger tread depths and controlling the point at which a tread might be wide enough to require more than one step to cross, which can vary significantly when considering ascent and descent movement patterns. Especially in areas where all segments of the public might use the stairs, those persons requiring two smaller sequential steps to cross the tread would progress at significantly different rates than those who might be able to stretch or jump and lead to dangerous compli-

**Figure 1011.3(2)**  
**EXAMPLE OF SECTION 1011.3, EXCEPTION 2**

cations, especially in egress. Of equal significance is the use of shorter risers without increasing tread depth resulting in a proportion that could cause overstepping. With these same limitations for proportion in mind, however, by controlling the minimum depth of rectangular treads and the minimum depth and angularity of winder treads, these components can control the configuration of the plan of a flight of stairs to provide for smooth and consistent travel.

Section 1011.5.1 provides for consistent identification of the surfaces that are to be measured. This is as critical to the users' experience throughout the built environment as it is to determining all the dimensions in this section as they must relate to each other and the ultimate design and construction of a safe stairway.

The remaining sections address the uniformity and essential attributes of the tread and riser. Of particular note is the nosing or leading edge of the tread. The nosing shape and projection affect the determination of the tread depth and the riser height and are regulated at all steps throughout the stairway, including the nosings at landings to provide for smooth and consistent travel. Furthermore, the line connecting the nosings is used to determine handrail height, guard height and headroom, causing consistent nosings to be a dependent integral of every element of the stairway design, construction and regulation.

**1011.5.1 Dimension reference surfaces.** For the purpose of this section, all dimensions are exclusive of carpets, rugs or runners.

❖ Carpets, rugs and runners, like furniture, are frequently changed by the occupants and are not regulated by the code. For this reason it is essential that the riser height and tread depth be regulated exclusive of these transitory surfaces to provide an enforceable standard. This practice minimizes the possible variation because of the removal of nonpermanent carpeting throughout the life of a structure and provides a standard enforcement methodology that will provide consistency across the build environment for all users. When owners or occupants add carpeting, rugs or runners, they need to add it to all tread and landing surfaces in the stairway. It is important that the tread and landing surfaces are consistent and comply with the code prior to the addition of carpet. This methodology of enforcement makes it unnecessary to reconstruct floor and stair elevations in the stairway when nonpermanent carpet surfaces are changed that do not require a building permit and eliminates the resulting variations in the built environment that will not comply with the tolerance in Section 1011.5.4 (see Commentary Figure 1011.5.1).

**1011.5.2 Riser height and tread depth.** *Stair* riser heights shall be 7 inches (178 mm) maximum and 4 inches (102 mm) minimum. The riser height shall be measured vertically between the *nosings* of adjacent treads. Rectangular tread depths shall be 11 inches (279 mm) minimum measured horizontally between the vertical planes of the foremost projec-

tion of adjacent treads and at a right angle to the tread's *nosing*. *Winder* treads shall have a minimum tread depth of 11 inches (279 mm) between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline and a minimum tread depth of 10 inches (254 mm) within the clear width of the *stair*.

**Exceptions:**

1. *Spiral stairways* in accordance with Section 1011.10.
2. *Stairways* connecting stepped *aisles* to cross *aisles* or concourses shall be permitted to use the riser/tread dimension in Section 1029.13.2.
3. In Group R-3 occupancies; within *dwelling units* in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual *dwelling units* in Group R-2 occupancies; the maximum riser height shall be 7<sup>3</sup>/<sub>4</sub> inches (197 mm); the minimum tread depth shall be 10 inches (254 mm); the minimum *winder* tread depth at the walkline shall be 10 inches (254 mm); and the minimum *winder* tread depth shall be 6 inches (152 mm). A *nosing* projection not less than <sup>3</sup>/<sub>4</sub> inch (19.1 mm) but not more than 1<sup>1</sup>/<sub>4</sub> inches (32 mm) shall be provided on *stairways* with solid risers where the tread depth is less than 11 inches (279 mm).
4. See Section 403.1 of the *International Existing Building Code* for the replacement of existing *stairways*.
5. In Group I-3 facilities, *stairways* providing access to guard towers, observation stations and control rooms, not more than 250 square feet (23 m<sup>2</sup>) in area, shall be permitted to have a maximum riser

height of 8 inches (203 mm) and a minimum tread depth of 9 inches (229 mm).

- ❖ The riser height—the vertical dimension from tread surface to tread surface or tread surface to landing surface—is typically limited to not more than 7 inches (178 mm) or less than 4 inches (102 mm). The minimum tread depth—the horizontal distance from the leading edge (nosing) of one tread to the leading edge (nosing) of the next adjacent tread or landing—is typically limited to not less than 11 inches (279 mm) [see Commentary Figure 1011.5.2]. The minimum tread depth of 11 inches (279 mm) is intended to accommodate the largest shoe size found in 95 percent of the adult population, allowing for an appropriate overhang of the foot beyond the tread nosing while descending a stairway. Tread depths under 11 inches (279 mm) could cause a larger overhang (depending on the size of the foot) and could force users with larger feet to increase the angle of their foot to the line of travel while descending a stairway. Based on the probability of adequate foot placement, the rate of misstep with various step sizes and consideration for the user’s comfort and energy expenditure, it was agreed that the 11-inch (279 mm) minimum tread depth and maximum 7-inch (178 mm) riser height resulted in the reasonable proportion of riser height and tread depth for stairway construction. A minimum riser height of 4 inches (102 mm) is considered to allow the visual identification of the presence of the riser in ascent or descent.

The precise location of rectangular tread depth and riser measurements is to be perpendicular to the tread’s nosing or leading edge. This is to duplicate the user’s anticipated foot placement in traveling the stairway.

The size for a winder tread is also considered for

proper foot placement along the walkline [see Commentary Figure 1011.9 and the commentary for Section 1011.4]. The dimensional requirements are consistent with the straight tread.

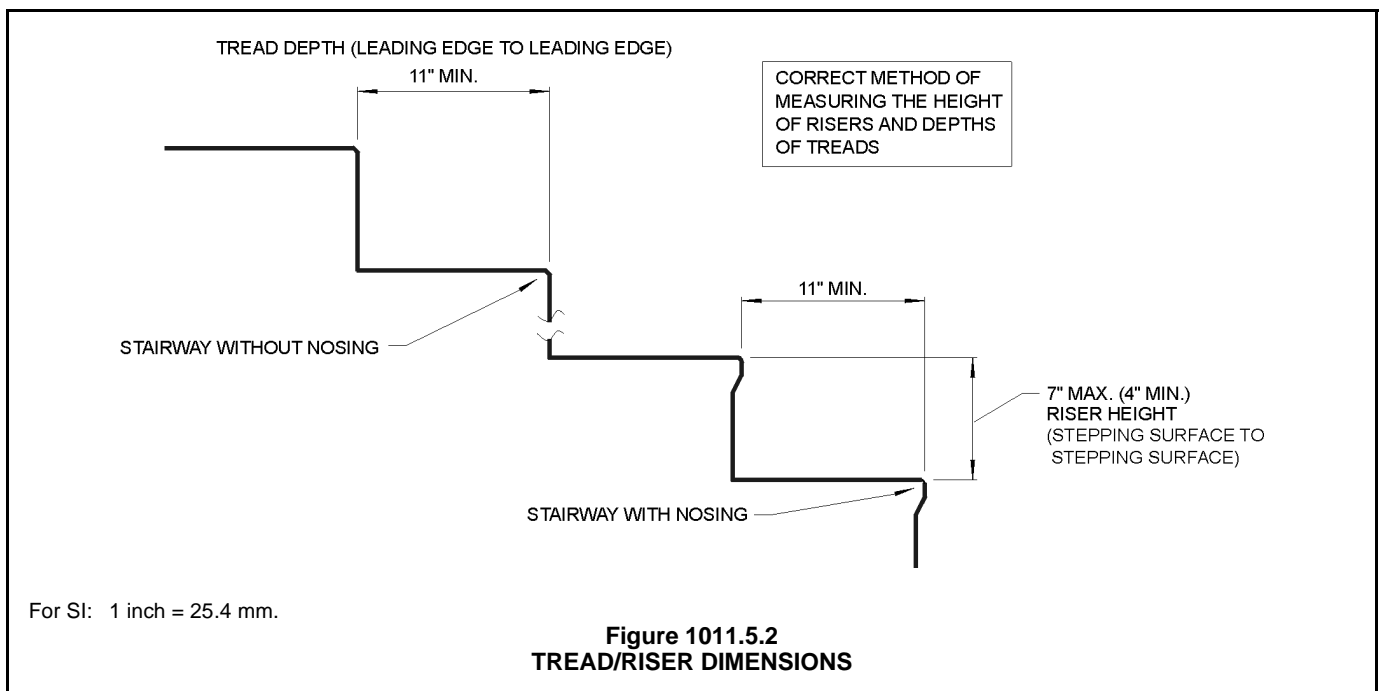

The exceptions apply only to the extent of the text of each exception. For example, the entire text of Section 1011.5.2 is set aside for spiral stairways conforming to Section 1011.10 (see Exception 3). However, Exception 3 allows a different maximum riser and minimum tread under limited conditions, but retains the minimum riser height and measurement method of Section 1011.5.2.

The requirements for dimensional uniformity are found in Sections 1011.5.4 and 1011.5.4.1.

Exception 1 is for spiral staircases, a unique type of stairway. Section 1011.5.2 is not applicable to this stair type, again because of construction issues and limited applications. For a discussion on spiral staircases, see Section 1011.10.

Exception 2 provides a practical exception where assembly facilities are designed for viewing. See Sections 1029.13 through 1029.13.2.4 for assembly stepped aisle-walking surfaces. This exception is limited to when stairways are a direct continuation of the path of travel from the level cross aisle to the stepped aisles. It is not permitted for other stairways within the assembly space.

Exception 3 allows revisions to the 7 inches/11 inches (178 mm/279 mm) riser/tread requirements for Group R-3 and any associated utility (such as barns, connected garages or detached garages) and within individual units of Group R-2 and their associated utility areas (such as attached garages). This change is allowed because of the low occupant load and the high degree of occupant familiarity with the stairways. When this exception is taken for stairways that have

## MEANS OF EGRESS

solid risers, each tread is required to have a nosing projection with a minimum dimension of  $\frac{3}{4}$  inch (19.1 mm) and maximum dimension of  $1\frac{1}{4}$  inches (32 mm) where the tread depth is less than 11 inches (279 mm). Nosing projections are created where the nosing of the tread above extends beyond the trailing edge of the tread below or when a solid riser is angled under the tread above and connected to the trailing edge of the tread below. Nosing projections are not required for residential stairs with open risers and 10-inch (254 mm) treads. A nosing projection provides a greater stepping surface for those ascending the stairway. For users descending the stairway, the nosing projection allows the toe of the foot to be placed further away from the riser above, providing the necessary clearance for the heel of the foot as it swings down in an arc to its position on the tread (see Commentary Figure 1011.5.3).

Exception 4 allows for the replacement of an existing stair. Where a change of occupancy would require compliance with current standards, this exception allows a stairway that may be steeper than that permitted, provided it does not constitute a hazard [see *International Existing Building Code*<sup>®</sup> (IEBC<sup>®</sup>) Section 403.1].

Exception 5 allows steeper stairs in spaces of not more than 250 square feet (23 m<sup>2</sup>) in correctional facilities (Group I-3) with a maximum riser height of 8 inches (203 mm) and a minimum tread depth of 9 inches (229 mm) because of the minimal occupant load and the familiarity of the users with the stairway. Although not stated in this exception, utilizing a nosing projection to provide effective tread depth, as

stated in Exception 3 for tread depths less than 11 inches (279 mm), is a good design practice.

**1011.5.3 Winder treads.** *Winder* treads are not permitted in *means of egress stairways* except within a *dwelling unit*.

### Exceptions:

1. Curved *stairways* in accordance with Section 1011.9.
2. *Spiral stairways* in accordance with Section 1011.10.

❖ The intent of this section is to coordinate the general provisions for stairway tread and riser dimensions in Section 1011.5.2 with the provisions for winder treads permitted in curved and spiral stairways (see Sections 1011.9 and 1011.10). Winders are permitted in *means of egress stairways* within *dwelling units* where occupant loads are smaller and occupants have increased familiarity (see Commentary Figure 1011.5.3 and Section 1011.5.2, Exception 3). This is consistent with provisions in the *International Residential Code*<sup>®</sup> (IRC<sup>®</sup>).

Winders are used to change the direction of a flight by introducing a consistent incremental turn associated with each tread. The risk of injury in the use of stairways constructed with winders is considered to be greater than for stairways constructed as straight runs where users may be restricted by the presence of other users limiting visual clues or influencing the rate of travel. Additional user attention in the turn and the aid of the turn in arresting falls similar to turns at landings is also understood to negate this.

The employment of winders in stairway construction may necessitate the change of the user's gait in both ascent and descent where the tread depth of the winder is not equal to the tread depth of any rectangular treads in the same flight. For example, a person descending a straight flight of stairs will develop a particular gait conforming to the proportion of the riser height and tread depth that will be consistent throughout the flight. However, in a flight that includes winders and rectangular treads, the user must accommodate a change in the proportion of the riser height and tread depth as determined by the path of travel chosen. Visual clues are important to the users' instinctive responses to alter the path of travel, the length of the stride, or a combination of both that may result in nonconcentric movement. To ensure users of the visual clues necessary to alter their gait and limit the need to alter the path of travel in conditions of higher occupant loading, flights with winders must meet the specific safety provisions listed for curved or spiral stairways unless they are within a dwelling unit.

**1011.5.4 Dimensional uniformity.** *Stair* treads and risers shall be of uniform size and shape. The tolerance between the largest and smallest riser height or between the largest and smallest tread depth shall not exceed  $\frac{3}{8}$  inch (9.5 mm) in any *flight of stairs*. The greatest *winder* tread depth at the

walkline within any *flight of stairs* shall not exceed the smallest by more than  $\frac{3}{8}$  inch (9.5 mm).

**Exceptions:**

1. *Stairways* connecting stepped *aisles* to cross *aisles* or concourses shall be permitted to comply with the dimensional nonuniformity in Section 1029.13.2.
2. Consistently shaped *winders*, complying with Section 1011.5, differing from rectangular treads in the same *flight of stairs*.
3. Nonuniform riser dimension complying with Section 1011.5.4.1.

❖ Dimensional uniformity in the design and construction of stairways contributes to safe stairway use. When ascending or descending a stair, users establish a gait based on the instinctive expectation or “feel” that each step taken will be at the same height and will land in approximately the same position on the tread as the previous steps in the pattern. A change in tread or riser dimensions in a stairway flight in excess of the allowed dimensional tolerance can break the rhythm and cause a misstep, stumbling or physical strain that may result in a fall or serious injury. Therefore, this section limits the dimensional variations to a tolerance of  $\frac{3}{8}$  inch (9.5 mm) between the largest and smallest riser or tread dimension in a flight of stairs. A “flight” of stairs is defined as a run of stairs between landings.

For special conditions of construction and as a practical matter, this section allows some greater variations in stairway tread and riser dimensions than the general limitations specified above.

Exception 1 provides a practical exception where

assembly facilities are designed for viewing. See Sections 1029.13 through 1029.13.2.4 for assembly stepped aisle walking surfaces. This exception is limited to when stairways are a direct continuation of the path of travel from the level cross aisle to the stepped aisles. It is not permitted for other stairways within the assembly space.

Exception 2 addresses winder treads, which must be consistent along the walkline (see Commentary Figure 1011.5.4) when compared to other winder treads in the same flight but are not required to meet the tolerance when compared to the uniform dimension of rectangular treads in the same flight.

Exception 3 is in recognition of the situation where a stairway moves down to a surface that slopes up or down perpendicular to the stairway. See the commentary to Section 1105.4.1.

**1011.5.4.1 Nonuniform height risers.** Where the bottom or top riser adjoins a sloping *public way*, walkway or driveway having an established grade and serving as a landing, the bottom or top riser is permitted to be reduced along the slope to less than 4 inches (102 mm) in height, with the variation in height of the bottom or top riser not to exceed one unit vertical in 12 units horizontal (8-percent slope) of *stair width*. The *nosings* or leading edges of treads at such nonuniform height risers shall have a distinctive marking stripe, different from any other *nosing* marking provided on the *stair flight*. The distinctive marking stripe shall be visible in descent of the *stair* and shall have a slip-resistant surface. Marking stripes shall have a width of not less than 1 inch (25 mm) but not more than 2 inches (51 mm).

❖ This section addresses the situation where the bottom riser of a flight of stairways meets a sloped land-

**Figure 1011.5.4**  
**CONSISTENTLY SHAPED WINDERS**

ing, such as a public way, walk or driveway (see Commentary Figure 1011.5.4.1). Because the sidewalk landing is sloped perpendicular to the stairway run, stepping off the bottom tread on one side will result in a higher riser than stepping off the bottom tread on the other side. This is permitted provided the bottom riser is marked so that someone using the stairs will be aware of the hazard of a nonuniform riser.

**1011.5.5 Nosing and riser profile.** *Nosings* shall have a curvature or bevel of not less than  $\frac{1}{16}$  inch (1.6 mm) but not more than  $\frac{9}{16}$  inch (14.3 mm) from the foremost projection of the tread. Risers shall be solid and vertical or sloped under the tread above from the underside of the *nosing* above at an angle not more than 30 degrees (0.52 rad) from the vertical.

❖ The profiles of treads and risers contribute to stairway safety. The radius or bevel of the nosing eases the otherwise square edge of the tread and prevents irregular chipping and wear that can become a maintenance issue and seriously affect the safe use of the stair. The minimum curvature or bevel of  $\frac{1}{16}$  inch (1.6 mm) eliminates a sharp square edge that will cause greater injury in falls and provides a certain contrast from the other surfaces of the stair for easier visual location of the start of the tread surface. The  $\frac{9}{16}$ -inch (14.3 mm) limit of beveling and maximum radius of curvature at the leading edge of the tread is intended to allow descending foot placement on a surface that does not pitch the foot forward or allow the ball of the foot to slide off the treads and ascending foot placement to slide onto the tread without catching on a square edge. This section also states that risers shall be solid; however, Section 1011.5.5.3 specifically states exceptions to this requirement that are to be applied. The sloping of risers allows the step profile to have a nosing projection without a lip that might cause a foot to catch when dragged up the face of the riser. Such designs are subject to the maximum nosing projection stated in Section 1011.5.5.1 that must

be considered when choosing the angle to slope the riser.

**1011.5.5.1 Nosing projection size.** The leading edge (*nosings*) of treads shall project not more than  $1\frac{1}{4}$  inches (32 mm) beyond the tread below.

❖ A nosing projection allows the descending foot to be placed further forward on the tread and the heel to then clear the nosing of the tread above as it swings down in an arc, landing on a tread that is effectively deeper than if no nosing projection is used. Nosing projections are so common in stair design that they are usually only noticed by users when they are absent since the lack of nose projection can affect one's gait. Treads with vertical risers are allowed with or without a nosing projection. A nosing projection may also be accommodated by slanting the riser under the tread above. The nosing projection is limited to  $1\frac{1}{4}$  inch (32 mm) maximum. Treads designed with rounding or bevel on the underside would reduce the chance that a user's toe might catch while ascending the stairway (see Commentary Figure 1011.5.5.1).

**1011.5.5.2 Nosing projection uniformity.** *Nosing* projections of the leading edges shall be of uniform size, including the projections of the *nosing's* leading edge of the floor at the top of a *flight*.

❖ See the commentary to Section 1011.5.5.1.

**1011.5.5.3 Solid risers.** Risers shall be solid.

**Exceptions:**

1. Solid risers are not required for *stairways* that are not required to comply with Section 1009.3, provided that the opening between treads does not permit the passage of a sphere with a diameter of 4 inches (102 mm).
2. Solid risers are not required for occupancies in Group I-3 or in Group F, H and S occupancies other

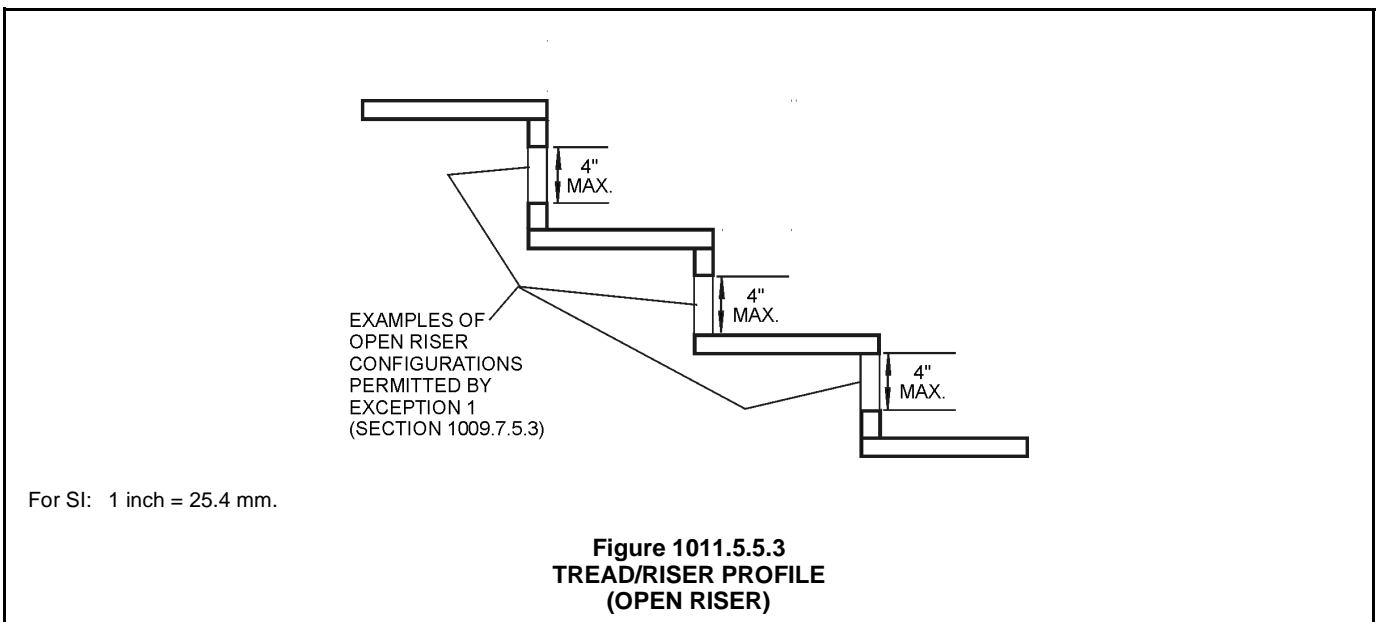

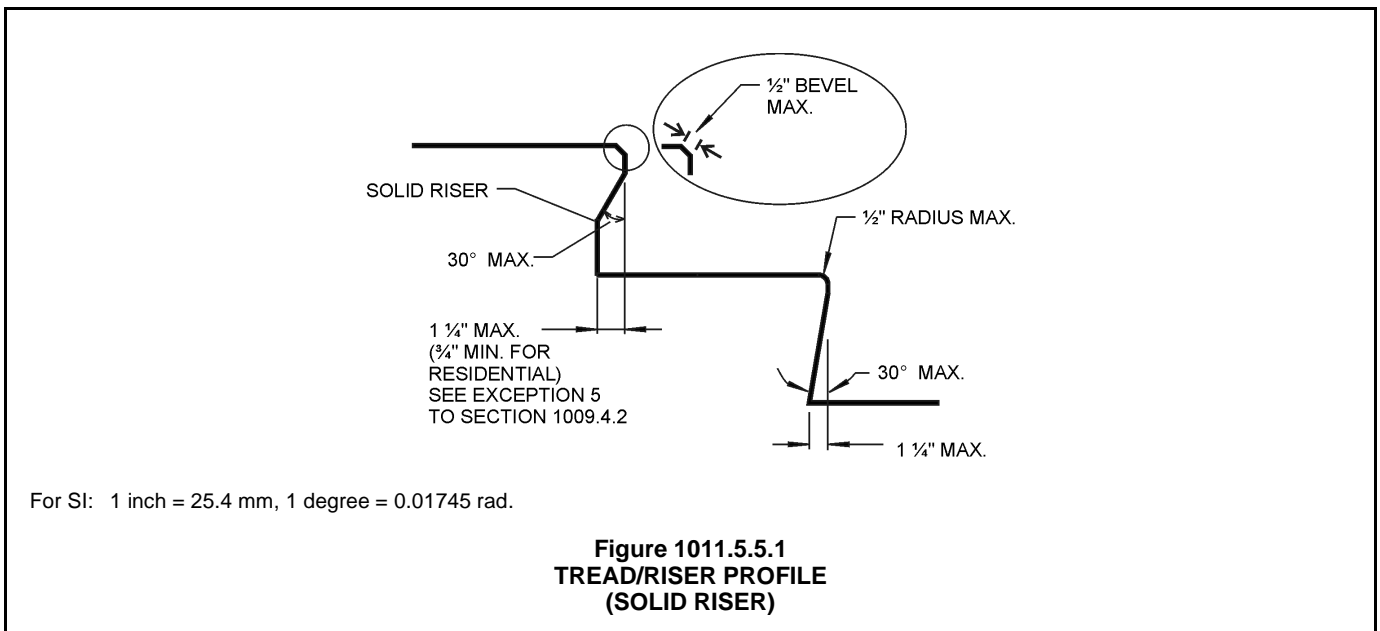

**Figure 1011.5.4.1 SLOPED LANDING**

than areas accessible to the public. There are no restrictions on the size of the opening in the riser.

3. Solid risers are not required for *spiral stairways* constructed in accordance with Section 1011.10.

❖ The code does not address when a riser could contain openings and still be considered “solid.” However, the intent is so that someone would not catch their toe as they moved up the stairway (see the commentary for nosing projections in Section 1011.5.5). It is not the intent to prohibit risers made of grills or other designs where a toe would not catch. Grill stairways are often used in exterior locations to allow for the passage of snow or rain and decrease the chance of accumulation and possible slips and falls on the stairways.

Exception 1 allows the use of open risers on all stairs that are not part of an accessible means of egress. Where the riser is allowed to be open, the opening is limited to be consistent with the requirements for guards (see Commentary Figure 1011.5.5.3). While not required, the second option shown in Commentary Figure 1011.5.5.3 would limit the possibility of a toe catch as someone moved up the stairways and would be a safer design. The code does not reference ICC A117.1 for stairways, because stairways are not part of an accessible route; however, the code and standard provide opening limitations in tread surfaces. Section 1011.7.1 does allow for treads to have a maximum opening that allows for a 1/2-inch (12.7 mm) sphere.

Exception 2 recognizes that open risers are commonly used for stairs in occupancies such as detention facilities, storage, industrial and high-hazard areas for practical reasons. In detention facilities, open risers provide a greater degree of security and supervision because people cannot effectively conceal themselves behind the stair. Factories, high-hazard buildings and storage facilities have areas where workers may need the open risers to decrease the chance of spillage, water or snow accumulating on the stairs. See Section 1011.7.1 for permitted openings in the treads.

Exception 3 recognizes open risers as necessary for adequate foot placement in spiral stairways. The 4-inch (102 mm) opening limitations of Exception 1 are not applicable to spiral stairways.

**1011.6 Stairway landings.** There shall be a floor or landing at the top and bottom of each *stairway*. The width of landings shall be not less than the width of *stairways* served. Every landing shall have a minimum width measured perpendicular to the direction of travel equal to the width of the *stairway*. Where the *stairway* has a straight run the depth need not exceed 48 inches (1219 mm). Doors opening onto a landing shall not reduce the landing to less than one-half the required width. When fully open, the door shall not project more than 7 inches (178 mm) into a landing. Where *wheelchair spaces* are required on the *stairway* landing in accordance with Section 1009.6.3, the *wheelchair space* shall not be located in the required width of the landing and doors shall not swing over the *wheelchair spaces*.

**Exception:** Where *stairways* connect stepped *aisles* to cross *aisles* or concourses, *stairway* landings are not required at the transition between *stairways* and stepped *aisles* constructed in accordance with Section 1029.

- ❖ A level portion of a stairway provides users with a place to rest in their ascent or descent, to enter a stairway and to adjust their gait before continuing. Landings also break up the run of a stairway, especially at a turn, to aid in the arrest of falls that may occur (see Section 1011.8).

The minimum size (width and depth) of all landings in a stairway is determined by the actual width of the stairway. If Section 1011.2 requires a stairway to have a width of at least 44 inches (1118 mm) and the stairway is constructed with that minimum width, then all landings serving that stairway must be at least 44 inches (1118 mm) wide and 44 inches (1118 mm) deep [see Commentary Figure 1011.6(1)]. If a stairway is constructed wider than required, landings must increase accordingly so as to not create a bottleneck situation in the egress travel. However, when a stairway is configured so that it has a straight run, the depth of the landing between flights in the direction of egress travel is not required to exceed 48 inches (1219 mm), even though the actual width of the stair may exceed 48 inches (1219 mm) [see Commentary Figure 1011.6(2)].

It is not the intent of this section to require that a stairway landing be shaped as a square or rectangle. A landing turning the stairway 90 degrees (1.57 rad) or more with a curved or segmented outside periphery would be permitted, as long as the landing provides an area described by an arc with a radius equal to the actual stairway width [see Commentary Figure 1011.6(3)]. In this case, the space necessary for means of egress will be available.

The last portion of the requirement limits the extent to which doors that swing onto landings may interfere or encroach upon the required landing space. This limits the arc of the door swing on a landing, so that the effect on the means of egress is minimized [see Commentary Figure 1011.6(4)]. This is consistent with a door opening into an exit access corridor in Section 1005.7. For safety reasons and to ensure the means of egress is continually available for everyone, where an area of refuge/wheelchair space must be located on a landing, the wheelchair spaces must not be within the required landing width and the entrance door to the stair enclosure may not swing over the wheelchair spaces [see Commentary Figure 1009.3(1)].

Exception 1 provides a practical exception where

assembly facilities are designed for viewing. See Sections 1029.13 through 1029.13.2.4 for assembly stepped aisle walking surfaces. This exception is limited to when stairways are a direct continuation of the path of travel from the level cross aisle to the stepped aisles. It is not permitted for other stairways within the assembly space.

**1011.7 Stairway construction.** *Stairways* shall be built of materials consistent with the types permitted for the type of construction of the building, except that wood *handrails* shall be permitted for all types of construction.

❖ In keeping with the different levels of fire protection provided by each of the five basic types of construction designated in Chapter 6, the materials used for stairway construction must meet the appropriate combustibility/noncombustibility requirements indicated in

Section 602 for the particular type of construction of the building in which the stairway is located. This is required whether or not the stair is part of the required means of egress. Any structure supporting the stairway and the stairway enclosure must be fire-resistance rated consistent with the construction type; however, the stairway components inside the enclosure need only comply with the material limits for the type of construction.

If desired, wood handrails may be used on the basis that the fuel load contributed by this combustible component of stairway construction is insignificant and will not pose a fire hazard.

**1011.7.1 Stairway walking surface.** The walking surface of treads and landings of a *stairway* shall not be sloped steeper than one unit vertical in 48 units horizontal (2-percent slope)

## MEANS OF EGRESS

in any direction. *Stairway* treads and landings shall have a solid surface. Finish floor surfaces shall be securely attached.

### Exceptions:

1. Openings in *stair* walking surfaces shall be a size that does not permit the passage of  $\frac{1}{2}$ -inch-diameter (12.7 mm) sphere. Elongated openings shall be placed so that the long dimension is perpendicular to the direction of travel.
  2. In Group F, H and S occupancies, other than areas of parking structures accessible to the public, openings in treads and landings shall not be prohibited provided a sphere with a diameter of  $1\frac{1}{8}$  inches (29 mm) cannot pass through the opening.
- ❖ It is the intent of this section that both landing and stair treads be solid and level with firmly attached surface materials; however, the 1:48 slope should be adequate to allow for drainage to limit the chance for an accumulation of water where someone might slip.

The exceptions permit the use of open grate-type material or slotted grill for stairway treads and landings in two different situations.

Exception 1 allows for a maximum  $\frac{1}{2}$ -inch (12.7 mm) opening on stairway treads in public areas and serving any use (see Commentary Figure 1011.7.1). This is very beneficial on exterior stairways where snow, ice or water may accumulate. The  $\frac{1}{2}$ -inch (12.7 mm) limitation is based on the size of a crutch or cane tip and is consistent with ICC A117.1 and federal accessibility requirements. The opening limitation is also small enough that most shoe heels will not get stuck. If a slotted grill pattern is used, the slots must run side to side on the stairway tread, not nosing to back.

Exception 2 is applicable in factory, industrial, storage and high-hazard occupancies. This provision is

intended to apply primarily to stairs that provide access to areas not required to be accessible, such as pits, catwalks, tanks, equipment platforms, roofs or mezzanines. Walking surfaces with limited-size openings are typically used because open grate-type material is less susceptible to accumulation of dirt, debris or moisture, as well as being more resistant to corrosion. Most commercially available grate material is manufactured with a maximum nominal 1-inch (25 mm) opening; therefore, the limitation that the openings not allow the passage of a sphere of  $1\frac{1}{8}$  inches (29 mm) diameter allows the use of most material as well as accounting for manufacturing tolerances.

The allowances for openings in risers is addressed in Section 1011.5.5.3.

OPEN TREAD IN ACCORDANCE WITH EXCEPTION 1

For SI: 1 inch = 25.4 mm.

Figure 1011.6(4)  
DOOR CLEARANCE REQUIREMENTS IN STAIRWAY

**1011.7.2 Outdoor conditions.** Outdoor *stairways* and outdoor approaches to *stairways* shall be designed so that water will not accumulate on walking surfaces.

- ❖ Outdoor stairways and approaches to stairways are to be constructed with a slope that complies with Section 1011.7.1 or are required to be protected such that walking surfaces do not accumulate water. While not specifically stated, any interior locations, such as near a pool, should also have the stair designed to limit the accumulation of water in order to maintain slip resistance (see Section 1003.4).

Where exterior stairways are used in moderate or severe climates, there may also be a concern to protect the stairway from accumulations of snow and ice to provide a safe path of egress travel at all times. Maintenance of the means of egress requires an unobstructed path to allow for full instant use in case of a fire or emergency (see Section 1031.3). Typical methods for protecting these egress elements include roof overhangs or canopies; heated slabs; grated treads and landings; or, when approved by the building official, a reliable snow removal maintenance program.

**1011.7.3 Enclosures under interior stairways.** The walls and soffits within enclosed usable spaces under enclosed and unenclosed stairways shall be protected by 1-hour fire-resistance-rated construction or the fire-resistance rating of the stairway enclosure, whichever is greater. Access to the enclosed space shall not be directly from within the stairway enclosure.

**Exception:** Spaces under *stairways* serving and contained within a single residential dwelling unit in Group R-2 or R-3 shall be permitted to be protected on the enclosed side with 1/2-inch (12.7 mm) gypsum board.

- ❖ This section addresses the fire hazard of storage under an interior stairway, whether it is an exit access stairway or exit stairway. The stairway must be protected from a storage area under it, even if the stair is not required to be enclosed. The section also requires that the storage area not open into a stairway enclosure. This limits the potential of a fire that starts in the storage area from affecting the means of egress. The exception provides specific criteria for separation for storage areas under an interior stairway for the indicated residential occupancies.

**1011.7.4 Enclosures under exterior stairways.** There shall not be enclosed usable space under *exterior exit stairways* unless the space is completely enclosed in 1-hour fire-resistance-rated construction. The open space under *exterior stairways* shall not be used for any purpose.

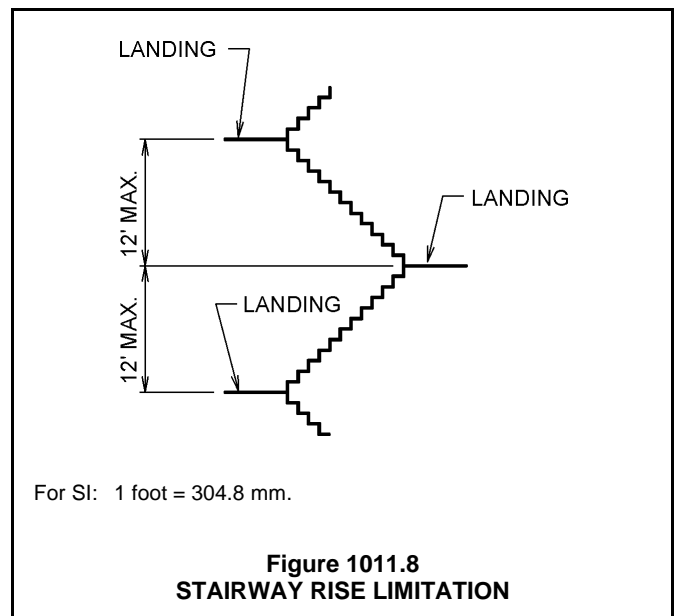

- ❖ If the space under an exterior stairway is to be used, such as for storage, the area below the stairway must be separated from the stairway with walls and a ceiling with a fire-resistance rating of at least 1 hour. If the space under the exterior stairway is open, it must remain free and clear. A fire occurring in this space would jeopardize the use of the stairway for exiting during an emergency.

**1011.8 Vertical rise.** A flight of stairs shall not have a vertical rise greater than 12 feet (3658 mm) between floor levels or landings.

**Exception:** Spiral stairways used as a means of egress from technical production areas.

- ❖ Between landings and platforms, the vertical rise is to be measured from one landing walking surface to another (see Commentary Figure 1011.8). The limited height provides a reasonable interval for users with physical limitations to rest on a level surface and also serves to alleviate potential negative psychological effects of long and uninterrupted stairway flights.

The exception allows for spiral stairways that only serve technical production areas to eliminate intermediate landings regardless of height. These stairways typically have limited use and serve areas such as catwalks or lighting booths in stadiums and theaters. In addition, there is the technical difficulty of maintaining proper headroom in a spiral stairway with an intermediate landing.

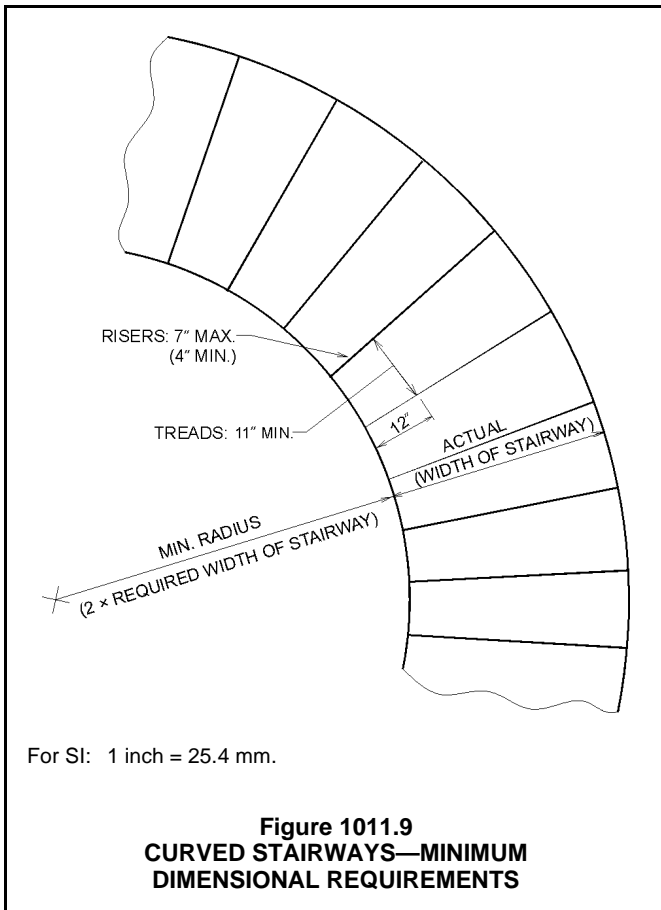

**1011.9 Curved stairways.** Curved stairways with winder treads shall have treads and risers in accordance with Section 1011.5 and the smallest radius shall be not less than twice the minimum width or required capacity of the stairway.

**Exception:** The radius restriction shall not apply to curved stairways in Group R-3 and within individual dwelling units in Group R-2.

- ❖ Curved stairway construction consists of a series of winder treads that form a stairway configuration. Options are many, including circular, S-shaped, oval, elliptical, hourglass, etc. The commentary to Section 1011.5.3 regarding the possible event of nonconcentric movement on stairways with winders also applies to curved stairways. This type of stairway is allowed to be used as a component of a means of egress when tread and riser dimensions meet the require-

ments or exceptions of Section 1011.5. This section also requires that the shorter radius must be equal to or greater than twice the required width (see Section 1011.2) of the stairway to limit the degree of turning thereby expediting egress from higher occupancies (see Commentary Figure 1011.9).

The exception for residential units eliminates the minimum radius requirement where the occupants are familiar with the extent of the turning of the stair through the curve.

**1011.10 Spiral stairways.** *Spiral stairways* are permitted to be used as a component in the *means of egress* only within *dwelling units* or from a space not more than 250 square feet (23 m<sup>2</sup>) in area and serving not more than five occupants, or from *technical production areas* in accordance with Section 410.6.

A *spiral stairway* shall have a 7½-inch (191 mm) minimum clear tread depth at a point 12 inches (305 mm) from the narrow edge. The risers shall be sufficient to provide a headroom of 78 inches (1981 mm) minimum, but riser height shall not be more than 9½ inches (241 mm). The minimum *stairway* clear width at and below the *handrail* shall be 26 inches (660 mm).

❖ Spiral stairways can be used within an individual dwelling unit, from small spaces in other occupancies

and from technical production areas in spaces such as theaters. Spiral stairways are permitted to provide access between the levels within a live/work unit (see Section 419.3.2).

Spiral stairways are generally constructed with a fixed center pole that serves as either the primary or the only means of support from which pie-shaped treads radiate to form a winding stairway. The term “spiral” in the geometrical sense describes a curve that diminishes in radius and relates to the form of the stair as viewed in perspective from above or below; however, “spiral” does not describe the actual geometry of the stair. The unique turning of spiral stairs allows the center pole to act as the guard at the inside of the stair and the typically narrow width requires users to choose a walkline along the outer perimeter near the only required handrail. On spiral stairways of larger widths, where two users can pass and restrict access to the single handrail, the provision of a handrail at both sides should be considered.

The commentary to Section 1011.5.3 regarding the possible event of nonconcentric movement on stairways with winders also applies to spiral stairways. The nature of stairway construction is such that it does not serve well when used in emergencies that require immediate evacuation, nor does a spiral stairway configuration permit the handling of a large occupant load in an efficient and safe manner. Furthermore, it is impossible for fire service personnel to use a spiral stairway at the same time and in a direction opposite that being used by occupants to exit the premises, possibly causing a serious delay in fire-fighting operations. Therefore, this section allows only very limited use of spiral stairways when used as part of a required means of egress. Spiral stairways may be used in any occupancy as long as such stairways are not a component of a required means of egress.

Spiral stairways are required to have dimensional uniformity. The stairway must have a clear width of at least 26 inches (660 mm) at and below the handrail. The depth of the treads must not be less than 7½ inches (191 mm) measured at a point that is 12 inches (305 mm) out from the narrow edge (see Commentary Figure 1011.10). Riser heights are required to be the same throughout the stairway, but are not to exceed 9½ inches (241 mm). Minimum headroom of 6 feet, 6 inches (1981 mm) is required.

**1011.11 Handrails.** Stairways shall have handrails on each side and shall comply with Section 1014. Where glass is used to provide the handrail, the handrail shall comply with Section 2407.

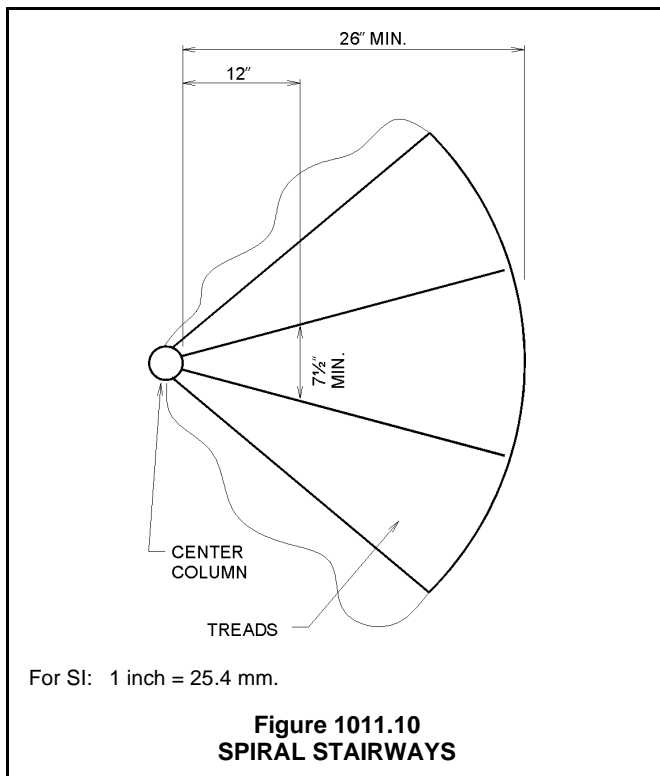

Exceptions:

1. Stairways within dwelling units and spiral stairways are permitted to have a handrail on one side only.
2. Decks, patios and walkways that have a single change in elevation where the landing depth on each side of the change of elevation is greater than what is required for a landing do not require handrails.

- 3. In Group R-3 occupancies, a change in elevation consisting of a single riser at an entrance or egress door does not require handrails.
- 4. Changes in room elevations of three or fewer risers within dwelling units and sleeping units in Group R-2 and R-3 do not require handrails.

❖ Handrails are required along each side of a flight of stairs; however, handrails are not required along stairway landings. Handrail continuity and extensions that will overlap the landings are addressed in Sections 1014.4 and 1014.6.

Handrails have four recognized functions in stairway use. First, they serve to guide persons in ascent and descent along the path of egress travel, especially important for those with low vision, and in cases of fire where vision might be obscured by smoke. Second, they provide a tool for the user to exert stabilizing forces longitudinally (along the length of the rail), vertically and, most importantly, transversely (perpendicular) to the rail as the body transfers weight from side to side with each leg swing of the unique gait used on stairs. Third, they provide for pulling when arms are used to augment legs in ascent of steeper angles or when such climbing strategies result in more efficient use of the strengths of the user. Fourth, they are a tool that can be utilized to help in the arrest of a fall. In these capacities handrails serve to aid in the use of the stairway and are required on both sides of stairways in compliance with Section 1014 to allow passing users unencumbered access to a handrail. Finally, when glass is the material used to provide the handrail, it must comply with IBC Section 2407.

Note that if the handrail extension is at a location that could be considered a protruding object, the handrail must return to the post at a height of less than 27 inches (686 mm) above the floor. Handrails along the stair runs are not considered protruding objects.

The exceptions state conditions where handrails are only required on one side or are not needed at all. By the nature of their construction, spiral stairways can only have a single handrail (see Exception 1). In accordance with Exceptions 1 and 4, within dwelling units, all stairways can have a handrail on one side only, and stairs with three or fewer risers are not required to have any handrails. Since “Stair” is defined as one or more risers, Exceptions 2 and 3 are necessary. Exception 3 exempts the single step at the front or back door of a Group R-3 dwelling unit (i.e., townhouse). Decks, patios and walkways often move down with the grade. When there are single steps, either off a patio or deck to grade, or along the surface, a handrail is not required (Exception 2, see Commentary Figure 1011.11). Many of these exceptions dealing with residential units are consistent with the IRC.

For guard requirements at stairways, see Section 1011.13.

**1011.12 Stairway to roof.** In buildings four or more stories above *grade plane*, one *stairway* shall extend to the roof surface unless the roof has a slope steeper than four units vertical in 12 units horizontal (33-percent slope).

**Exception:** Other than where required by Section 1011.12.1, in buildings without an occupied roof access to the roof from the top story shall be permitted to be by an *alternating tread device*, a ship’s ladder or a permanent ladder.

❖ Because of safety considerations, roofs used for habitable purposes such as roof gardens, observation decks, sporting facilities (including jogging or walking

**Figure 1011.11  
EXAMPLE OF SECTION 1011.11, EXCEPTION 2**

tracks and tennis courts) or similar uses, must be provided with conventional stairways that will serve as required means of egress. Access by ladders or an alternating tread device for such uses is not permitted.

In buildings four or more stories high, roofs that are not used for habitable purposes must be provided with ready access by conventional stairways or by an alternating tread device (see Section 1011.14). If this stair is also to provide access to an elevator penthouse on the roof, see additional requirements in Section 1011.12.1. Two reasons for this are access for roof or rooftop equipment repair and fire department access during a fire event. Sloping roofs with a rise greater than 4 inches (102 mm) for every 12 inches (305 mm) in horizontal measurement (4:12) are exempt from the requirements of this section because of the steepness of the construction and the inherent dangers to life safety.

While it is not specifically required that roof access be through an exit stairway enclosure, since part of the intent is for fire department access to the roof, it is strongly advised. Section 1023.9 requires signage at the level of exit discharge indicating whether the stairway has roof access.

**1011.12.1 Stairway to elevator equipment.** Roofs and penthouses containing elevator equipment that must be accessed for maintenance are required to be accessed by a stairway.

❖ The requirement for a stair to the roof for maintaining elevator equipment correlates the code with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. This referenced standard (see IBC Section 3001.2) has required stairs and a door to access elevator equipment since 1955. More specifically, Section 2.27.3.2.1 of ASME A17.1/CSA B44 states the following: “a stairway with a swinging door and platform at the top level, conforming to 2.7.3.3 shall be provided from the top floor of the building to the roof level. Hatch covers as a means of access to the roofs shall not be permitted.” Alternating tread devices or ladders are not permitted as an alternative to the stairway for access to the elevator penthouse. This provision is more specific; therefore, while not prohibiting using the same stairway for access to the roof and the elevator penthouse (see Sections 1011.12 and 1011.12.2), access to that elevator penthouse must be via a stairway with door access, not an alternating tread device and hatch.

**1011.12.2 Roof access.** Where a stairway is provided to a roof, access to the roof shall be provided through a penthouse complying with Section 1510.2.

**Exception:** In buildings without an occupied roof, access to the roof shall be permitted to be a roof hatch or trap door not less than 16 square feet (1.5 m<sup>2</sup>) in area and having a minimum dimension of 2 feet (610 mm).

❖ The purpose of the penthouse or stairway bulkhead requirement in this section is to protect the walking surface of the stairway to the roof. The exception pro-

vides for situations when roof access is only needed for service or maintenance purposes, and where the access may be permitted by alternatives such as alternating tread devices, ship’s ladders or ladders.

**1011.13 Guards.** Guards shall be provided along stairways and landings where required by Section 1015 and shall be constructed in accordance with Section 1015. Where the roof hatch opening providing the required access is located within 10 feet (3049 mm) of the roof edge, such roof access or roof edge shall be protected by guards installed in accordance with Section 1015.

❖ While guards are required at the edge of a normally occupied roof by Section 1015, there is also a safety concern for roof areas that need to be accessed by service personnel, inspectors and emergency responders. This requirement for guards provides a minimum measure of safety when the roof access is close to the roof edge. This is consistent with the requirements at mechanical equipment in Section 1015.6 and 1015.7.

**1011.14 Alternating tread devices.** *Alternating tread devices* are limited to an element of a *means of egress* in buildings of Groups F, H and S from a mezzanine not more than 250 square feet (23 m<sup>2</sup>) in area and that serves not more than five occupants; in buildings of Group I-3 from a guard tower, observation station or control room not more than 250 square feet (23 m<sup>2</sup>) in area and for access to unoccupied roofs. *Alternating tread devices* used as a means of egress shall not have a rise greater than 20 feet (6096 mm) between floor levels or landings.

❖ This type of device is constructed in such a way that each tread alternates with each adjacent tread so that the device consists of a system of right-footed and left-footed treads (see Commentary Figure 1011.14).

The use of center stringer construction, half-treads and an incline that is considerably steeper than allowed for ordinary stairway construction makes the alternating tread device unique. However, because of its structural feature, only single-file use of the device (between handrails) is possible, thus preventing the occupants from passing one another. The pace of occupant travel is set by the slowest user, a condition that could become critical in an emergency situation. Furthermore, it is impossible for fire service personnel to use an alternating tread device at the same time and in a direction opposite that being used by occupants to exit the premises, possibly causing a serious delay in fire-fighting operations. For these reasons, this section greatly restricts the use of alternating tread devices as a means of egress. Alternating tread devices may be used in any occupancy as long as such stairways are not a component of a required means of egress.

Alternating tread devices are considered a modest improvement to ladder construction and, therefore, can be used as an unoccupied roof access in accordance with the requirements of Section 1011.12.

Alternating tread devices are permitted 20 feet (6096 mm) between landings given their limited appli-

ation and low occupant loads. In addition, it is recognized a vertical rise higher than the typical stairway is needed for these steeper devices which are used where space is often too restrictive for a regular stairway.

**1011.14.1 Handrails of alternating tread devices.** Handrails shall be provided on both sides of alternating tread devices and shall comply with Section 1014.

❖ For the safety of occupants, this section references the dimensional requirements for handrail locations to be used in conjunction with the special construction features of alternating tread devices provided in Section 1011.14. Because of the steepness of these devices, handrails on both sides are essential for safe functional use and additional clearances are required so that hand movement will not be encumbered by obstructions. Section 1015.3, Exception 5, permits the handrails along alternating tread devices to also serve as guards.

**1011.14.2 Treads of alternating tread devices.** *Alternating tread devices* shall have a minimum tread depth of 5 inches (127 mm), a minimum projected tread depth of 8½ inches (216 mm), a minimum tread width of 7 inches (178 mm) and a maximum riser height of 9½ inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial

tread of the device shall begin at the same elevation as the platform, landing or floor surface.

**Exception:** *Alternating tread devices* used as an element of a *means of egress* in buildings from a mezzanine area not more than 250 square feet (23 m<sup>2</sup>) in area that serves not more than five occupants shall have a minimum tread depth of 3 inches (76 mm) with a minimum projected tread depth of 10½ inches (267 mm). The rise to the next alternating tread surface shall not exceed 8 inches (203 mm).

❖ Alternating tread stairways (see Section 1009.13) are required to have tread depths of at least 5 inches (127 mm). Tread projections are not to be less than 3½ inches (89 mm) when measured from tread nosing to tread nosing [next adjacent tread to the left or right to provide a minimum projected tread depth of 8½ inches (216 mm)] (see Commentary Figure 1011.14).

The risers are to be not more than 9½ inches (241 mm) when measured from tread to alternating tread (next adjacent tread to the left or right). The rise between treads on the same side would be 19 inches (482 mm) maximum. Applying the limiting dimensions stated above results in a device with a very steep incline that is common to ladders; however, because the device may be walked facing down in descent, it is considered a type of stairway in the code.

Tread widths are required to be a minimum of 7 inches (178 mm) or more. With a center support, the total width will be more than 15 inches (381 mm).

## MEANS OF EGRESS

Although no maximum width of the tread is stated, the device must be of a width to provide for functional use of both handrails at the same time in ascent and descent. For this same reason, handrail heights for alternating tread devices are modified from those stairways in Section 1014.2.

Just using the dimensions could result in an alternating tread device with an angle greater than 75 degrees (1.3 rad). In any case, the overall angle of the device must be between 50 and 70 degrees (0.87 and 1.22 rad).

For alternating tread devices used as a means of egress from small-area mezzanines as prescribed in the exception, the treads must project at least  $7\frac{1}{2}$  inches (191 mm) as compared to the  $3\frac{1}{2}$  inches (89 mm) stated above; treads are to be at least 3 inches (76 mm) in depth [compared to 5 inches (127 mm)] and risers are not to exceed 8 inches (203 mm) in height [compared to  $9\frac{1}{2}$  inches (341 mm)].

**1011.15 Ship's ladders.** Ship's ladders are permitted to be used in Group I-3 as a component of a *means of egress* to and from control rooms or elevated facility observation stations not more than 250 square feet (23 m<sup>2</sup>) with not more than three occupants and for access to unoccupied roofs. The minimum clear width at and below the *handrails* shall be 20 inches (508 mm).

❖ Ship's ladders can be used in correctional facilities for access to small control rooms, observation stations and unoccupied roofs. Where approved by the code

official, ship's ladders could be used for access to unoccupied roofs in other occupancies. Ship's ladders are of similar gradient or pitch to alternating tread devices; however, the treads span the full width like that of a ladder rather than being staggered to either side (see Commentary Figure 1011.15).

**1011.15.1 Handrails of ship's ladders.** *Handrails* shall be provided on both sides of ship's ladders.

❖ Handrails are needed on both sides to assist in ascent and descent and the absence of a maximum width. Section 1015.3, Exception 5, permits the handrails along ship's ladders to also serve as guards.

**1011.15.2 Treads of ship's ladders.** Ship's ladders shall have a minimum tread depth of 5 inches (127 mm). The tread shall be projected such that the total of the tread depth plus the *nosing* projection is not less than  $8\frac{1}{2}$  inches (216 mm). The maximum riser height shall be  $9\frac{1}{2}$  inches (241 mm).

❖ See Commentary Figure 1011.5 for an example of this configuration.

**1011.16 Ladders.** Permanent ladders shall not serve as a part of the *means of egress* from occupied spaces within a building. Permanent ladders shall be permitted to provide access to the following areas:

1. Spaces frequented only by personnel for maintenance, repair or monitoring of equipment.
2. Nonoccupiable spaces accessed only by catwalks, crawl spaces, freight elevators or very narrow passageways.

3. Raised areas used primarily for purposes of security, life safety or fire safety including, but not limited to, observation galleries, prison guard towers, fire towers or lifeguard stands.
  4. Elevated levels in Group U not open to the general public.
  5. Nonoccupied roofs that are not required to have *stairway* access in accordance with Section 1011.12.1.
  6. Ladders shall be constructed in accordance with Section 306.5 of the *International Mechanical Code*.
- ❖ Permanent ladders are permitted as a means of ingress and egress to very limited spaces. Typically, these spaces are not considered occupied and, as such, are not required to have a means of egress. While the term “technical production areas” is not used in this section, IBC Section 410.6.3.4, Item 6, allows for ladders to be used to access technical production areas. Item 6 of this section references the IMC for when ladders can be used to access mechanical equipment that is located in an elevated space or in a room. The details and construction requirements for a permanent ladder are also found in that section. This will help make sure that permanent ladders are safe and useable, while providing consistency for both the designer and the building official.

## SECTION 1012 RAMPS

**1012.1 Scope.** The provisions of this section shall apply to ramps used as a component of a *means of egress*.

### Exceptions:

1. Ramped *aisles* within assembly rooms or spaces shall comply with the provisions in Section 1029.
  2. Curb ramps shall comply with ICC A117.1.
  3. Vehicle ramps in parking garages for pedestrian *exit access* shall not be required to comply with Sections 1012.3 through 1012.10 where they are not an *accessible route* serving *accessible* parking spaces, other required *accessible* elements or part of an *accessible means of egress*.
- ❖ Ramps provide an alternative method of vertical means of access to or egress from a building. Ramps are required for access to building areas for persons who are mobility impaired (see Chapter 11) and for small changes in floor elevations that are a safety hazard in themselves (see Section 1003.5). All ramps intended for pedestrian usage, whether required or otherwise provided, must comply with the requirements of this section. The code considers any walking surface that has a slope steeper than one unit vertical in 20 units horizontal (5-percent slope) to be a ramp (see the definition for “Ramp” in Chapter 2).
- As with stairways, it is important to understand the terminology. Exit ramps are ramps that provide a protected path of travel between the exit access and the

exit discharge. Interior exit ramps are required to be enclosed in accordance with Section 1022. Exterior exit ramps are protected by the exterior wall of the building and must comply with Section 1027. Exit access ramps are typically unenclosed interior ramps and comply with Section 1019 when they provide access between stories. Exit access travel distance stops at an exit ramp enclosure, but includes any travel down an exit access ramp. Ramps that are outside and provide a route from the level of exit discharge to grade are considered part of the exit discharge. See the commentary in Chapter 2 for the defined term, “Exit discharge, level of.”

Exception 1 indicates that ramped aisles are addressed in Section 1029. Having this exception at the beginning of the ramp section negated the need for repeated exceptions throughout the ramp provisions. While ramps and ramped aisles may look similar, configurations and how occupants move on and off those walking surfaces are very different. Occupants leave and join ramped aisles along the entire run, while occupants only enter the ramp at the top and bottom. Ramped aisles may have no or only one handrail in order to allow for access to the seats, while most ramps have handrails on both sides. Ramped aisles can have steeper slopes to allow for seating bowls to address line of sight. Section 1029 should be used for ramped aisles between and immediately adjacent to seating or where the ramps are a direct continuation of the ramped aisles and lead to a level cross aisle or floor. Section 1012 is used for ramps that lead from the balcony, concourse or cross aisle to a floor level above or below the seating areas.

Exception 2 references specific curb cut requirements found in Section 406 of ICC A117.1. It is important to realize there are different provisions for curb ramps and ramps. For example, a curb ramp can have a rise of any height and not require handrails. Ramps require handrails when the rise is more than 6 inches.

Exception 3 addresses parking garages. An accessible route is required to and from any accessible parking space, and all ramp provisions must be followed. However, ramps that provide access to and from nonaccessible spaces in the remainder of the parking garage need only comply with the provisions for slope and guard requirements. This permits non-accessible portions of garages to be constructed as a continuous slope. Ramps that are strictly for vehicles, such as jump ramps, are not required to meet any of the ramp provisions.

**1012.2 Slope.** *Ramps* used as part of a *means of egress* shall have a running slope not steeper than one unit vertical in 12 units horizontal (8-percent slope). The slope of other pedestrian *ramps* shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

- ❖ Maximum slope is limited to facilitate the ease of ascent and to control the descent of persons with or without a mobility impairment. The maximum slope of a ramp in the direction of travel is limited to one unit

## MEANS OF EGRESS

vertical in 12 units horizontal (1:12) (see Commentary Figure 1012.2). Ramps in existing buildings may be permitted to have a steeper slope at small changes in elevation (see Sections 410.8.5 and 705.1.4 of the IEBC). An example of a ramp that is not part of a means of egress and, therefore, allowed to be a maximum slope of 1:8, is a loading dock or delivery ramp where the ramp is not part of any required exit discharge.

**1012.3 Cross slope.** The slope measured perpendicular to the direction of travel of a ramp shall not be steeper than one unit vertical in 48 units horizontal (2-percent slope).

❖ The limitation of one unit vertical in 48 units horizontal on the slope across the direction of travel is to prevent a severe cross slope that would pitch a user to one side (see Commentary Figure 1012.2).

**1012.4 Vertical rise.** The rise for any ramp run shall be 30 inches (762 mm) maximum.

Because pushing a wheelchair up a ramp requires a great deal of energy, landings must be situated so that a person can rest after each 30-inch (762 mm) elevation change (see Commentary Figure 1012.2).

**1012.5 Minimum dimensions.** The minimum dimensions of means of egress ramps shall comply with Sections 1012.5.1 through 1012.5.3.

❖ These minimum dimension requirements allow the ramp to function as a means of egress and an accessible route.

**1012.5.1 Width and capacity.** The minimum width and required capacity of a means of egress ramp shall be not less than that required for corridors by Section 1020.2. The clear width of a ramp between handrails, if provided, or other permissible projections shall be 36 inches (914 mm) minimum.

❖ The requirements for the width of a means of egress ramp is based on the width required for minimum width [typically 36 inches (941 mm)] and the capacity based on the occupant load to be served (see Section 1005.3.2). Note that the clear width of 36 inches (914 mm) is required between the handrails and any other obstructions (e.g., handrail supports, curbs) for proper clearance for a person in a wheelchair. This is different from stairways where handrails are permitted to project into the required width. The 36-inch (914 mm) minimum clear width between handrails is consistent with ICC A117.1 and the federal 2010 ADA Standard.

**1012.5.2 Headroom.** The minimum headroom in all parts of the means of egress ramp shall be not less than 80 inches (2032 mm).

❖ The requirement for headroom on any part of an egress ramp is identical to the requirement of a conventional (nonspiral) stairway (see Section 1011.3). General headroom heights along the means of egress are addressed in Section 1003.2.

**1012.5.3 Restrictions.** Means of egress ramps shall not reduce in width in the direction of egress travel. Projections

into the required *ramp* and landing width are prohibited. Doors opening onto a landing shall not reduce the clear width to less than 42 inches (1067 mm).

- ❖ The purpose of not allowing ramps to reduce in width in the direction of egress travel is to prevent a restriction that would interfere with the flow of occupants out of a facility. This would include ramp landings in accordance with Section 1012.6.2. Handrails are the only exception in accordance with Sections 1012.5.1 and 1014.8.

Doors that open onto a ramp landing, including those at the top and bottom landings, must not reduce the clear width to less than 42 inches (1067 mm). This is a more restrictive provision than for corridors that would permit the reduction to one-half the required width (see Section 1005.7). Since one of the purposes of a ramp is to accommodate persons with physical disabilities, it must provide the additional clear width for access by those confined to wheelchairs without the interference or potential blockage caused by the swing of a door (see Commentary Figures 1012.2 and 1012.5.3).

**1012.6 Landings.** *Ramps* shall have landings at the bottom and top of each *ramp*, points of turning, entrance, exits and at doors. Landings shall comply with Sections 1012.6.1 through 1012.6.5.

- ❖ Landings must be provided to allow users of a ramp to rest on a level floor surface and to adjust to the change in floor surface pitch.  
Landings are required at the top and bottom of

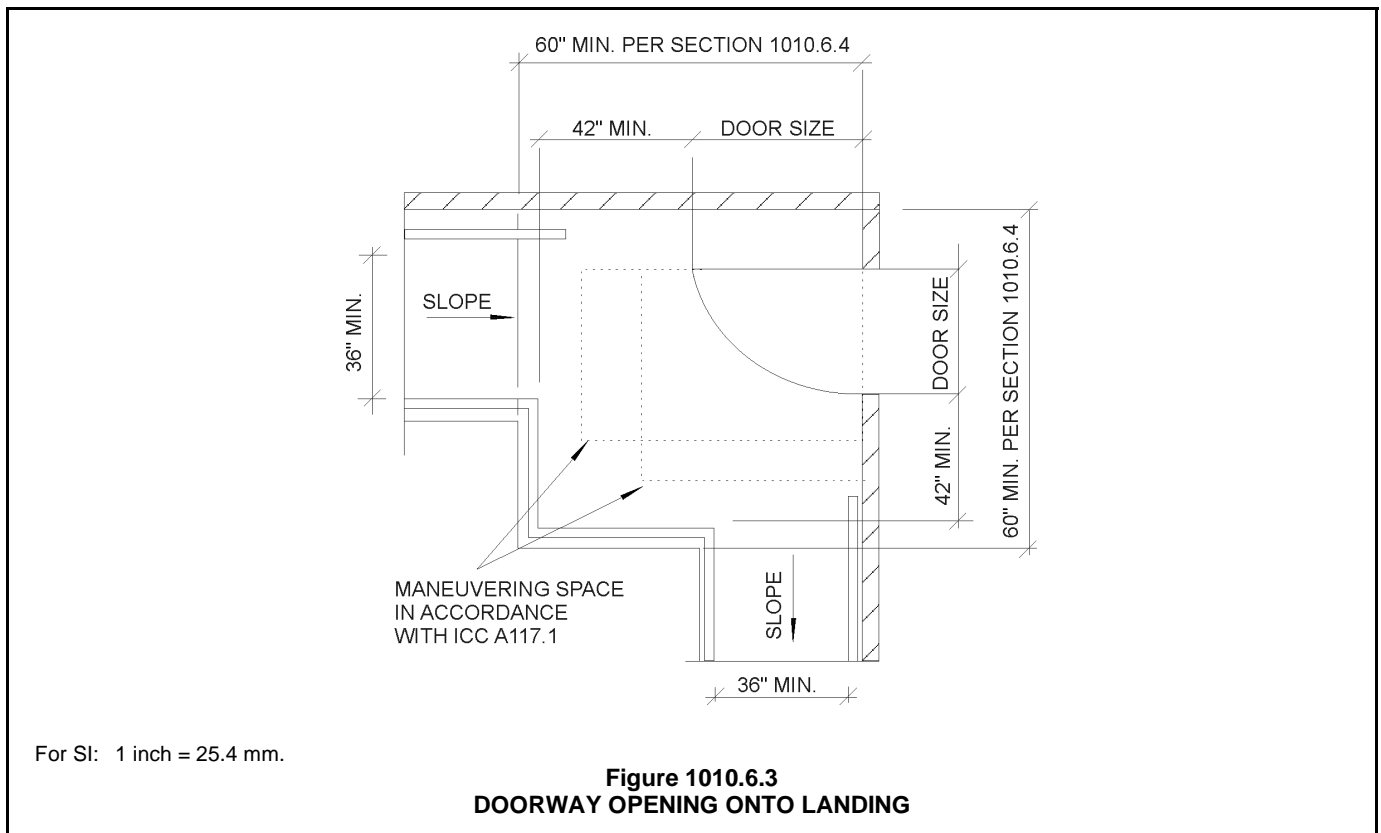

each ramp run (see Commentary Figure 1012.6). In addition, Section 1012.4 requires a landing every 30 inches (762 mm) of vertical rise of the ramp. The requirements for landings allow those occupants of the structure the ability to negotiate all changes in direction, and prepare themselves to either ascend or descend the ramp and to rest. If there is a door at the top or the bottom of the ramp, there are additional requirements in Section 1012.5.3 for door swing over the landing and Section 405 of ICC A117.1 for maneuvering space and turning space at the door.

**1012.6.1 Slope.** Landings shall have a slope not steeper than one unit vertical in 48 units horizontal (2-percent slope) in any direction. Changes in level are not permitted.

- ❖ Landings must be almost flat. This allows persons confined to a wheelchair to come to a complete stop without having to activate the brake or hold themselves stationary at the landing. The maximum slope or cross slope of the landing in any direction is 1:48 (see Commentary Figure 1012.2). This minimum slope is to allow for drainage to limit the accumulation of water on the landing surface.

**1012.6.2 Width.** The landing width shall be not less than the width of the widest *ramp* run adjoining the landing.

- ❖ The width of all landings must be consistently as wide as the widths of the ramp runs leading to them. Means of egress ramps cannot be reduced in width in the direction of egress travel. This is also applicable to the landings connecting the ramp runs (see Commentary Figure 1012.6).

## MEANS OF EGRESS

**1012.6.3 Length.** The landing length shall be 60 inches (1525 mm) minimum.

### Exceptions:

1. In Group R-2 and R-3 individual *dwelling* and *sleeping units* that are not required to be *Accessible units*, *Type A units* or *Type B units* in accordance with Section 1107, landings are permitted to be 36 inches (914 mm) minimum.
  2. Where the *ramp* is not a part of an *accessible route*, the length of the landing shall not be required to be more than 48 inches (1220 mm) in the direction of travel.
- ❖ The landings for ramps must be at least 60 inches (1524 mm) long (see Commentary Figure 1012.6). This allows persons confined to wheelchairs a sufficient distance to stop and rest along with any persons who may be assisting them. This requirement is directly applicable to straight-run ramps that may require an intermediate landing at every 30 inches (762 mm) of vertical rise (see Commentary Figure 1012.2). If the landing is also to be used to negotiate a change in the ramp's direction, Section 1012.6.4 is applicable. If a door overlaps the landing, Section 1012.5.3 is applicable.

The exceptions provide for smaller landings in dwelling and sleeping units and other locations where the ramp is not part of an accessible route. Exception 1 is consistent with the IRC. Exception 2 would be applicable in areas such as service ramps and ramps serving assembly seating areas that do not contain any wheelchair spaces.

**1012.6.4 Change in direction.** Where changes in direction of travel occur at landings provided between *ramp* runs, the landing shall be 60 inches by 60 inches (1524 mm by 1524 mm) minimum.

**Exception:** In Group R-2 and R-3 individual *dwelling* or *sleeping units* that are not required to be *Accessible units*,

*Type A units* or *Type B units* in accordance with Section 1107, landings are permitted to be 36 inches by 36 inches (914 mm by 914 mm) minimum.

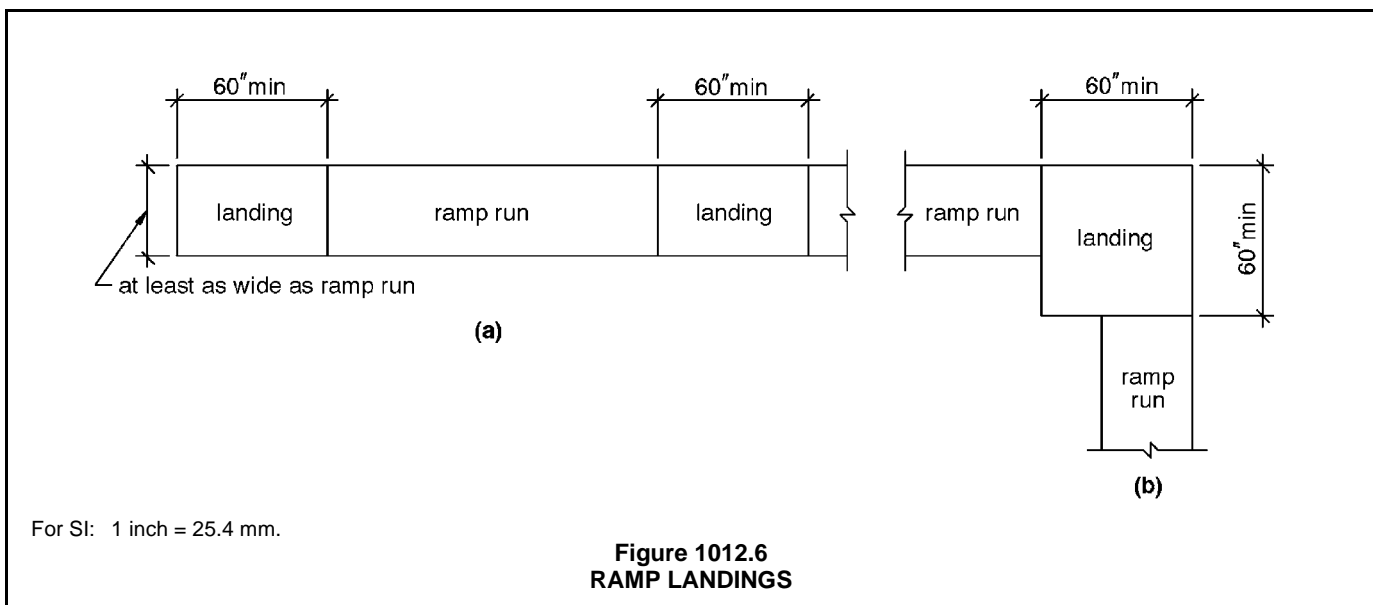

- ❖ When a change in direction is made in the ramp at a landing, the landing must be a square of at least 60 inches (1524 mm). This allows the person confined to a wheelchair enough room to negotiate the turn with minimal effort. The length of the landing may need to exceed 60 inches (1524 mm) to match the widths of the two ramp runs. In any case, the landing would still need to be 60 inches (1524 mm) wide (see Commentary Figures 1012.5.3 and 1012.6). If a door overlaps the landing, Section 1012.5.3 is applicable. It is not the intent of this provision to prohibit curved ramps. As long as the cross slope meets the limitations in Section 1010.4, the curved ramp is permitted.

The exception provides for smaller landings in dwelling and sleeping units where the ramp is not part of an accessible route. This is consistent with requirements in the IRC.

**1012.6.5 Doorways.** Where doorways are located adjacent to a *ramp* landing, maneuvering clearances required by ICC A117.1 are permitted to overlap the required landing area.

- ❖ This section specifies that the area required for maneuvering to open the door and the area of the landing are allowed to overlap. It is not necessary to provide the sum of the two area requirements (see Commentary Figure 1012.5.3). Requirements for maneuvering space and turning space at the top and bottom of ramps are found in Section 405 of ICC A117.1. ICC A117.1 requires a turning space at the top or bottom landing of a ramp where the door may be locked. This allows people to turn around to travel back along the ramp.

**1012.7 Ramp construction.** *Ramps* shall be built of materials consistent with the types permitted for the type of con-

struction of the building, except that wood *handrails* shall be permitted for all types of construction.

- ❖ Material requirements for the type of construction as required by Section 602 for floors are also the material requirements for ramp construction.

**1012.7.1 Ramp surface.** The surface of *ramps* shall be of slip-resistant materials that are securely attached.

- ❖ As the pace of exit travel becomes hurried during emergency situations, the probability of slipping on smooth or slick floor surfaces increases. To minimize the hazard, all floor surfaces in the means of egress are required to be slip resistant. The use of hard floor materials with highly polished, glazed, glossy or finely finished surfaces should be avoided. This is consistent with Section 1003.4.

Field testing and uniform enforcement of the concept of slip resistance is not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification KK-L-165C] and the floor surface is greater than 0.5. Laboratory test procedures such as ASTM D2047 can determine the static coefficient of resistance. Bulletin No. 4 entitled "Surfaces" issued by the U.S. Access Board (ATBCB) contains further information regarding slip resistance.

**1012.7.2 Outdoor conditions.** Outdoor *ramps* and outdoor approaches to *ramps* shall be designed so that water will not accumulate on walking surfaces.

- ❖ Outdoor ramps, landings and the approaches to the ramp must be sloped so that surfaces do not accumulate water so as to provide a safe path of egress travel at all times. While not specifically stated, any interior locations, such as near a pool, should also have the ramps designed to limit the accumulation of water in order to maintain slip resistance (see Sections 1003.4 and 1012.7.1).

Where exterior ramps are used in moderate or severe climates, there may also be a concern to pro-

tect the ramp from accumulations of snow and ice to provide a safe path of egress travel at all times, including inclement weather. Maintenance of the means of egress requires an unobstructed path to allow for full instant use in case of a fire or emergency (see Section 1031.3). Typical methods for protecting these egress elements include roof overhangs or canopies, heated slabs and, when approved by the building official, a reliable snow removal maintenance program.

**1012.8 Handrails.** *Ramps* with a rise greater than 6 inches (152 mm) shall have *handrails* on both sides. *Handrails* shall comply with Section 1014.

- ❖ To aid in the use of a ramp, handrails are to be provided. Handrails are intended to provide the user with a graspable surface for guidance and support. All ramps with a vertical rise greater than 6 inches (152 mm) between landings are to be provided with handrails on both sides [see Commentary Figures 1012.8(1) and 1014.2]. General strength requirements for handrails are found in Section 1014 with a reference to IBC Section 1607.8. Note that if the handrail extension is at a location that could be considered a protruding object, the handrail extension must return to the post at a height of less than 27 inches (686 mm) above the floor. Handrails along the ramp runs are not considered protruding objects.

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Commentary Figures 1012.8(1), 1012.8(2), 1012.8(3) and 1012.8(4) for illustrations of some alternatives.

**1012.9 Guards.** *Guards* shall be provided where required by Section 1015 and shall be constructed in accordance with Section 1015.

- ❖ To protect the user from falls to surfaces below, guards are to be provided where the sides of a ramp or landing are more than 30 inches (762 mm) above

## MEANS OF EGRESS

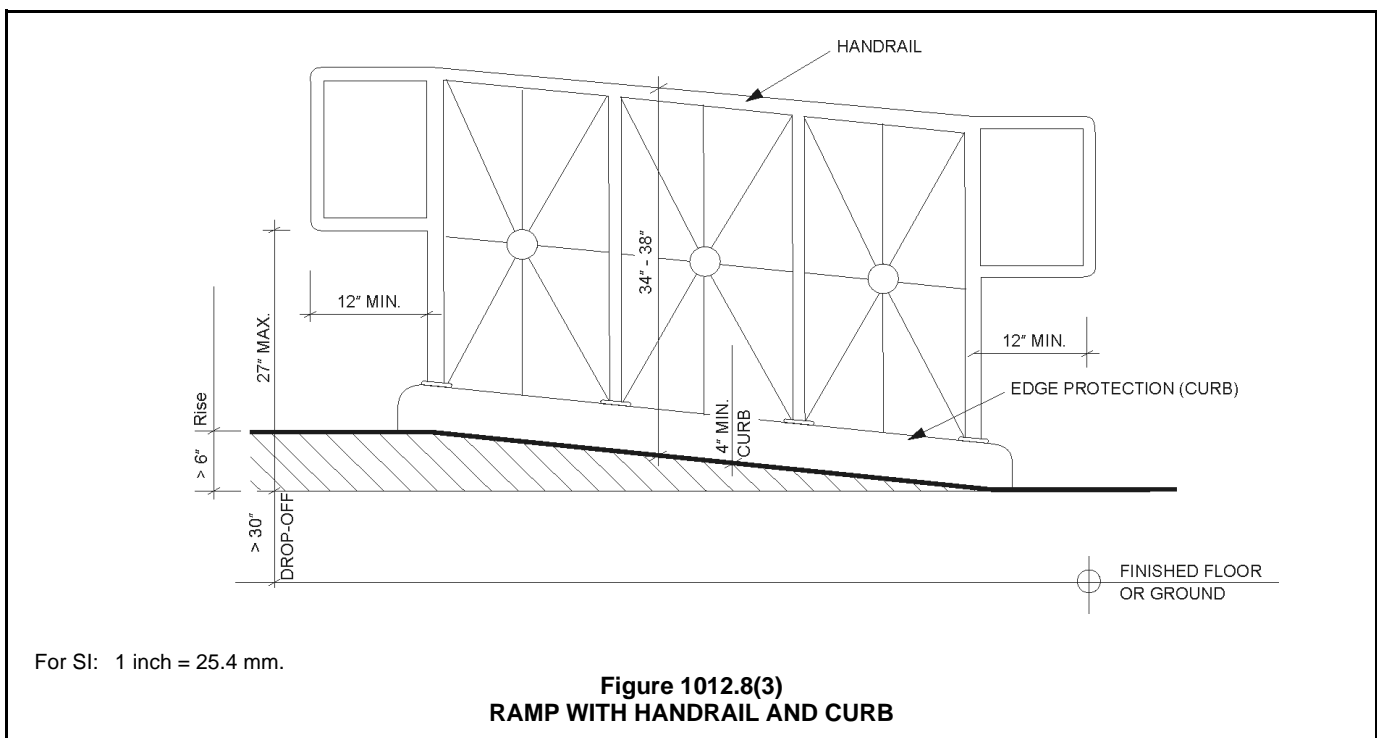

the adjacent grade. Guards are to be constructed in accordance with Section 1015, including the minimum height of 42 inches (1067 mm) [see Commentary Figure 1012.8(4)].

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Commentary Figures 1012.8(1), 1012.8(2), 1012.8(3) and 1012.8(4) for illustrations of some alternatives.

**1012.10 Edge protection.** Edge protection complying with Section 1012.10.1 or 1012.10.2 shall be provided on each side of *ramp* runs and at each side of *ramp* landings.

### Exceptions:

1. Edge protection is not required on *ramps* that are not required to have *handrails*, provided they have flared sides that comply with the *ICC A117.1* curb ramp provisions.
2. Edge protection is not required on the sides of *ramp* landings serving an adjoining *ramp* run or *stairway*.

3. Edge protection is not required on the sides of ramp landings having a vertical dropoff of not more than 1/2 inch (12.7 mm) within 10 inches (254 mm) horizontally of the required landing area.

❖ This section of the code now addresses the comprehensive requirements for edge protection for all ramps. It must be noted that edge protection is not the same as the requirements for guards. The presence of a guard does not necessarily provide adequate edge protection and the presence of adequate edge protection does not satisfy the requirements for a guard. Edge protection is necessary to prevent the wheels of a wheelchair from leaving the ramp surface or becoming lodged between the edge of the ramp and any adjacent construction. For example, a ramp may be located relatively adjacent to the exterior wall of a building. However, between the ramp edge and the exterior wall, there is a strip of earth for landscape purposes. Without adequate edge protection, persons confined to wheelchairs could possibly have their wheels run off the side of the ramp into the landscape, causing them to tip. These requirements are consistent with Section 405 of ICC A117.1 and those in the federal 2010 ADA Standard.

Exception 1 allows a ramp to have minimal edge protection as long as its vertical rise is 6 inches (152 mm) or less. The exception is predicated on the ramp not needing any handrails, which is established by the provisions of Section 1012.8. Such a ramp would only need flared sides or returned curbs. Edge protection without handrails or guards could be a tripping

hazard for ambulatory persons. For specific details of these types of edge protection, the provisions of Section 406 of ICC A117.1 for curb ramps must be followed.

Exception 2 reiterates that edge protection is not literally required entirely around a ramp landing. Obviously, edge protection is not required along that portion of the landing that directly adjoins a ramp run; it is only required along the edges of the landing with a dropoff (other than steps of ramp runs).

Exception 3 states that edge protection is not required for those sides of a ramp landing directly adjacent to the ground surface that gently slopes away from the edge of the landing. If the grade adjacent to the ramp landing slopes no more than 1/2:10 (which equates to 1:20) away from the landing, additional edge protection is not required. Such a gradual slope would not be detrimental to persons confined to wheelchairs as they negotiate the ramp landing. Note that this exception is limited to landings, not the ramp surface itself. The ramp must meet the edge protection in Section 1012.10.1 or 1012.10.2.

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Commentary Figures 1012.8(1), 1012.8(2), 1012.8(3) and 1012.8(4) for illustrations of some alternatives.

**1012.10.1 Curb, rail, wall or barrier.** A curb, rail, wall or barrier shall be provided to serve as edge protection. A curb shall be not less than 4 inches (102 mm) in height. Barriers

## MEANS OF EGRESS

shall be constructed so that the barrier prevents the passage of a 4-inch-diameter (102 mm) sphere, where any portion of the sphere is within 4 inches (102 mm) of the floor or ground surface.

❖ Edge protection for ramps and ramp landings may be achieved with a built-up curb or other barrier, such as a rail, wall or guard. The barrier must be located near the surface of the ramp and landing such that a 4-inch-diameter (102 mm) sphere cannot pass through any openings. An example of an effective barrier would be the bottom rail of a guard system. If the bottom rail is located less than 4 inches (102 mm) above the ramp and landing surface, edge protection has been provided. If a curb option is used, the curb must be a minimum of 4 inches (102 mm) high. The curb or barrier prevents the wheel of a wheelchair from running off the edge of the surface and provides people with visual disabilities a toe stop at the edge of the walking surface (see Commentary Figure 1012.10.1).

**1012.10.2 Extended floor or ground surface.** The floor or ground surface of the *ramp* run or landing shall extend 12 inches (305 mm) minimum beyond the inside face of a *hand-rail* complying with Section 1014.

❖ An alternative to providing some type of barrier at the edge of the ramp (see Section 1012.10.1) is to make the ramp surface wider than the handrails provided at either side. The combination of the wider surface and the handrail barrier would assist in preventing a wheelchair or crutch tip from moving very far off the ramp during a temporary slip (see Commentary Figure 1012.10.1).

### SECTION 1013 EXIT SIGNS

**1013.1 Where required.** *Exits* and *exit access* doors shall be marked by an *approved* exit sign readily visible from any direction of egress travel. The path of egress travel to *exits* and within *exits* shall be marked by readily visible exit signs to clearly indicate the direction of egress travel in cases where the *exit* or the path of egress travel is not immediately

visible to the occupants. Intervening *means of egress* doors within *exits* shall be marked by exit signs. Exit sign placement shall be such that no point in an *exit access corridor* or *exit passageway* is more than 100 feet (30 480 mm) or the *listed* viewing distance for the sign, whichever is less, from the nearest visible exit sign.

#### Exceptions:

1. Exit signs are not required in rooms or areas that require only one *exit* or *exit access*.
  2. Main exterior *exit* doors or gates that are obviously and clearly identifiable as *exits* need not have exit signs where *approved* by the *building official*.
  3. Exit signs are not required in occupancies in Group U and individual *sleeping units* or *dwelling units* in Group R-1, R-2 or R-3.
  4. Exit signs are not required in dayrooms, sleeping rooms or dormitories in occupancies in Group I-3.
  5. In occupancies in Groups A-4 and A-5, exit signs are not required on the seating side of vomitories or openings into seating areas where exit signs are provided in the concourse that are readily apparent from the vomitories. Egress lighting is provided to identify each vomitory or opening within the seating area in an emergency.
- ❖ Where an occupancy has two or more required exits or exit accesses, the means of egress must be provided with illuminated signs that readily identify the location of, and indicate the path of travel to, the exits. The signs must be illuminated with letters reading "Exit." The illumination may be internal or external to the sign. The signs should be visible from all directions in the exit access route. In cases where the signs are not visible to the occupants because of turns in the corridor or for other reasons, additional illuminated signs must be provided indicating the direction of egress to an exit. Exit signs must be located so that, where required, the nearest one is within 100 feet (30 480 mm), of the sign's listed viewing distance. UL 924 permits exit signs to be listed with a viewing distance of less than 100 feet (30 480

mm) (see Section 1013.5). When a sign is listed for a viewing distance of less than 100 feet (30 480 mm) the label on the sign will indicate the appropriate viewing distance. If such a sign is used, the spacing of the signs should be based on the listed viewing distance.

Typically, once an occupant enters an exit enclosure, exit signs are no longer needed; however, in buildings with more complicated egress layouts, it is possible that the direction for egress travel within the exit is not immediately apparent. For example, exit passageways can be part of the path of exit travel at the level of exit discharge or transfer floors. Evacuees may hesitate or be confused when the vertical travel becomes horizontal travel, which may result in a delay in evacuation. In these situations, exit signs may be needed within the exit enclosure (see Commentary Figure 1013.1).

The exceptions identify conditions where exit signs are not necessary since they would not increase the safety of the egress path.

For Exceptions 1 and 3, the assumption is that the occupants are familiar enough with the space to know the way out and/or the exits are obvious. In addition, in most cases, the way out is the same as the way in.

In accordance with Exception 2, when the main exterior door through which occupants enter the building is obviously an exit, exit signs are not required. For example, a two-story Group B building has a main employee/customer entrance. The entrance consists of a storefront arrangement with glass doors and sidelights. The entrance is centrally located within the building. These main exterior exit doors can be quickly observed as being an exit and would not need to be marked with an exit sign.

In accordance with Exception 4, exit signs are not

required in detainee living and sleeping room areas of Group I-3 buildings. In cases of emergency, occupants in Group I-3 are escorted by staff to the exits and to safety. exit sign materials can also be potential weapons when they are accessible to the detainees.

In the Group A-4 and A-5 occupancies described in Exception 5, the egress path is obvious and thus exit signs are not needed. Additionally, because of the configuration of the vomitories, the exit signs are not readily visible to the persons immediately adjacent to or above the vomitory.

**1013.2 Floor-level exit signs in Group R-1.** Where exit signs are required in Group R-1 occupancies by Section 1013.1, additional low-level exit signs shall be provided in all areas serving guest rooms in Group R-1 occupancies and shall comply with Section 1013.5.

The bottom of the sign shall be not less than 10 inches (254 mm) nor more than 12 inches (305 mm) above the floor level. The sign shall be flush mounted to the door or wall. Where mounted on the wall, the edge of the sign shall be within 4 inches (102 mm) of the door frame on the latch side.

❖ Because people may be sleeping and because most residents are transient (and thus unfamiliar with the space) in hotels (i.e., Group R-1), low-level exit signs must be provided for emergency exit routes from guestrooms. When smoke at the ceiling obscures the exit signs required by Section 1013.1, these signs will serve as a backup identification of the exit door. By the reference to Section 1013.5, these signs must be internally illuminated and listed and labeled in accordance with UL 924. It is not the intent of this section to require low level exit signs in the guestrooms. The low level exit signs are required only in areas where Section 1013.1 requires exit signs and only leading from the guestroom area, not throughout the entire hotel.

**Figure 1013.1**  
**EXIT SIGNS WITHIN AN EXIT ENCLOSURE**

The exit signs must be mounted on the exit door itself or to the side of the exit door on the latch side. The height of the bottom of the exit sign will allow for exit signs not to conflict with accessible route requirements. ICC A117.1 requires doors on an accessible route to have a smooth surface for the bottom 10 inches (254 mm) so that someone could use the footplates on their wheelchair to assist in opening the door.

The requirements do not indicate what low-level signage is appropriate for exit signs that provide direction rather than at the exit. It is also not clear on how an exit sign on a door will be visible from down the corridor if the door is perpendicular to the direction of the hallway.

**1013.3 Illumination.** Exit signs shall be internally or externally illuminated.

**Exception:** Tactile signs required by Section 1013.4 need not be provided with illumination.

❖ This section simply provides the scope for illumination of regulated exit signs. Exit signs must be illuminated so that they are readily apparent in situations where the lights may be off or the building has lost power. Exit signs with raised letters and braille are specifically addressed in Section 1013.4.

**1013.4 Raised character and braille exit signs.** A sign stating EXIT in visual characters, raised characters and braille and complying with ICC A117.1 shall be provided adjacent to each door to an *area of refuge*, an exterior area for assisted rescue, an *exit stairway* or *ramp*, an *exit passageway* and the *exit discharge*.

❖ The purpose of this sign is to serve as way finding for a person with vision impairments. This is in addition to the exit signs required by Section 1013.1.

“Tactile” is defined as “used for the sense of touch;” therefore, signage that has either raised letters or braille is considered tactile. For exit signage, visual, raised letters and braille are required. ICC A117.1 includes requirements for the sign and the correct placement. Typically, the sign is placed at about 4 feet, 6 inches (1375 mm) above the floor and on the wall at the latch side of the door. While not required to be illuminated by these provisions, illumination would be advantageous for a person with partial sight. High contrast is important (see Commentary Figure 1013.4).

This signage is needed to indicate which doors are serving as exits for those persons with visual impairments. Signs are needed on the required exit doors in the building: including at doors leading to an interior or exterior exit stairway or ramp; doors leading to an exit passageway; within the exit enclosures leading to the outside or to an exit passageway; and exit doors that lead directly to the outside.

While an area of refuge may be located within an enclosure for an exit stairway, Section 1009.3 also allows the area of refuge to be located immediately outside of the enclosure for the exit stairway. In this

situation, exit signage with visual, raised letters and braille would be required both at the door leading into the area of refuge and the door leading to the exit stairway. Exterior areas for assisted rescue are typically located immediately outside of an exit door (see Section 1009.7).

This is not intended to preclude the signage from including additional information as long as “Exit” is first. For example, labeling the door to the exit enclosure as “Exit Stairway” would indicate to the visually impaired person that once they moved through the door they would be dealing with vertical travel. This could be considered an additional safety feature. This section is also referenced in IBC Section 1111.3. For additional way-finding signage inside the stairway enclosure, see Section 1023.9.

**1013.5 Internally illuminated exit signs.** Electrically powered, *self-luminous* and *photoluminescent* exit signs shall be *listed* and *labeled* in accordance with UL 924 and shall be installed in accordance with the manufacturer’s instructions and Chapter 27. Exit signs shall be illuminated at all times.

❖ All exit signage must be listed and labeled as indicated in UL 924, *Standard for Safety of Emergency Lighting and Power Equipment*. Listed “Exit” signs are required by UL 924 to meet the same graphics, illumination and power sources defined in Sections 1013.6.1 through 1013.6.3 for externally illuminated signs. Internal illumination may be electrically powered or be of a self-luminous or photoluminescent product. Electrically powered would include LED, incandescent, fluorescent and electroluminescent types of signs. If a sign is photoluminescent, the “charging” source must be continually available (see the definitions in Chapter 2 for “Photoluminescent” and “Self-luminous”). “Exit” signs must be illuminated at all times, including when the building may not be fully occupied. If a fire occurs late at night, there may be cleaning crews or persons working overtime in the

**Figure 1013.4**  
**EXAMPLE OF EXIT SIGNAGE WITH VISUAL AND RAISED CHARACTERS WITH BRAILLE**

building who will need to be able to find the exits. The reference to Section 604 is so the signs will be equipped with a connection to an emergency power supply.

**1013.6 Externally illuminated exit signs.** Externally illuminated exit signs shall comply with Sections 1013.6.1 through 1013.6.3.

❖ Externally illuminated exit signage must meet the graphic, illumination and emergency power requirements in the referenced sections. The requirements are the same as for internally illuminated signage.

**1013.6.1 Graphics.** Every exit sign and directional exit sign shall have plainly legible letters not less than 6 inches (152 mm) high with the principal strokes of the letters not less than  $\frac{3}{4}$  inch (19.1 mm) wide. The word "EXIT" shall have letters having a width not less than 2 inches (51 mm) wide, except the letter "I," and the minimum spacing between letters shall be not less than  $\frac{3}{8}$  inch (9.5 mm). Signs larger than the minimum established in this section shall have letter widths, strokes and spacing in proportion to their height.

The word "EXIT" shall be in high contrast with the background and shall be clearly discernible when the means of exit sign illumination is or is not energized. If a chevron directional indicator is provided as part of the exit sign, the construction shall be such that the direction of the chevron directional indicator cannot be readily changed.

❖ Every exit sign and directional sign located in the exit access or exit route is required to have a color contrast vivid enough to make the signs readily visible, even when not illuminated. Letters must be at least 6 inches (152 mm) high and their stroke not less than  $\frac{3}{4}$  inch (19.1 mm) wide (see Commentary Figure 1013.6.1). The sizing of the letters is predicated on the readability of the wording from a distance of 100 feet (30 480 mm).

While red letters are common for exit signs, sometimes green on black is used in auditorium areas with

low-lighting levels, such as theaters, because that color combination tends not to distract the audience's attention. It is more important that the exit sign be readily visible with respect to the background.

Exit signs may be larger than the minimum size specified; however, the standardized proportion of the letters must be maintained. Externally illuminated signage that is smaller could use the requirements in UL 924 for guidance; however, sign spacing would need to be adjusted, and alternative approval would be through the building official having jurisdiction.

A "chevron directional indicator" is the same as a directional arrow. The language is intended to be consistent with UL 924.

**1013.6.2 Exit sign illumination.** The face of an exit sign illuminated from an external source shall have an intensity of not less than 5 footcandles (54 lux).

❖ Every exit sign and directional sign must be continuously illuminated to provide a light intensity at the illuminated surface of at least 5 footcandles (54 lux). It is not a requirement that the exit signs be internally illuminated. An external illumination source with the power capabilities specified by Section 1013.6.3 is acceptable.

**1013.6.3 Power source.** Exit signs shall be illuminated at all times. To ensure continued illumination for a duration of not less than 90 minutes in case of primary power loss, the sign illumination means shall be connected to an emergency power system provided from storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Chapter 27.

#### Exceptions:

1. *Approved* exit sign illumination means that provide continuous illumination independent of external power sources for a duration of not less than 90 minutes, in case of primary power loss, are not required to be connected to an emergency electrical system.
2. Group I-2 Condition 2 exit sign illumination shall not be provided by unit equipment battery only.

❖ Exit signs must be illuminated on a continuous basis so that when a fire emergency occurs, occupants will be able to identify the locations of the exits. The reliability of the power sources supplying the electrical energy required for maintaining the illumination of exit signs is important. When power interruptions occur, exit sign illumination must be obtained from an emergency power system. This does not imply that the sign must be internally illuminated. Whatever illumination system is used, whether internal or external, it must be connected to a system designed to pick up the power load required by the exit signs after loss of the normal power supply.

Per Exception 1, where self-luminous signs are used, connection to the emergency electrical supply system is not required. A trickle-charge battery to illuminate the exit sign is another option.

Exception 2 is really a more restrictive requirement for hospitals. Hospitals cannot only rely on equipment

batteries for the illumination of their exit signs. Typically, hospitals connect illumination of their exit signage to the emergency on-site generator.

The IFC requirements for emergency power for emergency egress lighting and exit signage in existing buildings only requires a 60-minute time duration. This is not a conflict, but rather recognition of the loss of battery storage capability over a length of time.

## SECTION 1014 HANDRAILS

**1014.1 Where required.** *Handrails* serving *stairways*, *ramps*, stepped *aisles* and ramped *aisles* shall be adequate in strength and attachment in accordance with Section 1607.8. *Handrails* required for *stairways* by Section 1011.11 shall comply with Sections 1014.2 through 1014.9. *Handrails* required for *ramps* by Section 1012.8 shall comply with Sections 1014.2 through 1014.8. *Handrails* for stepped *aisles* and ramped *aisles* required by Section 1029.15 shall comply with Sections 1014.2 through 1014.8.

❖ Handrails are required at stairways and ramps. In all situations, they must be designed in accordance with the structural requirements in Section 1607.8. There are, however, distinct differences in how the handrail requirements are applied in stairways, ramps, stepped aisles and ramped aisles. The specific section references allow for this consideration. Where and how many handrails for stairways and ramps are specified in Sections 1003.5, 1011.11 and 1012.8. Where handrails are required in assembly seating for stepped aisles and ramped aisles is specified in Section 1029.15.

Stairways and their handrails are not part of an accessible route and are not subject to the stairway technical requirements in ICC A117.1. Standards are only referenced to the extent specified by the code (see Section 102.4).

Handrails are also very distinct from guards, even though they are sometimes incorrectly called “guardrails.” The “handrail” is the element that is grasped during vertical travel for guidance, stabilization, pulling and as an aid in arresting a possible fall. Guards are located near the side of an elevated walking surface to minimize the possibility of a fall to a lower level and are discussed in Section 1015. However, in residential applications, in some locations in assembly seating and along alternating tread devices and ship’s ladders, the top rail of a guard may also serve as a handrail (see Section 1015.3, Exceptions 3, 4 and 5, and Section 1029.16).

**1014.2 Height.** *Handrail* height, measured above *stair* tread *nosings*, or finish surface of *ramp* slope, shall be uniform, not less than 34 inches (864 mm) and not more than 38 inches (965 mm). *Handrail* height of *alternating tread devices* and ship’s ladders, measured above tread *nosings*, shall be uni-

form, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

### Exceptions:

1. Where handrail fittings or bendings are used to provide continuous transition between *flights*, the fittings or bendings shall be permitted to exceed the maximum height.
2. In Group R-3 occupancies; within *dwelling units* in Group R-2 occupancies; and in Group U occupancies that are associated with a Group R-3 occupancy or associated with individual *dwelling units* in Group R-2 occupancies; where handrail fittings or bendings are used to provide continuous transition between *flights*, transition at *winder* treads, transition from *handrail* to *guard*, or where used at the start of a *flight*, the *handrail* height at the fittings or bendings shall be permitted to exceed the maximum height.
3. *Handrails* on top of a guard where permitted along stepped aisles and ramped aisles in accordance with Section 1029.15.

❖ It has been demonstrated that for safe use, the height of handrails must not be less than 34 inches (864 mm) nor more than 38 inches (965 mm) above the leading edge of stairway treads, landings or other walking surfaces (see Commentary Figure 1014.2). This requirement is applicable for all uses, including handrails within a dwelling unit.

The fundamental stairway requirements are not appropriate for alternating tread devices and ship’s ladders since they differ significantly from other types of stairways. The permitted range for handrail height for alternating tread devices and ship’s ladders allows for a lower height above the tread nosings. The minimum required height is reduced from 34 inches (864 mm) to 30 inches (762 mm), with a maximum permitted height of 34 inches (864 mm). The special features of an alternating tread device or ship’s ladder result in differences of handrail use, such as different arm posture, the hand gripping the handrail near a higher part of the body and the use of handrails under the arms for stabilization when descending. Therefore, a lower handrail height is more appropriate.

Exceptions 1 and 2 allow for the use of common fittings and bendings to provide for continuous transition of the handrail at specified turns and pitch changes in the stairway where the fitting or bending might exceed the maximum handrail height. In some cases, there is no reference for the height when the fitting or handrail might extend beyond the nosings at the intersection of adjoining flights. Exception 1 applies to all stairways between flights. This typically occurs at the center handrail at the landings on a dogleg or switchback stairway configuration. Although the handrails are not required on the land-

ing, the code requirement for handrail extensions or for handrail continuity often creates the need for some type of transition, especially at turns (see also Section 1014.6). This exception would allow for an easing or gooseneck riser over the landing to be used for a smooth transition of the handrail. The use of the new exceptions may permit a more gradual variation in the height even though it will allow for portions of the handrail to exceed the normal 38-inch (965 mm) maximum height. The belief is that handrail continuity is more important than staying within the height limitation.

Exception 2 applies to dwelling units with the intent to allow transition elements at common locations, such as the start of the flight, at winder treads or from handrail to guard at landings. Combined with the guard height reduction in Section 1015.3, Exception 1, the end result may be fewer transition pieces. This is consistent with provisions in the IRC.

Exception 3 is in recognition of the special allowances for the top rail of a guard to serve as a handrail in limited situations in an assembly seating area. See Section 1029.15 for specifics.

**1014.3 Handrail graspability.** Required *handrails* shall comply with Section 1014.3.1 or shall provide equivalent graspability.

**Exception:** In Group R-3 occupancies; within *dwelling units* in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual *dwelling units* in Group R-2 occupancies; *handrails* shall be Type I in accordance with Section 1014.3.1, Type II in accordance with Section 1014.3.2 or shall provide equivalent graspability.

❖ The abilities to grasp a handrail firmly and slide a hand along the rail's gripping surface without meeting obstructions are important factors in the safe use of stairways and ramps. These properties are largely functions of the shape of the handrail. Handrails for stairways and ramps must meet the specifications of Section 1014.3.1 or be determined to have grasping properties and attributes equivalent to profiles allowed in Section 1014.3.1. Such determinations of equivalence are an allowed option made by local building officials based on the profile presented and the building official's evaluation of its properties. A complete evaluation will consider the four basic functions of a handrail: guidance, stabilization, pulling and aid in arresting a fall. The determination is best made by comparative use on stairs or ramps of properly mounted samples. Handrails that meet neither Type I nor Type II characteristics may be considered to have equivalent graspability. Complete evaluation will also consider the mounting of the handrail and understanding the interference of handrail mounts on the gripping surfaces of smaller profiles. For a discussion of this, see Section 1014.4.

The exception allows for an alternative, Type II handrails, within residential units and their associated structures. A handrail on common stairways within an apartment building or on the steps to the front door of a townhouse could not use this exception unless approved by the building official as being equivalent to Type I. The residential allowance is consistent with the IRC.

**1014.3.1 Type I.** *Handrails* with a circular cross section shall have an outside diameter of not less than 1<sup>1</sup>/<sub>4</sub> inches (32 mm) and not greater than 2 inches (51 mm). Where the *handrail* is not circular, it shall have a perimeter dimension of not less than 4 inches (102 mm) and not greater than 6<sup>1</sup>/<sub>4</sub> inches (160 mm) with a maximum cross-sectional dimension of 2<sup>1</sup>/<sub>4</sub> inches (57 mm) and minimum cross-sectional dimension of 1 inch (25 mm). Edges shall have a minimum radius of 0.01 inch (0.25 mm).

❖ Handrails have traditionally been regulated as either circular or noncircular rails. The noncircular rails have previously been limited to a maximum perimeter dimension of 6<sup>1</sup>/<sub>4</sub> inches (160 mm), with other limitations addressing minimum perimeter and minimum and maximum cross-sectional dimensions. These handrails shapes are now referred to as Type I handrails.

Type I handrails include circular cross sections with an outside diameter of at least  $1\frac{1}{4}$  inches (32 mm) but not greater than 2 inches (51 mm). This limits the perimeter of the cross section such that the gripping surface incorporates the bottom of the rail. A handrail with either a very narrow or a large cross section is not graspable in a power grip by all able-bodied users and certainly not by those with hand-strength or flexibility deficiencies. A power grip typically accesses the bottom surface of the handrail, such as around a bar. A pinching grip is not as effective when there is a need to arrest a fall. An example of a pinching grip would be where a 2x4 stud on edge was used as a handrail. This would not comply with graspability concerns.

Noncircular Type I cross sections must meet the alternative noncircular criteria in this section, and the bottom of the rail must be considered part of the suitable gripping surface. Of note is that this criteria now includes a minimum cross section of 1 inch (25 mm) to provide for designs that reduce the interference of fingers and an opposing thumb that occurs when small objects are tightly grasped. Edges must be slightly rounded and not sharp. An example is shown in Commentary Figure 1014.3.1.

Ramp requirements in ICC A117.1 are referenced as part of the accessible route requirements in Chapter 11. Current handrail provisions are largely coordinated with the Type I handrail requirements in this section. Section 103 of ICC A117.1 would also permit alternative handrail shapes if they provided equivalent or better graspability.

**1014.3.2 Type II.** Handrails with a perimeter greater than  $6\frac{1}{4}$  inches (160 mm) shall provide a graspable finger recess area on both sides of the profile. The finger recess shall begin within a

distance of  $\frac{3}{4}$  inch (19 mm) measured vertically from the tallest portion of the profile and achieve a depth of not less than  $\frac{5}{16}$  inch (8 mm) within  $\frac{7}{8}$  inch (22 mm) below the widest portion of the profile. This required depth shall continue for not less than  $\frac{3}{8}$  inch (10 mm) to a level that is not less than  $1\frac{3}{4}$  inches (45 mm) below the tallest portion of the profile. The width of the handrail above the recess shall be not less than  $1\frac{1}{4}$  inches (32 mm) to not greater than  $2\frac{3}{4}$  inches (70 mm). Edges shall have a minimum radius of 0.01 inch (0.25 mm).

❖ Handrail profiles having a perimeter dimension greater than  $6\frac{1}{4}$  inches (160 mm), identified as Type II handrails, are acceptable within dwelling units and their associated structures when complying with all of the specific dimensional requirements.

Research has shown that Type II handrails have graspability that is essentially equal to or greater than the graspability of handrails meeting the long-accepted and codified shape and size now defined as Type I.

The key features of the graspability of Type II handrails are graspable finger recesses on both sides of the handrail. These recesses allow users to firmly grip a properly proportioned grasping surface on the top of the handrail, ensuring that the user can tightly retain a power-span grip on the handrail for all forces that are associated with attempts to arrest a fall.

This class of handrails incorporates a grip surface with controlled recesses for the purchase of the fingers and opposing thumb. These handrail shapes allow the use of power-span grips that need not encompass the bottom surfaces of the rail, allowing the design of taller cross sections that can eliminate the interference of mountings and provide a completely uninterrupted gripping surface for the user. The limits of the position and depth of the required recesses represent the minimum standard. Optimizing the design within the parameters with larger recesses and complete finger clearance from mountings will enhance the performance of these profiles. Although this standard allows design flexibility, it is important to follow the specifications accurately to comply. Each drawing in Commentary Figure 1014.3.2 illustrates the requirements of each sentence for clarity.

**1014.4 Continuity.** Handrail gripping surfaces shall be continuous, without interruption by newel posts or other obstructions.

#### Exceptions:

1. Handrails within *dwelling units* are permitted to be interrupted by a newel post at a turn or landing.
2. Within a *dwelling unit*, the use of a volute, turnout, starting easing or starting newel is allowed over the lowest tread.
3. Handrail brackets or balusters attached to the bottom surface of the handrail that do not project horizontally beyond the sides of the handrail within  $1\frac{1}{2}$  inches (38 mm) of the bottom of the handrail shall not be considered obstructions. For each  $\frac{1}{2}$  inch

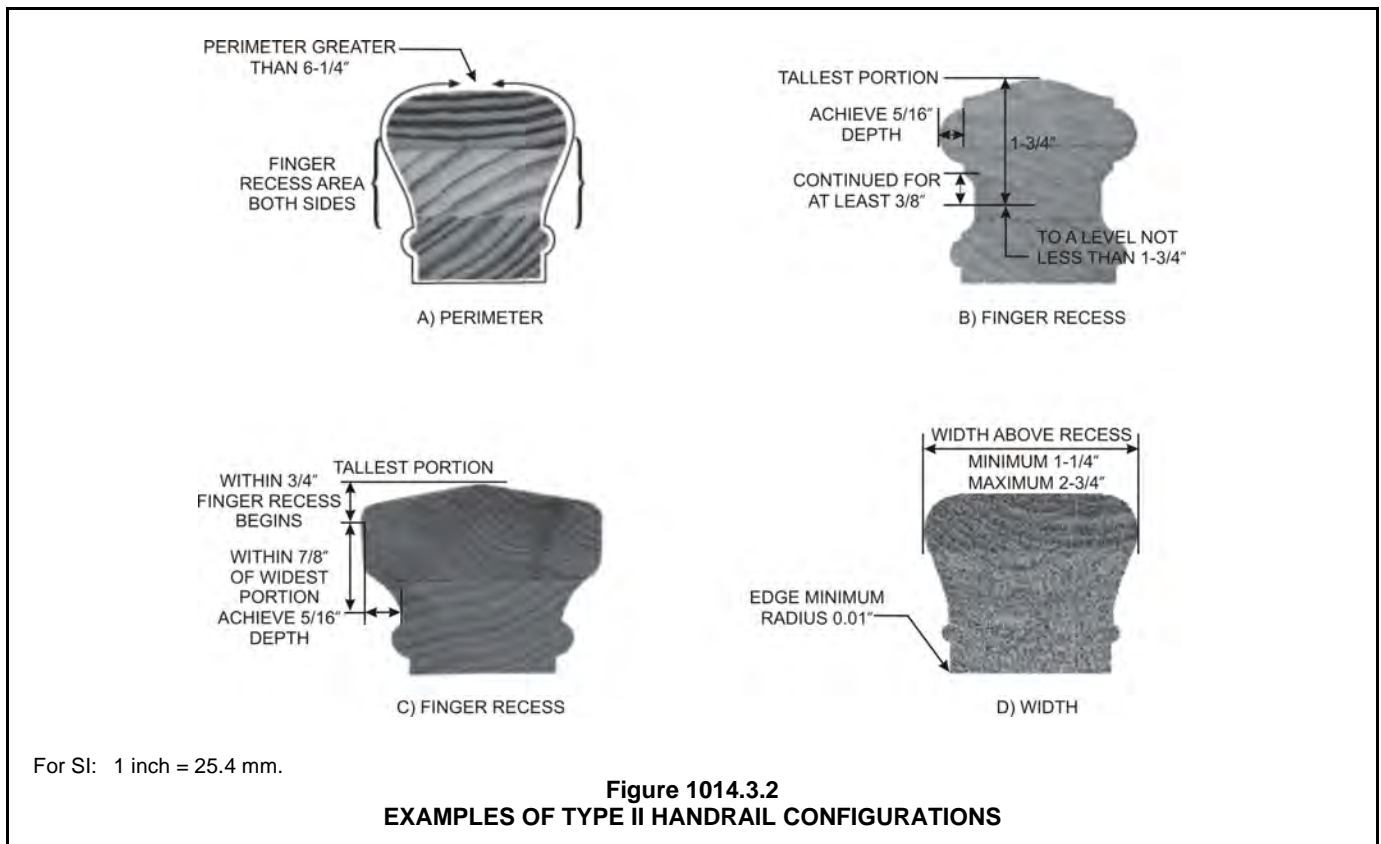

(12.7 mm) of additional handrail perimeter dimension above 4 inches (102 mm), the vertical clearance dimension of 1½ inches (38 mm) shall be permitted to be reduced by 1⁄8 inch (3.2 mm).

4. Where *handrails* are provided along walking surfaces with slopes not steeper than 1:20, the bottoms of the handrail gripping surfaces shall be permitted to be obstructed along their entire length where they are integral to crash rails or bumper guards.
5. *Handrails* serving stepped *aisles* or ramped *aisles* are permitted to be discontinuous in accordance with Section 1029.15.1.

❖ Handrails must be usable for their entire length without requiring the users to release their grasp. Typically, when using the handrail while traveling the means of egress, an individual's arm is extended to lead the body with the hand forming a loose grip on the top and sides of the rail. If handrails are to be of service to users, they must be uninterrupted and continuous. Oversize newels, changes in the guard system, or excessive supports at the bottom of small perimeter handrails can cause interruption of the handrail, requiring the occupants to release their grip [see Commentary Figure 1014.4(1)]. Exception 1 allows the interruption of the handrail by a newel post at the intersection of two handrail sections at a turn within a flight or at a landing in dwelling units; however, this exception is not applicable to curved or spiral stairs. Exception 2 provides for familiar and historical handrail details, often combined with

guards, that have been used for decades in dwelling units without substantiated detriment to the safety of the occupants. Exception 3 provides specifications for the attachment of brackets and balusters to the bottom of handrails to provide for minimum finger clearance such that they will not be considered obstructions. This method of handrail support limits interruptions of the grip surfaces at the bottom of smaller perimeter shapes that otherwise would deter or impede the user's ability to attain a stabilizing grip essential to safe stairway use. Larger handrail sizes permit shorter brackets since geometrically the finger clearance is still maintained [see Commentary Figure 1014.4(2)]. For example, a Type II handrail may elevate the fingertips completely above the supports, allowing the rail to be mounted by other means that do not obstruct when providing the clearances specified. Exception 4 allows for products that serve dual purposes, such as the bumper guard/handrail found in hospitals and nursing homes along corridors, to have a continuous bottom support. Since these are only permitted on slopes that are less than what is defined as a ramp, the handrails are more for assistance in mobility or balance rather than to arrest a fall.

Exception 5 references back to provisions for stepped and ramped aisles in assembly seating. Discontinuous handrails are permitted to allow for access to seats. Such discontinuous handrails must still extend the full run of the aisle stairs or ramp. See Section 1029.15.1.

**1014.5 Fittings.** *Handrails* shall not rotate within their fittings.

- ❖ Fittings are those component pieces of a continuous handrail that are shaped or bent and attached to the longer sections of straight or curved handrail to provide for transition at changes in pitch, direction or to provide for termination of a continuous handrail. Fittings and handrails must be securely joined to ensure a stable handrail that does not allow any portion to rotate when grasped.

**1014.6 Handrail extensions.** *Handrails* shall return to a wall, *guard* or the walking surface or shall be continuous to the handrail of an adjacent *flight of stairs* or *ramp* run. Where *handrails* are not continuous between *flights*, the *handrails* shall extend horizontally not less than 12 inches (305 mm) beyond the top riser and continue to slope for the depth of one tread beyond the bottom riser. At *ramps* where *handrails* are not continuous between runs, the *handrails* shall extend horizontally above the landing 12 inches (305 mm) minimum beyond the top and bottom of *ramp* runs. The extensions of

**Figure 1014.4(1)**  
**EXAMPLES OF PROHIBITED HANDRAIL DESIGNS**

**Figure 1014.4(2)**  
**REDUCED BRACKET EXTENSIONS EXAMPLE PER SECTION 1012.4, EXCEPTION 3**

*handrails* shall be in the same direction of the *flights of stairs* at *stairways* and the *ramp runs* at *ramps*.

**Exceptions:**

1. *Handrails* within a *dwelling unit* that is not required to be *accessible* need extend only from the top riser to the bottom riser.
2. *Handrails* serving aisles in rooms or spaces used for assembly purposes are permitted to comply with the handrail extensions in accordance with Section 1029.15.
3. *Handrails* for *alternating tread devices* and ship's ladders are permitted to terminate at a location vertically above the top and bottom risers. *Handrails* for *alternating tread devices* are not required to be continuous between *flights* or to extend beyond the top or bottom risers.

❖ The purpose of return requirements at handrail ends is to prevent a person from catching an article of clothing or satchel straps, or from being injured by falling on the extended end of a handrail.

The length that a handrail extends beyond the top and bottom of a stairway, ramp or intermediate landing where handrails are not continuous to another stair flight or ramp run is an important factor for the safety of the users. An occupant must be able to grasp securely a handrail beyond the last riser of a stairway or the last sloped segment of a ramp. Handrail terminations that bend around a corner do not provide this stability; therefore, the handrail must extend in the direction of the stair flight or ramp run. The handrail extensions are not required where a user could keep his or her hand on the handrail, such as the continuous handrail at the landing of a switch-back stairway or ramp (see Section 1014.2, Exception 1).

For stairways, handrails must be extended 12 inches (305 mm) horizontally beyond the top riser and sloped a distance of one tread depth beyond the bottom riser. For ramps, handrails must be extended 12 inches (305 mm) horizontally beyond the last sloped ramp segment at both the top and bottom locations. These handrail extensions are not only required at the top and bottom on both sides of stairways and ramps, but also at other places where handrails are not continuous, such as landings and platforms. These requirements are intended to reflect the current provisions of ICC A117.1 (see Commentary Figure 1014.2) and the 2010 ADA Standard. Note that if the handrail extension is at a location that could be considered a protruding object, the handrail must return to the post at a height of less than 27 inches (686 mm) above the floor (see Sections 1003.3.2 and 1003.3.3).

In accordance with Exception 1, handrail extensions are not required where a dwelling unit is not required to meet any level of accessibility (i.e., Accessible unit, Type A unit or Type B unit). Handrail exten-

sions are permitted to end at a newel post or turnaround.

Exception 2 provides for handrails along ramped or stepped aisles in assembly seating configurations, such as in sports facilities, theaters and lecture halls. It is necessary to limit handrail extensions in assembly aisles so that circulation in cross aisles that run perpendicular to the stepped or sloped aisles is not compromised.

Exception 3 allows for the unique construction considerations for alternating tread devices and ship's ladders. Again, usage of these devices is very limited. Since alternative tread devices and ship's ladders are typically utilized as a safer alternative to a vertical ladder, they are often located in tight spaces where traditional-type stairs cannot be used or are not required. With a much steeper angle than traditional stairs and differing usage, handrail extensions and continuity provisions are not practical.

**1014.7 Clearance.** Clear space between a handrail and a wall or other surface shall be not less than 1½ inches (38 mm). A handrail and a wall or other surface adjacent to the *handrail* shall be free of any sharp or abrasive elements.

❖ A clear space is needed between a handrail and the wall or other surface to allow the user to slide his or her hand along the rail with fingers in the gripping position without contacting the wall surface, which could have an abrasive texture. In climates where persons may be expected to be wearing heavy gloves during the winter, an open design with greater clearance would be desirable at an exterior stairway, or a stairway directly inside the entrance to a building. [See Commentary Figures 1014.4(2) and 1014.8(2) for an illustration of handrail clearance.]

**1014.8 Projections.** On *ramps* and on ramped *aisles* that are part of an *accessible route*, the clear width between *handrails* shall be 36 inches (914 mm) minimum. Projections into the required width of *aisles*, *stairways* and *ramps* at each side shall not exceed 4½ inches (114 mm) at or below the handrail height. Projections into the required width shall not be limited above the minimum headroom height required in Section 1011.3. Projections due to intermediate *handrails* shall not constitute a reduction in the egress width. Where a pair of intermediate *handrails* are provided within the *stairway* width without a walking surface between the pair of intermediate *handrails* and the distance between the pair of intermediate *handrails* is greater than 6 inches (152 mm), the available egress width shall be reduced by the distance between the closest edges of each such intermediate pair of *handrails* that is greater than 6 inches (152 mm).

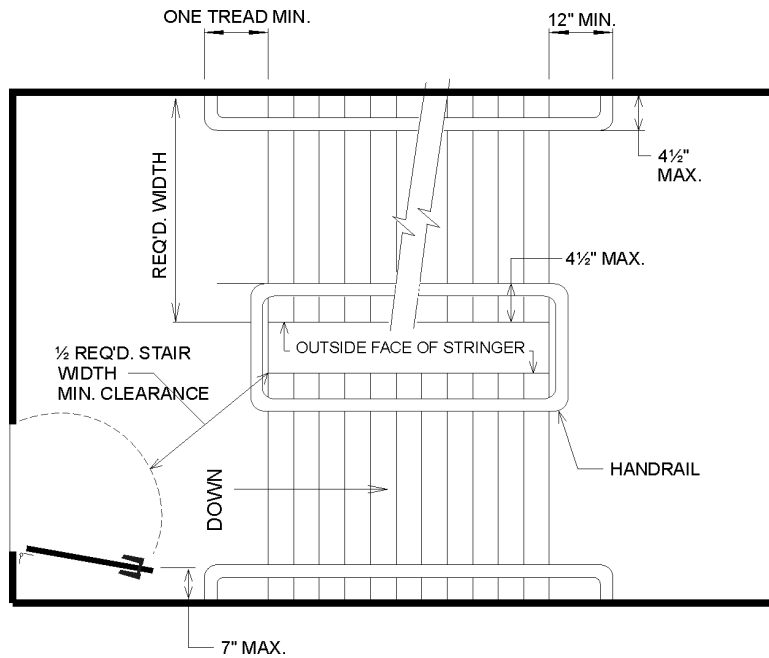

❖ Handrails may not project more than 4½ inches (114 mm) into the required width of a stairway, so that the clear width of the passage will not be seriously reduced [see Commentary Figure 1014.8(1)]. This is consistent with Section 1003.3.3. This projection may exist below the handrail height as well [see Commentary Figure 1014.8(2)]. The projection can be greater

**MEANS OF EGRESS**

on stairways or ramps exceeding minimum width requirements.

The requirement for some stairways to have center handrails (Section 1014.9) could result in a single or double handrail down the center of the flight of stairs. Since these stairways are 60 inches (1525 mm) or wider, a center handrail would typically not be an obstruction and, therefore, would not reduce the

capacity of the stairway. Schools and large assembly spaces commonly put in center handrails to aid in the flow up and down the stairs during peak usage times. If the center handrail is a double rail with a spacing of more than 6 inches (152mm), the width of the stairway may need to be adjusted to compensate for the loss of available width.

For SI: 1 inch = 25.4 mm.

**Figure 1014.8(1)**  
**TYPICAL HANDRAIL ARRANGEMENT**

For SI: 1 inch = 25.4 mm.

**Figure 1014.8(2)**  
**PROJECTION OF HANDRAIL**

**1014.9 Intermediate handrails.** *Stairways* shall have intermediate *handrails* located in such a manner that all portions of the *stairway* minimum width or required capacity are within 30 inches (762 mm) of a handrail. On monumental *stairs*, *handrails* shall be located along the most direct path of egress travel.

❖ In order to always be available to the user of the stairway, the maximum horizontal distance to a handrail from within the width required must not exceed 30 inches (762 mm). People tend to walk close to handrails, and if intermediate handrails are not provided for very wide stairways, the center portion of such stairways will normally receive less use. More importantly, in emergencies, the center portions of wide stairways with handrails would enhance egress travel rather than delay it by overcrowding at the sides with the handrails. This would especially be true under panic conditions where the use of wide interior stairways could become particularly hazardous.

The distance to the handrail applies to the "required" width of the stairway. If a stairway is greater than 60 inches (1524 mm) in width, but only 60 inches (1524 mm) total width is required based on occupant load (see Section 1005.3.1), intermediate handrails are not required. Adequate safety is provided since every user is within 30 inches (762 mm) of a handrail.

Monumental stairways are typically provided for architectural effect and may or may not be considered required egress stairs. The criteria for monumental egress stairways deal with the very wide stairway in relation to the required width. While hand-

rails on both sides of the stairway may be sufficient to accommodate the required width, the handrails may not be near the stream of traffic or even apparent to the user. In this case, the handrails are to be placed in a location more reflective of the egress path (see Commentary Figure 1014.9).

**SECTION 1015  
GUARDS**

**1015.1 General.** *Guards* shall comply with the provisions of Sections 1015.2 through 1015.7. Operable windows with sills located more than 72 inches (1829 mm) above finished grade or other surface below shall comply with Section 1015.8.

❖ Guards required along dropoffs must comply with the provisions for height, strength and opening limitations. Special provisions are provided for unique locations, such as screened-in porches, around mechanical equipment on platforms or roofs and at hatch openings.

Where there are operable windows on upper floors, there is a concern over the possibility of a child falling; thus, the placement of this requirement is in the guard section. Such windows must comply with Section 1015.8.

**1015.2 Where required.** *Guards* shall be located along open-sided walking surfaces, including *mezzanines*, *equipment platforms*, *aisles*, *stairs*, *ramps* and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. *Guards* shall

## MEANS OF EGRESS

be adequate in strength and attachment in accordance with Section 1607.8.

**Exception:** *Guards* are not required for the following locations:

1. On the loading side of loading docks or piers.
  2. On the audience side of *stages* and raised *platforms*, including *stairs* leading up to the *stage* and raised *platforms*.
  3. On raised *stage* and *platform* floor areas, such as runways, *ramps* and side *stages* used for entertainment or presentations.
  4. At vertical openings in the performance area of *stages* and *platforms*.
  5. At elevated walking surfaces appurtenant to *stages* and *platforms* for access to and utilization of special lighting or equipment.
  6. Along vehicle service pits not accessible to the public.
  7. In assembly seating areas at cross aisles in accordance with Section 1029.16.2.
- ❖ Where one or more sides of a walking surface are open to the floor level or grade below, a guard system must be provided to minimize the possibility of occupants accidentally falling to the surface below. A guard is required only where the difference in elevation between the higher walking surface and the surface below is greater than 30 inches (762 mm). When the ground slopes away from the edge, the vertical distance from the walking surface to the grade or floor below must also be more than 30 inches (762 mm) on

the lowest point within a 36-inch (914 mm) radius measured horizontally from the edge of the open-sided walking surface (see Commentary Figure 1015.2).

The loads for guard design are addressed in IBC Section 1607 and are typically 50 plf (222 N) along the top with a 200-pound (90.72 kg) concentrated force. If glazing is used as part of a guard system, or windows are located adjacent to stairways or ramps, the guard must also comply with Section 1015.2.1 (see Section 1015.2.1 and IBC Sections 1607.8 and 2407).

Most of the exceptions identify situations where guards are not practical, such as along loading docks, stages and their approaches, and vehicle service pits. Exception 7 references assembly spaces where a lower guard is permitted or the alternative of seat backs where the dropoff is adjacent to a cross aisle.

**1015.2.1 Glazing.** Where glass is used to provide a *guard* or as a portion of the *guard* system, the *guard* shall comply with Section 2407. Where the glazing provided does not meet the strength and attachment requirements of Section 1607.8, complying *guards* shall be located along glazed sides of open-sided walking surfaces.

❖ Glazing in guards may be infill or structural. The loads for guard design in Section 1015.2, which references IBC Section 1607, are typically 50 plf (222 N) along the top with a 200-pound (90.72 kg) concentrated force. Two different situations are addressed with glazing: where glazing is installed in a guard on the side of a stairway, ramp or landing; or when a stairway, ramp or landing is immediately adjacent to a window where the glazing has not been designed to resist the forces from a fall (see IBC Sections 1607.8 and 2407 and Commentary Figure 1015.2.1).

**Figure 1015.2.1**  
**GUARD SYSTEM WITH GLAZING**

**1015.3 Height.** Required *guards* shall be not less than 42 inches (1067 mm) high, measured vertically as follows:

1. From the adjacent walking surfaces.
2. On *stairways* and stepped *aisles*, from the line connecting the leading edges of the tread *nosings*.
3. On *ramps* and ramped *aisles*, from the *ramp* surface at the *guard*.

**Exceptions:**

1. For occupancies in Group R-3 not more than three stories above grade in height and within individual *dwelling units* in occupancies in Group R-2 not more than three stories above grade in height with separate *means of egress*, required *guards* shall be not less than 36 inches (914 mm) in height measured vertically above the adjacent walking surfaces or adjacent *fixed seating*.
2. For occupancies in Group R-3, and within individual *dwelling units* in occupancies in Group R-2, *guards* on the open sides of *stairs* shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.

3. For occupancies in Group R-3, and within individual *dwelling units* in occupancies in Group R-2, where the top of the *guard* also serves as a *handrail* on the open sides of *stairs*, the top of the *guard* shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm) measured vertically from a line connecting the leading edges of the treads.
4. The *guard* height in assembly seating areas shall comply with Section 1029.16 as applicable.
5. Along *alternating tread devices* and ship's ladders, *guards* where the top rail also serves as a *handrail* shall have height not less than 30 inches (762 mm) and not more than 34 inches (864 mm), measured vertically from the leading edge of the device tread *nosing*.

❖ *Guards* must not be less than 42 inches (1067 mm) in height as measured vertically from the top of the guard down to the sloped line connecting the leading edge of the tread along stairways or stepped aisles or to an adjacent walking surface for floors, ramps and ramped aisles [see Commentary Figures 1015.2, 1015.4(1) and (2) and 1012.8(4)]. Experience has shown that 42 inches (1067 mm) or more provides adequate height to minimize accidental falls in occupancies where crowding is more likely to occur. This puts the top of the guard above the center of gravity of the average adult. The height requirement is not intended to consider such items as planters or loose furniture next to the dropoff as walking surfaces. Because of safety concerns, the designer often chooses to install a barrier where there is a dropoff of less than 30 inches (762 mm). Decorative barriers may be utilized to support handrails or serve as part of the edge protection along a ramp. Where nonrequired guards/barriers are provided, provisions for guard height, openings and strength may be used for design, but are not required. It is common practice to follow the strength provisions, but not always the opening or height provisions for nonrequired guards.

Exception 1 measures the guard height differently. In Group R-2 and R-3 units that are three stories or less, where there is a fixed seat along the edge of deck or balcony, it is reasonable to consider the additional exposure for young children that may use the seat as standing or walking surfaces. In this situation, while the dropoff is measured from the floor, the guard height is measured from the top of the seat surface (see Commentary Figure 1015.3). Within dwelling units the incidence of the exposure to crowds and to egress from higher occupancy spaces is extremely limited, thus a minimum guard height of 36 inches (914 mm) is appropriate. Exception 1 is consistent with provisions in the 2012 IRC, however, the requirement to measure the guard height above a fixed seat has been deleted in the 2015 IRC.

Where the minimum guard height requirement is 42 inches (1067 mm), where both a guard and handrail are required, the handrail cannot be the top of the guard, but must be placed along the inside face of the

## MEANS OF EGRESS

guard unless specifically permitted in Exceptions 2 through 5.

Exceptions 2 and 3 are for nontransient residential occupancies and only address guard heights along the stairways, not at other dropoffs such as balconies or second-floor landings. For Group R-2, these guard height exceptions are only permitted for stairways within individual dwelling units, not common stairways within the building. The handrail provisions allow some residential stairways to only have one handrail (see Section 1011.11). Exceptions 2 and 3 allow for a reduced guard height when the guard is also used as a handrail and when it just serves the purpose of a guard along a stairway. The reduced allowable guard height along stairways is consistent with current construction practice. Unless a dwelling could comply with Exception 1, the guard height along other dropoffs would have to be 42 inches (1067 mm) measured from the floor.

Exception 4 references the lower guards permitted at limited locations where a line of sight for assembly spaces is part of the consideration. There are also allowances in Section 1029.16 that would allow for the top of the guard to serve as a handrail.

Exception 5 permits a reduction in guard heights based on the limited used and unique design considerations for alternating tread devices and ship's ladders (see Sections 1011.14 and 1011.15).

**1015.4 Opening limitations.** Required *guards* shall not have openings that allow passage of a sphere 4 inches (102 mm) in diameter from the walking surface to the required *guard* height.

### Exceptions:

1. From a height of 36 inches (914 mm) to 42 inches (1067 mm), *guards* shall not have openings that

allow passage of a sphere  $4\frac{3}{8}$  inches (111 mm) in diameter.

2. The triangular openings at the open sides of a *stair*, formed by the riser, tread and bottom rail shall not allow passage of a sphere 6 inches (152 mm) in diameter.
3. At elevated walking surfaces for access to and use of electrical, mechanical or plumbing systems or equipment, *guards* shall not have openings that allow passage of a sphere 21 inches (533 mm) in diameter.
4. In areas that are not open to the public within occupancies in Group I-3, F, H or S, and for *alternating tread devices* and ship's ladders, *guards* shall not have openings that allow passage of a sphere 21 inches (533 mm) in diameter.
5. In assembly seating areas, *guards* required at the end of aisles in accordance with Section 1029.16.4 shall not have openings that allow passage of a sphere 4 inches (102 mm) in diameter up to a height of 26 inches (660 mm). From a height of 26 inches (660 mm) to 42 inches (1067 mm) above the adjacent walking surfaces, *guards* shall not have openings that allow passage of a sphere 8 inches (203 mm) in diameter.
6. Within individual *dwelling units* and *sleeping units* in Group R-2 and R-3 occupancies, *guards* on the open sides of *stairs* shall not have openings that allow passage of a sphere  $4\frac{3}{8}$  (111 mm) inches in diameter.

❖ The opening limitations in a guard are based on anthropometric research that indicates children in the 99th percentile who have developed to the point of being able to crawl will have chest depth and head

size of at least 4<sup>3</sup>/<sub>4</sub> inches. Both the 4-inch (102 mm) and the 4<sup>3</sup>/<sub>8</sub>-inch (111 mm) sphere rules are intended to provide an additional margin of safety. Note that the opening limitations are stated as preventing the passage of a sphere, requiring the openings to be smaller than the dimension stated.

Exception 1 allows the 4<sup>3</sup>/<sub>8</sub>-inch (203 mm) opening limitation at heights where falling through the guard is not a risk for children of early development who cannot access the opening [i.e., above 36 inches (914 mm) in height] [see Commentary Figure 1015.4(1)].

Exception 2 allows a 6-inch (152 mm) opening limitation at openings formed by the riser, tread and bottom rail of guards at the open side of a stairway. The geometry of these openings is such that the entire body cannot pass through the triangular opening, and further limiting such openings is impractical to achieve with a sloped bottom member in the guard without intersecting the tread nosings [see Commentary Figure 1015.4(1)].

Exceptions 3 and 4 address areas where the presence of small children is unlikely and often prohibited. Guards along walkways leading to electrical, mechanical and plumbing systems or equipment and in occupancies in Groups I-3, F, H and S may be constructed in such a way that a sphere 21 inches (533 mm) in diameter will not pass through any of the openings [see Commentary Figure 1015.4(2)]. This requirement allows the use of one horizontal intermediate member with the standard top-of-guard height of 42 inches (1067 mm).

Exception 5, for the guard infill near the top of the aisle guard in assembly seating areas, is provided to reduce sightline problems in limited locations (see Section 1029.16.4).

Exception 6 recognizes a standard construction practice within residential units. In practicality this

allows a stairway with the 7-inch riser height/11-inch tread depth (178 mm riser height/279 mm tread depth) step geometry to have two common 1<sup>1</sup>/<sub>4</sub>-inch (32 mm) balusters per stair tread instead of three. Where the 7<sup>3</sup>/<sub>4</sub>-inch riser height/10-inch tread depth (197 mm riser height/254 mm tread depth) step geometry (see Section 1011.5.2, Exception 3) is utilized, the two balusters would meet the 4-inch (102 mm) opening limitation and most profiled or turned balusters would meet the 4<sup>3</sup>/<sub>8</sub>-inch (111 mm) sphere rule.

## MEANS OF EGRESS

The provisions of guards are to minimize accidental falls through or over a guard. Opening limitations do not prohibit the use of horizontal members or ornamentation infill as guard components. Research has shown that no practical design for guard infill, including solid panels, can prevent climbing; but good design practices can greatly reduce the opportunity for small children to “climb” the guard [see Commentary Figure 1015.4(3)]. In this example, the handrail stops a child from climbing the guard.

**Figure 1015.4(3)**  
**EXAMPLE OF GUARD WITH HORIZONTAL MEMBERS**

**1015.5 Screen porches.** Porches and decks that are enclosed with insect screening shall be provided with *guards* where the walking surface is located more than 30 inches (762 mm) above the floor or grade below.

❖ Insect screening located on the open sides of porches and decks does not provide an adequate barrier to reasonably protect an occupant from falling to the surface below. Guards are required on the open sides of porches and decks where the floor is located more than 30 inches (762 mm) above the surface below. The guards must comply with all of the provisions of Section 1015.

**1015.6 Mechanical equipment, systems and devices.** *Guards* shall be provided where various components that require service are located within 10 feet (3048 mm) of a roof edge or open side of a walking surface and such edge or open side is located more than 30 inches (762 mm) above the floor, roof or grade below. The *guard* shall extend not less than 30 inches (762 mm) beyond each end of such components. The *guard* shall be constructed so as to prevent the passage of a sphere 21 inches (533 mm) in diameter.

**Exception:** *Guards* are not required where permanent fall arrest/restraint anchorage connector devices that comply with ANSI/ASSE Z 359.1 are affixed for use during the entire roof covering lifetime. The devices shall be reevaluated for possible replacement when the entire roof covering is replaced. The devices shall be placed not more than

10 feet (3048 mm) on center along hip and ridge lines and placed not less than 10 feet (3048 mm) from the roof edge or open side of the walking surface.

❖ The purpose of this requirement is to protect workers from falls off of roofs or from open-sided walking surfaces when doing maintenance work on equipment. The guard opening is allowed to be up to 21 inches (533 mm) since children are not likely to be in such areas. Either the equipment should be located so that it is more than 10 feet from the roof edge, or a guard or raised parapet must be provided to prevent falls. The guard also has to extend at least 30 inches (762 mm) in all directions past the corners of the equipment (see Commentary Figure 1015.7).

The exception for the guards is an alternative of a personal fall arrest system with anchorage points, more commonly called tie down points for restraining harnesses. The code does not specify who has to provide the equipment that fits the maintenance crew and attaches to the system. If this option is chosen, when the roof covering is replaced, the system must also be reevaluated and possibly replaced. This system is more commonly used on sloped roofs while guards are more often used on flat roofs.

**1015.7 Roof access.** *Guards* shall be provided where the roof hatch opening is located within 10 feet (3048 mm) of a roof edge or open side of a walking surface and such edge or open side is located more than 30 inches (762 mm) above the floor, roof or grade below. The *guard* shall be constructed so as to prevent the passage of a sphere 21 inches (533 mm) in diameter.

**Exception:** *Guards* are not required where permanent fall arrest/restraint anchorage connector devices that comply with ANSI/ASSE Z 359.1 are affixed for use during the entire roof covering lifetime. The devices shall be reevaluated for possible replacement when the entire roof covering is replaced. The devices shall be placed not more than 10 feet (3048 mm) on center along hip and ridge lines and placed not less than 10 feet (3048 mm) from the roof edge or open side of the walking surface.

❖ The code already requires guards around equipment on the roof; this section is intended to provide the same level of safety at the hatch opening service personnel use to access the roof (see Commentary Figure 1015.7 and the commentary to Section 1015.6). While not specifically indicated for roof hatches, Section 1015.6 requires the guard to extend at least 30 inches (752 mm) past the corners of the equipment.

**1015.8 Window openings.** Windows in Group R-2 and R-3 buildings including *dwelling units*, where the top of the sill of an operable window opening is located less than 36 inches above the finished floor and more than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, shall comply with one of the following:

1. Operable windows where the top of the sill of the opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below and that are pro-

vided with window fall prevention devices that comply with ASTM F2006.

2. Operable windows where the openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the window is in its largest opened position.
  3. Operable windows where the openings are provided with window fall prevention devices that comply with ASTM F2090.
  4. Operable windows that are provided with window opening control devices that comply with Section 1015.8.1.
- ❖ The window limitations specified here are intended for Group R-2 and R-3 units. These facilities have the highest potential for infants and toddlers being present for an extended period of time. The requirement is intended to provide a level of protection to children and to help limit the chances of them falling through window openings. In most cases, these provisions are not applicable to first-floor windows. Typically, the 72 inches (1829 mm) to finished grade would make these provisions applicable for windows starting at the second floor. For windows in bedrooms that may also be required to serve as emergency escape and rescue openings, see Section 1030.

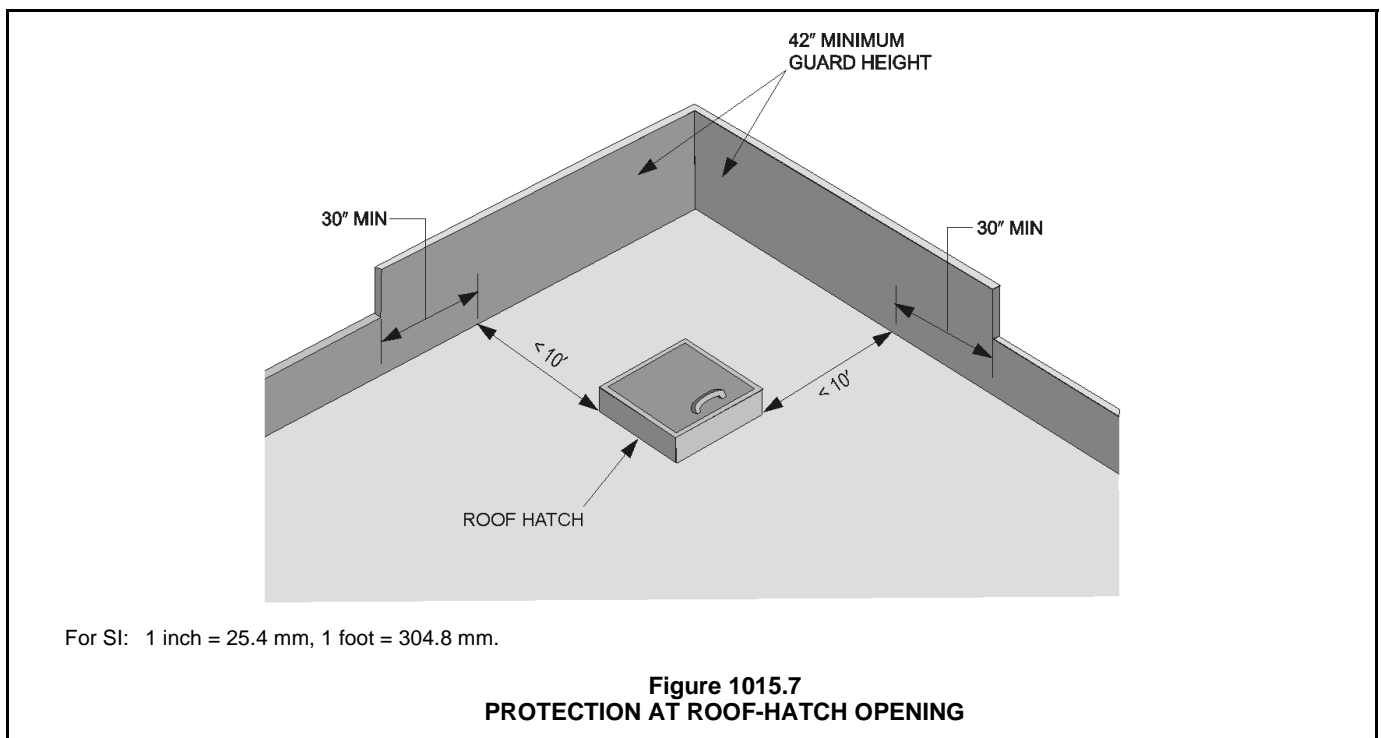

There are basically five options offered:

One option is to locate the window so that any opening is at least 36 inches (915 mm) above the floor. By raising the lowest operable portion of a window to 36 inches (915 mm) or more, the sill height is above the center of gravity of smaller children. The National Ornamental & Miscellaneous Metals Association (NOMMA) commissioned a paper on child

safety related to falls. The report indicates that the standing center of gravity of children aged 2 to 3.5 years is 24.1 inches (612 mm) [50th percentile is 22.2 inches (564 mm)] and of children aged 3.5 to 4.5 years is 25.2 inches (640 mm) [50th percentile is 23.6 inches (599 mm)]. The 36-inch (915 mm) sill height was chosen to reduce the ability of a child to climb onto the sill, enabling the fall through the opening. Windows that are also to serve as emergency escape windows must also comply with Section 1030.3 sill height requirements for 44 inches (1118 mm) maximum. Note that Section R612.2 of the IRC requires a minimum sill height of 24 inches (610 mm).

A second option (Item 1) would be for windows with an opening lower than 36 inches (915 mm) to limit the opening to 4 inches (102 mm) maximum. This opening size is consistent with the guard opening provisions (see Section 1015.4). Many awning or hopper-type casement windows have control arms that limit the opening width.

The third option offered (Item 2) allows for fixed fall-prevention devices to be installed in accordance with ASTM F2006. The limitation for window sills over 75 feet (22 860 mm) is for consistency with Section 1.3 of ASTM F2006, which states: "This safety specification applies only to devices intended to be applied to windows installed at height of more than 75 feet above the ground level in multiple family dwelling buildings. This safety specification is not intended to apply to windows below 75 feet (22 860 mm) because all windows below 75 feet (22 860 mm) that are operable could be used as a possible secondary means of escape." Since these devices will always prevent the opening of the window, they cannot be

used for windows that are required to also serve as emergency escape openings.

ASTM F2090 includes window fall prevention devices (Item 3) and window opening control devices (Item 4) (see Section 1015.8.1). Window fall-prevention devices (such as a window guard) must be removable from the interior of the building so the window can be used for emergency escape. Window opening-control devices allow the window to be opened beyond 4 inches, so that a window can be used for emergency escape. This standard is specifically written for window openings within 75 feet (22 860 mm) of grade and specifically allows for windows to be used for emergency escape and rescue. Both the code and IRC reference ASTM F2090, *Specification for Window Fall Prevention Devices with Emergency Escape (Egress Release Mechanisms)*. This standard was updated in 2008 to address window opening control devices. Opening control devices allow for normal operation to result in a 4-inch (102 mm) maximum opening (Section 1015.8 and Section R612.4.1 of the IRC). This control device can be released from the inside to allow the window to be fully opened in order to comply with the emergency escape provisions in both the code (Section 1030.2) and IRC (Section R310.1.1).

Criteria have also been added to IEBC to address window opening controls in existing buildings.

**1015.8.1 Window opening control devices.** Window opening control devices shall comply with ASTM F2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1030.2.

❖ See the commentary to Section 1015.8.

## SECTION 1016 EXIT ACCESS

**1016.1 General.** The *exit access* shall comply with the applicable provisions of Sections 1003 through 1015. *Exit access* arrangement shall comply with Sections 1016 through 1021.

❖ Sections 1016 through 1021 include the design requirements for exit access and exit access components. The general requirements that also apply to the exit access are in Sections 1003 through 1015.

The following sections are included under exit access:

- Section 1016 deals with egress through intervening spaces, as well as travel and separation of the common path of travel to the exit.
- Section 1017 lists the total exit access travel distance from an occupied space to an exit. This distance includes the common path of travel addressed in Sections 1006.2.1 and 1006.3.2.
- Section 1018 takes a look at requirements for aisles and aisle accessways for occupancies other than assembly spaces. Aisle and aisle

accessways in spaces used for assembly purposes are specifically addressed in Section 1029.

- Section 1019 provides criteria for when an open stairway between floors can serve as a required exit access stairway.
- Section 1020 deals with another type of confined part of the exit access path: corridors.
- Section 1021 addresses egress balconies, where the path of travel to the exterior exit stairway is partially open to the exterior.

**1016.2 Egress through intervening spaces.** Egress through intervening spaces shall comply with this section.

1. *Exit access* through an enclosed elevator lobby is permitted. Access to not less than one of the required *exits* shall be provided without travel through the enclosed elevator lobbies required by Section 3006. Where the path of exit access travel passes through an enclosed elevator lobby, the level of protection required for the enclosed elevator lobby is not required to be extended to the *exit* unless direct access to an *exit* is required by other sections of this code.
2. Egress from a room or space shall not pass through adjoining or intervening rooms or areas, except where such adjoining rooms or areas and the area served are accessory to one or the other, are not a Group H occupancy and provide a discernible path of egress travel to an *exit*.
 

**Exception:** *Means of egress* are not prohibited through adjoining or intervening rooms or spaces in a Group H, S or F occupancy where the adjoining or intervening rooms or spaces are the same or a lesser hazard occupancy group.
3. An *exit access* shall not pass through a room that can be locked to prevent egress.
4. *Means of egress* from *dwelling units* or sleeping areas shall not lead through other sleeping areas, toilet rooms or bathrooms.
5. Egress shall not pass through kitchens, storage rooms, closets or spaces used for similar purposes.

### Exceptions:

1. *Means of egress* are not prohibited through a kitchen area serving adjoining rooms constituting part of the same *dwelling unit* or *sleeping unit*.
2. *Means of egress* are not prohibited through stockrooms in Group M occupancies where all of the following are met:
  - 2.1. The stock is of the same hazard classification as that found in the main retail area.
  - 2.2. Not more than 50 percent of the *exit access* is through the stockroom.
  - 2.3. The stockroom is not subject to locking from the egress side.

2.4. There is a demarcated, minimum 44-inch-wide (1118 mm) *aisle* defined by full- or partial-height fixed walls or similar construction that will maintain the required width and lead directly from the retail area to the *exit* without obstructions.

- ❖ This section allows adjoining spaces to be considered a part of the room or space from which egress originates, provided that there are reasonable assurances that the continuous egress path will always be available. The code does not limit the number of intervening or adjoining rooms through which egress can be made, provided that all other code requirements (e.g., travel distance, number of doorways, etc.) are met. An exit access route, for example, may be laid out such that an occupant leaves a room or space, passes through an adjoining space, enters an exit access corridor, passes through another room and, finally, into an exit [see Commentary Figure 1016.2(2)], as long as all other code requirements are satisfied.

The intent of Item 1 is to correlate the provision for corridor continuity (Section 1020.6) and elevator lobbies. This is especially important since elevator lobbies for fire service access elevators require direction connection to a stairway. Therefore, occupants may need to egress through an elevator lobby to get to the exit stairway. In a two-exit building, only one exit can be through an elevator lobby, but at the same time, the elevator lobby will not be considered an intervening room [see Commentary Figure 1020.6(3)]. This also clarifies that the protection requirements for corridors would not be put on top of protection requirements for the elevator lobbies.

The intent of Item 2 is not that the accessory space be limited to the 10-percent area in IBC Section 508.2.3, but that the spaces be interrelated so that doors between the spaces will not risk being blocked or locked. For example, a conference room and managers' offices could exit through the secretary's office to reach the exit access corridor; or several office

spaces could exit through a common reception/lobby area. Requiring occupants to egress from an area and pass through an adjoining Group H that can be characterized by rapid fire buildup places them in an unreasonable risk situation [see Commentary Figure 1016.2(1)]; therefore, this illustrated egress path would be prohibited. As an exception to Item 2, in facilities that may contain a Group H area, buildings of Group H, S or F can exit through adjoining rooms or spaces that have the same or lesser hazard. For example, a person exiting from a Group H storage room (see IBC Section 415) could egress either through a similar Group H storage area or through the factory to get to an exit, but the person in the factory could not egress through the Group H storage rooms to get to the outside.

As expressed in Item 3, a common code enforcement problem is a locked door in the egress path. Twenty-five workers perished in September 1991 when they were trapped inside the Imperial Food Processing Plant in Hamlet, North Carolina, in part because of locked exit doors. As long as the egress door is readily openable in the direction of egress travel without the use of keys, special knowledge or effort (see Section 1010.1.9.5), the occupants can move unimpeded away from a fire emergency. Relying on an egress path through an adjacent dwelling unit to be available at all times is not a reasonable expectation. Egress through an adjacent business tenant space can be unreasonable given the security and privacy measures the adjacent tenant may take to secure such a space. However, egress through a reception area that serves a suite of offices of the same tenant is clearly accessible and is permitted.

Item 4 addresses concerns along the path of egress travel within individual dwelling or sleeping units. The concern once again is possible locking devices. Egress for one bedroom should not be through another bedroom or bathroom.

The concern in Item 5 is that kitchens, storage rooms and similar spaces may be subject to locking or blockage of the exit access path. This is not a gen-

## MEANS OF EGRESS

eral provision for all Group S occupancies; therefore, it is not the intent of this provision to address the situation of egress for offices through an associated warehouse space. Item 5, Exception 1, does not apply this same prohibition to areas within dwelling or sleeping units. However, for other spaces, a customer means of egress should not be through the working portions of a commercial kitchen in a restaurant or the stock storage area of a storage room in a mercantile occupancy. A dedicated path must be established through such space. The four items listed in Item 5, Exception 2, are intended to provide measurable criteria to increase the likelihood that the exit access path of travel would always be available and identifiable through the stock room of a store. It is not acceptable to just mark the path on the floor. Whatever defines the route must permanently establish the egress path in a manner to maintain the minimum required unobstructed width.

**1016.2.1 Multiple tenants.** Where more than one tenant occupies any one floor of a building or structure, each tenant space, *dwelling unit* and *sleeping unit* shall be provided with access to the required *exits* without passing through adjacent tenant spaces, *dwelling units* and *sleeping units*.

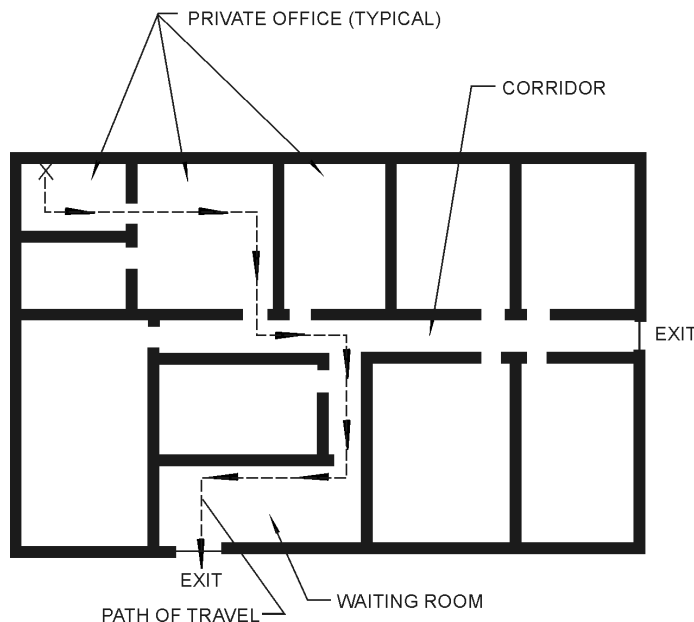

**Exception:** The *means of egress* from a smaller tenant space shall not be prohibited from passing through a larger adjoining tenant space where such rooms or spaces of the smaller tenant occupy less than 10 percent of the area of the larger tenant space through which they pass; are the same or similar occupancy group; a discernible path of egress travel to an *exit* is provided; and the *means of egress* into the adjoining space is not subject to locking from the egress side. A required *means of egress* serving

the larger tenant space shall not pass through the smaller tenant space or spaces.

- ❖ Where a floor is occupied by multiple tenants, each tenant must be provided with full and direct access to the required exits serving that floor without passing through another tenant space. Tenants typically lock the doors to their spaces for privacy and security. Should an egress door that is shared by both tenants be locked, occupants in one of the spaces could be trapped and unable to reach a secondary exit. Therefore, an egress layout where occupants from one tenant space travel through another tenant space to gain access to one of the required exits from that floor is prohibited.

This limitation is so that occupants from all tenant spaces will have unrestricted access to the required egress elements while maintaining the security and privacy of the individual tenants. This limitation is based on one of the fundamental principles of egress: to provide a means of egress where all components are capable of being used by the occupants without keys, tools, special knowledge or special effort (see Section 1010.1.9.5).

A common practice is to have a bank or small restaurant located within a large grocery store or department store. These can be separate tenants. In these situations, the small tenants are not open when the main store is closed. The intent of the exception is to allow those small tenants to egress through the large tenant. Since there may be times when the larger tenant is open and the smaller is closed (e.g., bank holidays), the larger tenant cannot exit through the smaller tenant.

**Figure 1016.2(2)**  
**EGRESS THROUGH ADJOINING ROOMS AND SPACES**

**SECTION 1017  
EXIT ACCESS TRAVEL DISTANCE**

**1017.1 General.** Travel distance within the *exit access* portion of the *means of egress* system shall be in accordance with this section.

❖ “Exit access” is defined as “that portion of a means of egress system that leads from any occupied portion of a building or structure to an exit” (see the commentary for the definition in Chapter 2). Exit access includes rooms, spaces, aisles and corridors that an occupant would travel along to get to an exit. This can also include stairways and ramps between levels, or between stories where permitted by Section 1019. Doors and doorways along this route are exit access doorways, but may sometimes be called “exit doors.” True exits for this exit access travel can be: 1. An exterior exit door at grade; 2. The door to an enclosure for an interior exit stairway, ramp or exit passageway; 3. The exit door leading to an exterior exit door or ramp; or 4. A door leading through a horizontal exit. How exit access travel distance is measured is one of the key differences between interior exit access stairways/ramps (see Section 1017.3.1) and interior exit stairways/ramps (see Section 1017.3).

It is important to understand the relationship between the common path of travel limitations of Sections 1006.2.1 and 1006.3.2 and the exit access travel distance limitations of this section. Measurements start at the same location, i.e., the most remote location in any occupied space. Both are measured in the exit access portion of the means of egress system. The common path of travel is measured to the point where the occupant has two distinct paths of travel, which will lead to two distinct exits. Travel distance is measured all the way until the exit is reached. The common path of travel measurement can end within a space or at a corridor where a single means of egress space (Section 1006.2.1) has its door to a corridor that provides access to two exits.

**1017.2 Limitations.** *Exit access* travel distance shall not exceed the values given in Table 1017.2.

❖ The table includes the travel distance measurements for buildings with or without sprinkler systems. “Not Permitted” is in support of the Chapter 9 requirements for all Group I and H occupancies to be sprinklered. While the other occupancies may also be required to be sprinklered, the exit access travel distance is indicated for existing buildings.

**TABLE 1017.2.** See next column.

❖ This table reflects the maximum distance a person is allowed to travel from any point in a building floor area to the nearest exit along a natural and unobstructed path. While quantitative determinations or formulas are not available to substantiate the tabular distances, empirical factors are utilized to make relative judgments as to reasonable limitations. Such considerations include the nature and fitness of the

occupants; the typical configuration within the space; the level of fire hazard with respect to the specific uses of the facilities, including fire spread and the potential intensity of a fire. The inclusion of an automatic sprinkler system throughout the building can serve to control, confine or possibly eliminate the fire threat to the occupants so an increased travel distance is permitted. Increased travel distances are permitted when an automatic sprinkler system is installed in accordance with NFPA 13 or 13R.

**[BE] TABLE 1017.2  
EXIT ACCESS TRAVEL DISTANCE<sup>a</sup>**

OCCUPANCY	WITHOUT SPRINKLER SYSTEM (feet)	WITH SPRINKLER SYSTEM (feet)
A, E, F-1, M, R, S-1	200	250 <sup>b</sup>
I-1	Not Permitted	250 <sup>b</sup>
B	200	300 <sup>c</sup>
F-2, S-2, U	300	400 <sup>c</sup>
H-1	Not Permitted	75 <sup>d</sup>
H-2	Not Permitted	100 <sup>d</sup>
H-3	Not Permitted	150 <sup>d</sup>
H-4	Not Permitted	175 <sup>d</sup>
H-5	Not Permitted	200 <sup>c</sup>
I-2, I-3, I-4	Not Permitted	200 <sup>c</sup>

For SI: 1 foot = 304.8 mm.

- a. See the following sections for modifications to exit access travel distance requirements:
  - Section 402.8 of the *International Building Code*: For the distance limitation in malls.
  - Section 404.9 of the *International Building Code*: For the distance limitation through an atrium space.
  - Section 407.4 of the *International Building Code*: For the distance limitation in Group I-2.
  - Sections 408.6.1 and 408.8.1 of the *International Building Code*: For the distance limitations in Group I-3.
  - Section 411.4 of the *International Building Code*: For the distance limitation in special amusement buildings.
  - Section 412.7 of the *International Building Code*: For the distance limitations in aircraft manufacturing facilities.
  - Section 1006.2.2.2: For the distance limitation in refrigeration machinery rooms.
  - Section 1006.2.2.3: For the distance limitation in refrigerated rooms and spaces.
  - Section 1006.3.2: For buildings with one *exit*.
  - Section 1017.2.2: For increased distance limitation in Groups F-1 and S-1.
  - Section 1029.7: For increased limitation in assembly seating.
  - Section 3103.4 of the *International Building Code*: For temporary structures.
  - Section 3104.9 of the *International Building Code*: For pedestrian walkways.
- b. Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2. See Section 903 for occupancies where *automatic sprinkler systems* are permitted in accordance with Section 903.3.1.2.
- c. Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
- d. Group H occupancies equipped throughout with an *automatic sprinkler system* in accordance with Section 903.2.5.1.

When measuring travel distance, it is important to consider the natural path of travel [see Commentary Figure 1017.3(1)]. In many cases, the actual layout of furnishings and equipment is not known or is not identified on the plans submitted with the permit application. In such instances, it may be necessary to measure travel distance using the legs of a triangle instead of the hypotenuse [see Commentary Figure 1017.3(2)]. Since most people tend to migrate to more open spaces while egressing, measurement of the natural path of travel typically excludes floor areas within 1 foot (305 mm) of walls, corners, columns and other permanent construction. Where the travel path includes passage through a doorway, the natural route is generally measured through the centerline of the door openings.

The common path of travel addressed in Sections 1006.2.1 and 1006.3.2 is part of the overall exit access travel distance, with both starting at the same point. Common path of travel stops when the occupant has a choice of at least two exits, and overall travel distance stops when an occupant gets to the closest exit. The references in Note a are to sections where specific requirements are addressed—this can be an increase or decrease in travel distance.

Note a is a reference to other travel distance limitations in the code. Notes b and c are simply references to the allowed types of sprinkler system—NFPA 13 or 13R. Some travel distance increases are based on the type of sprinkler system provided. The table does not currently address a building with an NFPA 13D sprinkler system.

Note d addresses the sprinkler requirements in Group H. Group H occupancies are only required to be sprinklered within Group H and not throughout the building; therefore, Note d distinguishes this requirement from Notes b and c. The travel distance is the same if the path is through Group H or leaves Group H and continues through a nonsprinklered occupancy (see Section 1018.2, Item 2.)

**1017.2.1 Exterior egress balcony increase.** *Exit access* travel distances specified in Table 1017.2 shall be increased up to an additional 100 feet (30 480 mm) provided the last portion of the *exit access* leading to the *exit* occurs on an exterior egress balcony constructed in accordance with Section 1021. The length of such balcony shall be not less than the amount of the increase taken.

❖ This section allows an additional travel distance on exterior egress balconies since smoke disperses rapidly. Note that the length of the increase is not to be more than the length of the exterior balcony. For example, if the length of the balcony is 75 feet (22 860 mm), the additional travel distance is limited to 75 feet (22 860 mm). In order for the increase to apply, the exterior balcony must be located at the end of the path of egress travel and not in some other portion of the egress path.

**1017.2.2 Group F-1 and S-1 increase.** The maximum *exit access* travel distance shall be 400 feet (122 m) in Group F-1

or S-1 occupancies where all of the following conditions are met:

1. The portion of the building classified as Group F-1 or S-1 is limited to one story in height.
2. The minimum height from the finished floor to the bottom of the ceiling or roof slab or deck is 24 feet (7315 mm).
3. The building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

❖ This section provides the criteria for an increased exit access travel distance of 400 feet in Group F-1 and S-1 occupancies when three criteria are met: the S-1/F-1 area is one story, has a ceiling height of at least 24 feet, and is sprinklered.

The travel distance increase is only applicable to portions of the building that are one story in height. This is not intended to preclude a building with a one-story storage warehouse or factory area and a two-story office or a mezzanine from also utilizing this section. The section is written so that the one-story limitation is only applicable to the area where the 400-foot travel distance is utilized.

The 24 feet of clearance is based on the "Fire Modeling Analysis Report" by Aon Fire Protection Engineering. The ceiling height is used to provide a volume for the smoke to accumulate during the fire and provide time for egress, much like the concept used for smoke-protected seating. Control mode sprinklers were utilized in the fire modeling to demonstrate the more conservative approach.

The building is required to be sprinklered in accordance with NFPA 13 requirements. While not required, ESFR or specialty sprinklers would be more effective.

**1017.3 Measurement.** *Exit access* travel distance shall be measured from the most remote point within a story along the natural and unobstructed path of horizontal and vertical egress travel to the entrance to an *exit*.

**Exception:** In *open parking garages*, *exit access* travel distance is permitted to be measured to the closest riser of an *exit access stairway* or the closest slope of an *exit access ramp*.

❖ The length of travel, as measured from the most remote point within a structure to an exit, is limited to restrict the amount of time that the occupant is exposed to a potential fire condition [see Commentary Figure 1017.3(1)]. The route must be assumed to be the natural path of travel without obstruction. This commonly results in a rectilinear path similar to what can be experienced in most occupancies, such as a schoolroom or an office with rows of desks [see Commentary Figure 1017.3(2)]. The "arc" method, using an "as the crow flies" linear measurement, must be used with caution, as it seldom represents typical floor design and room layout and, in most cases, would not be the natural, unobstructed path.

The travel distance is measured from every occupi-

able point on a floor to the closest exit. While each occupant may be required to have access to a second or third exit, the travel distance limitation is only applicable to the distance to the nearest exit. In effect, this means that the distance an occupant must travel to the second or third exit is not regulated.

For exit access travel distances that include vertical elements, such as stairways or ramps, see Section 1017.3.1. For outdoor assembly seating, see Section 1029.7.

The exception provides for a travel distance terminating at the top of an open exit access stairway in an open parking structure (see Section 1019.3, Exception 6). This is appropriate in view of the low hazard and minimal possible smoke accumulation in these facilities. While Section 1006.3 does say that an open

exit access stairway can only be used for one story, travel distance typically does include the exit access stairway. With the exception here for travel distance, the intent is to allow open parking garages to have open exit access stairways all the way down and out of the building. The number of means of egress requirements are met when the exit access travel distance requirement is met on each floor.

The distance of travel within an exit enclosure (e.g., enclosed interior exit stairway or ramp or exit passageway) and in the exit discharge portion of the means of egress are also not regulated. Section 1006.3.2 permits certain buildings to be provided with a single exit. In instances where there is a single exit, travel distances less than those permitted in Table 1017.2 apply [see Tables 1006.3(1) and 1006.3(2)].

**1017.3.1 Exit access stairways and ramps.** Travel distance on *exit access stairways* or *ramps* shall be included in the *exit access* travel distance measurement. The measurement along *stairways* shall be made on a plane parallel and tangent to the *stair tread nosings* in the center of the *stair* and landings. The measurement along *ramps* shall be made on the walking surface in the center of the *ramp* and landings.

❖ Travel distance is measured along the exit access path. Exit access travel distance may include travel on an interior stairway or ramp if it is not enclosed and constructed to meet the definition of an exit (see Section 1023). An example of exit access stairways would be unenclosed exit access stairways from a mezzanine level, open exit access stairways from a second floor (see Section 1019.3, Exception 1), or steps along the path of travel in a split floor-level situation. An example of an open exit access ramp would be a ramp between levels or ramps leading from the upper levels in an open parking garage (see Section 1019.3, Exception 7). For the last example, Section 1016.3, Exception 1, allows for the exit access travel distance to be measured to the top of the ramp or stairway rather than down the ramp or stairway and to the exit.

When Section 1019.3 permits an exit access stairway to be unenclosed, the travel distance would also include travel down the open stairway and to an enclosed exit stairway, a horizontal exit or an exit door to the outside. An example of this would be an open exit stairway within an individual dwelling unit (see Section 1019.3, Exception 2) or an open exit stairway from a press box (see Section 1019.3, Exception 8).

## SECTION 1018 AISLES

**1018.1 General.** *Aisles* and *aisle accessways* serving as a portion of the *exit access* in the *means of egress* system shall comply with the requirements of this section. *Aisles* or *aisle accessways* shall be provided from all occupied portions of the *exit access* that contain seats, tables, furnishings, displays and similar fixtures or equipment. The minimum width or required capacity of *aisles* shall be unobstructed.

**Exception:** Encroachments complying with Section 1005.7.

❖ This section addresses aisles and aisle accessways, primarily in occupancies other than assembly seating areas. Current provisions address aisles in all uses, but only address aisle accessways for assembly spaces and mercantile.

“Aisle accessway” is defined in Chapter 2 as “that portion of exit access that leads to an aisle.” The term “Aisle” is defined in Chapter 2 as “an exit access component that defines and provides a path of egress travel.” Given the many possible configurations of fixtures and furniture, both permanent and movable, the determination of where aisle accessways stop and

aisles begin is often subject to interpretation.

Typically, the aisle accessways lead to the aisles, which in turn lead to the exits. Since the aisle serves as a path for means of egress similar to a corridor, the requirements for doors obstructing the aisle are the same (see Section 1005.7).

A cross reference back to Section 1005.7 from the exceptions for width in aisles (see Section 1018.1), corridors (see Section 1020.3), exit passageways (see Section 1024.2) and exit courts (see Section 1028.4.1) reinforces the fact that encroachment limits are generally applicable for these types of confined routes.

**1018.2 Aisles in assembly spaces.** *Aisles* and *aisle accessways* serving a room or space used for assembly purposes shall comply with Section 1029.

❖ The provisions for aisles and aisle accessways in spaces with assembly seating, such as restaurants, theaters and sports arenas, are unique. See Section 1029 for criteria.

**1018.3 Aisles in Groups B and M.** In Group B and M occupancies, the minimum clear aisle width shall be determined by Section 1005.1 for the *occupant load* served, but shall be not less than that required for corridors by Section 1020.2.

**Exception:** Nonpublic *aisles* serving less than 50 people and not required to be *accessible* by Chapter 11 need not exceed 28 inches (711 mm) in width.

❖ This requirement establishes aisle-width criteria for Group B and M occupancies based on the occupant load served by the aisle. While not providing as confined a path as corridors, the displays or equipment would limit the choice of paths, so the minimum width is the same as corridors (see Section 1020.2). The reference to Section 1005.1 would trigger a requirement for aisles wider than 44 inches (914 mm) when the anticipated occupant load that the aisle served was larger than 220 (44 inches/0.2 = 220 occupants for nonsprinklered buildings and 44 inches/0.15 = 293 occupants in sprinklered buildings). When an aisle allows for access to exits in two directions, the occupant load could be split, similar to corridors. The exception addresses aisles that may be found in an archival file room or stock storage racks.

For mercantile, if fixtures are permanent, such as in a typical grocery store or office cubicles in a business, the aisle provisions would be applicable throughout. In a situation where there were groups of displays separated by aisles, the area within the displays may be considered aisle accessways (see Section 1018.4).

**1018.4 Aisle accessways in Group M.** An *aisle accessway* shall be provided on not less than one side of each element within the *merchandise pad*. The minimum clear width for an *aisle accessway* not required to be *accessible* shall be 30 inches (762 mm). The required clear width of the *aisle accessway* shall be measured perpendicular to the elements and merchandise within the *merchandise pad*. The 30-inch

(762 mm) minimum clear width shall be maintained to provide a path to an adjacent *aisle* or *aisle accessway*. The *common path of egress travel* shall not exceed 30 feet (9144 mm) from any point in the *merchandise pad*.

**Exception:** For areas serving not more than 50 occupants, the *common path of egress travel* shall not exceed 75 feet (22 860 mm).

- ❖ The definition for “Merchandise pad” can be found in Chapter 2. The idea is that a merchandise pad contains movable displays and aisle accessways. A surrounding aisle or permanent walls or displays would define the extent of the merchandise pad. Large department stores will have numerous merchandise pads (see Commentary Figure 1018.3). In accordance with IBC Section 105.2, Item 13, movable cases, counters and partitions not over 5 feet, 9 inches (1753 mm) in height do not require a building permit to move, add or alter. Every element within a merchandise pad must adjoin a minimum 30-inch-wide (762 mm) aisle accessway on at least one side. Travel within a merchandise pad is limited, with a maximum common path of travel of 30 feet (9144 mm). The common path of travel limitation is extended to 75 feet (22 m) in those areas serving a maximum occupant load of 50.

**Figure 1018.3**  
**AISLES AND AISLE ACCESSWAYS IN MERCANTILE**

**1018.5 Aisles in other than assembly spaces and Groups B and M.** In other than rooms or spaces used for assembly purposes and Group B and M occupancies, the minimum clear *aisle* capacity shall be determined by Section 1005.1 for the occupant load served, but the width shall be not less than that required for corridors by Section 1020.2.

**Exception:** Nonpublic *aisles* serving less than 50 people and not required to be *accessible* by Chapter 11 need not exceed 28 inches (711 mm) in width.

- ❖ Aisles can occur in other occupancies when there is a confined path of travel to the exit access or exit door leading from a space.

While not providing as confined a path as corridors, the displays or equipment would limit the choice of paths, so the minimum width is the same as corridors (see Section 1020.2). The reference to Section 1005.1 would trigger a requirement for aisles wider than 44 inches (914 mm) when the anticipated occupant load that the aisle served was larger than 220 (44 inches/0.2 = 220 occupants for nonsprinklered buildings and 44 inches/0.15 = 293 occupants in sprinklered buildings). When an aisle allows for access to exits in two directions, the occupant load could be split, similar to corridors. The exception addresses aisles that may be found in an archival file room or stock storage racks.

## SECTION 1019 EXIT ACCESS STAIRWAYS AND RAMPS

**1019.1 General.** *Exit access stairways* and *ramps* serving as an *exit access* component in a *means of egress* system shall comply with the requirements of this section. The number of stories connected by *exit access stairways* and *ramps* shall include *basements*, but not *mezzanines*.

- ❖ This is a general scoping section. Exit access stairways can be between levels or between stories. Section 1019.3 addresses egress between stories. It is important to clarify that basements are considered a story, but not mezzanines. While the exit access travel distance would be measured along the open stairway or ramp for a change in level, a mezzanine, a basement or a second floor, a mezzanine is a space that is considered part of the room to which it is open and is addressed accordingly. Exit stairways are addressed under Sections 1023 and 1027. All stairways and ramps are required to comply with Sections 1011 and 1012, respectively.

**1019.2 All occupancies.** *Exit access stairways* and *ramps* that serve floor levels within a single story are not required to be enclosed.

- ❖ Exit access stairways and ramps between levels on the same story and between a story and an associated mezzanine are always permitted to be open unless they are part of a fire-resistance-rated corridor (see Section 1020.6).

**1019.3 Occupancies other than Groups I-2 and I-3.** In other than Group I-2 and I-3 occupancies, floor openings containing *exit access stairways* or *ramps* that do not comply with one of the conditions listed in this section shall be enclosed with a shaft enclosure constructed in accordance with Section 713.

1. *Exit access stairways* and *ramps* that serve or atmospherically communicate between only two stories. Such interconnected stories shall not be open to other stories.
2. In Group R-1, R-2 or R-3 occupancies, *exit access stairways* and *ramps* connecting four stories or less serving and contained within an individual *dwelling unit* or *sleeping unit* or *live/work unit*.

3. *Exit access stairways* serving and contained within a Group R-3 congregate residence or a Group R-4 facility are not required to be enclosed.
  4. *Exit access stairways* and *ramps* in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, where the area of the vertical opening between stories does not exceed twice the horizontal projected area of the *stairway* or *ramp* and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13. In other than Group B and M occupancies, this provision is limited to openings that do not connect more than four stories.
  5. *Exit access stairways* and *ramps* within an *atrium* complying with the provisions of Section 404.
  6. *Exit access stairways* and *ramps* in *open parking garages* that serve only the parking garage.
  7. *Exit access stairways* and *ramps* serving open-air seating complying with the *exit access* travel distance requirements of Section 1029.7.
  8. *Exit access stairways* and *ramps* serving the balcony, gallery or press box and the main assembly floor in occupancies such as theaters, *places of religious worship*, auditoriums and sports facilities.
- ❖ This section includes conditions which permit unprotected floor openings for exit access stairways and ramps. Groups I-2 and I-3 use smoke compartments as part of their defend-in-place strategies; as such, they are addressed separately in Section 1019.4.

The allowances listed are for “interior exit access stairways and ramps” that are between stories. Exit access stairways and ramps between elevation changes on the same story or serving mezzanines do not serve different stories; therefore, the enclosure requirements in this section are not applicable. The general provisions for stairways in Section 1011 and ramps in Section 1012 would be applicable. For simplicity in the commentary to Sections 1019.3 and 1019.4, when interior exit access stairways are mentioned, let it be understood that the same rules apply to interior exit access ramps.

The primary difference between “interior exit access stairways” and “interior exit stairways” is how exit access travel distance is measured (see Section 1017.3). Where a designer chooses to use an exit access stairway, the exit access travel distance includes travel along the slope of the exit access stairway, similar to stairways leading from an open mezzanine or steps at a change in level on a floor.

The base requirement is that exit access stairways between floors are protected in a similar manner as floor openings (see IBC Section 713). The enclosure is needed because a stairway penetrates the floor/ceiling assemblies between the levels, thus creating a vertical opening or shaft. In cases of fire, a vertical opening may act as a chimney, causing smoke, hot gases and light-burning products to flow upward (buoyant force). If an opening is unprotected, these

products of combustion will be forced by positive pressure differentials to spread horizontally into the building spaces. There are exceptions for shaft protection around openings in IBC Section 712.1 or exit access stairways as permitted in this section in Items 1 through 8 (see also IBC Section 712.1.12).

Exit access stairways are not required to discharge directly to the exterior as are interior exit stairways (see Section 1023.3). Instead, exit access stairways are part of the route that leads to the exit (i.e., exterior exit door, horizontal exit or enclosed interior exit stairway). See the commentary to IBC Sections 712 and 713 for a discussion of other differences in protection permitted for the enclosure of exit access stairways versus exit stairways.

While this section does not state that exit access stairways cannot be used for any purpose other than means of egress (see Section 1021.1), the provisions for no obstructions in the path of travel or reduction of the capacity for means of egress (Section 1003.6) are applicable. If one of the items eliminating enclosures for a stairway is utilized, the exit access stairway openings would still have to meet the exit and exit access door separation requirement specified in Section 1006 for the space or floor.

It is important to remember that while exit access stairways may be open for multiple floors, Section 1006.3 states “Access to exits at other levels shall be from an adjacent story.” However, single-exit buildings do allow for exit access from any story. Therefore, if there are provisions in both Sections 1006.3.3 and 1019.3, the exit access travel distance could be measured all the way down the open exit access stairway.

Item 1 allows an open exit access stairway when the opening is only between two floors. There cannot be any other unprotected openings that connect to other floors since this could create a staggered stack effect for the movement of smoke between multiple stories. In two-story buildings, this would allow for open stairways between the basement and ground level or between the first and second floors. Another example would be an open exit access stairway between the fifth and sixth floors of a building, provided there were no other unprotected openings between the fourth and fifth floor or the sixth and seventh floors. This is consistent with IBC Section 712.1.9 for openings between two stories.

In Item 2, for residential occupancies, exit access stairways within a single-family home or townhouse are not required to be enclosed because of the small occupant load and resident familiarity with the space. Examples of “within an individual dwelling or sleeping unit” would be a two-story hotel suite or a multistory apartment unit. See Section 1006.3.3, Items 3 and 7, for the allowance for these to be single-exit stories. Live/work units call for the egress to be designed for the “function served,” and vertical opening are not required to be enclosed (see IBC Sections 419.3 and 419.4); therefore, it is appropriate to allow open exit

access stairways to serve the dwelling portion of the live/work unit. Note that IBC Section 712.1.2 limits any vertical opening within dwelling units, including stairways, to four stories or less.

Item 3 - A congregate residence would not be considered an individual dwelling unit so Item 2 would not be applicable; however, these small facilities operate similarly to a single-family home. Thus, they have an allowance for open exit access stairways for the same reasons as dwelling units in Item 2. See Section 1006.3.2, Item 4, which allows a single exit in Group R-3 and R-4 congregate residences. These congregate residences are limited to 16 occupants that are capable of self-preservation in IBC Sections 308.3.3, 310.5 and 310.6. If a facility offers medical care, it needs to comply with Section 1019.4.

Item 4 discusses buildings sprinklered throughout with an NFPA 13 system. The size of the opening is limited to twice the size of the stairway footprint. The opening must be protected with a draft curtain and

closely spaced sprinklers (see Commentary Figure 1019.3). This allows for such an opening to extend the entire height of the building; however, to serve as part of the means of egress, the exit access stairway must still be able to meet the exit access travel distance and provide the number of exits or access to exits from each story (see Section 1006.3). This item is similar to what is permitted for escalators (see IBC Sections 712.1.3 and 712.1.3.1). The power-operated automatic shutter permitted in IBC Section 712.1.3.2 would not be an option for exit access stairways since they must be available for exit access travel. For groups other than business and mercantile, there is the additional limitation of a maximum of four stories.

Item 5 allows for exit access stairways to travel down through an atrium. Atriums often penetrate more than two floors. Atriums must meet the provisions in IBC Section 404 for sprinklers, fire alarms, smoke control, enclosure, limitations on flame spread

and smoke development of interior finishes, and the reduction in the normal exit access travel distance. In no case can the exit access travel distance through the atrium, including travel along the stairway, be more than 200 feet (60 960 mm). If the stairway in the atrium serves as part of the required means of egress, each story must also meet the number of exits or access to exits required by Section 1006.

In Item 6, exit access stairways located in open parking structures are exempt from the enclosure requirements because of the ease of accessibility by the fire services, the natural ventilation of such structures, the low level of fire hazard, the small number of people using the structure at any one time and the excellent fire record of such structures. The exception to Section 1017.3 permits the exit access travel distance to be measured to the top step of the exit access stairway in open parking garages. In essence, open parking garages using this item can have open stairways for the full height of the building. By the travel distance being met at the top of the stairway, the means of egress requirements have been met.

In Item 7, stairways in outdoor facilities (i.e., Group A-5) in which the means of egress is essentially open to the outside need not be enclosed because of the ability to vent the fire to the outside. This item is coordinated with the requirements for open-air seating as regulated by Section 1028.7, which allows unlimited travel distance in noncombustible construction that has open-air seating and 400 feet in combustible construction.

Item 8 addresses the unique situation for large indoor assembly seating areas. Since press boxes, galleries and balconies all have the same atmosphere and fire recognition ability as the rest of the seating, the stairways serving these spaces are protected by the same system as the seating (e.g., open to the interior volume and smoke protected; open to the outside); therefore, it is logical to treat the access to these spaces the same as the seating bowl. Open exit access stairways can serve the press box where those stairways move the occupants directly from the press box into the seating bowl. See Sections 1029.5 and 1029.8 for the number of exit access stairways required.

**1019.4 Group I-2 and I-3 occupancies.** In Group I-2 and I-3 occupancies, floor openings between stories containing *exit access stairways* or *ramps* are required to be enclosed with a shaft enclosure constructed in accordance with Section 713.

**Exception:** In Group I-3 occupancies, *exit access stairways* or *ramps* constructed in accordance with Section 408 are not required to be enclosed.

❖ Groups I-2 and I-3 use smoke compartments as part of their defend-in-place strategies; as such, they are addressed separately in this section. Any openings in the floors must be protected the same as a shaft.

The exception allows for observation and security needs in detention facilities, and exit access stair-

ways within a housing unit to not be required to be enclosed (see IBC Section 408.5.1). Section 1023.2 also includes a limited exception for enclosure of exit stairways within jails per IBC Section 408.3.8.

## SECTION 1020 CORRIDORS

**1020.1 Construction.** *Corridors* shall be fire-resistance rated in accordance with Table 1020.1. The *corridor* walls required to be fire-resistance rated shall comply with Section 708 for *fire partitions*.

### Exceptions:

1. A *fire-resistance rating* is not required for *corridors* in an occupancy in Group E where each room that is used for instruction has not less than one door opening directly to the exterior and rooms for assembly purposes have not less than one-half of the required *means of egress* doors opening directly to the exterior. Exterior doors specified in this exception are required to be at ground level.
2. A *fire-resistance rating* is not required for *corridors* contained within a *dwelling unit* or *sleeping unit* in an occupancy in Groups I-1 and R.
3. A *fire-resistance rating* is not required for *corridors* in *open parking garages*.
4. A *fire-resistance rating* is not required for *corridors* in an occupancy in Group B that is a space requiring only a single *means of egress* complying with Section 1006.2.
5. *Corridors* adjacent to the *exterior walls* of buildings shall be permitted to have unprotected openings on unrated *exterior walls* where unrated walls are permitted by Table 602 and unprotected openings are permitted by Table 705.8.

❖ It is not the intent of this section to require corridors. Once corridors are provided, so that occupants are limited to a confined path of travel, then these provisions apply.

The purpose of corridor enclosures is to provide fire protection to occupants as they travel the confined path, perhaps unaware of a fire buildup in an adjacent floor area. The base protection is a fire partition having a 1-hour fire-resistance rating (see Table 1020.1). The table allows a reduction or elimination of the fire-resistance rating depending on the occupant load and the presence of an NFPA 13 or 13R automatic sprinkler system throughout the building.

IBC Section 708 addresses the continuity of fire partitions serving as corridor walls. In addition to allowing the fire partitions to terminate at the underside of a fire-resistance-rated floor/ceiling or roof/ceiling assembly, the supporting construction need not have the same fire-resistance rating in buildings of Type IIB, IIIB and VB construction as specified in IBC Section 708. If such walls were required to be sup-

ported by fire-resistance-rated construction, the use of these construction types would be severely restricted when the corridors are required to have a fire-resistance rating. IBC Section 407.3 requires that corridor walls in Group I-2 occupancies that are required to have a fire-resistance rating must be continuous to the underside of the floor or roof deck above or at a smoke-limiting ceiling membrane. Continuity is required because of the defend-in-place protection strategy utilized in such buildings. Requirements for corridor construction within Group I-3 occupancies are found in IBC Section 408.8. Dwelling unit separation in Groups I-1, R-1, R-2 and R-3 is found in IBC Sections 420.2 and 420.3. Ambulatory care facilities have special requirements in IBC Section 422.2 when some of the patients can be incapable of self-preservation. For additional requirements for an elevator lobby that is adjacent to or part of a corridor, see the commentaries to IBC Sections 713.14 and 3006.

Exception 1 indicates a fire-resistance rating is not required for corridors in Group E when any room adjacent to the corridor that is used for instruction or assembly purposes has a door directly to the outside. The need for a fire-resistance-rated corridor is eliminated because these rooms are provided with an alternative egress path because of the requirement for exterior exits. This option is typically utilized in nonsprinklered buildings, such as day care facilities, since a sprinkler system would also allow for unrated corridors in Group E (see Table 1020.1). Grade schools and high schools have security concerns that sometimes make the outdoor exit for every classroom not a preferred option.

In accordance with Exception 2, a fire-resistance rating for a corridor contained within a single dwelling unit (e.g., apartment, townhouse) or sleeping unit (e.g., hotel guestroom, assistive living suite) is not required for practical reasons. It is unreasonable to expect fire doors and the associated hardware and closing devices to be within dwellings and similar occupancies.

Given the relatively smoke-free environment of open parking structures, Exception 3 does not require rated corridors in these types of facilities.

If an office suite is small enough that only one means of egress is required from the suite, Exception 4 indicates that a rated corridor would not be required in that area. The main corridor that connected these suites to the exits would be evaluated in accordance with Table 1020.1.

Exception 5 addresses when the exterior wall of a building is also the wall of the corridor. The exterior wall is not required to be rated by the corridor provisions where there is a sufficient fire separation distance for the exterior wall to be able to have unprotected openings. This is similar to the exterior wall for an enclosed interior exit stairway. The fire is assumed to be inside the building, so that is where the protection is required.

**TABLE 1020.1**  
**CORRIDOR FIRE-RESISTANCE RATING**

OCCUPANCY	OCCUPANT LOAD SERVED BY CORRIDOR	REQUIRED FIRE-RESISTANCE RATING (hours)	
		Without sprinkler system	With sprinkler system <sup>c</sup>
H-1, H-2, H-3	All	Not Permitted	1
H-4, H-5	Greater than 30	Not Permitted	1
A, B, E, F, M, S, U	Greater than 30	1	0
R	Greater than 10	Not Permitted	0.5
I-2 <sup>a</sup> , I-4	All	Not Permitted	0
I-1, I-3	All	Not Permitted	1 <sup>b</sup>

- For requirements for occupancies in Group I-2, see Sections 407.2 and 407.3.
- For a reduction in the *fire-resistance rating* for occupancies in Group I-3, see Section 408.8.
- Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 where allowed.

❖ The required fire-resistance ratings of corridors serving adjacent spaces are provided in Table 1020.1. The fire-resistance rating is based on the group classification (considering characteristics such as occupant mobility, density and familiarity with the building as well as the fire hazard associated with the classification), the total occupant load served by the corridor and the presence of an automatic sprinkler system.

Where the corridor serves a limited number of people (second column in Table 1020.1), the fire-resistance rating is eliminated because of the limited size of the facility and the likelihood that the occupants would become aware of a fire buildup in sufficient time to exit the structure safely. The total occupant load that the corridor serves is used to determine the requirement for a rated corridor enclosure. The number of occupants served is the total occupants that will move into the corridor to egress. Corridors serving a total occupant load equal to or less than that indicated in the second column of Table 1020.1 are not required to be enclosed with fire-resistance-rated construction. For example, a corridor serving an occupant load of 30 or less in an unsprinklered Group B occupancy is not required to be enclosed with fire-resistance-rated construction. This example is illustrated in Commentary Figure 1020.1.

The purpose of corridor enclosures is to provide fire protection to occupants as they travel the confined path, perhaps unaware of a fire buildup in an adjacent floor area. The base protection is a fire partition having a 1-hour fire-resistance rating. The table allows a reduction or elimination of the fire-resistance rating depending on the occupant load and the presence of an NFPA 13 or 13R automatic sprinkler system throughout the building.

A common mistake is assuming a building is sprinklered throughout and utilizing the corridor rating reductions, when in fact certain requirements in NFPA 13 would not consider the building sprinklered throughout. For example, a health club installs a

sprinkler system, but chooses to eliminate the sprinklers over the swimming pool in accordance with the exception in IBC Section 507.4. Any corridors within the building that serve greater than 30 occupants must be rated because the building would not be considered sprinklered throughout in accordance with NFPA 13 requirements.

Note that because of the hazardous nature of occupancies in Groups H-1, H-2 and H-3, fire-resistance-rated corridors are required under all conditions. Regardless of the presence of a fire sprinkler system, a 1-hour-rated corridor enclosure is required in high-hazard occupancies with detonation, deflagration, accelerated burning, readily supported combustion or physical hazards. Group H-4 and H-5 occupancies that contain semiconductor fabrication materials or operations constituting a health hazard do not pose the same relative fire or explosion hazard as Group H-1, H-2 or H-3 materials. As such, in Group H-4 or H-5, where the corridor serves a total occupant load of 30 or less, a fire-resistance-rated enclosure is not required. The “not permitted” in the third column is in coordination with Section 903.2.5, which requires all Group H buildings to be fully sprinklered.

The code acknowledges that an automatic sprinkler system can serve to control or eliminate fire development that could threaten the exit access corridor. Most occupancies where sleeping rooms are not present (Groups A, B, E, F, M, S and U) are permitted to have nonfire-resistance-rated corridors if a sprinkler system is installed throughout the building in accordance with NFPA 13.

In residential facilities, the response time to a fire may be delayed because the residents may be sleeping. With this additional safety concern, the requirements for corridors are more restrictive than for nonresidential occupancies. If the corridor serves more than 10 occupants, it is required to be rated for 1 hour. If the building is sprinklered throughout with either an NFPA 13 or 13R system, then the rating of

the corridor may be reduced to 1/2 hour. Note the exception for fire-resistance-rated corridors within an individual dwelling or sleeping unit in Section 1020.1. Also note that the reduction in the rating of the corridor walls is not permitted when an NFPA 13D sprinkler system is provided.

While all Group I facilities are supervised environments, the level of supervision in Group I-2 and I-4 occupancies would permit assisted evacuation by staff in an emergency; therefore, corridors are not required to be rated. Corridors in Groups I-2 are also regulated by IBC Section 407.3. Because of the lower staff/resident ratio in Group I-1 and the limitation on free egress in Group I-3, corridors must have a 1-hour fire-resistance rating (see IBC Section 408.8 for a reduction in the corridors in Group I-3). The “not permitted” in the third column is in coordination with Section 903.2.6, which requires all Group I buildings to be fully sprinklered.

**1020.2 Width and capacity.** The required capacity of *corridors* shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

**Exception:** In Group I-2 occupancies, *corridors* are not required to have a clear width of 96 inches (2438 mm) in areas where there will not be stretcher or bed movement for access to care or as part of the defend-in-place strategy.

❖ The corridor widths specified in Table 1020.2 are long-established minimums originally derived from human dimensions, practical concerns, occupant loads and psychological considerations. Additional corridor capacity, when necessary for large crowds, is determined in accordance with Section 1005.

The number of occupants using a corridor for egress establishes the required capacity of a corridor, as well as for any specific portion of a multilevel corridor system. Portions of a corridor system may differ in width for a variety of reasons not related to code minimums. The designer and building official are

expected to verify that corridor widths and corridor fire-resistance ratings are in accordance with Sections 1005 and 1020, whichever is more restrictive.

The required occupant capacity of a corridor is based on the total occupant load of the rooms and spaces served by the corridor as determined by Section 1004. Where a corridor is served by two exits in opposite directions, the corridor capacity is split to determine the minimum required width of those exits (i.e., exit door, exit stairway) at each end of the corridor. The total occupant load served by a corridor is not split to establish the corridor fire-resistance rating (see Section 1020.1) or the required capacity.

The exception is because of an item in Table 1020.2 that requires a 96-inch-wide (2438 mm) corridor in Group I-2 facilities. In a hospital, while this is required in the area of patient sleeping rooms and patient care areas, there are a large number of areas that will not be for the movement of beds, either for patient care or for the hospital's defend-in-place strategies. For example, the hospital may have office or therapy areas where patients are brought in walking on their own or using wheelchairs. Many nursing homes do not move patients in beds at all. The intent of the exception is to clarify that the 96-inch (2438 mm) corridor width is not a minimum for all corridors throughout a hospital or nursing home, but only in certain areas.

**TABLE 1020.2  
MINIMUM CORRIDOR WIDTH**

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a <i>dwelling unit</i>	36
In Group E with a <i>corridor</i> having an occupant load of 100 or more	72
In <i>corridors</i> and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

For SI: 1 inch = 25.4 mm.

❖ The widths of passageways, aisles and corridors are functional elements of building construction that allow the occupants to circulate freely and comfortably throughout the floor area under nonemergency conditions. Under emergency situations, the egress paths must provide the needed width to accommodate the number of occupants that must utilize the corridor for egress.

When the occupant load of the space exceeds 49, the minimum width of the passageway, aisle or corridor serving that space is required to be at least 44 inches (1118 mm) to permit two unimpeded parallel columns of users to travel in opposite directions. When the total occupant load served by a corridor is 49 or less, a minimum width of 36 inches (914 mm) is permitted and the users are expected to encounter some intermittent travel interference from fellow users, but the lower occupant load makes those occasions infrequent and tolerable. The 36-inch (914 mm) minimum width is also required within a dwelling unit.

Passageways that lead to building equipment and systems must be at least 24 inches (610 mm) in width to provide a means to access and service the equipment when needed. Because of the frequency of the servicing intervals and the limited number of occupants in these normally unoccupied areas, a reduced width is warranted. This minimum width criteria applies to many common situations, such as stage lighting and special-effects catwalks; catwalks leading to heating and cooling equipment; as well as passageways providing access to boilers, furnaces, transformers, pumps, piping and other equipment.

Except for small buildings, Group E occupancies are required to have minimum 72-inch-wide (1829 mm) corridors where the corridors serve educational areas. This width is needed not only for proper functional use, but also because of the edge effect caused by student lockers and other boundary attractions and objects. Service and other corridors outside of educational areas, such as an administrative area, would be regulated consistent with their use. Note that Section 1020.3 would not allow the wall lockers to overlap the required corridor width.

In Group I-2 occupancies, where the corridor is utilized during a fire emergency for moving patients confined to beds, it is required to be at least 96 inches (2438 mm) in clear width. This width requirement is applicable to all areas where there are patient sleeping rooms, and may also be required in some of the treatment room areas where in-house patients will be brought in on beds or rolling stretchers. This minimum width allows two rolling beds or stretchers to pass in a corridor and permits the movement of a bed/stretcher into the corridor through a room door. In Group I-2 and ambulatory care center areas, where the movement of beds is not anticipated, such as administrative and some outpatient areas of a hospital or clinic, the corridor would not be required to be 96 inches (2438 mm) wide. The minimum width would be determined by one of the appropriate applicable criteria. For outpatient medical care, where the patient may be incapable of self-preservation, such as some outpatient surgery areas or dialysis treatment areas, the 72-inch-wide (1829 mm) corridor is required. This would include Group I surgical areas, areas such as MRI suites or dialysis centers, emergency rooms or Group B ambulatory care centers.

## MEANS OF EGRESS

**1020.3 Obstruction.** The minimum width or required capacity of *corridors* shall be unobstructed.

**Exception:** Encroachments complying with Section 1005.7.

❖ It is important to maintain required corridor width so that the path of travel to an exit is continually available and unobstructed. Because corridors tend to be lined with user passage doors, there are allowances under Section 1005.7. In no case may a door block more than 50 percent of the required corridor width. In addition, when fully open, the doors must not protrude more than 7 inches (178 mm) into the required width. Where doors swing out into the corridor, options would be to move doors back into alcoves or to provide corridors wider than the required width. The alcoves would have to be deep enough to also meet the 7-inch (118 mm) maximum protrusion when doors are open, or at least 29 inches (737 mm) deep. For an example of the wider corridor: a standard door is 36 inches (914 mm) wide, and the typical minimum corridor width is 44 inches (1118 mm). By adding the door leaf and half the required corridor width ( $36+22=58$ ), a designer could provide a corridor width of 58 inches (1473 mm) and not have any issues with encroachment of doors. This is consistent with the provisions in aisles, corridors, stairways, ramps, exit passageways and exit discharge courts.

A cross reference back to Section 1005.7 from the exceptions for width in (see Section 1019.1), corridors (see Section 1020.3), aisles exit passageways (see Section 1024.2) and exit courts (see Section 1028.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

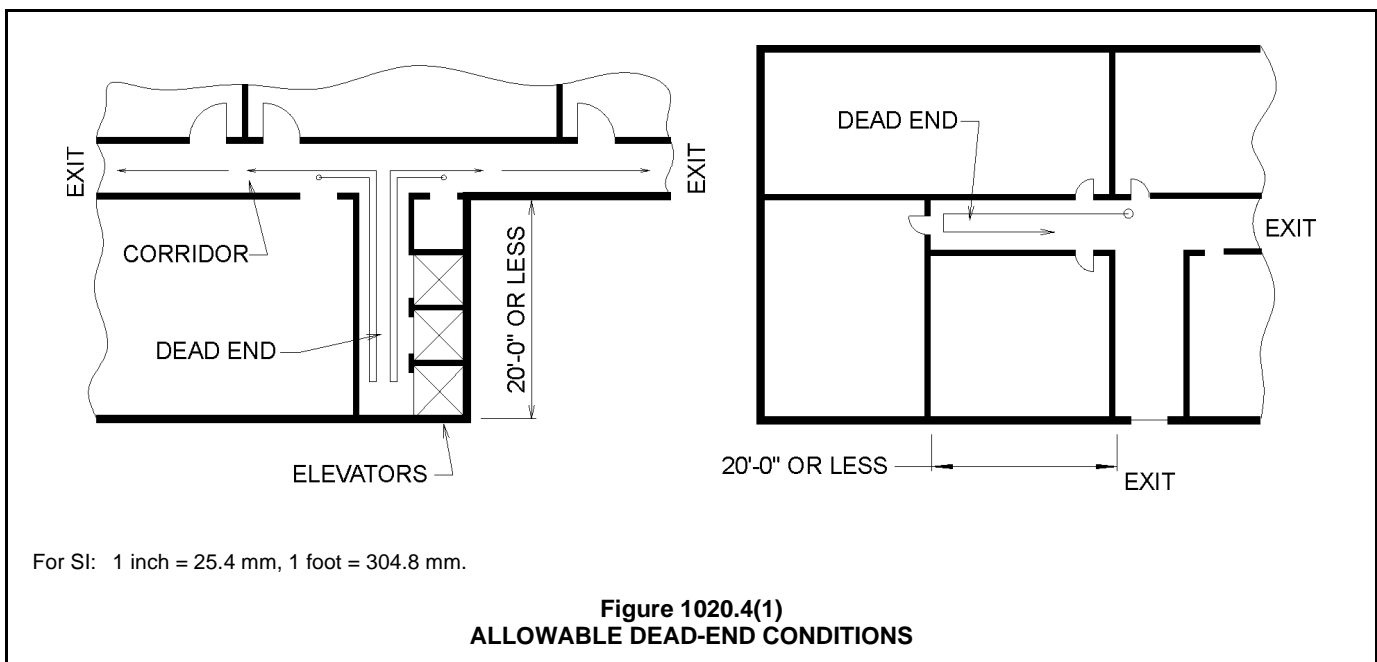

**1020.4 Dead ends.** Where more than one *exit* or *exit access doorway* is required, the *exit access* shall be arranged such

that there are no dead ends in *corridors* more than 20 feet (6096 mm) in length.

### Exceptions:

1. In occupancies in Group I-3 of Condition 2, 3 or 4, the dead end in a *corridor* shall not exceed 50 feet (15 240 mm).
  2. In occupancies in Groups B, E, F, I-1, M, R-1, R-2, R-4, S and U, where the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, the length of the dead-end *corridors* shall not exceed 50 feet (15 240 mm).
  3. A dead-end *corridor* shall not be limited in length where the length of the dead-end *corridor* is less than 2.5 times the least width of the dead-end *corridor*.
- ❖ The requirements of this section apply where a space is required to have more than one means of egress according to Section 1006.2.

Dead ends in corridors and passageways can seriously increase the time needed for an occupant, especially if unfamiliar with the space, to locate the exits. More importantly, dead ends will allow a single fire event to eliminate access to all of the exits by trapping the occupants in the dead-end area. A dead end exists whenever a user of the corridor or passageway has only one direction to travel to reach any building exit [see Commentary Figure 1020.4(1)]. While a preferred building layout would be one without dead ends, a maximum dead-end length of 20 feet (6096 mm) is permitted and is to be measured from the extreme point in the dead end to the point where occupants have a choice of two directions to separate exits. Having to go back only 20 feet (6096 mm) after coming to a dead end is not such a signifi-

cant distance as to cause a serious delay in reaching an exit during an emergency situation.

A dead end results whether or not egress elements open into it. A dead end is a hazard for occupants who enter the area from adjacent spaces, travel past an exit into a dead end or enter a dead end with the mistaken assumption that an exit is directly accessible from the dead end.

Note that IBC Section 402.8.6 deals with dead-end distances in a covered mall and assumes that, with a sufficiently wide mall in relation to its length, alternative paths of travel will be available in the mall itself to reach an exit (i.e., the common mall area is not to be construed as a corridor).

Under special conditions, exceptions to the 20-foot (6096 mm) dead-end limitation apply.

Exception 1 is permitted based on the considerations of the functional needs of Group I-3 Occupancy Condition 2, 3 or 4, the requirements for smoke compartmentalization in IBC Section 408.6 and the requirement for automatic sprinkler protection of the facility in Section 903.2.6.

Exception 2 recognizes the fire protection benefits and performance history of automatic fire sprinkler systems. While the degree of hazard in Group B, E, F, M, S and U occupancies does not initially require an automatic fire suppression system, the length of a dead-end corridor or passageway is permitted to be extended to 50 feet (15 240 mm) where an automatic fire sprinkler system in accordance with NFPA 13 is provided throughout the building. This exception is also permitted in Group I-1, R-1, R-2 and R-4 occupancies, but only when they use an NFPA 13 system, not an NFPA 13R system. In addition, these provisions are consistent with those in the IEBC and IFC in the regulation of dead-end corridors in existing buildings undergoing alterations. Dead-end provisions are not applicable in single-exit spaces; therefore, dead-

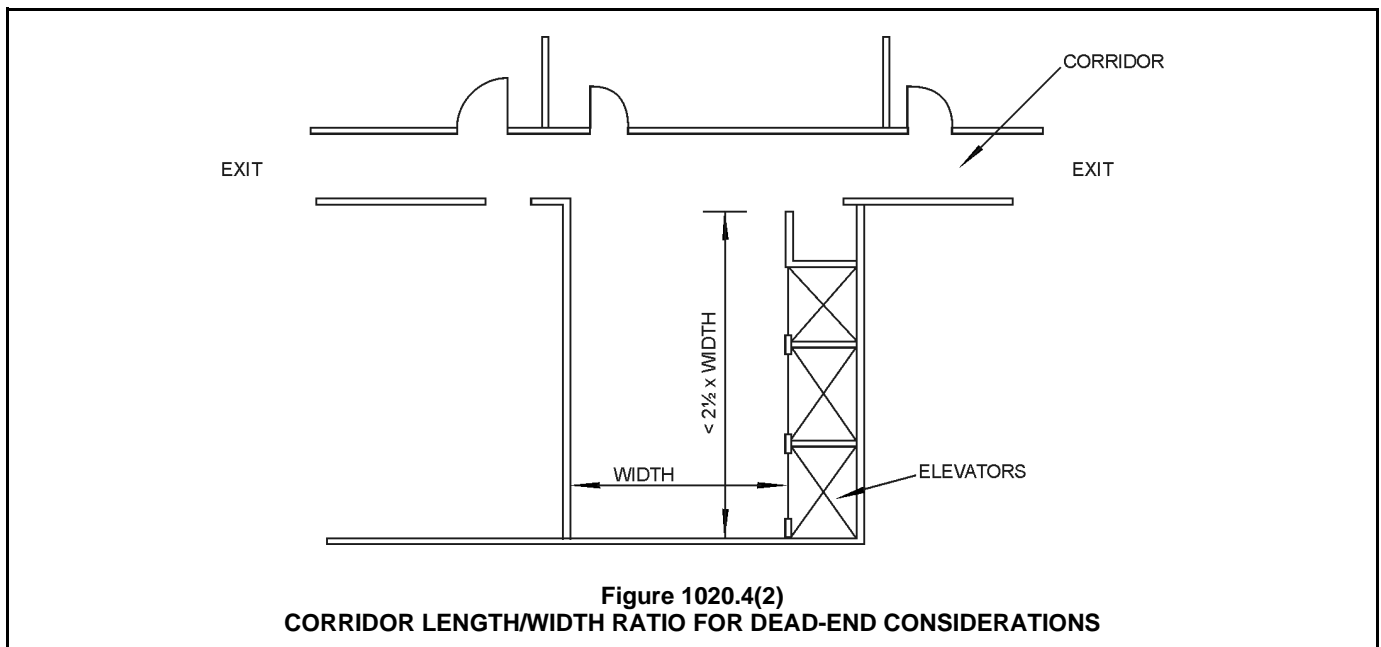

end provisions are not applicable in Group R-3 and R-4 occupancies.

Exception 3 addresses the condition presented by “cul-de-sac” elevator lobbies directly accessible from exit access corridors. In such an elevator lobby, lengths of 20 to 30 feet (6096 to 9144 mm) are common for three- or four-car elevator banks. Typically, the width of this elevator lobby is such that the possibility of confusion with a path of egress is minimized. Below the  $2\frac{1}{2}$ :1 ratio, the dead end becomes so wide that it is less likely to be perceived as a corridor leading to an exit. For example, based on the  $2\frac{1}{2}$ :1 ratio limitation, a 25-foot-long (7620 mm) dead end over 10 feet (3048 mm) in width would not be considered a dead-end corridor [see Commentary Figure 1020.4(2)]. For additional elevator lobby requirements, see the commentaries to IBC Sections 713.14 and 3006.

**1020.5 Air movement in corridors.** *Corridors* shall not serve as supply, return, exhaust, relief or ventilation air ducts.

**Exceptions:**

1. Use of a *corridor* as a source of makeup air for exhaust systems in rooms that open directly onto such *corridors*, including toilet rooms, bathrooms, dressing rooms, smoking lounges and janitor closets, shall be permitted, provided that each such *corridor* is directly supplied with outdoor air at a rate greater than the rate of makeup air taken from the *corridor*.
2. Where located within a *dwelling unit*, the use of *corridors* for conveying return air shall not be prohibited.
3. Where located within tenant spaces of 1,000 square feet (93 m<sup>2</sup>) or less in area, utilization of *corridors* for conveying return air is permitted.

## MEANS OF EGRESS

4. Incidental air movement from pressurized rooms within health care facilities, provided that the *corridor* is not the primary source of supply or return to the room.
- ❖ Two of the most critical elements of the means of egress are the required exit stairways and corridors. Exit stairways serve as protected areas in the building that provide occupants with safe passage to the level of exit discharge. Since required exits and corridors are critical elements in the means of egress, the potential spread of smoke and fire into these spaces must be minimized. The scope of this section is corridors. For requirements for the exits, see Section 1023.

The use of these corridors as part of the air distribution system could render those egress elements unusable. The intent is to have positive pressure in the corridors. Therefore, any air movement condition that could introduce smoke into these vital egress elements is prohibited. It is not the intent of this section to prohibit the air movement necessary for ventilation and space conditioning of corridors, but rather to prevent those spaces from serving as conduits for the distribution of air to, or the collection of air from, adjacent spaces. This restriction also extends to door transoms and door grilles that would allow the spread of smoke into a corridor. This limitation is not, however, intended to restrict slight pressure differences across corridor doors, such as a negative pressure differential maintained in kitchens to prevent odor migration into dining rooms. Note that air distribution via ducted systems located in or above corridors is acceptable since the corridor itself would not be functioning as a duct.

The four exceptions to this section identify conditions where a corridor can be utilized as part of the air distribution system. The exceptions apply only to exit access corridors, not to exit passageways.

Exception 1 addresses the common practice of using air from the corridor as makeup air for small exhaust fans in adjacent rooms. Where the corridor is supplied directly with outdoor air at a rate equal to or greater than the makeup air rate, negative pressure will not be created in the corridor with respect to the adjoining rooms and smoke would generally not be drawn into the corridor.

Regarding Exception 2, it is common practice to locate return air openings in the corridors of dwelling units and draw return air from adjoining spaces through the corridor. Such use of dwelling unit corridors for conveying return air is not considered to be a significant hazard and is permitted. Individual dwelling units are permitted to have unprotected openings between floors. Corridors within dwelling units that serve small occupant loads are short in length and are not required to be fire-resistance rated. For these reasons, the use of the corridor or the space above a corridor ceiling for conveying return air does not constitute an unacceptable hazard.

Exception 3 permits corridors located in small ten-

ant spaces to be used for conveying return air based on the relatively low occupant load and the relatively short length of the corridor. These conditions do not pose a significant hazard. In the event of an emergency, the occupants of the space would tend to simply retrace their steps to the entrance.

Health care facilities require direct pressurization control of certain rooms to provide a clean and sterile environment for patients. For example, operating rooms and pharmacies are required to have positive air pressure in the room, resulting in a general air movement out of the room. This ensures that airborne contaminants do not infect a sterile procedure or supplies. Pressurization is achieved by supplying air at a greater or lesser rate than the return air. Exception 4 recognizes the need of infection control and clarifies that the corridor should not be the primary source of supply return. There should be supply and return air in the room.

**1020.5.1 Corridor ceiling.** Use of the space between the *corridor* ceiling and the floor or roof structure above as a return air plenum is permitted for one or more of the following conditions:

1. The *corridor* is not required to be of *fire-resistance-rated* construction.
  2. The *corridor* is separated from the plenum by *fire-resistance-rated* construction.
  3. The air-handling system serving the *corridor* is shut down upon activation of the air-handling unit *smoke detectors* required by the *International Mechanical Code*.
  4. The air-handling system serving the *corridor* is shut down upon detection of sprinkler water flow where the building is equipped throughout with an *automatic sprinkler system*.
  5. The space between the *corridor* ceiling and the floor or roof structure above the *corridor* is used as a component of an approved engineered smoke control system.
- ❖ This section identifies five different conditions where the space above the corridor ceiling is permitted to serve as a return air plenum. Since a return air plenum operates at a negative pressure with respect to the corridor, any smoke and gases within the plenum should be contained within that space. Conversely, a supply plenum operates at a positive pressure with respect to the corridor, thus increasing the likelihood that smoke and gases will infiltrate the corridor enclosure. Where any one of the five conditions is present, the use of the corridor ceiling space as a return air plenum is permitted. This is consistent with IMC Section 601.2.1.

Where the corridor is permitted to be constructed without a fire-resistance rating (see Section 1020.1), Item 1 permits the space above the ceiling to be utilized as a return air plenum without requiring it to be separated from the corridor with fire-resistance-rated construction.

Item 2 is only applicable to corridors that are required to be enclosed with fire-resistance-rated construction. Compliance with this item requires the plenum to be separated from the corridor by fire-resistance-rated construction equivalent to the rating of the corridor enclosure itself. Therefore, the ceiling membrane itself must provide the fire-resistance rating required of the corridor enclosure. IBC Section 708.4, Exception 3, is an example of this method of construction.

Items 3 and 4 recognize that the hazard associated with smoke spread through a plenum is minimized if the air movement is stopped.

It is not uncommon for an above-ceiling plenum to be utilized as part of the smoke removal system. This practice is permitted by Item 5. Because of the way these systems are designed, the higher equipment ratings and the power supply provisions, this is considered acceptable.

**1020.6 Corridor continuity.** *Fire-resistance-rated corridors* shall be continuous from the point of entry to an *exit*, and shall not be interrupted by intervening rooms. Where the path of egress travel within a *fire-resistance-rated corridor* to the exit includes travel along unenclosed *exit access stairways* or *ramps*, the *fire-resistance rating* shall be continuous for the length of the *stairway* or *ramp* and for the length of the connecting *corridor* on the adjacent floor leading to the *exit*.

**Exceptions:**

1. Foyers, lobbies or reception rooms constructed as required for *corridors* shall not be construed as intervening rooms.
2. Enclosed elevator lobbies as permitted by Item 1 of Section 1016.2 shall not be construed as intervening rooms.

❖ This section requires that where fire protection is offered by a corridor, it is to be continuous from the

point of entry into the corridor to an exit. This is to protect occupants from the accumulation of smoke or fire exposure and to allow for sufficient time to evacuate the building. Where a corridor is served by two or more exits, only one of the exits is required to be accessed directly from the corridor. Other exits may be accessed through intervening spaces in accordance with Section 1016.2, provided that there is an opening protective at the end of the corridor to separate the rated corridor from the intervening rooms. Thus, occupants will always have their protected path to an exit, and at the same time a reasonable degree of design freedom is allowed [see Commentary Figures 1020.6(1) and 1020.6(3)].

When a level is permitted to have unenclosed exit access stairways in accordance with Section 1019.3, the corridor protection is required to continue down the exit access stairway to an enclosure for an interior exit stairway or to an exit door leading to the outside. Since the exit access stairway effectively becomes part of the corridor, doors would not be required at the top and bottom of the open exit access stairway as they are when entering enclosures for exit stairways.

Exception 1 allows a foyer, lobby or reception room to be located on the path of egress from a corridor or as part of the fire-resistance-rated corridor, provided the room has the same fire-resistance-rated walls and doors as required for the corridor. The use of this provision should be viewed as limiting the types of uses that may occur within the protected corridor. Occupied spaces within the corridor should have very limited uses and hazards. Foyers and lobbies are included in this exception based on the low fire hazard of the contents in such rooms [see Commentary Figure 1020.6(2)].

Another consideration is corridor continuity at an elevator opening. When an elevator opens into a cor-

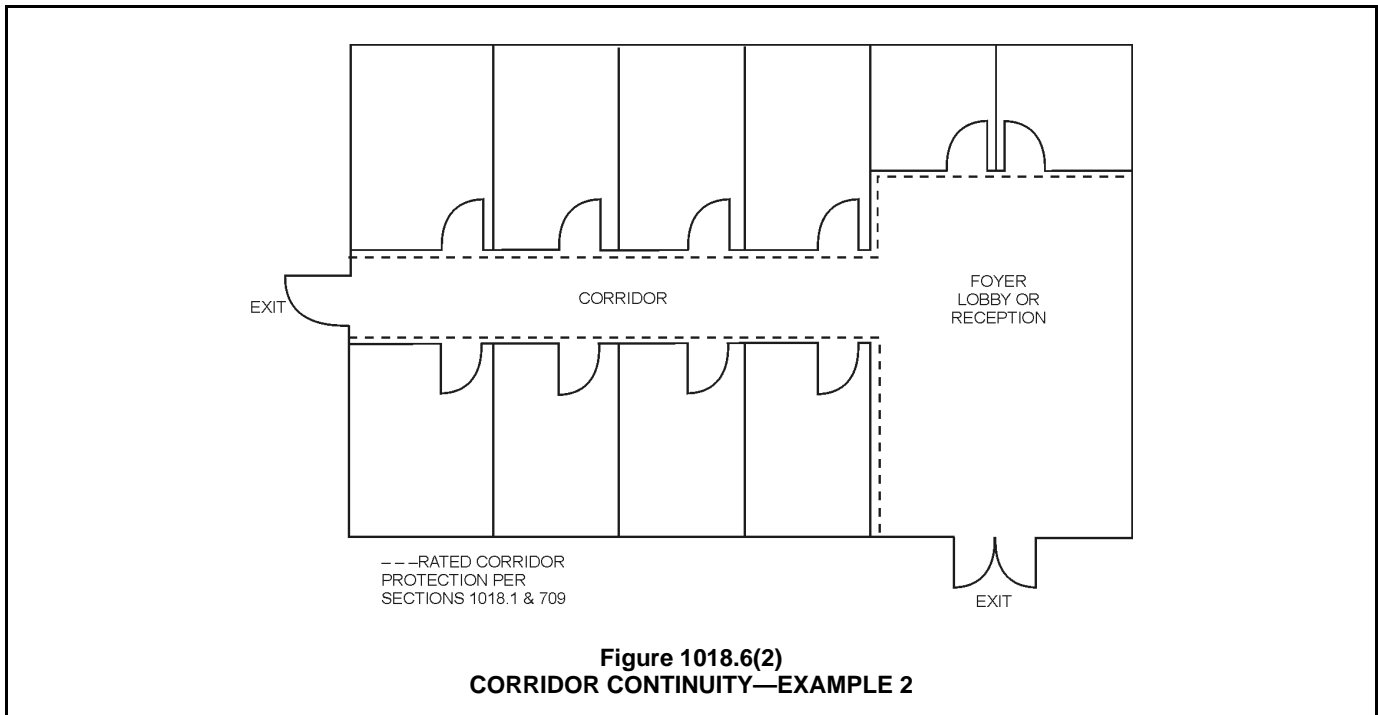

**MEANS OF EGRESS**

ridor that is required to be of fire-resistance-rated construction, the opening between the elevator shaft and the corridor must be protected to meet not only the shaft's fire protection rating but also the additional smoke and draft protection requirements necessary to limit the spread of smoke into the corridor. This additional smoke and draft control requirement is found in IBC Section 716.5.3.1. Because elevator hoistway doors do not typically comply as smoke- and draft-control assemblies, they would not be able to open directly into a corridor that is required to have protected openings. The provisions in IBC Sections 713.14 and 3006 waiving the requirements for an ele-

vator lobby do not waive the corridor opening protection requirements. Therefore, to maintain the integrity of the corridor, the elevator hoistway shaft doors opening into such rated corridors will need to be separated from the corridor by one of the following methods of protection:

1. A lobby needs to be provided with the appropriate walls and doors [see Commentary Figure 1020.6(4) and IBC Section 3006.3, Items 1 and 2] to separate the lobby from the corridor.
2. Additional doors must be provided at the hoistway [see Commentary Figure 1020.6(5) and

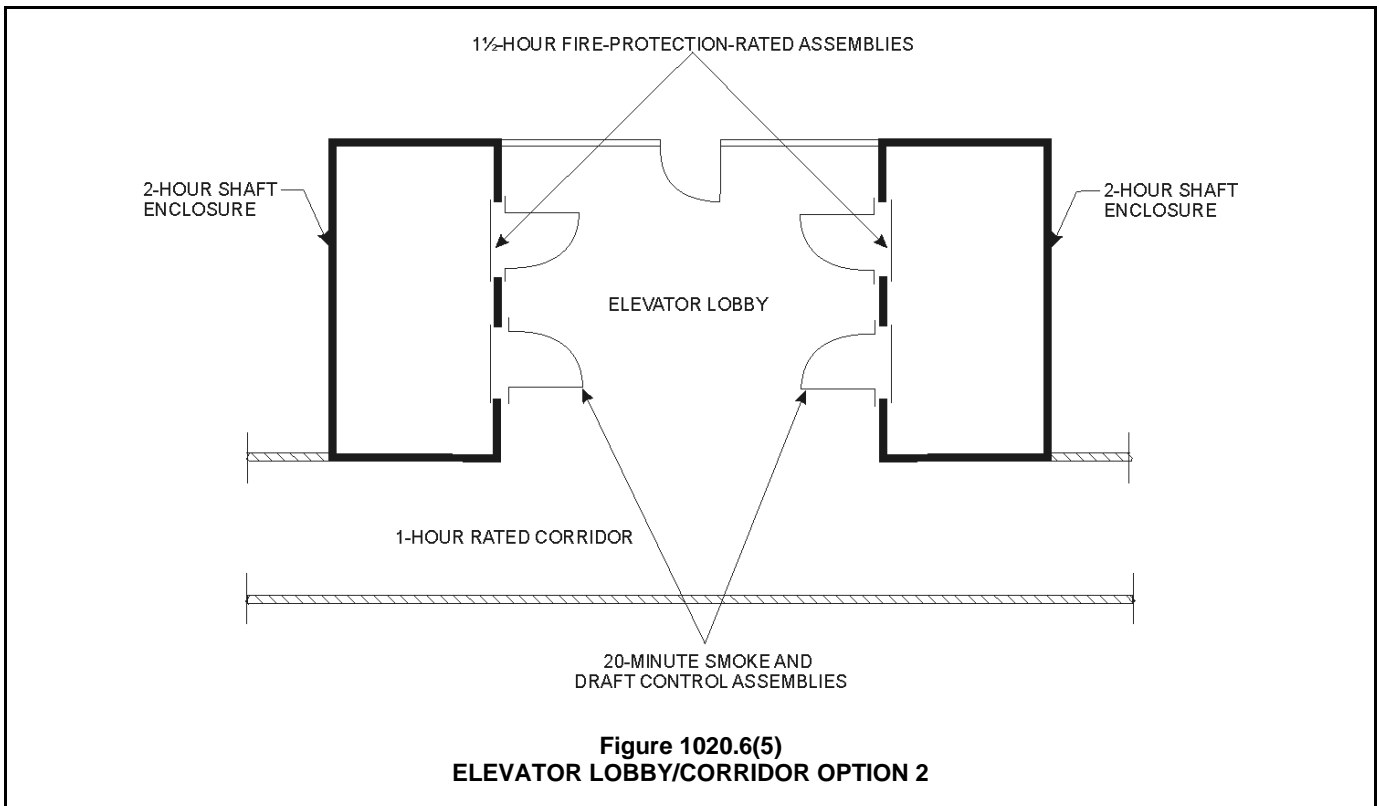

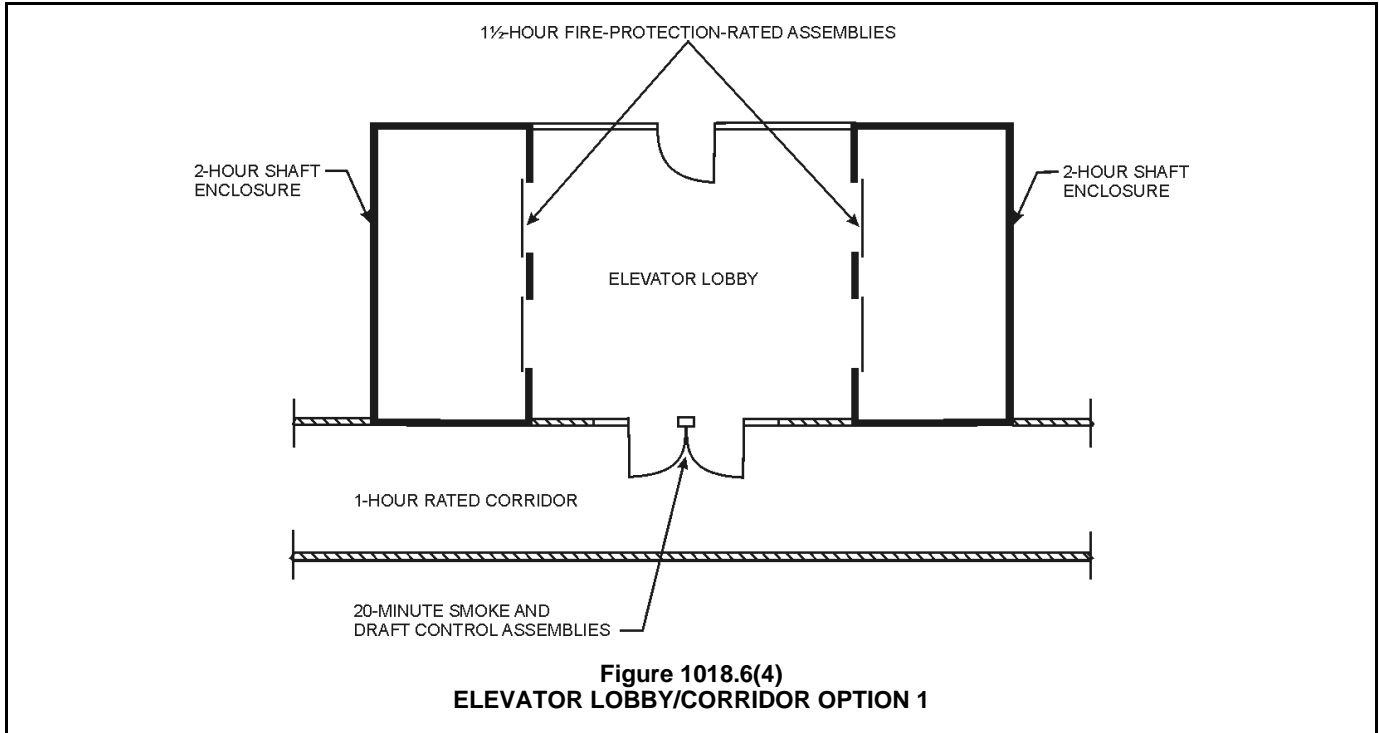

IBC Section 3006.3, Item 3] that will protect the shaft openings the same as required for the corridor doors.

3. An elevator shaft door meeting both the smoke and draft protection requirements for corridor doors in IBC Section 716.5.3.1 and the appropriate fire protection rating of IBC Table 716.5 for the shaft must be provided.

appropriate fire protection rating of IBC Table 716.5 for the shaft must be provided.

4. The corridor must be separated from the lobby [see Commentary Figure 1020.6(6) and IBC Section 3006.3, Items 1 and 2]. Per Exception 2 of Section 1020.6, Option 4 is permitted for cor-

## MEANS OF EGRESS

ridor continuity since the elevator lobby is also not considered an intervening room. Section 1016.2, Item 1, states that at least one end of a fire-resistance-rated corridor leads directly to an exit without going through the lobby. Alternatively, the second means of egress serving the corridor can be an elevator lobby with direct access to an exit [see Commentary Figure 1020.6(3)].

5. The elevator hoistway can be pressurized so that smoke will not move up the shaft (see Section 3006.3, Item 4).

While many elevator hoistway shaft doors are tested and labeled for the 1-hour or 1½-hour fire-resistance rating (see Section 716.5), very few, if any of the doors typically sold in the U.S. will also meet the smoke and draft requirements (see Section 716.5.3.1) that would allow them to open directly into a fire-resistance-rated corridor. Because of this, Items 1, 2 and 4 above will be the general methods for protecting such openings.

For additional explanation of the requirements for elevator lobbies that are adjacent to rated corridors, see Section 3006. For requirements for exit enclosures, see Section 1023.

### SECTION 1021 EGRESS BALCONIES

**1021.1 General.** Balconies used for egress purposes shall conform to the same requirements as *corridors* for minimum

width, required capacity, headroom, dead ends and projections.

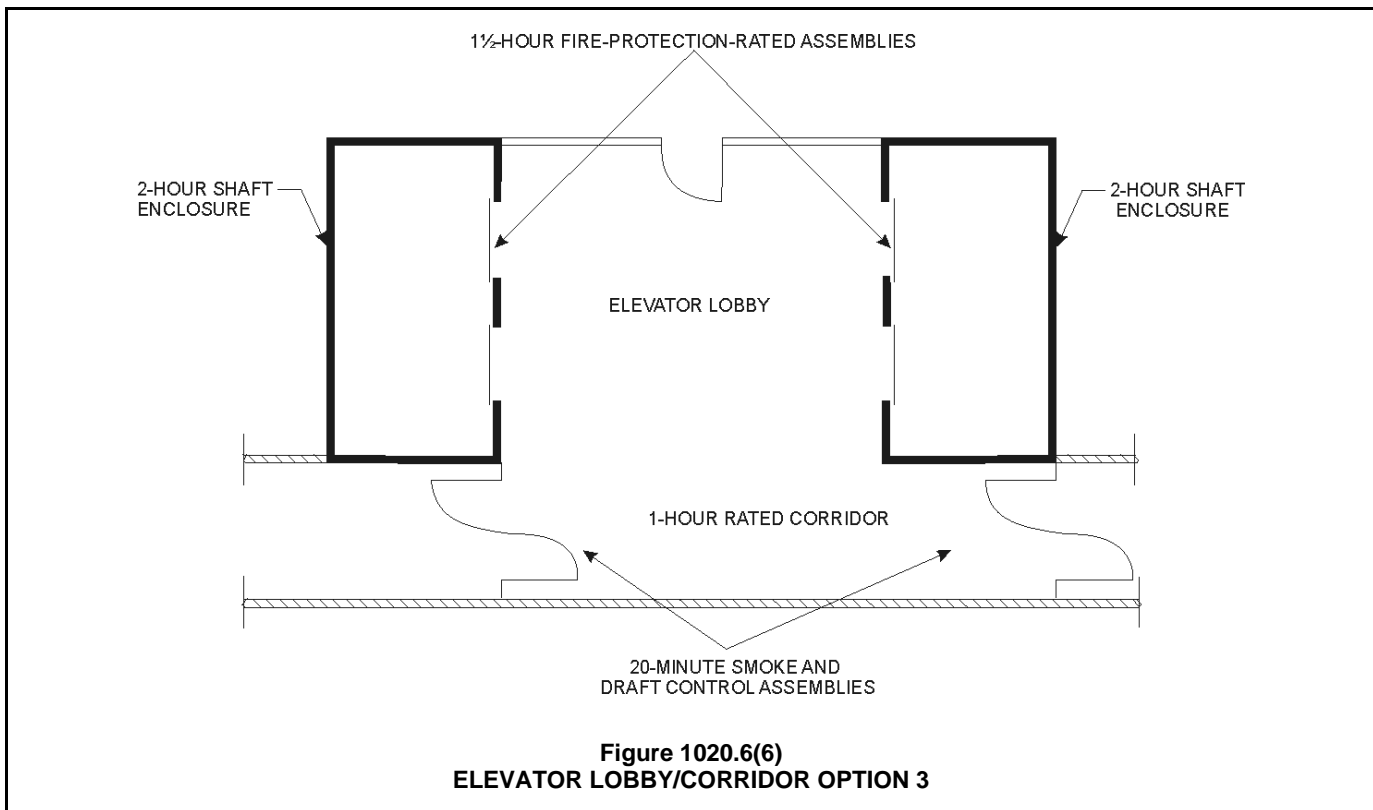

- ❖ This section regulates balconies that are used as an exit access element. Requirements are the same as exit access corridors, except for the enclosure.

Where exterior egress balconies are used in moderate or severe climates, there may also be a concern to protect the egress balcony from accumulations of snow and ice to provide a safe path of egress travel at all times, including winter. Maintenance of the means of egress in the IFC requires an unobstructed path to allow for full instant use in case of a fire or emergency. Typical methods for protecting these egress elements include roof overhangs or canopies, a heated slab and, when approved by the building official, a reliable snow removal maintenance program.

**1021.2 Wall separation.** Exterior egress balconies shall be separated from the interior of the building by walls and opening protectives as required for *corridors*.

**Exception:** Separation is not required where the exterior egress balcony is served by not less than two *stairways* and a dead-end travel condition does not require travel past an unprotected opening to reach a *stairway*.

- ❖ An exterior exit access balcony has a valuable attribute in that the products of combustion may be freely vented to the open air. In the event of a fire in an adjacent space, the products of combustion would not be expected to build up in the balcony area as would commonly occur in an interior corridor. How-

ever, there is still a concern for the egress of occupants who must use the balcony for exit access, and, consequently, may have to pass the room or space where the fire is located. Therefore, an exterior exit access balcony is required to be separated from interior spaces by fire partitions, as is required for interior corridors. The other provisions of Section 1020 relative to dead ends and opening protectives also apply.

If there are no dead-end conditions that require travel past an unprotected opening and the balcony is provided with at least two stairways, then the wall separating the balcony from the interior spaces need not have a fire-resistance rating (see Commentary Figure 1021.2). Such an arrangement reduces the probability that occupants will need to pass the area with the fire to gain access to an exit.

**1021.3 Openness.** The long side of an egress balcony shall be at least 50 percent open, and the open area above the *guards* shall be so distributed as to minimize the accumulation of smoke or toxic gases.

❖ This section provides an opening requirement that is intended to preclude the rapid buildup of smoke and toxic gases. A minimum of one side of the exterior balcony is required to have a minimum open exterior area of 50 percent of the side area of the balcony. The side openings are to be uniformly distributed along the length of the balcony.

**1021.4 Location.** Exterior egress balconies shall have a minimum *fire separation distance* of 10 feet (3048 mm) measured at right angles from the exterior edge of the egress balcony to the following:

1. Adjacent *lot lines*.
2. Other portions of the building.
3. Other buildings on the same lot unless the adjacent building *exterior walls* and openings are protected in accordance with Section 705 based on *fire separation distance*.

For the purposes of this section, other portions of the building shall be treated as separate buildings.

❖ The location requirements for exterior egress balconies given by this section protect the users of the egress balcony from the effects of a fire in another building on the same lot or an adjacent lot. The separation distance reduces the exposure to heat and smoke. If the egress balcony is closer than specified, then the adjacent buildings' exterior walls and openings are to be protected in accordance with IBC Section 705 so that the users of the egress balcony are protected. The reason for the required distance to a lot line is to provide for a future building that could be built on the adjacent lot. While buildings on the same lot can be considered one building for height and area limitations (see IBC Section 503.1.2), they must be separated by a minimum of 10 feet (3048 mm) if there is a path for exit discharge between them. The purpose of the last sentence is to clarify that an egress balcony needs a minimum 10-foot separation where a building wraps around on itself, such as a U-shaped building. It is not intended that the distance be measured to the imaginary lot line between buildings on the same lot.

Requirements are the same for exterior exit stairways and ramps. For an illustration of how exterior egress balconies and exterior exit stairways work together, see Commentary Figure 1027.5.

## SECTION 1022 EXITS

**1022.1 General.** *Exits* shall comply with Sections 1022 through 1027 and the applicable requirements of Sections 1003 through 1015. An *exit* shall not be used for any purpose that interferes with its function as a *means of egress*. Once a given level of *exit* protection is achieved, such level of protection shall not be reduced until arrival at the *exit discharge*. *Exits* shall be continuous from the point of entry into the *exit* to the *exit discharge*.

❖ This group of sections is applicable to the “exit” portion of the three-part means of egress system. Sections 1003 through 1015 are also applicable to exits. The following sections are covered in this group:

- Section 1022 provides general requirements for exterior exit doorways.

- Section 1023 provides criteria for interior exit stairways and ramps.
- Section 1024 covers horizontal portions of the exit and exit passageways.
- Section 1025 is referenced by the high-rise provisions in IBC Section 403. This section addresses a backup system for means of egress lighting (see Section 1008). “Glow-in-the-dark” stripes identify steps, handrails, obstructions and doorways within the enclosure for interior exit stairways.
- Section 1026 discusses the option of horizontal exits. This type of system is most commonly used for buildings such as hospitals and jails where building evacuation is not always the best option.
- Section 1027 provides criteria for stairways or ramps that are primarily open to the exterior, thus reducing the chance of accumulation of smoke or fumes.

The use of required exterior exit doors, exit stairways, exit passageways and horizontal exits for any purpose other than exiting is prohibited, because it might interfere with use as an exit. This is *not* intended to prohibit a door or stairway being used as part of normal circulation patterns, such as the exit doors also serving as entrances, or using the stairway to move between floors when there is not an emergency. However, these spaces must not include furniture, storage or work space. For example, the use of an exit stairway landing for storage, vending machines, copy machines, displays or any purpose other than for exiting is not permitted. Such a situation could not only lead to obstruction of the path of exit travel, thereby creating a hazard to life safety, but if the contents consist of combustible materials, then the use of the stairway as a means of egress could be jeopardized by fire or smoke in the exit enclosure.

It is recognized that standpipe risers are provided within the stair enclosure and that vertical electrical conduit may be necessary for power or lighting. However, such risers must be located so as not to interfere with the required clear width of the exit. For example, a standpipe riser located in the corner of a stairway will not reduce the required clear radius of the landing. This also applies when the stairway landing is used as an area of refuge. The spaces for wheelchairs must not obstruct the general path of egress travel [see Commentary Figures 1009.3(1) and 1009.3(2)]. Electrical conduit and mechanical equipment are permitted when necessary to serve the exit enclosure.

In existing buildings, sometimes the only viable option for providing access into the space is a platform lift. These platform lifts can be located within the enclosure for the exit (see IEBC Section 410.8.3 and IBC Section 705.1.3). Regulations in ASME A18.1 would limit the potential for any concerns for platform lifts because a fuel load in an exit stairway. However, the plat-

form lift must be located so that it is not an obstruction to the exit pathway. Typically, this is reviewed when the platform lift is in the off and folded position.

Sections 1022 through 1027 apply to all exits but do not apply to elements of the means of egress that are not actually exits, such as exit access stairways, ramps, corridors and passageways or elements of the exit discharge. Once an exit is entered, that same level of protection must be available until the occupants leave the building at the level of exit discharge. For exit discharge options for the enclosure, other than a door leading directly to the outside, see the requirements for exit passageways in Section 1024 or the options permitting usage of a lobby or vestibule in the exceptions to Section 1028.1.

**1022.2 Exterior exit doors.** Buildings or structures used for human occupancy shall have not less than one exterior door that meets the requirements of Section 1010.1.1.

❖ The purpose of this section is to specify that at least one exterior exit door is required to meet the door size requirements in Section 1010.1.1. It is not the intent of this section to specify the number of exit doors required, which is addressed in Section 1006.

**1022.2.1 Detailed requirements.** Exterior *exit* doors shall comply with the applicable requirements of Section 1010.1.

❖ The purpose of this section is simply to provide a cross reference from the exit section to all of the detailed requirements for doors that are included in Section 1010.1 and all of its subsections. For example, the requirements for door operation on exterior exit doors are controlled by Section 1010.1.9.

**1022.2.2 Arrangement.** Exterior *exit* doors shall lead directly to the *exit discharge* or the *public way*.

❖ The exterior exit door is to be the entry point of the exit discharge or lead directly to the public way. When a person reaches the exterior exit door, he or she is directly outside, where smoke and toxic gases are not a health hazard. Additionally, this section will keep exterior doors at other locations, such as to an egress balcony, from being viewed as an exit element.

## SECTION 1023 INTERIOR EXIT STAIRWAYS AND RAMPS

**1023.1 General.** *Interior exit stairways* and *ramps* serving as an *exit* component in a *means of egress* system shall comply with the requirements of this section. *Interior exit stairways* and *ramps* shall be enclosed and lead directly to the exterior of the building or shall be extended to the exterior of the building with an *exit passageway* conforming to the requirements of Section 1024, except as permitted in Section 1028.1. An *interior exit stairway* or *ramp* shall not be used for any purpose other than as a *means of egress* and a circulation path.

❖ The first sentence is a general reference to the rest of the section. Sections 1023.2 through 1023.7 deal

with the construction of the walls and ceiling that enclose the exit stairway or exit ramp. Sections 1023.8 and 1023.9 deal with information required in the enclosure for safe exiting. Section 1023.10 provides criteria for stairways in high-rise or underground buildings where a smokeproof enclosure and pressurization of the stair tower are required (see IBC Sections 403.5.4 and 405.7.2).

Most exit stairways or ramps have an exterior door at the level of exit discharge that leads directly to the outside. From this doorway, there must be a path for exit discharge that leads to the public way; however, there are other options. Exit passageways are considered an extension of the exit enclosure. The stairway enclosure discharges into the exit passageway, which in turn leads to the outside of the building. There are limited allowances for the exit enclosure to discharge through a lobby or vestibule (see Section 1028.1, Exceptions 1 and 2). A stairway enclosure could also discharge through a horizontal exit (see Section 1028.1, Exception 3). The termination requirements are the same as stated in Section 1023.3.

It is important that an exit stairway or ramp not be used for any purpose other than as a means of egress. For example, there is a tendency to use stairway landings for storage purposes. Such a situation obstructs the path of exit travel and if the stored contents consist of combustible materials, the use of the exit stairway as part of the path for a means of egress may be jeopardized, creating a hazard to life safety. It is not the intent of these provisions to prohibit an exit stairway from being used as part of the normal building circulation system. If the tenants or building owner have security concerns that would prompt them to wish to limit stairway access, consult Section 1010.1.9.11.

It is not the intent of this provision to exclude inclined platform lifts in the enclosure for the stairway; however, it is important that when not in operation they do not block access to the exit stairway or handrails. The referenced technical standard, ASME A18.1, basically requires noncombustible elements, so there is not a fire load issue associated with the lifts. Platform lifts are an important option for providing accessibility in a building. IBC Section 1109.7 limits the use of platform lifts in new construction to mainly areas with minimal occupant loads or where elevators and ramps are impracticable. Platform lifts can be part of an accessible means of egress in limited situations (Section 1007.5). IEBC Section 410.8.3 and IBC Section 705.1.3 allow for platform lifts anywhere in existing buildings in order to gain accessibility for persons with mobility impairments. The industry is currently working on different options to address the concern that the lift may be in operation during an event that requires evacuation.

**1023.2 Construction.** Enclosures for *interior exit stairways* and *ramps* shall be constructed as *fire barriers* in accordance with Section 707 or *horizontal assemblies* constructed in

accordance with Section 711, or both. *Interior exit stairway* and *ramp* enclosures shall have a *fire-resistance rating* of not less than 2 hours where connecting four stories or more and not less than 1 hour where connecting less than four stories. The number of stories connected by the *interior exit stairways* or *ramps* shall include any *basements*, but not any *mezzanines*. *Interior exit stairways* and *ramps* shall have a *fire-resistance rating* not less than the floor assembly penetrated, but need not exceed 2 hours.

**Exceptions:**

1. *Interior exit stairways* and *ramps* in Group I-3 occupancies in accordance with the provisions of Section 408.3.8.
  2. *Interior exit stairways* within an *atrium* enclosed in accordance with Section 404.6.
- ❖ This section requires that all interior exit stairways or ramps are to be enclosed with rated walls (i.e., fire barriers) and floor/ceiling assemblies (i.e., horizontal assemblies). The fire-resistance rating required depends on the number of connected stories and the required fire-resistance rating of the penetrated floors. The minimum fire-resistance rating of an enclosure for an exit stairway or ramp is at least 1 hour. The fire-resistance rating of the enclosure must be increased to 2 hours if the stairway or ramp connects four or more stories or if it penetrates a floor system with a fire-resistance rating of 2 hours or more (see Table 602 for Type I construction). Note that the criteria are based on the number of stories connected by the stairway or ramp and not the height of the building. Therefore, a building that has three stories located entirely above the grade plane and a basement would require an enclosure with a 2-hour fire-resistance rating if the stairway or ramp connects all four stories. Where the floor construction penetrated by the enclosure has a fire-resistance rating, the enclosure must have the same minimum rating. For example, an enclosure that penetrates a 2-hour floor assembly must have a minimum fire-resistance rating of 2 hours, regardless of the number of stories the enclosure connects. The fire-resistance rating of an enclosure need never exceed 2 hours. If the floor assembly penetrated requires a minimum 3-hour fire-resistance rating, the enclosure rating is only required to be 2-hour fire-resistance rated. All linear voids at joints between fire-resistance-rated wall and floor/ceiling assemblies and where an enclosure would intersect with an exterior wall must be filled so that the integrity of the enclosure is maintained (see Section 715). The fire-resistance-rated requirements for enclosures for exit stairways and ramps are consistent with those for shaft enclosures and enclosures for exit access stairways and ramps.

The enclosure is needed because an exit stairway or ramp penetrates the floor/ceiling assemblies between the levels, thus creating a vertical opening or shaft. In cases of fire, a vertical opening may act as a chimney, causing smoke, hot gases and light-burning products to flow upward (buoyant force). If an opening

is unprotected, these products of combustion will be forced by positive pressure differentials to spread horizontally into the building spaces. There are exceptions for shaft protection around stairways and ramps that are not part of a required means of egress in IBC Section 712 or exit access stairways as permitted in Section 1019.3.

The enclosure of interior stairways or ramps with construction having a fire-resistance rating is intended to prevent the spread of fire from floor to floor. Another important purpose is to provide a safe path of travel for the building occupants and to serve as a protected means of access to the fire floor by fire department personnel. For this reason, Sections 1023.4 through 1023.6 limit the penetrations and openings permitted in the enclosure for an exit stairway or ramp.

For travel distance measurements at the exit stairways, see the commentary to Section 1017.3. While not specifically mentioned as an exception, Section 1027 for exterior exit stairways is considered to provide an equivalent level of protection to enclosed interior stairways.

Per Exception 1, because of security needs in detention facilities, one of the exit stairways is permitted to be glazed in a manner similar to atrium enclosures. Specific limitations and requirements are discussed in IBC Section 408.3.8. Exit access stairways within housing units are addressed in IBC Sections 408.5.1 and Section 1019.4 of the code.

Exception 2 is in consideration of an increased level of safety in an atrium. IBC Section 404 for atriums requires the space to be enclosed by a 1-hour passive enclosure and also protected by various active systems including fire suppression and smoke control features. The natural configuration of an atrium affords building occupants immediate views of the entire egress to the bottom of the atrium.

**1023.3 Termination.** *Interior exit stairways and ramps shall terminate at an exit discharge or a public way.*

**Exception:** A combination of *interior exit stairways, interior exit ramps and exit passageways*, constructed in accordance with Sections 1023.2, 1023.3.1 and 1024, respectively, and forming a continuous protected enclosure, shall be permitted to extend an *interior exit stairway or ramp* to the *exit discharge or a public way*.

- ❖ The intent of this section is to provide safety in all portions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway. Exit passageways (see Section 1024) are a continuation of the enclosure for the exit stairway. This would include, but not be limited to, the fire-resistance rating of the exit enclosure walls and the opening protection rating of the doors. While an exit passageway is most commonly found on the level of exit discharge as a means to connect a stairway enclosure to the exterior, in buildings that step back in footprint as the rise, the stairways may not be totally vertical shafts, but move out as they move down to keep the required separation distance. Exit

passageways can be at any level to connect the stair towers. There are special exit signage considerations for this particular issue in Section 1013.1 (see Commentary Figure 1013.1).

Section 1028.1 would allow for an alternative for direct access to the outside via an intervening lobby or vestibule.

Horizontal exits (see Section 1026), while not providing direct access to the outside of the structure, do move occupants to another “building” by moving through a fire wall (see Sections 1026 and 1028.1, Exception 3) into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

**1023.3.1 Extension.** Where *interior exit stairways and ramps* are extended to an *exit discharge* or a *public way* by an *exit passageway*, the *interior exit stairway and ramp* shall be separated from the *exit passageway* by a *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 711, or both. The *fire-resistance rating* shall be not less than that required for the *interior exit stairway and ramp*. A *fire door* assembly complying with Section 716.5 shall be installed in the *fire barrier* to provide a *means of egress* from the *interior exit stairway and ramp* to the *exit passageway*. Openings in the *fire barrier* other than the *fire door* assembly are prohibited. Penetrations of the *fire barrier* are prohibited.

**Exceptions:**

1. Penetrations of the *fire barrier* in accordance with Section 1023.5 shall be permitted.
  2. Separation between an *interior exit stairway or ramp* and the *exit passageway* extension shall not be required where there are no openings into the *exit passageway* extension.
- ❖ Once a person enters the enclosure surrounding an exit stairway, that same level of protection should be provided to them until they can leave the building. When an enclosure for an exit stairway connects to an exit passageway, either at the ground level or at an intermediate transition floor, the exit passageway must provide the same level of protection as the enclosure for the exit stairway, including fire-resistance of the walls, floor, ceiling and supporting construction and protection of any openings. At the junction between the enclosure for the exit stairway and the exit passageway, there must be both a rated fire barrier and a fire door. This has the additional benefit of preventing any smoke that may migrate into the exit passageway from also moving up the exit stairway or ramp. Permitted penetrations for the exit passageway are the same as those limitations set for the enclosure for the exit stairway. See Sections 1013.1 and 1025 for egress markings and signage within these types of spaces.

For the situation when an exit stairway is constructed as a smokeproof enclosure or a pressurized stairway, see Section 1023.10.1.

Exception 1—The penetrations for the exit passageway are allowed to be the same as permitted for the stairway enclosure.

Exception 2—The purpose in having a door at this interface in the existing requirement is to prevent smoke from a possible open door or other penetration in the passageway from traveling up the exit enclosure. This is prevented if there are no openings or penetrations in the exit passageway. Then the exit passageway is horizontal offset of the exit enclosure and does not propose the same hazard. Egress can proceed faster if there are no intermediate doors contained at the enclosure transitions.

**1023.4 Openings.** *Interior exit stairway and ramp* opening protectives shall be in accordance with the requirements of Section 716.

Openings in *interior exit stairways* and *ramps* other than unprotected exterior openings shall be limited to those necessary for *exit access* to the enclosure from normally occupied spaces and for egress from the enclosure.

Elevators shall not open into *interior exit stairways* and *ramps*.

❖ In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will be self-latching. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80. Automatic-closing doors that are provided at protected openings in exits are also required to close on the actuation of smoke detectors or loss of power to the smoke detectors (see Section 716.5.9.3).

The only openings that are permitted in fire-resistance-rated enclosures for exit stairways or ramps are doors that lead from normally occupied spaces into the enclosure and doors leading out of the enclosure to the outside. This restriction on openings essentially prohibits the use of windows in an exit enclosure except for those exterior windows that are not exposed to any hazards. This requirement is not intended to prohibit windows or other openings in the exterior walls of the exit enclosure. The verbiage “unprotected exterior openings” includes windows or doors not required to be protected by either IBC Section 705.8 or Section 1023.7 of the code. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E119 or UL 263. The objective of this provision is to minimize the possibility of fire spreading into an enclosure and endangering the occupants or even preventing the use of the exit at a time when it is most needed. The limitation on openings applies regardless of the fire protection rating of the opening protective.

The limitation on openings from normally occupied areas is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, which has an opening into the stairway, thereby possibly resulting in fire spread into the stairway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. For connection between the vertical exit enclosure and an exit passageway, see Section 1023.3.1.

Elevators may not open into exit enclosures. The difficulty is to have elevator doors that can meet the opening protectives for a fire barrier, but still operate effectively as elevator doors. For additional information on elevator lobbies and doors, see the commentary for IBC Section 713.14, Section 1020.6 of the code and IBC Section 3006.

These opening limitations are very similar to those required for an exit passageway (see Section 1024.5).

**1023.5 Penetrations.** Penetrations into or through *interior exit stairways* and *ramps* are prohibited except for equipment and ductwork necessary for independent ventilation or pressurization, sprinkler piping, standpipes, electrical raceway for fire department communication systems and electrical raceway serving the *interior exit stairway* and *ramp* and terminating at a steel box not exceeding 16 square inches (0.010 m<sup>2</sup>). Such penetrations shall be protected in accordance with Section 714. There shall not be penetrations or communication openings, whether protected or not, between adjacent *interior exit stairways* and *ramps*.

**Exception:** Membrane penetrations shall be permitted on the outside of the *interior exit stairway* and *ramp*. Such penetrations shall be protected in accordance with Section 714.3.2.

❖ This section specifically lists the items that are allowed to penetrate the walls and ceiling of the enclosure for the exit stairway. This is consistent for all types of enclosures for exits, including interior exit stairways or interior exit ramps and exit passageways (see Section 1024.6). In general, only portions of the building service systems that serve the enclosure are allowed to penetrate the enclosure. As indicated in the commentary to Section 1022.1, standpipe systems are commonly located in the exit stair enclosures. If two exit enclosures are adjacent to one another, there must be no penetrations between them, thereby limiting the chances of smoke being in both stairwells.

IBC Section 714 addresses through penetrations and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. This section and Section 1023.6 are meant to work together. Penetrations in exterior walls are addressed in Section 1023.7.

The exception allows for electrical boxes, “Exit” signs or fire alarm pull stations to be installed on the outside of the enclosure, provided that the boxes are installed so that the required fire-resistance rating is not reduced (see IBC Section 714.3.2).

**1023.6 Ventilation.** Equipment and ductwork for *interior exit stairway* and *ramp* ventilation as permitted by Section 1023.5 shall comply with one of the following items:

1. Such equipment and ductwork shall be located exterior to the building and shall be directly connected to the *interior exit stairway* and *ramp* by ductwork enclosed in construction as required for shafts.
2. Where such equipment and ductwork is located within the *interior exit stairway* and *ramp*, the intake air shall be taken directly from the outdoors and the exhaust air shall be discharged directly to the outdoors, or such air shall be conveyed through ducts enclosed in construction as required for shafts.
3. Where located within the building, such equipment and ductwork shall be separated from the remainder of the building, including other mechanical equipment, with construction as required for shafts.

In each case, openings into the *fire-resistance-rated* construction shall be limited to those needed for maintenance and operation and shall be protected by opening protectives in accordance with Section 716 for shaft enclosures.

The *interior exit stairway* and *ramp* ventilation systems shall be independent of other building ventilation systems.

❖ The purpose of the requirements for ventilation system equipment and ductwork is to maintain the fire resistance of the enclosure for the exit stairway. The ventilation system serving the enclosure is to be independent of other building systems to prevent smoke in the enclosure from traveling to other areas of the building. This section and Section 1023.5 are meant to work together. Where ductwork penetrates the outside wall, if it is not required to be rated by Section 1023.7, then the duct does not require a fire and smoke damper. If the ductwork serving the shaft does penetrate a rated wall or rated floor/ceiling assembly, a fire and smoke damper would be required by IBC Section 717.5.3. Openings required for access to the ventilation system for maintenance and operation shall be protected in accordance with IBC Section 716.

**1023.7 Interior exit stairway and ramp exterior walls.**

*Exterior walls* of the *interior exit stairway* or *ramp* shall comply with the requirements of Section 705 for *exterior walls*. Where nonrated walls or unprotected openings enclose the exterior of the *stairway* or *ramps* and the walls or openings are exposed by other parts of the building at an angle of less than 180 degrees (3.14 rad), the building *exterior walls* within 10 feet (3048 mm) horizontally of a nonrated wall or unprotected opening shall have a *fire-resistance rating* of not less than 1 hour. Openings within such *exterior walls* shall be protected by opening protectives having a *fire protection rating* of not less than  $\frac{3}{4}$  hour. This construction shall extend vertically from the ground to a point 10 feet (3048 mm) above the topmost landing of the *stairway* or *ramp*, or to the roof line, whichever is lower.

❖ This section does not require exterior walls of an enclosure for an exit stairway or ramp to have the

same fire-resistance rating as the interior walls. IBC Table 602 and IBC Section 705 establish when exterior walls are required to be rated and openings limited due to adjacent buildings or lot lines. This exposure is different from exterior load-bearing walls that are required to be rated because of the type of construction per IBC Table 601. What is unique to exterior walls at exit stairways is the need to stop fires from burning through an exterior wall adjacent to the enclosure, which may then jeopardize the occupant's ability to continue to use that exit stairway. Essentially, there are two alternatives where an exposure hazard exists: 1. Provide protection to the stairway by having a fire-resistance rating on its exterior wall; or 2. Provide a fire-resistance rating to the walls adjacent to the stairway. The ratings apply for a distance of 10 feet (3048 mm) measured horizontally and vertically from the stairway enclosure where those walls are at an angle of less than 180 degrees (3.14 rad) from the exterior wall portion of the enclosure [see Condition 1 in Commentary Figure 1023.7(1)]. When the adjacent exterior wall is protected in lieu of the stairway enclosure wall, the protection is to extend from the ground to a level of 10 feet (3048 mm) above the highest landing of the stairway. However, the protection is not required to extend beyond the normal roof line of the building.

The 180-degree (3.14 rad) angle criterion is based on the scenario where the exterior wall of the stair enclosure is in the same plane and flush with the exterior wall of the building [see Conditions 2 and 3 in Commentary Figure 1023.7(1)]. In this scenario, heat or fire would need to travel 180 degrees (3.14 rad) around in order to impinge on the stair. Based on studies of existing buildings, this 180-degree (3.14 rad) spread of fire does not appear to be a problem. This criterion is only applicable when the angle between the walls is 180 degrees (3.14 rad) or less.

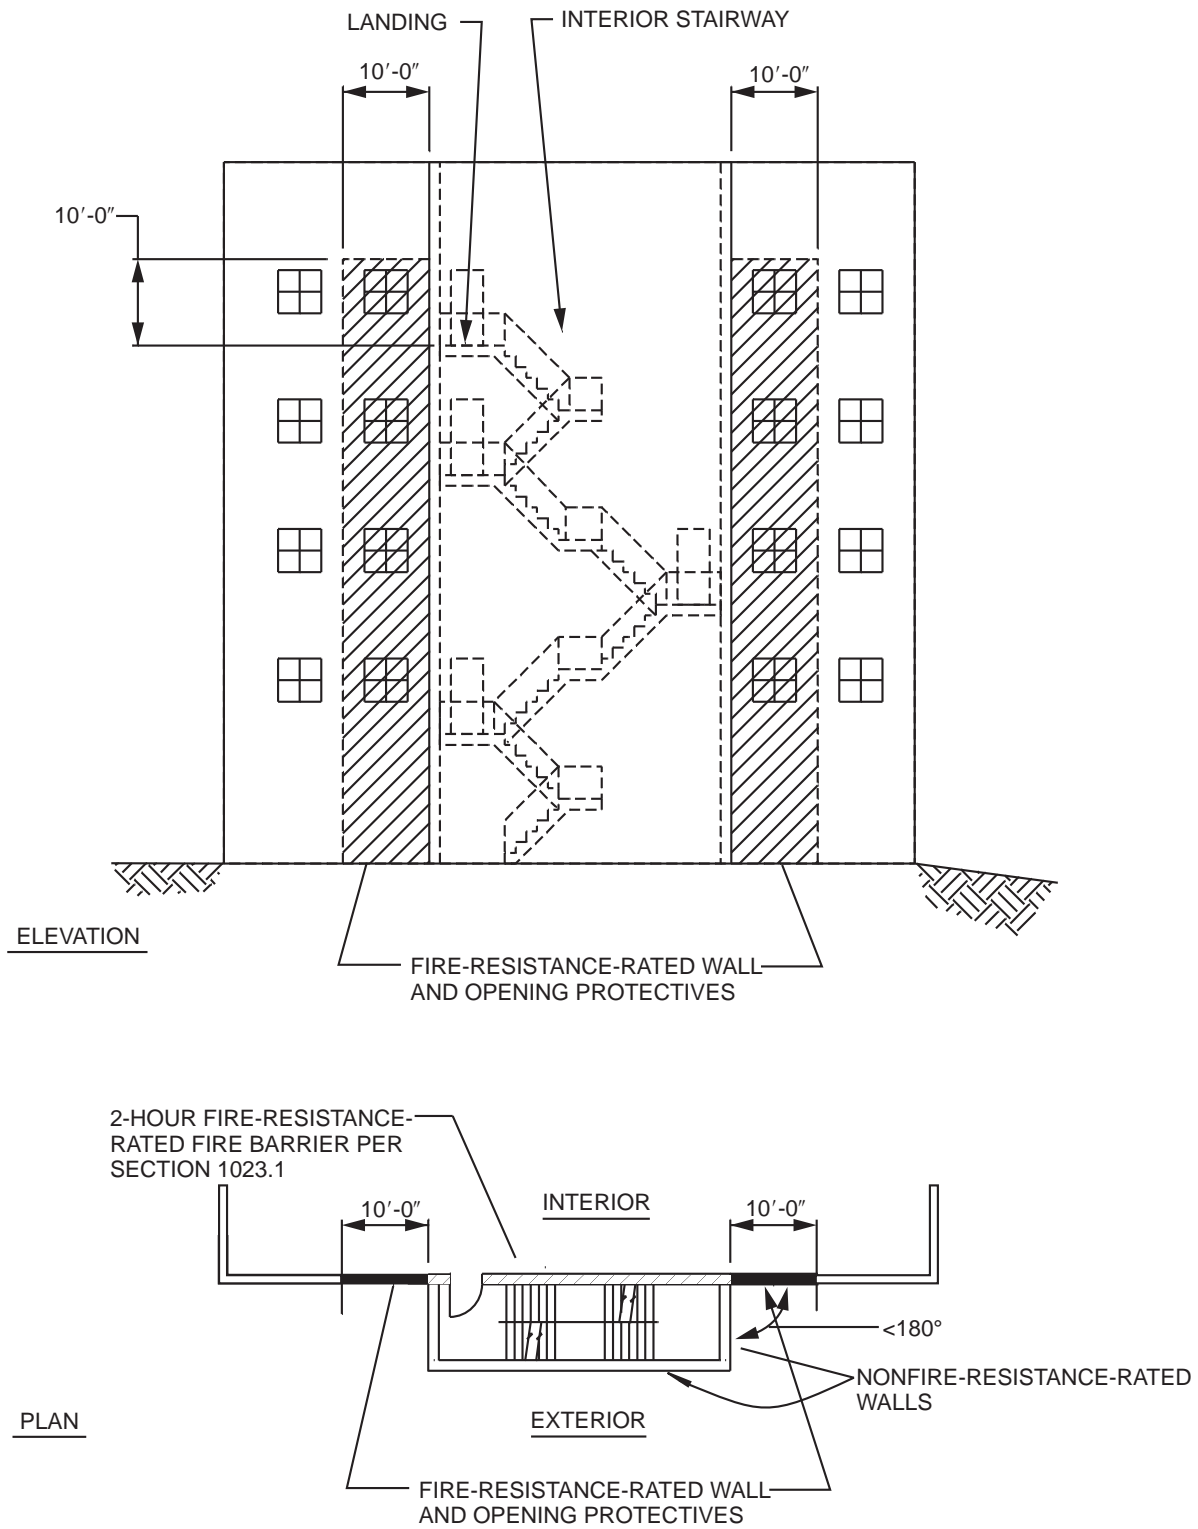

As the fire exposure on the exterior is different than can be expected on the interior, the fire-resistance rating of the exterior wall is not required to exceed 1 hour, regardless of whether it is the stairway enclosure wall or the adjacent exterior wall, unless the exterior wall is required by other sections of the code to have a higher fire-resistance rating (see IBC Tables 601 and 602). The fire protection rating on any openings in the exterior wall of a stairway enclosure or adjacent exterior wall within 180 degrees (3.14 rad) is to be a minimum of  $\frac{3}{4}$  hour [see Commentary Figure 1023.7(2)].

In a situation where the upper levels are smaller than lower levels, an interior stairway can end up having an exterior wall when it moves above the roof of the lower levels. In this situation, the question is the rating requirements for the exterior wall of the stairway over the roof. Therefore, the exterior wall of the stairway must meet the vertical opening provisions in IBC Section 705.8.6.

For SI: 1 foot = 304.8 mm, 1 degree = 0.01745 rad.

**Figure 1023.7(1)**  
**EXAMPLES OF EXTERIOR WALL PROTECTIVES**

For SI: 1 foot = 304.8 mm, 1 degree = 0.01745 rad.

**Figure 1023.7(2)**  
**EXTERIOR WALL PROTECTION**

**1023.8 Discharge identification.** An *interior exit stairway* and *ramp* shall not continue below its *level of exit discharge* unless an *approved* barrier is provided at the *level of exit discharge* to prevent persons from unintentionally continuing into levels below. Directional exit signs shall be provided as specified in Section 1013.

❖ So that building occupants using an exit stairway during an emergency situation will be prevented from going past the level of exit discharge, the run of the stairway is to be interrupted by a partition, door, gate or other approved means. These devices help the users of the stairway to recognize when they have reached the point that is the level of exit discharge. Exit signs, including raised letters and braille, are to be provided for occupant guidance at the door leading to the way out (i.e., directly to the exterior, or via an exit passageway, lobby or vestibule). Furthermore, signs are to be placed at each floor landing in all interior exit stairways connecting more than three floor levels, designating the level or story of the landings in accordance with Section 1023.9.

The code does not specify the type of material or construction of the barrier used to identify the level of exit discharge. The key issues to be considered in the selection and approval of the type of barrier to be used are: 1. Whether the barrier provides a visible and physical means of alerting occupants who are exiting under emergency conditions that they have reached the level of exit discharge; and 2. Whether the barrier is constructed of materials that are permitted by the construction type of the building. In an emergency situation, some occupants are likely to

come in contact with the barrier during exiting before realizing that they are at the level of exit discharge. Therefore, the barrier should be constructed in a manner that is substantial enough to withstand the anticipated physical contact, such as pushing or shoving. It would be reasonable, as a minimum, to design the barrier to withstand the structural load requirements of IBC Section 1607.5 for interior walls and partitions. The barrier could be opaque (such as gypsum wallboard and stud framing) or not (such as a wire grid-type material).

The use of signage only or relatively insubstantial barriers, such as ropes or chains strung across the opening, is typically not sufficient to prevent occupants from attempting to continue past the level of exit discharge during an emergency.

Commentary Figure 1023.8 is an example of one method of discharge identification.

**1023.9 Stairway identification signs.** A sign shall be provided at each floor landing in an *interior exit stairway* and *ramp* connecting more than three stories designating the floor level, the terminus of the top and bottom of the *interior exit stairway* and *ramp* and the identification of the *stairway* or *ramp*. The signage shall also state the story of, and the direction to, the *exit discharge* and the availability of roof access from the *interior exit stairway* and *ramp* for the fire department. The sign shall be located 5 feet (1524 mm) above the floor landing in a position that is readily visible when the doors are in the open and closed positions. In addition to the *stairway* identification sign, a floor-level sign in visual characters, raised characters and braille complying with ICC A117.1 shall be located at each floor-level landing adjacent to

**Figure 1023.8**  
**EXAMPLE OF A STAIRWAY BARRIER AT THE LEVEL OF EXIT DISCHARGE**

the door leading from the *interior exit stairway* and *ramp* into the *corridor* to identify the floor level.

❖ This section discusses two distinct sign requirements that have totally different purposes.

Signs are to be placed at each floor landing in all exit stairways connecting more than three stories. The signs are to designate the level or story of the landings above or below the level of exit discharge. The purpose is to inform the occupants of their location with respect to the level of exit discharge as they use the stairway to leave the building. More importantly, it allows the fire service to locate and gain quick access to the fire floor. At each level, the direction to the exit discharge is required to be indicated. The identification of the level that is the exit discharge is also to be indicated at each level. The identification of the roof access availability is for the fire department (see Commentary Figure 1023.9.1). Roof access is required by Section 1011.13. For visibility, the signs are required to be located approximately 5 feet (1524 mm) above the floor surface and to be visible when the stairway door is open. The need to designate levels remaining to reach the level of exit discharge may mean that the numbering is other than the normal designation used by building management. For example, a designation of P1, P2, P3, etc., would not be acceptable for stairways in the basement parking garage, since in themselves they do not designate the floor level below the level of exit discharge.

To aid people with vision impairments, the floor designation must also be available in visual and raised letters and braille at each door. The intent is to let persons with vision impairments be able to find out what floor they are on without leaving the stairway

enclosure. Visual and raised letters and braille signage indicating the door leading to the exterior is covered in Section 1013.4.

**1023.9.1 Signage requirements.** *Stairway* identification signs shall comply with all of the following requirements:

1. The signs shall be a minimum size of 18 inches (457 mm) by 12 inches (305 mm).
2. The letters designating the identification of the *interior exit stairway* and *ramp* shall be not less than 1½ inches (38 mm) in height.
3. The number designating the floor level shall be not less than 5 inches (127 mm) in height and located in the center of the sign.
4. Other lettering and numbers shall be not less than 1 inch (25 mm) in height.
5. Characters and their background shall have a nonglare finish. Characters shall contrast with their background, with either light characters on a dark background or dark characters on a light background.
6. Where signs required by Section 1023.9 are installed in the *interior exit stairways* and *ramps* of buildings subject to Section 1025, the signs shall be made of the same materials as required by Section 1025.4.

❖ The requirements for stairway identification signage will provide for a consistent approach. The intent is to make signs visible and immediately recognizable to occupants and emergency responders using the stairway (see Commentary Figure 1023.9.1).

In addition, if the building is a high-rise and luminous egress path markings are required (see Section 1025.1), the stairway identification signage must also be self-luminous or photoluminescent. In order to also meet the contrast requirements in Item 5, typically the sign will have dark letters on a glow-in-the-dark background.

**1023.10 Elevator lobby identification signs.** At landings in *interior exit stairways* where two or more doors lead to the floor level, any door with direct access to an enclosed elevator lobby shall be identified by signage located on the door or directly adjacent to the door stating “Elevator Lobby.” Signage shall be in accordance with Section 1023.9.1, Items 4, 5 and 6.

❖ This section is mainly related to fire service access elevators required in IBC Section 403.6.1 for a building with an occupied floor more than 120 feet (3048 mm) above the street. The elevator lobby is required to have direct access to an exit stairway (see IBC Section 3007.6.1). In addition, that same exit enclosure has to have access to the floor without going back through the elevator lobby (see IBC Section 3007.9.1). This leads to two doors at each floor landing. Elevator lobby signs identify the correct door through which fire fighters should access the floor so that lobby smoke protection is maintained.

Since typically the fire service access elevators will use the same lobby as the occupant evacuation elevators (when provided), this signage would effectively be

required for the doors in the stairway enclosure that lead to occupant evacuation elevator lobbies as well.

**1023.11 Smokeproof enclosures.** Where required by Section 403.5.4 or 405.7.2, *interior exit stairways* and *ramps* shall be *smokeproof enclosures* in accordance with Section 909.20.

❖ While smokeproof enclosures and pressurized stairways for exiting can, at the designer's option, be used in buildings of any occupancy, height or area, this section specifically requires smokeproof enclosures or pressurized stairways to be provided when either of two conditions occur.

The first condition requires all exit stairways in high-rise buildings [i.e., buildings with floor levels higher than 75 feet (22 860 mm) above the level of exit discharge (see IBC Section 403.5.4)] to be smokeproof enclosures or pressurized stairways. The reason for this provision is that in very tall buildings, often during fire emergencies, total and immediate evacuation of the occupants cannot be readily accomplished. In such situations, exit stairways become places of safety for the occupants and must be adequately protected with smokeproof enclosures or pressurization to provide a safe egress environment. In order to provide this safe environment, the enclosure must be constructed to resist the migration of smoke caused by the "stack effect." Stack effect occurs in tall enclosures such as chimneys, when a fluid such as smoke, which is less dense than the ambient air, is introduced into the enclosure. The smoke will rise because of the effects of buoyancy and will induce additional flow into the enclosure through openings of any size at the lower levels.

The second condition applies for underground buildings [i.e., when an occupiable floor level is located more than 30 feet (9144 mm) below the level of exit discharge (see IBC Section 405.7.2)]. Stairways serving those levels are also required to be protected by smokeproof enclosures or pressurization because underground portions of a building present unique problems in providing not only for life safety but also access for fire-fighting purposes. The choice of a 30-foot (9144 mm) threshold for this requirement is intended to provide a reasonable limitation on vertical travel distance before the requirement applies.

Detailed system requirements for a smokeproof enclosure or pressurization are in Section 909.20. Note that IBC Sections 403 and 405 each have exceptions for specific building types that are not to be regulated by those sections. Likewise, the requirements of this section do not apply to buildings identified in those exceptions.

**1023.11.1 Termination and extension.** A *smokeproof enclosure* shall terminate at an *exit discharge* or a *public way*. The *smokeproof enclosure* shall be permitted to be extended by an *exit passageway* in accordance with Section 1023.3. The *exit passageway* shall be without openings other than the *fire door assembly* required by Section 1023.3.1 and those necessary for egress from the *exit passageway*. The *exit passageway* shall be separated from the remainder of the building by

2-hour *fire barriers* constructed in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both.

**Exceptions:**

1. Openings in the *exit passageway* serving a *smokeproof enclosure* are permitted where the *exit passageway* is protected and pressurized in the same manner as the *smokeproof enclosure*, and openings are protected as required for access from other floors.
2. The *fire barrier* separating the *smokeproof enclosure* from the *exit passageway* is not required, provided the *exit passageway* is protected and pressurized in the same manner as the *smokeproof enclosure*.
3. A *smokeproof enclosure* shall be permitted to egress through areas on the *level of exit discharge* or vestibules as permitted by Section 1028.

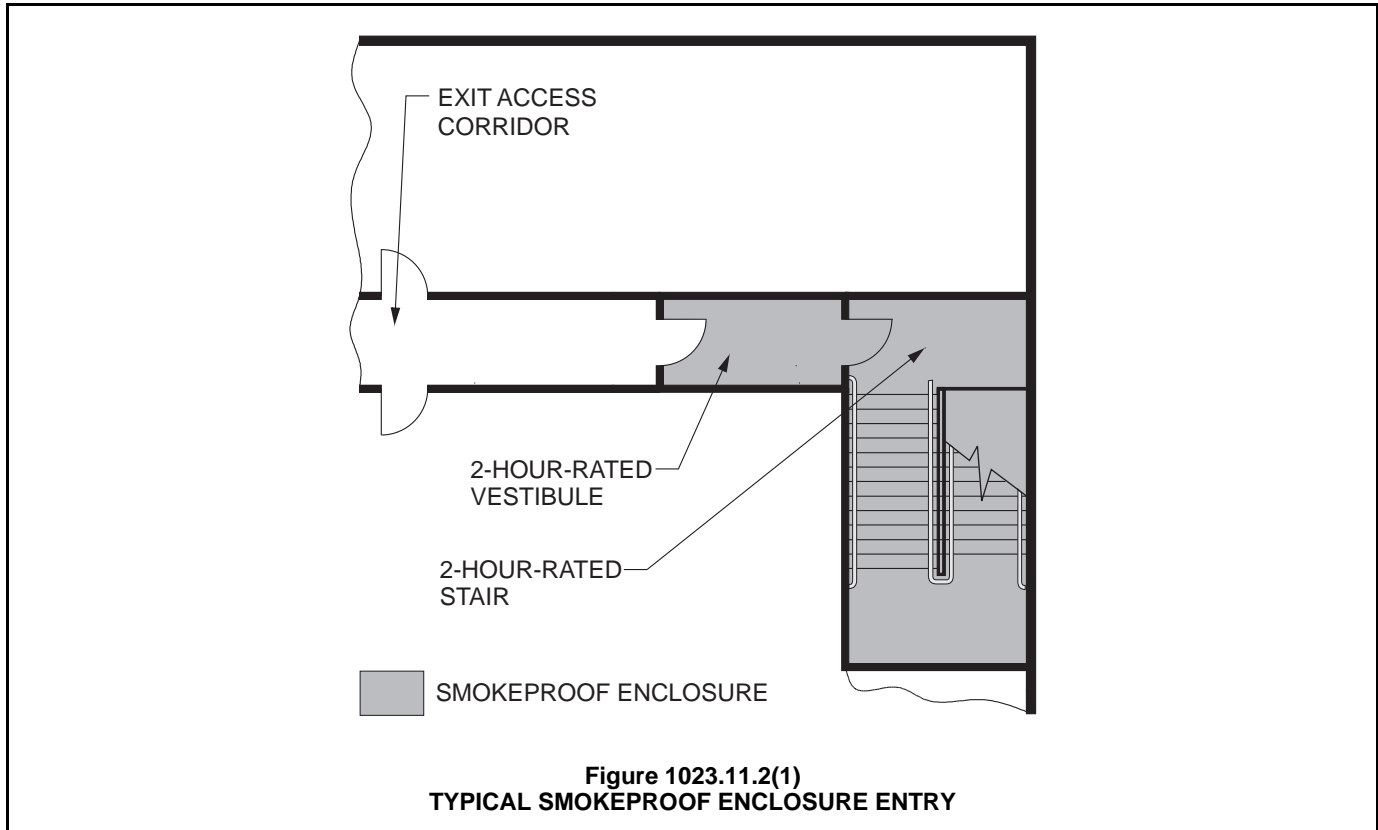

❖ The walls forming the smokeproof enclosure, which includes the stairway shaft and the vestibules, must be fire barriers having a fire-resistance rating of at least 2 hours. This level of fire endurance is specified because exit stairways in high-rise buildings serve as principal components of the egress system and as the source of fire service access to the fire floor. This supersedes any allowed reduction of enclosure rating, even if the stair from the level that is more than 30 feet (9144 mm) below exit discharge connects three stories or less. A pressurized stairway is a special case of a smokeproof enclosure; therefore, the requirements would be the same.

The first exception applies to openings in the exit passageway that are permitted, provided the exit passageway is protected and pressurized. If the exit stairway enclosure is connected to an exit passageway, Exception 2 allows the elimination of a door between, since this would interfere with the pressurization of the stairway and passageway as a combined exit system. In accordance with Exception 3, 50 percent of the stairways in smokeproof enclosures or pressurized stairways can use the exit discharge exceptions in Section 1028 to egress through a lobby or vestibule.

**1023.11.2 Enclosure access.** Access to the *stairway* or *ramp* within a *smokeproof enclosure* shall be by way of a vestibule or an open exterior balcony.

**Exception:** Access is not required by way of a vestibule or exterior balcony for *stairways* and *ramps* using the pressurization alternative complying with Section 909.20.5.

❖ See Commentary Figures 1023.11.2(1) and 1023.11.2(2) for illustrations of access to the smokeproof stairway or ramp by way of a vestibule or an exterior balcony. The purpose of this requirement is to keep the enclosure clear of smoke. Where a pressurized stairway is used, these elements are not necessary.

## SECTION 1024 EXIT PASSAGEWAYS

**1024.1 Exit passageways.** *Exit passageways* serving as an exit component in a *means of egress* system shall comply with the requirements of this section. An *exit passageway* shall not be used for any purpose other than as a *means of egress* and a *circulation path*.

❖ This section provides acceptable methods of continuing the protected path of travel for building occupants. The building designer or owner is given different options for achieving this protected path of travel. See Commentary Figure 1024.1 for an illustration of an exit passageway arrangement. In the case of office buildings or similar structures, the exit stairways are often located at the central core or in line with the centrally located exit access corridors. Exit passageways may be used to connect the exit stair to the exterior exit door or to connect enclosures for exit stairways that are not vertically continuous. Such an arrangement provides great flexibility in the design use of the building. Without an exit passageway at the grade floor or the level of exit discharge, the occupants of the upper floors or basement levels would have to leave the safety of the exit stairway to travel to the exterior doors. Such a reduction of protection is not acceptable (see Section 1028 for exit discharge alternatives).

Exit passageways may also be used on their own in locations not connected with an enclosure for an exit stairway. The exit passageway is often used as a protected horizontal exit path, such as in a mall or unlimited area building. Sometimes on large floor plans, an exit passageway may be used to extend an exit into areas that would not otherwise be able to meet the travel distance requirements. Like exit stairways, there is no travel distance limitation within an exit passageway.

**1024.2 Width.** The required capacity of *exit passageways* shall be determined as specified in Section 1005.1 but the minimum width shall be not less than 44 inches (1118 mm), except that *exit passageways* serving an occupant load of less than 50 shall be not less than 36 inches (914 mm) in width. The minimum width or required capacity of *exit passageways* shall be unobstructed.

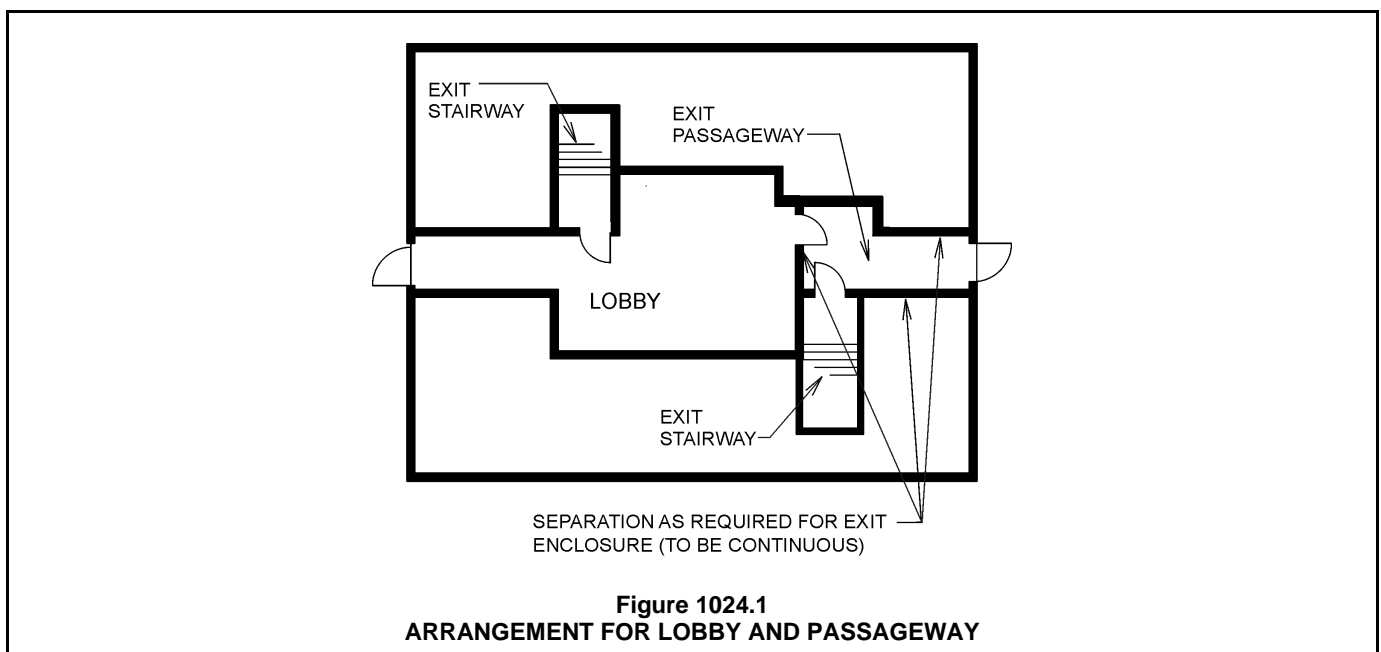

**Exception:** Encroachments complying with Section 1005.7.

❖ The width of an exit passageway is to be determined in accordance with Section 1005.1, based on the number of occupants served in the same manner as for corridors. The greater of the minimum required width or the width determined based on occupancy is to be used. In situations where the exit passageway also serves as an exit access corridor for the first floor, the corridor width must comply with the stricter requirement.

A cross reference back to Section 1005.7 from the exceptions for encroachments in the required width in aisles (see Section 1011.1), corridors (see Section 1020.3), exit passageways (see Section 1024.2) and exit courts (see Section 1028.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

**1024.3 Construction.** *Exit passageway* enclosures shall have walls, floors and ceilings of not less than a 1-hour *fire-resistance rating*, and not less than that required for any connecting *interior exit stairway* or *ramp*. *Exit passageways* shall be constructed as *fire barriers* in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both.

❖ The entire exit passageway enclosure is to be fire-resistance rated as specified. The floors and ceilings are required to be rated in addition to the walls. When used separately, a minimum 1-hour fire-resistance

rating is required. Where extending an enclosure for an exit stairway, the rating must not be less than the enclosure for the exit stairway so that the degree of protection is kept at the same level. Remember that if the exit passageway extends over a lower level, such as a basement, all supporting construction is to have the same fire-resistance rating as the elements supported in accordance with the continuity requirements for fire barriers and horizontal assemblies (see IBC Sections 707.5 and 711.2.3). The continuity requirements would also be a concern for the rated ceiling of the exit passageway. An alternative for the ceiling of the exit passageway could be a top-of-shaft enclosure (see IBC Section 713.12).

**1024.4 Termination.** *Exit passageways on the level of exit discharge shall terminate at an exit discharge. Exit passageways on other levels shall terminate at an exit.*

❖ This is consistent with the exit continuity and enclosure requirements in Section 1023.3. Section 1023.3 has an exception that allows for combinations of interior exit stairways and ramps with the exit passageway. The intent of this section is to provide safety in all portions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway in combination with an exit passageway. This would include, but not be limited to, the fire-resistance rating of the enclosure walls for the exit stairways and the opening protection rating of the doors. When an exit passageway is supported by the structure, the supporting construction must be fire-resistance rated equal to the walls and floors of the passageway being supported.

Section 1028.1, Exceptions 1 and 2, allow for an alternative for direct access to the outside via an intervening lobby or vestibule.

Horizontal exits, while not providing direct access to the outside of the structure, do move occupants to another “building” by moving through a fire wall (see Sections 1026 and 1028.1, Exception 3) into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

An exit passageway may be used to move between vertical enclosures for exit stairways. This may occur when a building is shaped like a wedding cake, so the stairway towers move outward as the building gets larger toward grade level. If this situation happens, it is very important to let occupants know how to proceed. See Section 1013.1 for exit signage requirements for within the exit passageways.

**1024.5 Openings.** *Exit passageway opening protectives shall be in accordance with the requirements of Section 716.*

Except as permitted in Section 402.8.7, openings in *exit passageways* other than unprotected exterior openings shall be limited to those necessary for *exit access* to the *exit passageway* from normally occupied spaces and for egress from the *exit passageway*.

Where an *interior exit stairway* or *ramp* is extended to an *exit discharge* or a *public way* by an *exit passageway*, the *exit passageway* shall comply with Section 1023.3.1.

Elevators shall not open into an *exit passageway*.

❖ In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will be self-latching. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80. Automatic-closing doors that protect openings into exits are also required to close on the actuation of smoke detectors or loss of power to the smoke detectors (see Section 716.5.9.3).

The requirements for exit passageways are very similar to those required for enclosures for interior exit stairways (see Section 1023.4). The only openings that are permitted in fire-resistance-rated exit passageways are doors that lead from normally occupied spaces, from the enclosure for the exit stairway and to the outside. This restriction on openings essentially prohibits the use of windows in an exit passageway except for those exterior windows that are not exposed to any hazards. This requirement is not intended to prohibit windows or other openings in the exterior walls of the exit enclosure. The verbiage “unprotected exterior openings” includes windows or doors not required to be protected by either IBC Section 705.8 or Section 1023.7 of the code. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E119 and UL 263. The objective of this provision is to minimize the possibility of fire spreading into an exit passageway and endangering the occupants or even preventing the use of the exit at a time when it is most needed. The limitation on openings applies regardless of the fire protection rating of the opening protective. The limitation on openings from normally occupied areas is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, that has an opening into the exit passageway, thereby resulting in smoke spreading into the exit passageway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. Note that exit passageways prohibit elevators from opening directly into the passageway. There are some exceptions for these unoccupied spaces in exit passageways in covered malls (see IBC Section 402.4.6).

The third paragraph addresses when the vertical enclosure for an exit stairway or ramp transitions to

the exit passageway. While the exit passageway is an extension of the protection offered by the vertical exit, there must still be a door (i.e., opening protective) between the bottom of the stairway or ramp enclosure and the exit passageway. This is to prevent any smoke that may migrate into the exit passageway from also moving up the exit stairway or ramp. This door is not required if the exit stairway and exit passageway are protected by pressurization (see Section 1023.10.1).

Elevators may not open into exit passageways. The difficulty is to have elevator doors that can meet the opening protectives for a fire barrier, but still operate effectively. For additional information on elevator lobbies and doors, see the commentary to IBC Sections 713.14 and 1020.6.

These opening limitations are very similar to those required for an exit enclosure (see Section 1023.3).

**1024.6 Penetrations.** Penetrations into or through an *exit passageway* are prohibited except for equipment and ductwork necessary for independent pressurization, sprinkler piping, standpipes, electrical raceway for fire department communication and electrical raceway serving the *exit passageway* and terminating at a steel box not exceeding 16 square inches (0.010 m<sup>2</sup>). Such penetrations shall be protected in accordance with Section 714. There shall not be penetrations or communicating openings, whether protected or not, between adjacent *exit passageways*.

**Exception:** Membrane penetrations shall be permitted on the outside of the *exit passageway*. Such penetrations shall be protected in accordance with Section 714.3.2.

❖ This section specifically lists the items that are allowed to penetrate an exit passageway. This is consistent for all types of exit enclosures, including enclosures for exit stairways or ramps (see Section 1023.5) and exit passageways. In general, only portions of the building service systems that serve the exit passageways are allowed to penetrate the exit passageway. IBC Section 714 addresses through penetrations and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. If the ductwork serving the exit passageway penetrates a rated wall or floor/ceiling assembly, a fire and smoke damper is required by IBC Section 717.5.3. This requirement is not intended to prohibit windows in the exterior walls of exit passageways that are not required to be rated.

The exception allows for electrical boxes or fire alarm pull stations to be installed on the outside of the enclosure, provided that the boxes are installed so that the required fire-resistance rating is not reduced (see IBC Section 714.3.2).

**1024.7 Ventilation.** Equipment and ductwork for *exit passageway* ventilation as permitted by Section 1024.6 shall comply with one of the following:

1. The equipment and ductwork shall be located exterior to the building and shall be directly connected to the

*exit passageway* by ductwork enclosed in construction as required for shafts.

2. Where the equipment and ductwork is located within the *exit passageway*, the intake air shall be taken directly from the outdoors and the exhaust air shall be discharged directly to the outdoors, or the air shall be conveyed through ducts enclosed in construction as required for shafts.
3. Where located within the building, the equipment and ductwork shall be separated from the remainder of the building, including other mechanical equipment, with construction as required for shafts.

In each case, openings into the fire-resistance-rated construction shall be limited to those needed for maintenance and operation and shall be protected by opening protectives in accordance with Section 716 for shaft enclosures.

*Exit passageway* ventilation systems shall be independent of other building ventilation systems.

❖ As a continuation of an exit stairway enclosure, an exit passageway has the same considerations for protection. While an exit passageway may look like a regular hallway, it is important that it be maintained as free of smoke as the exit stairway. See the commentary to Section 1023.6.

## SECTION 1025 LUMINOUS EGRESS PATH MARKINGS

**1025.1 General.** *Approved* luminous egress path markings delineating the exit path shall be provided in *high-rise buildings* of Group A, B, E, I, M, and R-1 occupancies in accordance with Sections 1025.1 through 1025.5.

**Exception:** Luminous egress path markings shall not be required on the *level of exit discharge* in lobbies that serve as part of the exit path in accordance with Section 1028.1, Exception 1.

❖ Improved safety for individuals negotiating stairs during egress of a high-rise building is provided by improving the visibility of stair treads and handrails under emergency conditions. A second source of emergency power for exit illumination, exit signs and stair shaft pressurization systems in smokeproof enclosures is currently mandated for high-rise buildings. In the event of an emergency that disconnects utility power, the emergency power source should engage, causing the stair shaft to be illuminated and kept smoke free by the pressurization system. Unfortunately, such systems can fail under demand conditions. The provisions of Section 1025 add an additional level of safety to the egress path by requiring the installation of photoluminescent or self-illuminating marking systems that do not require electrical power and its associated wiring and circuits. An additional means for ensuring that occupants can safely egress a building via exit stairways is now available even if the emergency power supply and system fails to operate. The groups indicated have a high anti-

pated occupant load or occupants may not be as familiar with the space. Note that the provisions only require these markings within the enclosure for the exit stairway, exit ramp and the exit passageway used for enclosure continuation. The markings are not required before reaching the exit (i.e., exit access) or after leaving the exit (i.e., exit discharge).

The exception indicates that if the exit stairway enclosure discharges through the lobby (see Section 1028.1, Exception 1), the egress markings would not be required outside the stairway enclosure for the portion from the stairway enclosure to the door leading to the outside. If the exit stairway discharges through an exit passageway, the exit path markings must continue to the door leading to the outside. The current text is silent for the options of vestibules and horizontal exits, but since Sections 1025.1 through 1025.5 only address within the enclosure for the exit, and not the exit discharge, exit path markings in the vestibule or after the horizontal exit are not required.

**1025.2 Markings within exit components.** Egress path markings shall be provided in *interior exit stairways*, *interior exit ramps* and *exit passageways*, in accordance with Sections 1025.2.1 through 1025.2.6.

❖ Luminous egress path markings are required inside the enclosure for exit stairways or ramps for all floors. If the stairway connects to an exit passageway as part of the travel down to the level of exit discharge or on the level of exit discharge, the path markings must also be continued in the exit passageway.

The subsections include marking the tread nosings, the surrounding edges of landings and any exit passageways, handrails and any protruding objects within the protected enclosure.

All exit path markings are required to be solid and continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent along the entire exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

**1025.2.1 Steps.** A solid and continuous stripe shall be applied to the horizontal leading edge of each step and shall extend for the full length of the step. Outlining stripes shall have a minimum horizontal width of 1 inch (25 mm) and a maximum width of 2 inches (51 mm). The leading edge of the stripe shall be placed not more than 1/2 inch (12.7 mm) from the leading edge of the step and the stripe shall not overlap

the leading edge of the step by not more than 1/2 inch (12.7 mm) down the vertical face of the step.

**Exception:** The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

❖ Luminous stripes are required the full width of the stairway on all tread nosings and along the leading edge of stair landings. These demarcation lines serve to identify the transition from the stair steps to the landing, which is important to minimize the risk of a fall inside of a stairway enclosure that is not illuminated. In order to clearly identify the leading edge of the step, the front edge of the stripe must be within 1/2 inch (13 mm) plus or minus of the leading edge of the tread (see Commentary Figure 1025.2.1).

The code does not specify any minimum slip-resistance requirements for luminous products installed on walking surfaces. However, Section 1003.4 requires all walking surfaces for means of egress to be slip resistant. Persons with vision impairments often rely on high-contrast elements to delineate changes in elevation such as that required in Sections 1011.5.4 and 1029.13.2.2. In medium light conditions, the luminous materials may be hard to discern. Luminous materials installed adjacent to dark contrasting materials may help with both situations.

For SI: 1 inch = 25.4 mm.

**Figure 1025.2.1  
LEADING EDGE OF STEP AND LANDING**

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

**1025.2.2 Landings.** The leading edge of landings shall be marked with a stripe consistent with the dimensional requirements for steps.

- ❖ The edge of the landing at the top of the steps must be marked in the same manner as the tread nosing so that a person can tell where the steps start. See the commentary to Section 1025.2.1 and Commentary Figure 1025.2.1.

**1025.2.3 Handrails.** *Handrails* and handrail extensions shall be marked with a solid and continuous stripe having a minimum width of 1 inch (25 mm). The stripe shall be placed on the top surface of the *handrail* for the entire length of the *handrail*, including extensions and newel post caps. Where *handrails* or handrail extensions bend or turn corners, the stripe shall not have a gap of more than 4 inches (102 mm).

**Exception:** The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

- ❖ The handrail must have a glow-in-the-dark stripe down the entire length. The 1-inch (25 mm) minimum width stripe must be on the top of the handrail so it can charge and maximize its visibility in the dark. Bends or turns may result in a break in the marking, which must not be more than 4 inches (102 mm) maximum (see Commentary Figure 1025.2.3).

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

**Figure 1025.2.3  
HANDRAIL MARKINGS**

**1025.2.4 Perimeter demarcation lines.** Stair landings and other floor areas within *interior exit stairways*, *interior exit ramps* and *exit passageways*, with the exception of the sides of steps, shall be provided with solid and continuous demar-

cation lines on the floor or on the walls or a combination of both. The stripes shall be 1 to 2 inches (25 mm to 51 mm) wide with interruptions not exceeding 4 inches (102 mm).

**Exception:** The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

- ❖ In addition to the leading edge of the landing, the landing must have a luminous stripe all the way around the edge. If the enclosure includes any type of exit passageway, that corridor must also have a perimeter stripe. The stripe can be on the floor or on the wall at baseboard height (see Sections 1025.2.4.1 and 1025.2.4.2).

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

**1025.2.4.1 Floor-mounted demarcation lines.** Perimeter demarcation lines shall be placed within 4 inches (102 mm) of the wall and shall extend to within 2 inches (51 mm) of the markings on the leading edge of landings. The demarcation lines shall continue across the floor in front of all doors.

**Exception:** Demarcation lines shall not extend in front of *exit discharge* doors that lead out of an *exit* and through which occupants must travel to complete the exit path.

- ❖ Luminous stripes shall extend all the way around any stair landings. This section specifies the option of stripes on the floor (see Commentary Figure 1025.2.4.1). On a typical landing, the stripe will extend across the front of the door, indicating to someone moving down the stairway that they should continue (see Commentary Figure 1025.2.4.3). At the level of exit discharge the occupant has a different visual cue. The line should not extend in front of the door leading to the exterior (see Commentary Figure 1025.2.6). This should allow people to understand which door they need to move through to get to safety.

**1025.2.4.2 Wall-mounted demarcation lines.** Perimeter demarcation lines shall be placed on the wall with the bottom edge of the stripe not more than 4 inches (102 mm) above the finished floor. At the top or bottom of the *stairs*, demarcation lines shall drop vertically to the floor within 2 inches (51 mm) of the step or landing edge. Demarcation lines on walls shall transition vertically to the floor and then extend across the floor where a line on the floor is the only practical method of outlining the path. Where the wall line is broken by a door, demarcation lines on walls shall continue across the face of the door or transition to the floor and extend across the floor in front of such door.

**Exception:** Demarcation lines shall not extend in front of *exit discharge* doors that lead out of an *exit* and through which occupants must travel to complete the exit path.

- ❖ Luminous stripes that surround the stairway landings can be on the floor or on the wall. This section specifies the option of stripes on the wall (see Commen-

**MEANS OF EGRESS**

tary Figure 1025.2.4.2). See the commentary to Sections 1025.2.4 and 1025.2.4.1.

**1025.2.4.3 Transition.** Where a wall-mounted demarcation line transitions to a floor-mounted demarcation line, or vice versa, the wall-mounted demarcation line shall drop vertically to the floor to meet a complimentary extension of the floor-mounted demarcation line, thus forming a continuous marking.

❖ While the luminous perimeter stripes on a landing can be on either the wall or the floor, when they transition from one to another, the lines should appear continuous. See Section 1025.2.4.2 for special requirements for when the wall perimeter marking transitions to the floor stripe indicating the leading edge of the landing.

When perimeter lines cross a door frame, the lines can transition or stay on the same plain (see Commentary Figure 1025.2.4.3).

**1025.2.5 Obstacles.** Obstacles at or below 6 feet 6 inches (1981 mm) in height and projecting more than 4 inches (102 mm) into the egress path shall be outlined with markings not less than 1 inch (25 mm) in width comprised of a pattern of alternating equal bands, of luminous material and black, with the alternating bands not more than 2 inches (51 mm) thick and angled at 45 degrees (0.79 rad). Obstacles shall include, but are not limited to, standpipes, hose cabinets, wall projections and restricted height areas. However, such markings shall not conceal any required information or indicators including but not limited to instructions to occupants for the use of standpipes.

❖ Any obstacles within the stairway must be marked with a dashed line of diagonal slashes (see Commentary Figure 1025.2.5). The markings of obstacles are

consistent with the intent of protruding object provisions in Section 1003.3. However, there is a difference in the height of 6 feet, 6 inches (1981 mm) instead of 6 feet, 8 inches (2032 mm). Items permit-

FLOOR-MOUNTED OPTION**

**Figure 1025.2.4.3  
PERIMETER DEMARCATION LINES—  
OPTIONS AT DOORS INTO EXIT ENCLOSURES**

ted within the enclosures for exit stairways are limited by Sections 1023.2 and 1023.5.

**1025.2.6 Doors within the exit path.** Doors through which occupants must pass in order to complete the exit path shall be provided with markings complying with Sections 1025.2.6.1 through 1025.2.6.3.

- ❖ Doors within an enclosure for an exit stairway can:
  - Lead directly to the exterior.
  - Pass through a horizontal exit (Section 1028.1, Exception 3).
  - Lead to an exit passageway on the level of exit discharge, to a lobby or vestibule at the level of exit discharge (Section 1028.1, Exceptions 2 and 3).
  - Lead to an exit passageway on a transition level.

Doors at these locations should be marked as indicated in the following three subsections. Combined with the landing markings not extending across the bottom of this door, this will provide several visual cues to indicate that this is the door to continue through to get out of the building (see Commentary Figure 1025.2.6).

The NIST egress study of the World Trade Center indicated that transition floors can cause delays in egress because people hesitate when it is unclear about which way they should continue. Effectively marking these doors in four different ways will decrease that hazard. Which doors to mark is consistent with the exit sign requirements within exit enclosures in Section 1013.1.

**1025.2.6.1 Emergency exit symbol.** The doors shall be identified by a low-location luminous emergency exit symbol complying with NFPA 170. The exit symbol shall be not less than 4 inches (102 mm) in height and shall be mounted on the door, centered horizontally, with the top of the symbol not higher than 18 inches (457 mm) above the finished floor.

- ❖ The door shall include a low luminous level exit symbol within 18 inches (457 mm) of the floor. For an example of the emergency exit symbol, see Commentary Figure 1025.2.6.1. The sign on the door can be just this symbol or it can also contain additional information such as a directional arrow or "EXIT."

**1025.2.6.2 Door hardware markings.** Door hardware shall be marked with not less than 16 square inches (406 mm<sup>2</sup>) of luminous material. This marking shall be located behind, immediately adjacent to, or on the door handle or escutcheon. Where a panic bar is installed, such material shall not be less than 1 inch (25 mm) wide for the entire length of the actuating bar or touchpad.

❖ Door hardware locations must be clearly visible. If a panic bar is used, a luminous stripe with a minimum width of 1 inch (25 mm) should be provided down the entire length of the activation bar/paddle [see Commentary Figure 1025.2.6, Example 1]. If lever hardware is used, a donut, square or rectangle with a minimum area of 16 square inches (10 322 mm<sup>2</sup>) should be provided behind the hardware [see Commentary Figure 1025.2.6, Example 2]. There is also the option of marking the door handle itself, but it would be difficult to get 16 square inches (10 322 mm<sup>2</sup>) of visible surface area. Plus, over time, a finish on the hardware has a greater chance of wearing off with normal use. The language allows the designer the freedom to decide (with wear and hardware options) which configuration would give the best results.

**1025.2.6.3 Door frame markings.** The top and sides of the door frame shall be marked with a solid and continuous 1-inch- to 2-inch-wide (25 mm to 51 mm) stripe. Where the door molding does not provide sufficient flat surface on which to locate the stripe, the stripe shall be permitted to be located on the wall surrounding the frame.

❖ Doors must be marked along the sides and top with stripes similar to those provided on the stair nosing. Door frames come in a variety of shapes. If there is not space on the door for the marking stripe, the stripe can be around the perimeter of the door [see Commentary Figure 1025.2.6, Examples 1 and 2].

**1025.3 Uniformity.** Placement and dimensions of markings shall be consistent and uniform throughout the same enclosure.

❖ All exit path markings are required to be solid and have continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent for the path of travel along the exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

**1025.4 Self-luminous and photoluminescent.** Luminous egress path markings shall be permitted to be made of any material, including paint, provided that an electrical charge is not required to maintain the required luminance. Such materials shall include, but not be limited to, *self-luminous* materials and *photoluminescent* materials. Materials shall comply with either of the following standards:

1. UL 1994.
2. ASTM E2072, except that the charging source shall be 1 footcandle (11 lux) of fluorescent illumination for 60 minutes, and the minimum luminance shall be 30 milicandelas per square meter at 10 minutes and 5 milicandelas per square meter after 90 minutes.

❖ Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see IBC Section 411.7 and Section 1025 of the code) or exit signs (see Section 1013.5) may be photoluminescent or self-luminous (see definitions in Chapter 2). An example of photoluminescent material is paint or tape that is charged by exposure to light. When the lights are turned off, the product will “glow” in the dark. Self-luminous products do not need an outside light source to charge them like photoluminescent materials do.

A variety of materials can comply with the referenced standards for egress path markings (UL 1994, and ASTM E2072) and for signs (UL 924).

ASTM E2072 allows the use of paints and coatings, which can be useful because it avoids a potential tripping hazard, especially in locations where the surface substrate may not be even. The luminescence of the selected marking system must provide an illumination of 1 footcandle (11 lux) for 60 minutes, which is consistent with the requirement in Section 1008.2 for the illumination of walking surfaces. Section 1008.3 requires the emergency lighting system to have power for 90 minutes; however, because of normal battery considerations, the IFC only requires a 60-minute duration in existing buildings.

**1025.5 Illumination.** Where *photoluminescent* exit path markings are installed, they shall be provided with not less than 1 footcandle (11 lux) of illumination for not less than 60 minutes prior to periods when the building is occupied and continuously during occupancy.

❖ Analogous to rechargeable batteries, many photoluminescent egress path markings require exposure to light to perform properly. Thus, photoluminescent egress path markings must be exposed to a minimum 1 footcandle (11 lux) of light energy at the walking surface for at least 60 minutes prior to the building being occupied. The charging rate for photoluminescent egress path markings is based on the wattage of lamps used to provide egress path illumination. Therefore it is important to verify that the specified lamps have sufficient wattage to meet the specified time period. This requirement may be a concern for buildings developed with the IECC or trying for LEED certification.

Note that this requirement does not apply to self-luminous materials since these materials operate independently of the external power source. See the definitions for “Photoluminescent” and “Self-luminous” in Chapter 2.

**SECTION 1026  
HORIZONTAL EXITS**

**1026.1 Horizontal exits.** *Horizontal exits* serving as an *exit* in a *means of egress* system shall comply with the requirements of this section. A *horizontal exit* shall not serve as the only *exit* from a portion of a building, and where two or more *exits* are required, not more than one-half of the total number of *exits* or total *exit* minimum width or required capacity shall be *horizontal exits*.

**Exceptions:**

1. *Horizontal exits* are permitted to comprise two-thirds of the required *exits* from any building or floor area for occupancies in Group I-2.
2. *Horizontal exits* are permitted to comprise 100 percent of the *exits* required for occupancies in Group I-3. Not less than 6 square feet (0.6 m<sup>2</sup>) of accessible space per occupant shall be provided on each side of the *horizontal exit* for the total number of people in adjoining compartments.

❖ Horizontal exits can provide up to 50 percent of the exits from a given area of a building. The percentage is higher for Group I-2 and I-3 occupancies where the evacuation strategy is defend in place rather than direct egress (see Commentary Figure 1026.1 for a typical horizontal exit arrangement). However, a horizontal exit cannot serve as the only exit from a single exit space. Section 1026.4 allows for some areas to have all the exits from a space to be horizontal exits under specific conditions. A horizontal exit can be designed for either one-way or two-way operation, depending on the exiting needs of each side of the wall providing the horizontal exit.

A horizontal exit may be an element of a means of egress when in compliance with the requirements of this section. The actual horizontal exit is the protected door opening in a wall, or the open-air balcony or bridge that separates two areas of a building. A horizontal exit is often used in hospitals and in prisons where it is not feasible or desirable that all occupants exit the facility (see Chapter 2 for the definition of a “Horizontal exit”).

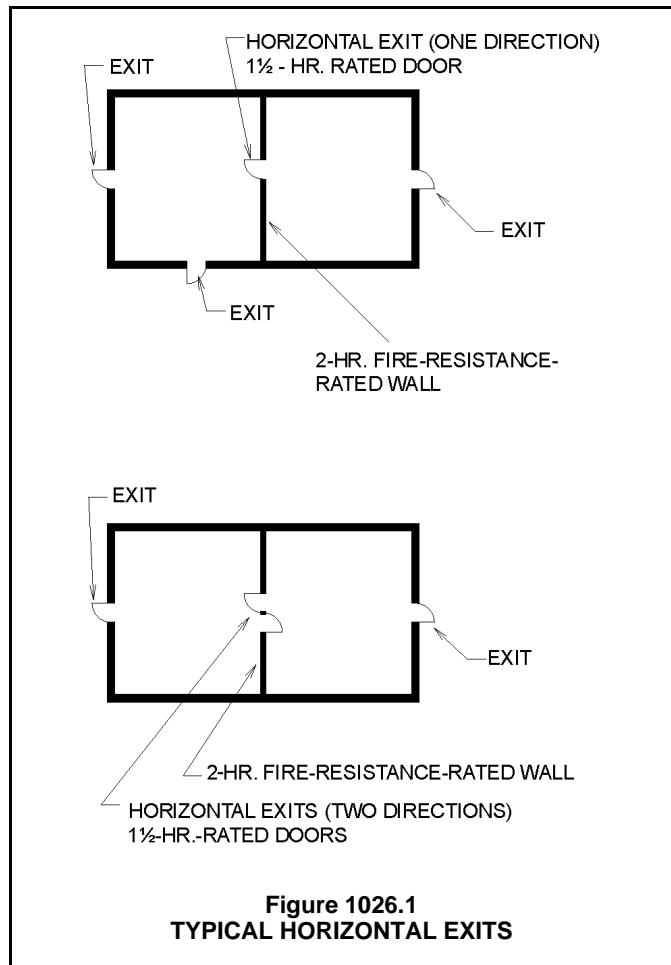

Horizontal exits and their associated “refuge areas” are considered to provide the same or higher level of protection as an “area of refuge” for people who cannot use the egress system. Sections 1009.3 and 1009.4 allow for a horizontal exit or an area of refuge as alternatives. See these sections for exceptions for buildings with sprinkler systems and/or where the path of travel has protection from the accumulation of smoke (i.e., open parking garages, open air assembly seating, smoke-protected assembly seating).

**1026.2 Separation.** The separation between buildings or refuge areas connected by a *horizontal exit* shall be provided by a *fire wall* complying with Section 706; or by a *fire barrier* complying with Section 707 or a *horizontal assembly* complying with Section 711, or both. The minimum *fire-resistance rating* of the separation shall be 2 hours. Opening protectives in *horizontal exits* shall also comply with Section 716. Duct and air transfer openings in a *fire wall* or *fire barrier* that serves as a *horizontal exit* shall also comply with Section 717. The *horizontal exit* separation shall extend vertically through all levels of the building unless floor assemblies have a *fire-resistance rating* of not less than 2 hours with no unprotected openings.

**Exception:** A *fire-resistance rating* is not required at *horizontal exits* between a building area and an above-grade *pedestrian walkway* constructed in accordance with Section 3104, provided that the distance between connected buildings is more than 20 feet (6096 mm).

*Horizontal exits* constructed as *fire barriers* shall be continuous from *exterior wall* to *exterior wall* so as to divide completely the floor served by the *horizontal exit*.

❖ The basic concept of a horizontal exit is that during a fire emergency, the occupants of a floor will transfer from one fire area to another. Separation between areas of a building can be accomplished by a fire wall

**Figure 1026.1  
TYPICAL HORIZONTAL EXITS**

(see IBC Section 706), a fire barrier (see IBC Section 707), horizontal assemblies (see IBC Section 711) or a combination thereof, with a fire-resistance rating not less than 2 hours. Any fire shutters or fire doors must have an opening protective of not less than 1½ hours (see IBC Table 716.5). Ducts and air transfer openings must comply with IBC Section 717.

In buildings of Groups I-2 and I-3, it may also be desirable (while not mandatory) for the horizontal exit to serve as a smoke barrier. In such cases, the wall containing the horizontal exit must also comply with the requirements for a smoke barrier (see IBC Section 709).

In order to decrease the amount of smoke able to migrate around the edges of a horizontal exit, the horizontal exit must extend from at least the floor to the deck above (i.e., fire barrier), as well as across the floor level from one side of the building to another. Moving up from floor to floor, there are two choices. One option is that the horizontal exit can extend vertically through all levels of the building (i.e., fire wall or fire barriers). The second option is to utilize fire barriers that are not aligned vertically (i.e., a combination of fire barriers and horizontal assemblies), but then the floor must have a 2-hour fire-resistance rating and no unprotected openings are permitted between any two refuge areas. The supporting construction would also have to be a minimum of 2 hours.

The exception is permitting a pedestrian walkway or sky bridge to act as a horizontal exit when buildings are at least 20 feet (6096 mm) apart.

**1026.3 Opening protectives.** *Fire doors in horizontal exits* shall be self-closing or automatic-closing when activated by a *smoke detector* in accordance with Section 716.5.9.3. Doors, where located in a cross-corridor condition, shall be automatic-closing by activation of a *smoke detector* installed in accordance with Section 716.5.9.3.

❖ For the safety of occupants using a horizontal exit, it is important for the doors to be fire doors that are self-closing or automatic-closing by activation of a smoke detector. Smoke detectors that initiate automatic-closing should be located at both sides of the doors (see the commentary to Section 907.3 for an additional explanation of the installation requirements). Any openings in the fire barriers or fire walls used as horizontal exits must be protected in coordination with the rating of the wall. There is a reference to IBC Section 716 for opening protectives.

**1026.4 Refuge area.** The refuge area of a *horizontal exit* shall be a space occupied by the same tenant or a public area and each such refuge area shall be adequate to accommodate the original *occupant load* of the refuge area plus the *occupant load* anticipated from the adjoining compartment. The anticipated *occupant load* from the adjoining compartment shall be based on the capacity of the *horizontal exit doors* entering the refuge area.

❖ The building area on the discharge side of a horizontal exit must serve as a refuge area for the occupants

of both sides of the floor areas connected by the horizontal exit. Therefore, adequate space must be available on each side of the wall to hold the full occupant load of that side, plus the number of occupants from the other side that may be required to use the horizontal exit. Explaining the anticipated occupant load is easiest with an example. If one side of the horizontal exit contained an assembly space with 750 occupants, three exits would be required. If one of the exits through the horizontal exit was a double door, that double exit door would have a capacity of 320 (64 inches/0.2 = 320 occupants). Therefore, the refuge area must be sized for the occupant load in the space, plus the 320 people who might come through the horizontal exit. This is a higher number than would be anticipated if the occupant load of the assembly space was divided equally between the three exits, but it is also not the entire occupant load of the assembly space.

**1026.4.1 Capacity.** The capacity of the refuge area shall be computed based on a *net floor area* allowance of 3 square feet (0.2787 m<sup>2</sup>) for each occupant to be accommodated therein.

**Exceptions:** The *net floor area* allowable per occupant shall be as follows for the indicated occupancies:

1. Six square feet (0.6 m<sup>2</sup>) per occupant for occupancies in Group I-3.
2. Fifteen square feet (1.4 m<sup>2</sup>) per occupant for ambulatory occupancies in Group I-2.
3. Thirty square feet (2.8 m<sup>2</sup>) per occupant for nonambulatory occupancies in Group I-2.

❖ These refuge areas are meant to hold the occupants temporarily in a safe place until they can evacuate the premises in an orderly manner or, in the case of hospitals and like facilities, to hold bedridden patients and other nonambulatory occupants in a protected area until the fire emergency has ended. This is commonly referred to as a defend-in-place strategy. The size of the refuge area is based on the nature of the expected occupants. In the case of Group I-3, the area will be used to hold the occupants until deliberate egress can be accomplished with staff assistance or supervision. In other cases, it is assumed that the occupants simply wait in line to egress through the required exit facilities provided on the discharge side. Although similar language is used in describing the “area of refuge” for an accessible means of egress, Section 1009.6 specifies area requirements that are insufficient for use as a “refuge area” for a horizontal exit. Care must be taken when applying both principles to the same horizontal exit.

The 3-square-foot (0.28 m<sup>2</sup>) per occupant requirement is based on the maximum permitted occupant density at which orderly movement to the exits is reasonable. The 30-square-foot (2.8 m<sup>2</sup>) per hospital or nursing home patient requirement is based on the space necessary for a bed or litter. It should be noted that 30 square feet (2.8 m<sup>2</sup>) is not based on the total

## MEANS OF EGRESS

occupant load, as would be determined in accordance with Section 1004.1, but rather on the number of nonambulatory patients. The 15-square-foot (1.4 m<sup>2</sup>) requirement for occupancies in Group I-2 facilities is based on each ambulatory patient having a staff attendant.

**1026.4.2 Number of exits.** The refuge area into which a *horizontal exit* leads shall be provided with *exits* adequate to meet the occupant requirements of this chapter, but not including the added *occupant load* imposed by persons entering the refuge area through *horizontal exits* from other areas. Not less than one refuge area exit shall lead directly to the exterior or to an *interior exit stairway* or *ramp*.

**Exception:** The adjoining compartment shall not be required to have a *stairway* or door leading directly outside, provided the refuge area into which a *horizontal exit* leads has *stairways* or doors leading directly outside and are so arranged that egress shall not require the occupants to return through the compartment from which egress originates.

❖ In a single-tenant facility, any of the spaces that are constantly available (i.e., not lockable) can be used as places of refuge. However, in spaces housing more than one tenant, public refuge areas, such as corridors or passageways, must be provided and be accessible at all times. This requirement is necessary because if a horizontal exit connected two areas occupied by different tenants, the tenants could (for privacy and security purposes) render the necessary free access through the horizontal exit ineffective. When the horizontal exit discharges into a public or common space, such as a corridor leading to an exit, each tenant can obtain the desired security.

Note that the capacity of exits (such as an exit stairway) from a refuge area into which a horizontal

exit leads is required to be sufficient for the design occupant load in the area, and does not include those who come into the space from other areas via the horizontal exit. This is because the adjacent refuge area is of sufficient safety to house occupants during a fire or until the egress system is available.

The door through the horizontal exit and the second exit must meet the separation requirements in Section 1007.1.1. Measurement of the travel distance stops at the doorway that serves as the horizontal exit. There are no requirements for travel distance from the horizontal exit to the exit (i.e., exterior exit doorway, exit stairway or exit ramp) on the other side; however, the areas on each side need to be evaluated for all means of egress requirements individually.

When there is one horizontal exit and two fire compartments, at least one exit from each side of the horizontal exit must go directly to the outside of an exit stairway or ramp enclosure (see Commentary Figure 1026.1). The exception allows for a central building/fire area with access to two horizontal exits and no direct exterior exit door or exit stairway/ramp enclosure as long as the piece on each side has access to exterior exits or exit stairways/ramps (see Commentary Figure 1026.4.2).

## SECTION 1027 EXTERIOR EXIT STAIRWAYS AND RAMPS

**1027.1 Exterior exit stairways and ramps.** *Exterior exit stairways* and *ramps* serving as an element of a required *means of egress* shall comply with this section.

❖ Stairways and ramps can be exit access, exit or exit discharge elements. Exterior exit access and exit dis-

charge stairways and ramps typically involve a change of elevation of less than a story. Exterior exit access stairways or ramps between stories must comply with Section 1019.3 and, where permitted as part of the required means of egress, are limited by Section 1006.3. Exit stairways and ramps traverse a full story or more. Interior exit stairways and ramps must be enclosed in accordance with Section 1023. This section addresses exterior stairways and ramps that function as exit elements.

Exterior exit stairways and ramps are an important element of the means of egress system and must be designed and constructed so that they will serve as a safe path of travel. The general requirements in Section 1011 also apply to exterior stairways (for ramp provisions, see Section 1012).

Outdoor stadiums and open parking garages are examples of buildings that may appear to have exterior exit stairways, but actually have open exit access stairways (Sections 1017, 1019 and 1029).

**1027.2 Use in a means of egress.** *Exterior exit stairways* shall not be used as an element of a required *means of egress* for Group I-2 occupancies. For occupancies in other than Group I-2, *exterior exit stairways* and *ramps* shall be permitted as an element of a required *means of egress* for buildings not exceeding six stories above *grade plane* or that are not *high-rise buildings*.

❖ This section specifies the conditions where exterior exit ramps or stairways can be used as required exits. Exterior exit stairways are not permitted for Group I-2 since quick evacuation of nonambulatory patients from buildings using exterior stairways is impractical. Some patients may not be capable of self-preservation and, therefore, may require assistance from staff. The period of evacuation of nonambulatory patients could become lengthy, especially in bad weather conditions.

Exterior stairways or ramps are not allowed to be required exits in buildings that exceed six stories in height because of the hazard of using such a stairway or ramp in poor weather. Some persons may not be willing to use such a stair due to vertigo. When confronted with a view from a great height, vertigo sufferers can become confused, disoriented and dizzy. They could injure themselves, become disoriented or refuse to move (freeze). In a fire situation, they could become an obstruction in the path of travel, possibly causing panic and injuries to other users of the exit.

**1027.3 Open side.** *Exterior exit stairways* and *ramps* serving as an element of a required *means of egress* shall be open on not less than one side, except for required structural columns, beams, *handrails* and *guards*. An open side shall have not less than 35 square feet (3.3 m<sup>2</sup>) of aggregate open area adjacent to each floor level and the level of each intermediate

landing. The required open area shall be located not less than 42 inches (1067 mm) above the adjacent floor or landing level.

❖ An important factor in exterior exit stairways or ramps is natural ventilation. Sufficient natural ventilation is necessary so that smoke will not be trapped above the stairway or ramp walking surfaces, thereby compromising safe egress.

The exterior exit stairway or ramp must have at least one of its sides directly facing an outer court, yard or public way. This will allow the products of combustion escaping from the interior of the building to quickly vent to the outdoor atmosphere and let the building occupants egress down the exterior exit stairway or ramp. Since exterior exit stairways or ramps are partially bounded by exterior walls, a minimum amount of exterior openness is specified by the code.

The openings on each and every floor level and landing must total 35 square feet (3.3 m<sup>2</sup>) or greater. The openings for which credit is given must occur higher than 42 inches (1067 mm) above each floor and intermediate landing level. [The bottom edge of the opening is consistent with the height requirements for guards (see Section 1015.3)]. With a standard 8-foot (2438 mm) ceiling height minus the 42-inch-high (1067 mm) guard and a typical 8-foot-wide (2438 mm) opening, the result would be 4½ feet x 8 feet = 36 square feet (3.34 m<sup>2</sup>). Openings of this height and area readily dissipate the smoke buildup from the exterior exit stairway or ramp (see Commentary Figure 1027.3).

**1027.4 Side yards.** The open areas adjoining *exterior exit stairways* or *ramps* shall be either *yards*, *courts* or *public ways*; the remaining sides are permitted to be enclosed by the *exterior walls* of the building.

❖ This section simply specifies the type of areas that the exterior opening of the exterior exit stairway or ramp is to adjoin. These open spaces will enable the smoke to dissipate from the exterior exit stairway or ramp so it will be usable as a required exit. See Section 1027.3 for a discussion of the opening requirements. See Sections 1027.4 and 1206 for the minimum sizes of yards and courts.

**1027.5 Location.** *Exterior exit stairways* and *ramps* shall have a minimum fire separation distance of 10 feet (3048 mm) measured at right angles from the exterior edge of the *stairway* or *ramps*, including landings, to:

1. Adjacent *lot lines*.
2. Other portions of the building.
3. Other buildings on the same lot unless the adjacent building *exterior walls* and openings are protected in accordance with Section 705 based on *fire separation distance*.

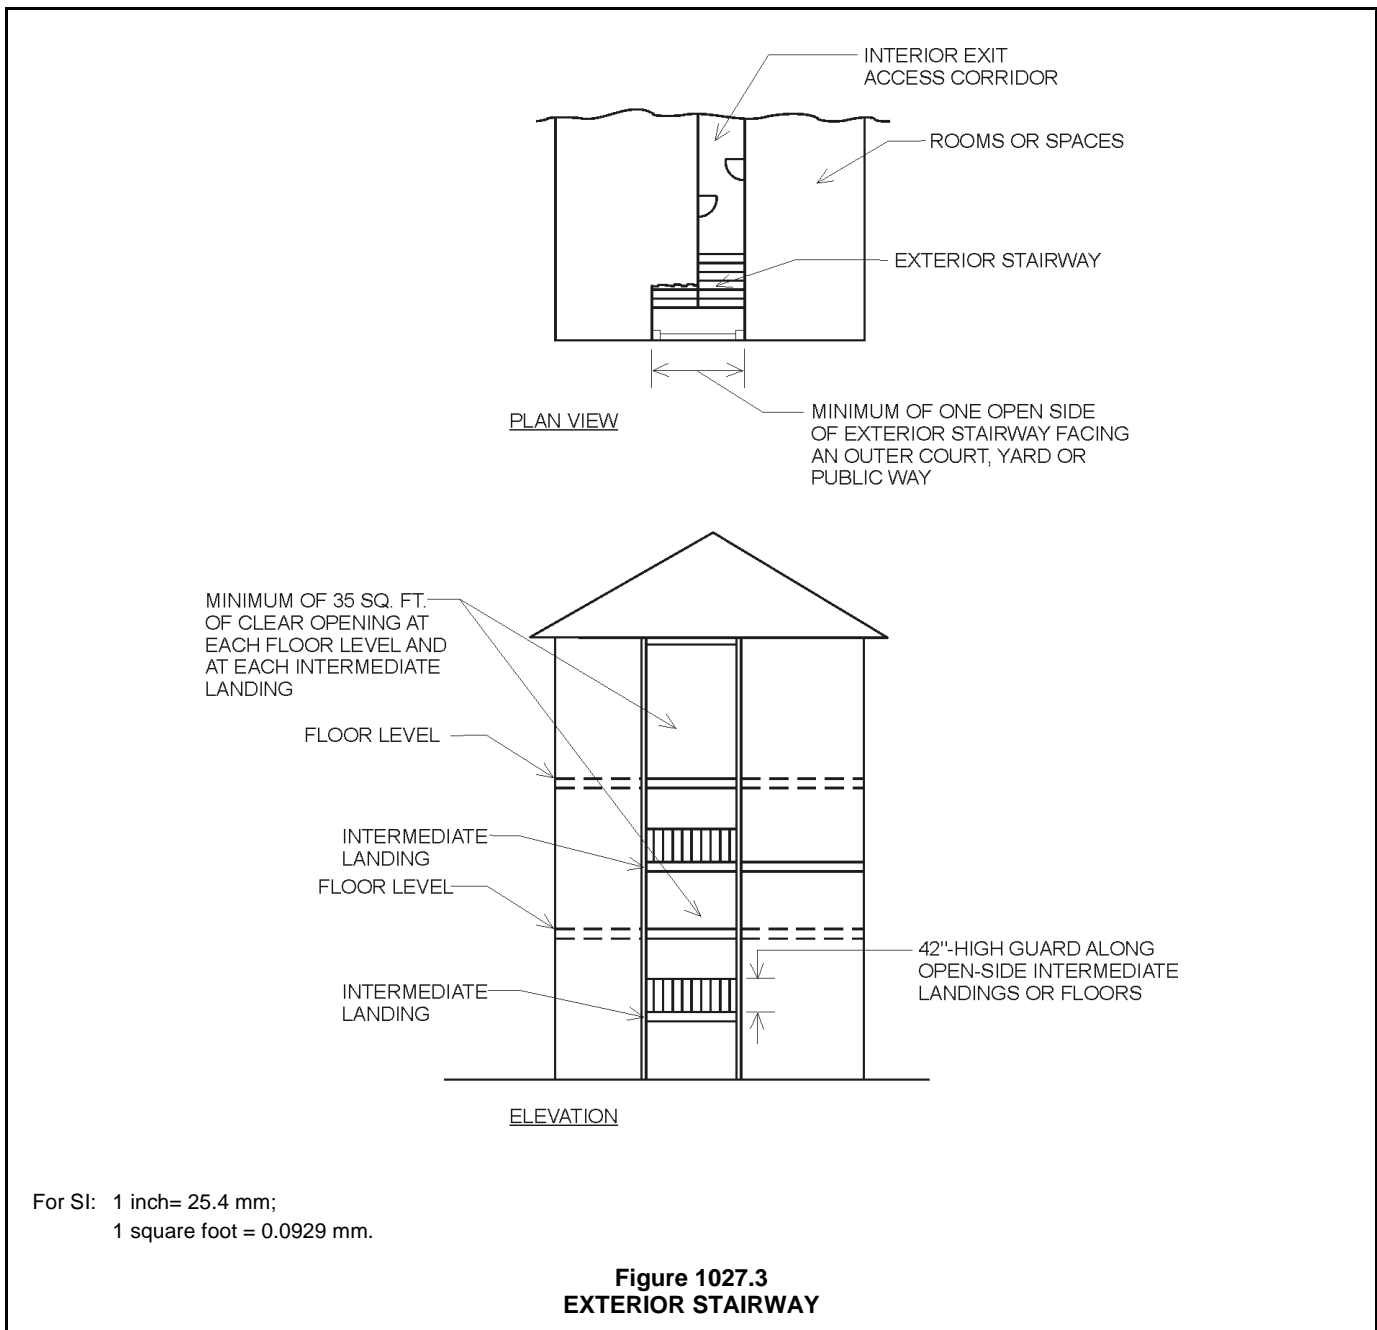

## MEANS OF EGRESS

For the purposes of this section, other portions of the building shall be treated as separate buildings.

- ❖ The location requirements of this section protect the users of the exterior exit stairway or ramp from the effects of a fire in another building on the same lot or an adjacent lot. The separation distance reduces the exposure to heat and smoke. If the exterior exit stairway or ramp is closer than specified, then adjacent buildings' exterior walls and openings are to be protected in accordance with IBC Section 705 so that the users of the exterior exit stairway or ramp are protected. The reason for a minimum required distance to a lot line is to provide for a future building that could be built on an adjacent lot. While buildings on

the same lot can be considered one building for height and area limitations (see IBC Section 503.1.2), they must be separated by a minimum of 10 feet (3048 mm) if there is a path for exit discharge between them. The purpose of the last sentence is to clarify that an exterior exit stairway or ramp needs a minimum 10-foot separation where a building wraps around on itself, such as a U-shaped building. It is not intended that the distance be measured to an imaginary lot line between buildings on the same lot.

Requirements are the same for exterior egress balconies (Section 1021.4). For an illustration of exterior egress balconies and exterior exit stairways working together, see Commentary Figure 1027.5.

**1027.6 Exterior exit stairway and ramp protection.** *Exterior exit stairways and ramps* shall be separated from the interior of the building as required in Section 1023.2. Openings shall be limited to those necessary for egress from normally occupied spaces. Where a vertical plane projecting from the edge of an *exterior exit stairway or ramp* and landings is exposed by other parts of the building at an angle of less than 180 degrees (3.14 rad), the exterior wall shall be rated in accordance with Section 1023.7.

**Exceptions:**

1. Separation from the interior of the building is not required for occupancies, other than those in Group R-1 or R-2, in buildings that are not more than two stories above *grade plane* where a *level of exit discharge* serving such occupancies is the first story above *grade plane*.
2. Separation from the interior of the building is not required where the *exterior exit stairway or ramp* is served by an *exterior exit ramp* or balcony that connects two remote *exterior exit stairways* or other *approved exits* with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be not less than 50 percent of the height of the enclosing wall, with the top of the openings not less than 7 feet (2134 mm) above the top of the balcony.
3. Separation from the open-ended *corridor* of the building is not required for *exterior exit stairways or ramps*, provided that Items 3.1 through 3.5 are met:
  - 3.1. The building, including open-ended *corridors*, and *stairways and ramps*, shall be equipped throughout with an *automatic*

*sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2.

- 3.2. The open-ended *corridors* comply with Section 1020.
- 3.3. The open-ended *corridors* are connected on each end to an *exterior exit stairway or ramp* complying with Section 1027.
- 3.4. The *exterior walls* and openings adjacent to the *exterior exit stairway or ramp* comply with Section 1023.7.
- 3.5. At any location in an open-ended *corridor* where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3.3 m<sup>2</sup>) or an *exterior stairway or ramp* shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

- ❖ Exterior exit stairways or ramps must be protected from interior fires that may project through windows or other openings adjacent to the exit stairway or ramp, possibly endangering the occupants using this means of egress to reach grade. The protection of an exterior exit stairway or ramp is to be obtained by separating the exterior exit from the interior of the building using exterior walls having a fire-resistance rating of at least 1 hour with opening protectives. Consistent with the protection required in Sections 1023.2 and 1023.7 for interior exit stairways, the fire-resistance rating must be provided for a distance of 10 feet (3048 mm) horizontally and vertically from the ramp or stairway

For SI: 1 foot = 304.8 mm.

**Figure 1027.5**  
**EXTERIOR BALCONY AND STAIRWAY ADJACENT TO LOT LINE**

**MEANS OF EGRESS**

edges, and from the ground to a level of 10 feet (3048 mm) above the highest landing.

All window and door openings falling inside the 10-foot (3048 mm) horizontal separation distance as well as all window and door openings 10 feet (3048 mm) above the topmost landing and below the stairway must be protected with minimum 3/4-hour fire protection-rated opening protectives [see Commentary Figure 1027.6(1)]. The last sentence is similar to Section 1023.7 except that instead of measuring the angle between the building exterior walls and the unprotected walls at the exterior of the stairway or ramp, the measurement is between the building exterior walls and a vertical projection for the planes of the guard of the exterior stairway and ramp including landings.

Openings within the width of the stairway must only

be from normally occupied spaces. This is consistent with the requirements for vertical exit enclosures (see Sections 1023.4 and 1023.5).

Exception 1 indicates that opening protectives are not required for occupancies (other than Groups R-1 and R-2) that are two stories or less above grade when the level of exit discharge is at the lower story. The reason for this exception is that in cases of fire in low buildings, the occupants are usually able to evacuate the premises before the fire can emerge through exterior wall openings and endanger the exit ramp or stairways. In hotels and apartments, however, the occupants' response to a fire emergency could be significantly reduced because they may be either unfamiliar with the surroundings or sleeping.

Exception 2 allows the opening protectives to be

omitted when an exterior exit access balcony is served by two exits and when the exits are remote from each other. Remoteness is regulated by Section 1007. This exception is applicable to all groups. In such instances, it is unlikely that the users of the exterior stairway or ramp will become trapped by fire, since they have the option of using the balcony to gain access to either of the two available exits, and the products of combustion will be vented directly to the outside (see Section 1021.1 regarding exterior balconies). At least one-half of the total perimeter of the exterior balcony must be permanently open to the outside. The requirement for at least one-half the height of that level to be open allows for columns, solid guards and architectural or decorative elements, such as arches. With the top of the opening at least 7 feet (2134 mm) above the walking surface, products of combustion can vent and allow occupant passage below the smoke layer [see Commentary Figure 1027.6(2)].

An open-ended corridor is not defined in Chapter 2. Exception 3 deletes the requirement for a separation between the interior of the building and the exterior wall area immediately adjacent to the exit stairway where an open-ended corridor (breezeway) interfaces with an exterior stairway or ramp. In other words, a door is not required between the exterior exit stairway and the open-ended corridor. The separation is not needed because of the NFPA 13 or 13R sprinkler system is required in all areas of the building, including the open-ended corridor. The other characteristics of the open-ended corridor described in this exception are needed so that it is safe to be used in the event of a fire. The requirements for an exterior stairway or ramp at each end, and the additional openings or

exterior stairways or ramps where the open-ended corridor has a change of direction of greater than 45 degrees (0.79 rad), are for adequate ventilation of the open-ended corridor. The corridor may be required to be rated per Table 1020.1. The reference back to Section 1023.7 results in any exterior walls that form an angle less than 180 degrees (3.14 rad) from the side of the exterior exit stairway to be protected for a distance of 10 feet (3048 mm) [see Commentary Figure 1027.6(3)]. Exit access travel distance on an open-ended corridor is measured to the first riser of an exterior stair or the beginning slope of an exterior ramp.

Similar separation language is used in describing the exterior wall requirements for an exterior area for assisted rescue that is provided at an exit located above grade level. Where there are steps, they are merely part of the exit discharge, not exterior exit stairways as addressed in this section.

**SECTION 1028  
EXIT DISCHARGE**

**1028.1 General.** Exits shall discharge directly to the exterior of the building. The *exit discharge* shall be at grade or shall provide a direct path of egress travel to grade. The *exit discharge* shall not reenter a building. The combined use of Exceptions 1 and 2 shall not exceed 50 percent of the number and minimum width or required capacity of the required exits.

**Exceptions:**

1. Not more than 50 percent of the number and minimum width or required capacity of *interior exit stairways and ramps* is permitted to egress through

## MEANS OF EGRESS

areas on the level of discharge provided all of the following conditions are met:

- 1.1. Discharge of *interior exit stairways* and *ramps* shall be provided with a free and unobstructed path of travel to an exterior *exit* door and such *exit* is readily visible and identifiable from the point of termination of the enclosure.
- 1.2. The entire area of the *level of exit discharge* is separated from areas below by construction conforming to the *fire-resistance rating* for the enclosure.
- 1.3. The egress path from the *interior exit stairway* and *ramp* on the *level of exit discharge* is protected throughout by an *approved automatic sprinkler system*. Portions of the *level of exit discharge* with access to the egress path shall be either equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, or separated from

the egress path in accordance with the requirements for the enclosure of *interior exit stairways* or *ramps*.

- 1.4. Where a required *interior exit stairway* or *ramp* and an *exit access stairway* or *ramp* serve the same floor level and terminate at the same *level of exit discharge*, the termination of the *exit access stairway* or *ramp* and the *exit discharge* door of the *interior exit stairway* or *ramp* shall be separated by a distance of not less than 30 feet (9144 mm) or not less than one-fourth the length of the maximum overall diagonal dimension of the building, whichever is less. The distance shall be measured in a straight line between the *exit discharge* door from the *interior exit stairway* or *ramp* and the last tread of the *exit access stairway* or termination of slope of the *exit access ramp*.
2. Not more than 50 percent of the number and minimum width or required capacity of the *interior exit stairways* and *ramps* is permitted to egress through a

vestibule provided all of the following conditions are met:

- 2.1. The entire area of the vestibule is separated from areas below by construction conforming to the *fire-resistance rating* of the *interior exit stairway* or *ramp enclosure*.
- 2.2. The depth from the exterior of the building is not greater than 10 feet (3048 mm) and the length is not greater than 30 feet (9144 mm).
- 2.3. The area is separated from the remainder of the *level of exit discharge* by a *fire partition* constructed in accordance with Section 708.

**Exception:** The maximum transmitted temperature rise is not required.

- 2.4. The area is used only for *means of egress* and *exits* directly to the outside.
3. *Horizontal exits* complying with Section 1026 shall not be required to discharge directly to the exterior of the building.

❖ The exit discharge is the third piece of the means of egress system, which includes exit access, exit and exit discharge. The general provisions for means of egress in Sections 1003 through 1015 are applicable to the exit discharge. The basic provision is that exits must discharge directly to the outside of the building. The exit discharge is the path from the termination of the exit to the public way. When it is not practical to discharge directly to the outside, there are four alternatives: an exit passageway (see Section 1024), an exit discharge lobby (see Section 1028.1, Exception 1), an exit discharge vestibule (see Section 1028.1, Exception 2) or a horizontal exit (see Sections 1026 and 1028.1, Exception 3). While Exceptions 1 and 2 could be applicable for exit passageways and exit ramps, they are most often applied for exit stairways. The commentary for Section 1027 will be limited to interior exit stairways that are enclosed in accordance with Section 1023 (see Sections 1006 and 1019.3 for exit access stairway requirements). Up to 50 percent of the interior exit stairways in a building may use either Exception 1 or 2; therefore, neither exception is viable for a single-exit building. In a two- or three-exit building, either a lobby or a vestibule can be used for exit discharge for one of the exit stairways. In a four-exit building, two of the exit stairways can use either a lobby or a vestibule for exit discharge.

An interior exit discharge lobby is permitted to receive the discharge from an exit stairway in lieu of the stairway discharging directly to the exterior. A fire door must be provided at the point where the exit stairway discharges into the lobby. Without an opening protective between the stairway and a lobby, it would be possible for the stairway to be directly exposed to smoke movement from a fire in the lobby. The opening protective provides for full continuity of

the vertical component of the exit arrangement. Additionally, in buildings where stair towers must be pressurized, pressurization would not be possible without a door at the lobby level.

An exit discharge lobby is the sole location recognized in the code where an exit element can be used for purposes other than pedestrian travel for means of egress. The lobby may contain furniture or decoration and nonoccupiable spaces may open directly into the lobby. The lobby, and all other areas on the same level that are not separated from the lobby by fire barriers consistent with the rating of the stair enclosure, must be sprinklered in accordance with an NFPA 13 or NFPA 13R system [see Commentary Figure 1028.1(1)]. If the entire level is sprinklered, no separation is required. In this case, the automatic sprinkler system is anticipated to control and (perhaps) eliminate the fire threat so as not to jeopardize the path of egress of the occupants. The lobby floor and any supporting construction must be rated the same as the stairway enclosure. If the lobby is slab on grade, this requirement is not applicable. This is consistent with the fundamental concept that an exit enclosure provides the necessary level of protection from adjacent areas. A path of travel through the lobby must be continually clear and available. The exit door leading out of the building must be visible and identifiable immediately when a person leaves the exit. This does not mean the exterior exit door must be directly in front of the door at the bottom of the stairway, but the intent is that it should be within the general range of vision. A person should not have to turn completely around or go around a corner to be able to see the way out.

Item 1.4 addresses when an exit access stairway and an exit stairway both discharge into the same lobby on the ground floor. For example, many hotels have meeting rooms on the level immediately above the lobby. This heavier occupant load, or circulation considerations, may result in an exit access stairway coming down from that second level into the same lobby that is being used for discharge from the upper floors for one of the required exit stairways. This limitation for a 30-foot (9144) separation is to prevent an exit access stairway and an exit stairway from termination too close together on the level of exit discharge. The intent is that one localized fire event in the lobby will not jeopardize the use of both means of egress components. The 30-foot or  $1/4$  diagonal separation distances were based on the 30-foot or  $1/4$  diagonal that is specified for separation of interior stairways in a high-rise building (see IBC Section 403.5.1). This measurement is taken only at the bottom of the exit access stairway and the door to the exit enclosure. It is not required to be maintained the entire length of the stairway as required for two exit access stairways in Section 1007.1.3. The enclosure of the exit stairway offers sufficient separation protection. The intent of the exception is to allow for glazing that meets the smoke partition requirements.

## MEANS OF EGRESS

An exit is also allowed to discharge through a vestibule, provided it complies with the specified requirements of Exception 2. Vestibules utilizing this provision are not to be used for other purposes, such as access to closets, furniture/seating, drinking fountains, vending machines, etc. The vestibule floor and any supporting construction must be rated the same as the stairway enclosure. If the vestibule is slab on grade, this requirement is not applicable. The size of the vestibule is limited so that it cannot be used for other activities, and the travel distance from the exit stairway to the exterior exit doorway is limited [see Commentary Figures 1028.1(2) and 1028.1(3)]. The interior walls of the vestibule must be constructed as fire partitions with a fire-protection rating of at least 1 hour. IBC Section 708 does not reference a specific test standard for fire partitions. As such, fire partitions must comply with ASTM E119 or UL 263 per IBC Section 703.2 (see IBC Section 703.2 for additional commentary on the tests). ASTM E119 and UL 263 have a transmission of heat criterion for nonbearing partitions to be considered as having passed the test. The exception exempts fire partitions for the separation of a vestibule from having to comply with the transmission of heat criterion. Glass panels set in a metal frame can be used for the vestibule as long as they meet the rest of the ASTM E119 criteria.

Exception 3 acknowledges that horizontal exits offer refuge areas that will have access to an exit on

the other side; therefore, a stairway that exits through a horizontal exit is not required to exit to the exterior. Many hospitals and correctional facilities use horizontal exits to “defend in place” rather than require an immediate building evacuation. There are exit stairways or exits available from the refuge areas, so occupants can move to the outside if needed (see Section 1026 for additional information).

**1028.2 Exit discharge width or capacity.** The minimum width or required capacity of the *exit discharge* shall be not less than the minimum width or required capacity of the *exits* being served.

❖ This section specifies the exit discharge width based on minimum width and the number of occupants exiting (capacity). The exit discharge is required to be designed for the occupant from all of the exits it serves. If the exit discharge serves two exits, it is to be designed for the sum of the occupants served by both exits. Note that the capacity of the exit discharge is not required to match the total provided capacity of both exits, which is typically higher than the sum of the occupants served by both exits.

**1028.3 Exit discharge components.** *Exit discharge* components shall be sufficiently open to the exterior so as to minimize the accumulation of smoke and toxic gases.

❖ An exit discharge component could be a large open space where people could discharge in a number of

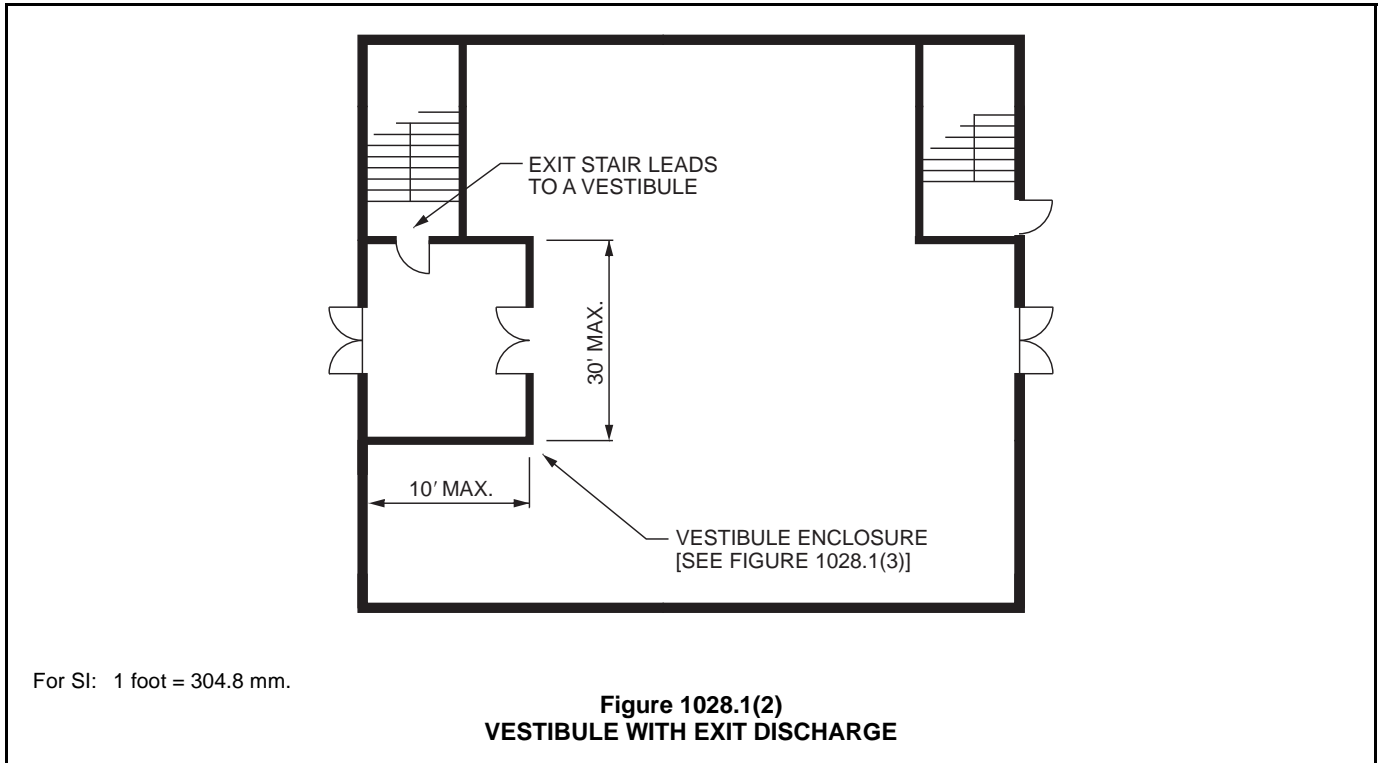

**Figure 1028.1(1)**  
**PROTECTION OF LOBBY WITH AN EXIT DISCHARGE**

different directions or it could be limited to a narrower path by landscaping or walls (i.e., egress court). In all cases, the space must be open enough to the outside that smoke and fumes will vent upward and away from people evacuating the building.

**1028.4 Egress courts.** *Egress courts* serving as a portion of the *exit discharge* in the *means of egress* system shall comply with the requirements of Sections 1028.4.1 and 1028.4.2.

❖ A portion of the exit discharge that is partially confined by exterior walls or other elements that confine

## MEANS OF EGRESS

the discharge path to a single narrow route is regulated as an egress court.

This section and the following subsections address the detailed requirements for egress courts. It is essential that exterior egress courts serving occupants from an exit to a public way be sufficiently open to prevent the accumulation of smoke and toxic gases in the event of a fire as well as wide enough to accommodate the number of occupants leaving in that direction.

See IBC Section 1206 for additional minimum width and openness requirements when yards and courts are needed for natural light or ventilation.

**1028.4.1 Width or capacity.** The required capacity of *egress courts* shall be determined as specified in Section 1005.1, but the minimum width shall be not less than 44 inches (1118 mm), except as specified herein. *Egress courts* serving Group R-3 and U occupancies shall be not less than 36 inches (914 mm) in width. The required capacity and width of *egress courts* shall be unobstructed to a height of 7 feet (2134 mm).

**Exception:** Encroachments complying with Section 1005.7.

Where an *egress court* exceeds the minimum required width and the width of such *egress court* is then reduced along the path of exit travel, the reduction in width shall be gradual. The transition in width shall be affected by a guard not less than 36 inches (914 mm) in height and shall not create an angle of more than 30 degrees (0.52 rad) with respect to the axis of the *egress court* along the path of egress travel. The width of the *egress court* shall not be less than the required capacity.

❖ The width of an exterior court is to be determined in the same fashion as for an interior corridor. The width is not to be less than required to serve the number of occupants from the exit or exits and not less than the minimum specified in this section (see also IBC Section 1206). A cross reference back to Section 1005.7 for obstructions in the width in aisles (see Section 1018.1), corridors (see Section 1020.3), exit passageways (see Section 1024.2) and exit courts (see Section 1028.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

Many egress courts are significantly larger than required. Thus, the code allows such an egress court to decrease in width along the path of travel to the public way. The gradual transition requirement is so the flow of the occupants will be uniform without pockets of congestion. The transition requirements should be applied to egress courts where a reduction results in a width that is near the minimum based on the number of occupants served. It is this condition where the uniform flow of occupants is essential.

**1028.4.2 Construction and openings.** Where an *egress court* serving a building or portion thereof is less than 10 feet (3048 mm) in width, the *egress court* walls shall have not less than 1-hour *fire-resistance-rated* construction for a distance of 10

feet (3048 mm) above the floor of the *egress court*. Openings within such walls shall be protected by opening protectives having a fire protection rating of not less than  $\frac{3}{4}$  hour.

### Exceptions:

1. *Egress courts* serving an *occupant load* of less than 10.
2. *Egress courts* serving Group R-3.

❖ The purpose of this section is to protect the occupants served by the egress court from the building that they are exiting from. If occupants must walk closely by the exterior walls of the court, the walls are required to have the specified fire-resistance rating and the openings are required to be protected as specified. This requirement is only for the first 10 feet (3048 mm) above the level of the egress court since the exposure hazard from walls and openings above 10 feet (3048 mm) is reduced. The two exceptions provide for egress courts that serve a very low number of occupants and the specified residential occupancy where the protection requirement would be located.

**1028.5 Access to a public way.** The *exit discharge* shall provide a direct and unobstructed access to a *public way*.

**Exception:** Where access to a *public way* cannot be provided, a safe dispersal area shall be provided where all of the following are met:

1. The area shall be of a size to accommodate not less than 5 square feet (0.46 m<sup>2</sup>) for each person.
2. The area shall be located on the same lot not less than 50 feet (15 240 mm) away from the building requiring egress.
3. The area shall be permanently maintained and identified as a safe dispersal area.
4. The area shall be provided with a safe and unobstructed path of travel from the building.

❖ There are instances where the path of travel to the public way is not safe or not achievable because of site constraints or security concerns. The provisions in this section specify what would constitute a safe area to allow occupants of a building to assemble in an emergency. The requirement of 5 square feet (0.28 m<sup>2</sup>) would allow adequate space for standing persons as well as some space for persons in wheelchairs or on stretchers. Everyone who is expected to wait in this dispersal area for fire department assistance must be a minimum of 50 feet (15 240 mm) away from the building. This refuge must always remain open and not be used for parking, storage or temporary structures. A safe dispersal area is commonly found at schools or jails. Stadiums are more specifically addressed in Section 1010.2.1. Walls or fences may surround the building and part of the site due to other safety concerns. These walls and fences could stop occupants from reaching the public way.

## SECTION 1029 ASSEMBLY

**1029.1 General.** A room or space used for assembly purposes that contains seats, tables, displays, equipment or other material shall comply with this section.

- ❖ Any room that is used for assembly purposes, regardless of the occupancy of the rest of the building, must comply with this section. Spaces used for assembly seating may appear in buildings of other occupancy types; for example, a library in a school, or a meeting room in an office building. This includes spaces with less than 50 occupants in other occupancies. For evaluation of the occupant load and the means of egress in these spaces, these spaces are regulated based on their function, rather than their occupancy group.

Although most of the provisions in Section 1029 focus on fixed seating auditoriums or theaters, this section also addresses loose seats, tables, displays, equipment, etc. Rooms or spaces used for assembly purposes contain elements that would affect the path of travel for the means of egress. These spaces require special consideration because of the larger occupant loads and possible low lighting (e.g., night-clubs, theaters), which can possibly lead to slower fire recognition or crowd concerns.

Since this section is extensive, here is a basic breakdown:

- Sections 1029.1.1 and 1029.1.1.1 deal with bleachers and grandstands.
  - Sections 1029.3 through 1029.5 deal with number and dispersment of exits.
  - Section 1029.6 and subsections discuss aisle widths based on the required capacity.
  - Sections 1029.7 and 1029.8 are for travel distances and aisle accessways.
  - Section 1029.9 deals with where aisles are required, minimum widths, and layouts. This includes provisions for where stairways are a direct continuation of a stepped aisle (Sections 1029.9.7 through 1029.10.3).
  - Section 1029.11 discusses types of materials and walking surfaces.
  - Section 1029.12 covers the aisle accessways that lead to the main aisles as they move through tables (Section 1029.12.1) and seating in rows (Section 1029.12.2).
  - Section 1029.13 deals with slope, landings and edge protection for ramped aisles (Sections 1029.13.1 through 1029.13.1.3) and treads and risers for stepped aisles (Sections 1029.13.2 through 1029.13.2.4).
  - Section 1029.14 discusses where seating needs to be fastened to the floor in order for aisles and accessways to be maintained.
- Section 1029.15 includes handrail provisions for ramped and stepped aisles.
  - Section 1029.16 states where guards are required.

**1029.1.1 Bleachers.** *Bleachers, grandstands and folding and telescopic seating*, that are not building elements, shall comply with ICC 300.

- ❖ On February 24, 1999, the Bleacher Safety Act of 1999 was introduced in the House of Representatives. The bill, which cites the ICC and the code, authorizes the U.S. Consumer Product Safety Commission (CPSC) to issue a standard for bleacher safety. This was in response to concerns relative to accidents on bleacher-type structures. As a result, the CPSC developed and revised the *Guidelines for Retrofitting Bleachers*. The ICC Board of Directors decided that a comprehensive standard dealing with all aspects of both new and existing bleachers was warranted and authorized the formation of the ICC Consensus Committee on Bleacher Safety. The committee is composed of 12 members, including the requisite balance of general, user interest and producer interest.

ICC 300 was completed in December 2001, and submitted to ANSI on January 1, 2002. ICC 300 was reissued with some revisions in 2007 and 2012. While the term “bleachers” is generic, the standard addresses all aspects of tiered seating associated with bleachers, grandstands, and folding and telescopic seating. These types of seating are supported on dedicated structural systems, which in turn may sit on the ground or on a building floor system. Single seats or bench seats bolted down to a stepped floor are not considered a bleacher or grandstand and should comply with Section 1029. See the definitions in Chapter 2 for “Building element,” “Bleachers,” “Grandstands” and “Folding and telescopic seating.” While ICC 300 is consistent and also relies on Chapter 10 of the code for some provisions, the standard addresses items specific to these types of seating arrangements. For example, the minimum number of exits from a bleacher is addressed in ICC 300, IBC Section 404.1; however, to determine the minimum number of exits from the room the bleacher is located in, Section 1006 is applicable. The bleacher standard references IBC Chapter 11 and ICC A117.1 for accessibility requirements.

The ICC 300 has minimum requirements for new, alterations, repair, operation and maintenance of bleacher systems. A bleacher or grandstand is defined as “Tiered seating supported on a dedicated structural system and two or more rows high and is not a building element.” The intent of the terms “dedicated structural system” and “not a building element” in the definition is to recognize that bleacher systems sit on the floor or ground and have a support system separate from the building system. However, the bleacher could rely on the building system for lateral or gravity support. The intent of “two or more rows” is

so that a tiered floor system with a bench or row of seats on each tier would not be considered a bleacher.

The criteria in ICC 300 include provisions for construction; means of egress within the bleacher system; inspection and maintenance for existing bleachers; and for when seating systems are relocated.

#### 1029.1.1.1 Spaces under grandstands and bleachers.

Where spaces under *grandstands* or *bleachers* are used for purposes other than ticket booths less than 100 square feet (9.29 m<sup>2</sup>) and toilet rooms, such spaces shall be separated by *fire barriers* complying with Section 707 and *horizontal assemblies* complying with Section 711 with not less than 1-hour *fire-resistance-rated* construction.

❖ Sometimes spaces under grandstands are used for other purposes such as bathrooms, concession stands, storage, etc. If that space caught on fire, it could jeopardize the safe evacuation options for persons on the bleachers. For safety, the spaces below must be separated from the bleachers by fire-resistance-rated construction. This is typically the roof and back walls of the concession stand or storage room. If the space below is either a small ticket booth or bathrooms of any size, the potential fire load is low enough that these spaces are not required to be separated.

Note that Section 903.2.1.5 requires enclosed spaces with an area of over 1,000 square feet (93 m<sup>2</sup>) and under an outdoor bleacher system to be sprinklered.

While the path for means of egress passing under the bleachers (i.e., vomitory) is not specifically addressed in this section, when a bleacher system is outside, the capacity factors for determining minimum egress width [Table 404.5(3) of ICC 300] are based on the assumption that the egress route is essentially open to the outside and, therefore, has a limited chance for the accumulation of smoke along that route. Two of the three legacy codes specifically exempted open means of egress routes under bleachers from separation requirements.

**1029.2 Assembly main exit.** A building, room or space used for assembly purposes that has an *occupant load* of greater than 300 and is provided with a main *exit*, that main *exit* shall be of sufficient capacity to accommodate not less than one-half of the *occupant load*, but such capacity shall be not less than the total required capacity of all *means of egress* leading to the *exit*. Where the building is classified as a Group A occupancy, the main *exit* shall front on not less than one street or an unoccupied space of not less than 10 feet (3048 mm) in width that adjoins a street or *public way*. In a building, room or space used for assembly purposes where there is not a well-defined main *exit* or where multiple main *exits* are provided, *exits* shall be permitted to be distributed around the perimeter of the building provided that the total capacity of egress is not less than 100 percent of the required capacity.

❖ Assembly buildings, as well as other buildings including spaces that function as assembly spaces (e.g.,

the band classroom in a school, the training room in an office, the cafeteria in a large factory), present an unusual life safety problem that includes frequent higher occupant densities and, therefore, larger occupant loads and the opportunity for irrational mass response to a perceived emergency (i.e., panic). For this reason, the code requires a specific arrangement of the exits. Studies have indicated that in any emergency, occupants will tend to egress via the same path of travel used to enter the room and building. Therefore, a main entrance to the building or space must also be designed as the main exit to accommodate this behavior, even if the required exit capacity might be more easily accommodated elsewhere. The main entrance (and exit) must be sized to accommodate at least 50 percent of the total occupant load of the structure and must front on a large, open space, such as a street or lobby, for rapid dispersal of the occupants outside the building or space. The remaining exits must also accommodate at least 50 percent of the total occupant load from each level (see Commentary Figure 1029.2). The total occupant load includes those within the theater seating area, the foyer and any other space (e.g., ticket booth, concession stand, offices, storage and the like). When the assembly space is within a mixed use building, the intent is that the main exits from the space comply with these provisions for one-half the capacity, but not necessarily that they lead directly to the outside. Egress requirements from the building would depend on how it was anticipated for the assembly space occupants to disperse. For example, an office building may have a large training/conference room where the path of exit access travel from the room goes out a main exit from the space and then disseminates into the general floor egress system. The room exit access doors may need to meet the 50-percent criterion, but once the occupants leave the room and enter the general floor egress system, exit capacity can be dispersed.

The required width of the means of egress in places of assembly is more often determined by the occupant load than in most other occupancies. In other occupancies, the minimum required widths and the travel distances will often determine the required widths and locations of the exits.

This section only requires the main exit to accommodate 50 percent of the occupant load when there is a single main entrance. Therefore, a large stadium or civic center, in which there are numerous entrances (and exits), need not comply with the main entrance criteria.

**1029.3 Assembly other exits.** In addition to having access to a main *exit*, each level in a building used for assembly purposes having an *occupant load* greater than 300 and provided with a main *exit*, shall be provided with additional *means of egress* that shall provide an egress capacity for not less than one-half of the total *occupant load* served by that level and shall comply with Section 1007.1. In a building used for assembly purposes where there is not a well-defined main

*exit* or where multiple main *exits* are provided, *exits* for each level shall be permitted to be distributed around the perimeter of the building, provided that the total width of egress is not less than 100 percent of the required width.

❖ This section provides for the egress of one-half of the total occupant load by way of exits other than the main exit that is described in Section 1029.2. Assembly buildings, as well as other buildings including spaces that function as assembly spaces, that are provided with multiple entrances but no single main entrance do not provide a well-defined main exit; therefore, the total required exit width needs to be distributed around the perimeter of the space or building. Examples of these assemblies would be a school gymnasium or a large stadium or civic center in which there are numerous entrances (and exits).

**1029.4 Foyers and lobbies.** In Group A-1 occupancies, where persons are admitted to the building at times when seats are not available, such persons shall be allowed to wait in a lobby or similar space, provided such lobby or similar space shall not encroach upon the minimum width or required capacity of the *means of egress*. Such foyer, if not directly connected to a public street by all the main entrances or *exits*, shall have a straight and unobstructed *corridor* or path of travel to every such main entrance or *exit*.

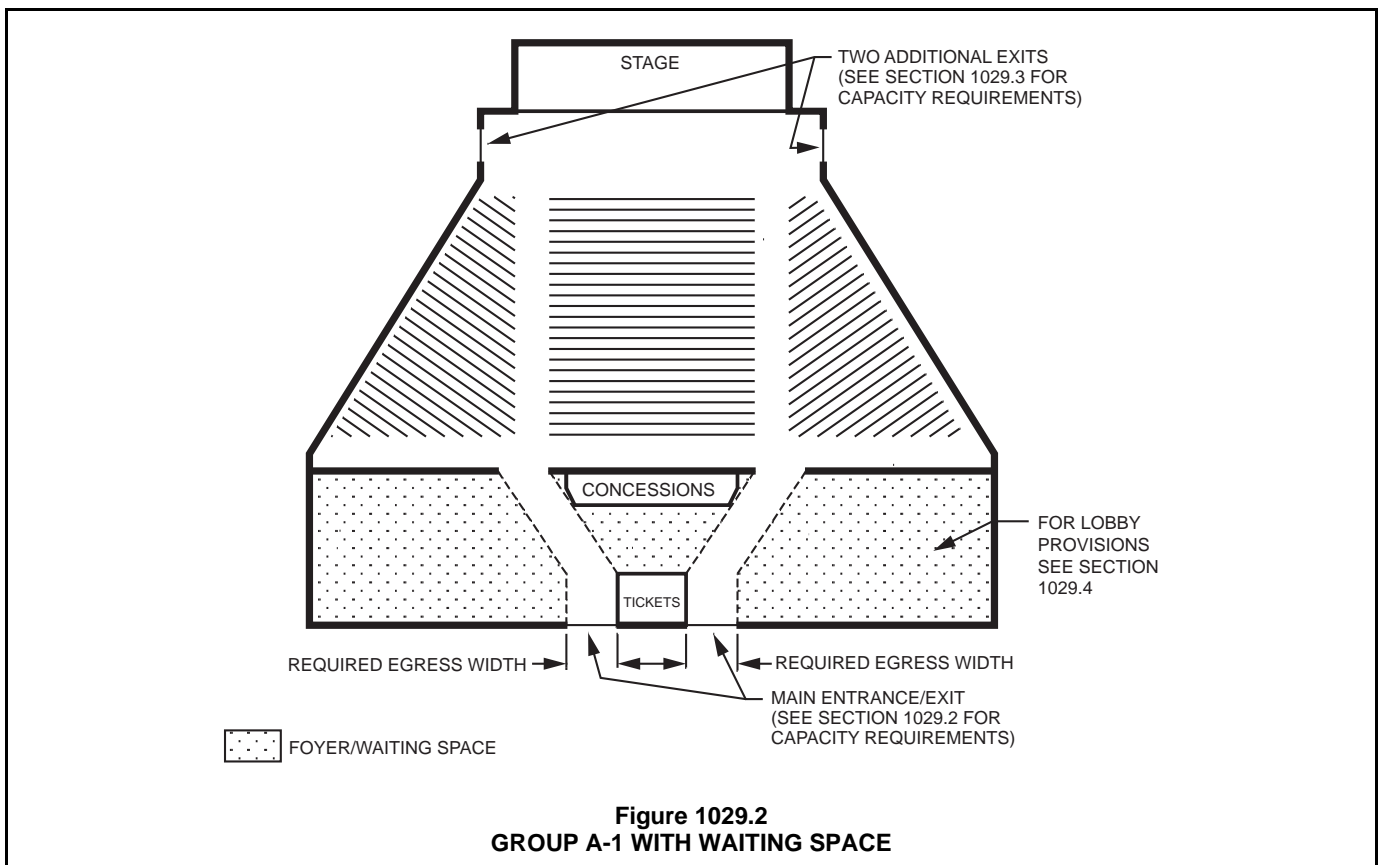

❖ In theaters, people may arrive and wait for the next show while another group has yet to exit. This is extremely common in multiplex theater complexes. In every case, the main entrance (exit) and all other

exits are to be constantly available for the entire building occupant load.

For example, because of the queuing of large crowds, particularly in theaters where a performance may be in progress and people must wait to attend the next one, standing space is often provided. For reasons of safety, such spaces cannot be located in or interfere with established paths of egress from the assembly areas. While a facility may choose to separate the route for means of egress using partitions or railings from the general lobby space to allow for easy traffic flow through the lobby to the street, it is not required to designate these areas (see Commentary Figure 1029.2).

**1029.5 Interior balcony and gallery means of egress.** For balconies, galleries or press boxes having a seating capacity of 50 or more located in a building, room or space used for assembly purposes, not less than two *means of egress* shall be provided, with one from each side of every balcony, gallery or press box.

❖ This section states the threshold where two means of egress are required based on the occupant load of the interior balcony, gallery or press box. Those two exits need to be dispersed. Section 1019.3, Exception 8, allows for both stairways to be unenclosed exit access stairways where they are effectively part of the main seating bowl. These requirements will ensure that at least one path of travel is always available and occupants face a minimum number of hazards.

**Figure 1029.2**  
**GROUP A-1 WITH WAITING SPACE**

For balconies, galleries or press boxes with 50 or fewer occupants, see Section 1029.8. When balconies, galleries or press boxes contain wheelchair spaces, the area must also meet the accessible means of egress requirements (Sections 1009.1, Exception 3, and 1029.8).

**1029.6 Capacity of aisle for assembly.** The required capacity of *aisles* shall be not less than that determined in accordance with Section 1029.6.1 where *smoke-protected assembly seating* is not provided and with Section 1029.6.2 or 1029.6.3 where *smoke-protected assembly seating* is provided.

❖ The means of egress width for spaces used for assembly is to be in accordance with this section and the referenced sections instead of the criteria specified in Section 1005 when dealing with the means of egress within the seating area. The width factors in Section 1029.6 and its subsections apply to those doorways, passageways, stepped aisles, ramped aisles and level aisles that are within the assembly seating areas.

The Board for the Coordination of Model Codes (BCMC) issued a report on means of egress dated June 10, 1985. The provisions in Section 1029 are based on this report. This report limits the application of these provisions to aisles and aisle accessways that provide exit access within the room or space with the assembly seating. This would include aisle accessways, level aisles, stepped aisles and ramped aisles. The primary concern for occupant safety would be that where the different provisions for the capacity requirements in Sections 1005 and 1029 were utilized, there would not be a bottleneck in the path of travel for means of egress. For example, a common configuration at football fields is to have the seating area raised several feet above grade. Where a step or series of steps leading to grade from a raised seating area are a continuation of the stepped aisle, the width of the stepped aisle between seats and the continuation without adjacent seats should be the same. In theaters, commonly the occupants leave the seating area for a concourse or lobby area that leads to exit stairways between floor levels. In this situation, the capacity requirement in Section 1005.3 would be applicable for the exit stairway. For the many situations between these two scenarios, the decision would be based on the configuration of the seating and exit stairways between levels.

For example, in a facility without smoke protection and an occupant load of 800, doorways would need to be calculated based on 0.20 inches (5.1 mm) per occupant (see Item 4 of Section 1029.6.1). An occupant load of 800 x 0.2 inches (4064 mm) = 160 inches (4064 mm) of egress width capacity, which translates into not less than five doors [assuming each with a minimum 32-inch (813 mm) clear opening]. This facility needs to have not less than three distinct means of egress (Section 1006.3). A main exit must accommodate not less than one-half of the occupant load (Section 1029.2). Therefore, the result would be not less

than six doors: three located at the main exit and three others distributed to at least two other locations (Section 1029.3).

Different means of egress width criteria are also specified for assembly seating where smoke protection is provided versus areas where smoke protection is not provided. The egress width for smoke-protected seating is allowed to be less than for areas where smoke protection is not provided, since the smoke level is required to be maintained at least 6 feet (1829 mm) above the floor of the means of egress, according to Section 1029.6.2.1.

**1029.6.1 Without smoke protection.** The required capacity in inches (mm) of the *aisles* for assembly seating without smoke protection shall be not less than the *occupant load* served by the egress element in accordance with all of the following, as applicable:

1. Not less than 0.3 inch (7.6 mm) of *aisle* capacity for each occupant served shall be provided on stepped *aisles* having riser heights 7 inches (178 mm) or less and tread depths 11 inches (279 mm) or greater, measured horizontally between tread *nosings*.
2. Not less than 0.005 inch (0.127 mm) of additional *aisle* capacity for each occupant shall be provided for each 0.10 inch (2.5 mm) of riser height above 7 inches (178 mm).
3. Where egress requires stepped *aisle* descent, not less than 0.075 inch (1.9 mm) of additional *aisle* capacity for each occupant shall be provided on those portions of *aisle* capacity having no *handrail* within a horizontal distance of 30 inches (762 mm).
4. Ramped *aisles*, where slopes are steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have not less than 0.22 inch (5.6 mm) of clear *aisle* capacity for each occupant served. Level or ramped *aisles*, where slopes are not steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have not less than 0.20 inch (5.1 mm) of clear *aisle* capacity for each occupant served.

❖ This section prescribes the criteria needed to calculate the clear widths of aisles and aisle accessways in order to provide sufficient capacity to handle the occupant loads established by the “catchment areas” described in Section 1029.9.2. Clear width is to be measured to walls, edges of seating and tread edges.

The criteria for determining the required widths are based on analytical studies and field tests that used people to model egress situations [see Commentary Figures 1029.6.1(1) and 1029.6.1(2)].

Criterion 1 addresses the method for determining the required egress width for stepped aisles. This method corresponds with the requirements of Section 1005.3.1 for egress width per occupant of stairways in an unsprinklered building.

Criterion 2 addresses the method for determining the additional stepped aisle width required where the risers along that stepped aisle are greater than 7 inches (178 mm) high.

Criterion 3 addresses the method for determining the additional stepped aisle width where a handrail is not located within 30 inches (762 mm). With a center handrail, that would be stepped aisles wider than 60 inches (1524 mm). Side aisles have handrails along the wall. If the handrail is the top of the guard, then this requirement would apply to any side aisles greater than 30 inches (762 mm) wide. Because of the increased chance of falling and not being within reach of a handrail, the capacity per occupant is increased by 25 percent for the entire stepped aisle. For example, to calculate the capacity of a 72-inch-wide (1829 mm) stepped aisle, the answer would be 72 inches/0.375 inch = 192 occupants.

Criterion 4 addresses the method for determining the required widths for level or ramped and level means of egress. Where slopes are less than 1:12 (see definition for "Ramp"), the capacity requirements are also less. Level floors are quicker to negotiate than ramped surfaces for persons with limited mobility. Ramped aisle slopes are addressed in Section 1029.13.1.

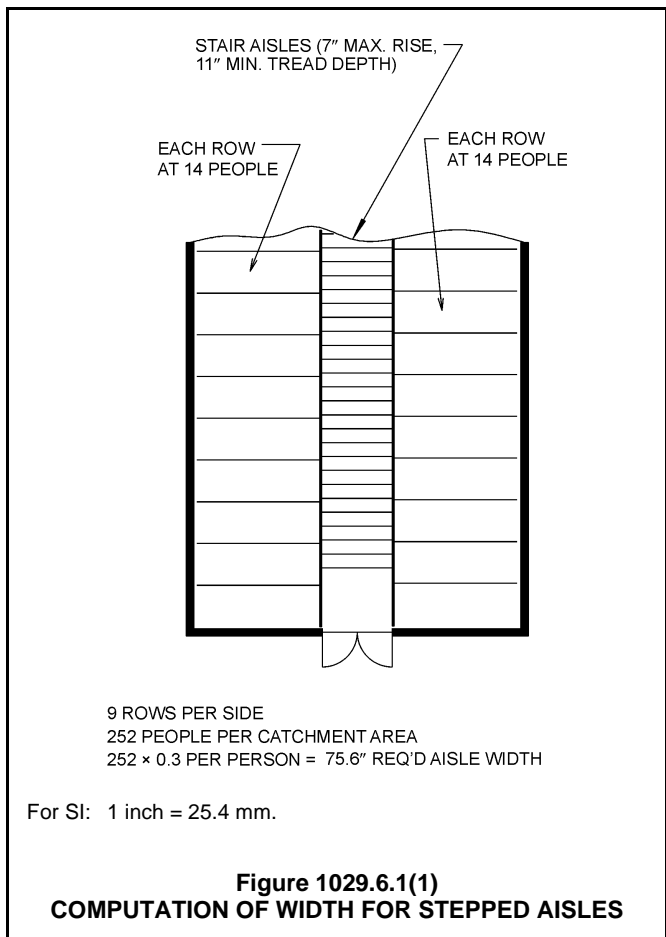

These provisions are applicable within the seating area itself. When the occupants have left the seating bowl and have moved to stairways outside of the room, or have moved to cross aisles and then stairways or ramps leaving the balcony level, Section 1005.3 would be applicable. See Sections 1029.9.6.1

through 1029.10.3 for stairways that are a direct continuation of stepped aisles.

**1029.6.2 Smoke-protected assembly seating.** The required capacity in inches (mm) of the aisle for *smoke-protected assembly seating* shall be not less than the occupant load served by the egress element multiplied by the appropriate factor in Table 1029.6.2. The total number of seats specified shall be those within the space exposed to the same smoke-protected environment. Interpolation is permitted between the specific values shown. A life safety evaluation, complying with NFPA 101, shall be done for a facility utilizing the reduced width requirements of Table 1029.6.2 for *smoke-protected assembly seating*.

**Exception:** For outdoor *smoke-protected assembly seating* with an *occupant load* not greater than 18,000, the required capacity in inches (mm) shall be determined using the factors in Section 1029.6.3.

❖ Special consideration is given to facilities with features that will prevent the means of egress from being blocked by smoke. Facilities to be considered smoke protected by Sections 1029.6.2.1 through 1029.6.2.3 are permitted increases in travel distance, egress capacity, and dead-end aisle and row lengths. Smoke control increases allowable egress time. Typically, model codes based on research by Dr. John Fruin and others recognize the need for occupants exposed to the fire environment to evacuate to a safe

## MEANS OF EGRESS

area within 90 seconds of notification and to reach the exterior or enclosed exit stairway within 5 minutes. With the increases permitted for smoke-protected facilities, these times are effectively doubled since the time available for safe egress also increases.

The exception is a pointer to the specific criteria for outdoor seating areas. For outdoor stadiums with 18,000 seats or greater, use Table 1029.6.2.

**TABLE 1029.6.2.** See page 10-187.

❖ This section requires the egress component to be of adequate size to accommodate the occupant load. For smoke-protected seating, the egress width per occupant is based on Table 1029.6.2. Typically, the larger the facility, the higher the ceiling; therefore, more space for smoke containment is associated with more time for egress. The egress width per occupant for nonsmoke-protected seating is to be based on Section 1029.6.1 and is similar to the provisions in Section 1005.3.

Where the entire means of egress is smoke protected, the concourse and any stairways and ramps can also use the same capacity numbers (see Section 1005.3.1, Exception 2, and Section 1005.3.2, Exception 2) to determine egress width. If the concourse surrounding the smoke-protected seating bowl is not also smoke protected, the requirements in Sections 1005.3.2 and 1005.3.1 would be applicable to determine widths required for capacity of the concourse, stairways and ramps providing means of egress from the seating bowl to the exterior of the building. See Sections 1029.9.6.1 through 1029.10.3 for stairways that are a direct continuation of stepped aisles.

**1029.6.2.1 Smoke control.** *Aisles and aisle accessways* serving a *smoke-protected assembly seating* area shall be provided with a smoke control system complying with Section 909 or natural ventilation designed to maintain the smoke level not less than 6 feet (1829 mm) above the floor of the *means of egress*.

❖ The means of egress (aisles and aisle accessways) within the assembly seating area are required to have some type of smoke control system that will prevent smoke buildup from encroaching on the egress path. This may be a mechanical smoke control system,

designed in accordance with Section 909, or natural ventilation as in open-air stadiums.

In either type of system, the major consideration is that a smoke-free environment be maintained at least 6 feet (1829 mm) above the floor of the means of egress for a period of at least 20 minutes.

**1029.6.2.2 Roof height.** A *smoke-protected assembly seating* area with a roof shall have the lowest portion of the roof deck not less than 15 feet (4572 mm) above the highest *aisle* or *aisle accessway*.

**Exception:** A roof canopy in an outdoor stadium shall be permitted to be less than 15 feet (4572 mm) above the highest *aisle* or *aisle accessway* provided that there are no objects less than 80 inches (2032 mm) above the highest *aisle* or *aisle accessway*.

❖ One element of a smoke-protected assembly seating facility is that the lowest portion of the roof is required to be at least 15 feet (4572 mm) above the highest *aisle* or *aisle accessway*. The objective of this provision is to have a minimum 6-foot (1829 mm) smoke-free height to accommodate safe egress through the area. The additional 9 feet (2743 mm) of height is to provide a volume of space that will act to dissipate smoke. The measurement of the height is shown in Commentary Figures 1029.6.2.2(1) and 1029.6.2.2(2).

**1029.6.2.3 Automatic sprinklers.** Enclosed areas with walls and ceilings in buildings or structures containing *smoke-protected assembly seating* shall be protected with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1.

### Exceptions:

1. The floor area used for contests, performances or entertainment provided the roof construction is more than 50 feet (15 240 mm) above the floor level and the use is restricted to low-fire-hazard uses.
2. Press boxes and storage facilities less than 1,000 square feet (93 m<sup>2</sup>) in area.
3. Outdoor seating facilities where seating and the *means of egress* in the seating area are essentially open to the outside.

❖ If there are areas in the smoke-protected assembly seating structure enclosed by walls and ceilings, the entire structure is to be provided with an automatic sprin-

**TABLE 1029.6.2**  
**WIDTH OF AISLES FOR SMOKE-PROTECTED ASSEMBLY**

TOTAL NUMBER OF SEATS IN THE SMOKEPROTECTED ASSEMBLY SEATING	INCHES OF CLEAR WIDTH PER SEAT SERVED			
	Stairs and aisle steps with handrails within 30 inches	Stairs and aisle steps without handrails within 30 inches	Passageways, doorways and ramps not steeper than 1 in 10 in slope	Ramps steeper than 1 in 10 in slope
Equal to or less than 5,000	0.200	0.250	0.150	0.165
10,000	0.130	0.163	0.100	0.110
15,000	0.096	0.120	0.070	0.077
20,000	0.076	0.095	0.056	0.062
Equal to or greater than 25,000	0.060	0.075	0.044	0.048

For SI: 1 inch = 25.4 mm.

kler designed to meet the requirements of NFPA 13.

Exception 1 indicates that the area over the playing field or performance area is not required to be sprinklered if the use of the floor area is restricted. If the facility is used for conventions, trade shows, displays or similar purposes, sprinklers are required throughout, since the occupancy would no longer be a low-fire-hazard use. A characteristic of a low-fire-hazard occupancy is that the fuel load caused by combustibles is approximately 2 pounds per square foot (9.8 kg/m<sup>2</sup>) or less.

In order for the contest, performance or entertain-

ment area to be nonsprinklered, the roof over that area must be at least 50 feet (15 240 mm) above the floor in addition to the floor area meeting the low fire-hazard criteria. The 50-foot (15 240 mm) criterion was selected because the response time for sprinklers at this height is extremely slow. It is estimated that the response time for standard sprinklers [50 feet (15 240 mm) above a floor with a fire having a heat release rate of 5 British thermal units (Btu) per square foot per second] exceeds 15 minutes. Therefore, it is not reasonable to install sprinklers at that height with little expectation of timely activation [see Commen-

tary Figure 1029.6.2.3(1)]. Note that if this exception is utilized, the tradeoffs for a fully sprinklered building, such as increased height and area limitations or decreased corridor ratings, are no longer permitted.

Exception 2 indicates that automatic sprinklers are not required in small spaces in buildings. Sprinklers are required in press box and storage areas of outdoor facilities when the area exceeds 1,000 square feet (93 m<sup>2</sup>). The primary reason for sprinklers in these areas is that both are anticipated to have a relatively large combustible load when compared to the main seating and participant areas. Additionally, in the case of storage areas, there is an increased potential for an undetected fire condition to occur [see Commentary Figure 1029.6.2.3(2)].

Exception 3 provides for outdoor seating facilities where smoke entrapment is not a safety concern.

**1029.6.3 Outdoor smoke-protected assembly seating.** The required capacity in inches (mm) of aisles shall be not less than the total *occupant load* served by the egress element multiplied by 0.08 (2.0 mm) where egress is by stepped *aisle* and multiplied by 0.06 (1.52 mm) where egress is by level *aisles* and ramped *aisles*.

**Exception:** The required capacity in inches (mm) of *aisles* shall be permitted to comply with Section 1029.6.2 for the number of seats in the outdoor *smoke-protected assembly seating* where Section 1029.6.2 permits less capacity.

❖ This section lists the coefficients determining the width of aisles required for outdoor smoke-protected

assembly seating areas. Note that the coefficients are significantly less when compared to the values in Section 1029.6.1 for assembly areas without smoke protection. The coefficients are also less than those for smoke-protected assembly seating in Table 1029.6.2 except for very large assembly areas. The exception in this section would apply where the coefficients in Table 1029.6.2 are less than those in this section.

Low coefficients are a result of the very low hazards for outdoor smoke-protected assembly areas and increased egress time. Where the entire means of egress is essentially open to the exterior, the concourse and any stairways and ramps can also use the same capacity numbers (see Section 1005.3.1, Exception 2, and Section 1005.3.2, Exception 2) to determine egress width. If the concourse surrounding the outdoor seating bowl is enclosed, the requirements in Sections 1005.3.2 and 1005.3.1 would be applicable to determine widths required for capacity of the concourse, stairways and ramps providing means of egress from the seating bowl to the exterior of the building. See Sections 1029.9.6.1 through 1029.10.3 for stairways that are a direct continuation of stepped aisles.

Generally, an outdoor assembly area meets the smoke control requirements of Section 1029.6.2 by natural ventilation and does not require an automatic sprinkler system according to Section 1029.6.2.3, Exception 3.

**1029.7 Travel distance.** *Exits* and *aisles* shall be so located that the travel distance to an *exit* door shall be not greater than 200 feet (60 960 mm) measured along the line of travel in nonsprinklered buildings. Travel distance shall be not more than 250 feet (76 200 mm) in sprinklered buildings. Where *aisles* are provided for seating, the distance shall be measured along the *aisles* and *aisle accessways* without travel over or on the seats.

**Exceptions:**

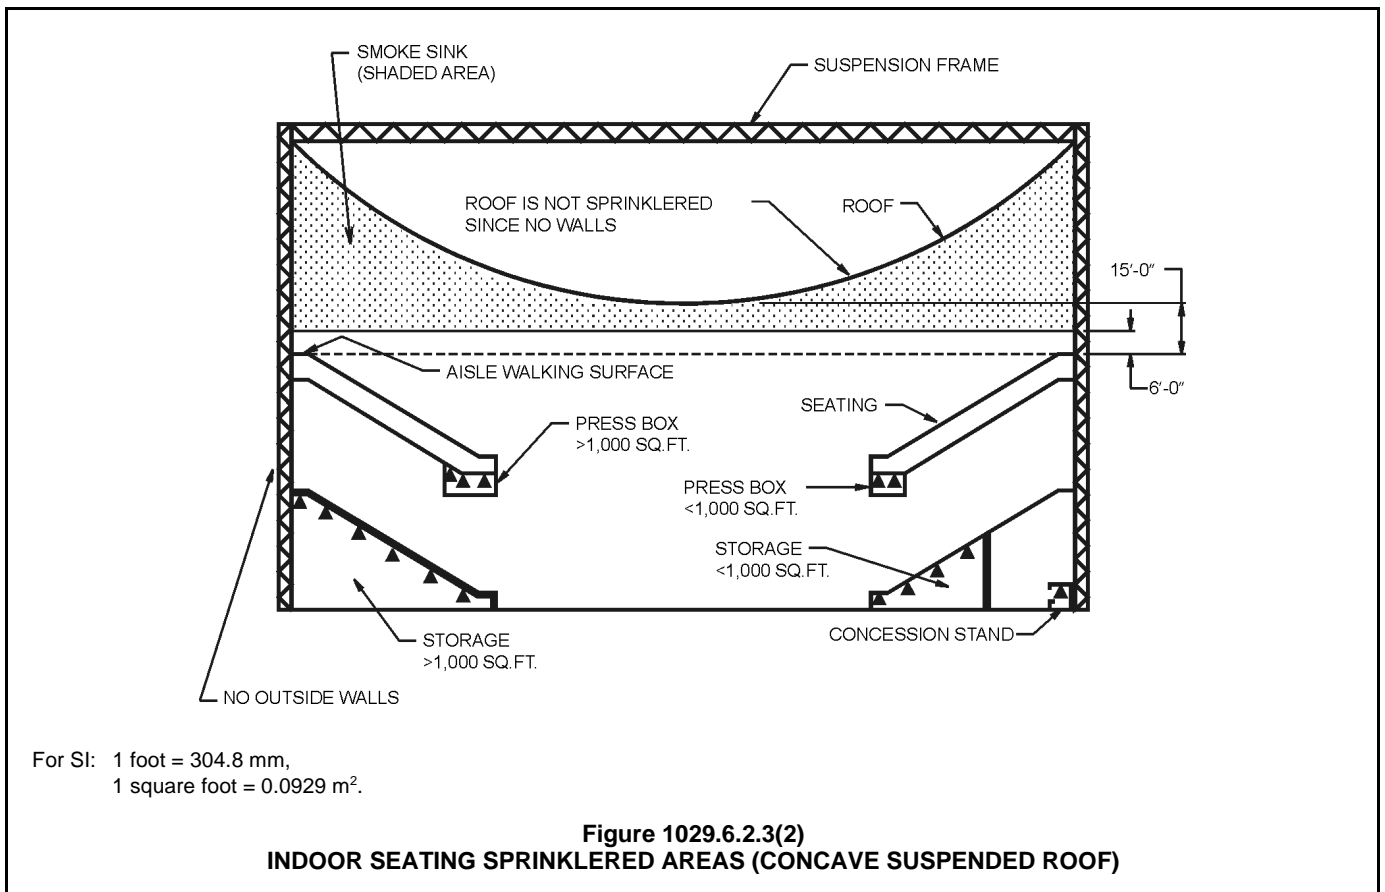

1. *Smoke-protected assembly seating:* The travel distance from each seat to the nearest entrance to a vomitory or concourse shall not exceed 200 feet (60 960 mm). The travel distance from the entrance to the vomitory or concourse to a *stairway*, *ramp* or walk on the exterior of the building shall not exceed 200 feet (60 960 mm).
  2. *Open-air seating:* The travel distance from each seat to the building exterior shall not exceed 400 feet (122 m). The travel distance shall not be limited in facilities of Type I or II construction.
- ❖ This section includes the travel distance limits for an assembly occupancy, which are the same as those in Table 1017.2 for Group A. The travel distance is to be measured along the same path the occupants would normally take to exit the facility.
- Exception 1 provides an extended travel distance for smoke-protected assembly seating that meets the requirements of Sections 1029.6.2 through 1029.6.2.3.

Exception 2 applies to open-air seating areas where the smoke and fire hazard is very low. The Type I and II construction referred to in this exception is described in IBC Section 602.

**1029.8 Common path of egress travel.** The *common path of egress travel* shall not exceed 30 feet (9144 mm) from any seat to a point where an occupant has a choice of two paths of egress travel to two *exits*.

**Exceptions:**

1. For areas serving less than 50 occupants, the *common path of egress travel* shall not exceed 75 feet (22 860 mm).
  2. For *smoke-protected assembly seating*, the *common path of egress travel* shall not exceed 50 feet (15 240 mm).
- ❖ The maximum travel distance down a single aisle accessway between rows of seating to a location where a patron would have two choices for a way out of the space is 30 feet (9144 mm). In smoke-protected seating, the common path of travel can be up to 50 feet (15 240 mm).
- If the room or space (e.g., box, gallery or balcony) has 50 or fewer occupants, the travel distance can be increased to 75 feet (22 860 mm). For example, this allows for a path of travel from a box seat, out of the box and to a main aisle or even a corridor located outside the assembly room itself.

## MEANS OF EGRESS

When this section is referenced for accessible means of egress (see Section 1009.1, Exception 3), the utilization of Exception 1 would include the entire occupant load of the seating area, box, gallery or balcony, not just the number of wheelchair spaces and/or companion seats. Wheelchair spaces that are integrated into the general seating would have the same common path of travel distance of 30 feet (9144 mm) before the person needing the accessible route could choose two different paths for accessible means of egress. This provides the same level of protection for the persons in the accessible seating as provided for others within the space.

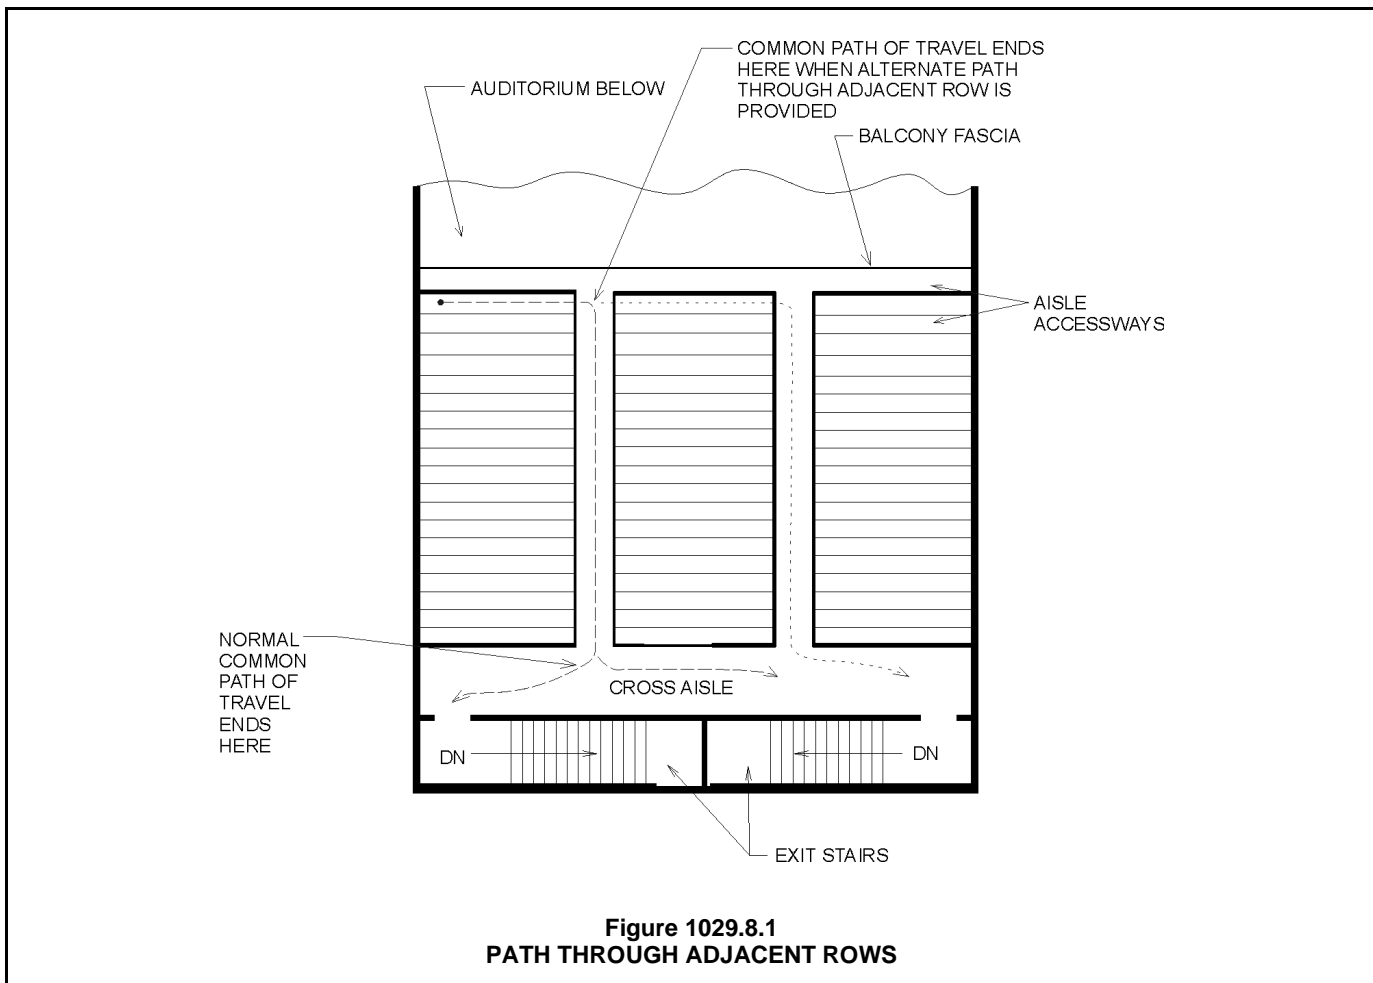

Sections 1006.2.1, 1006.3.2 and 1029.8 must be considered when determining the common path of travel requirements for a building. Section 1006.2.1 regulates the means of egress from a room or space. Section 1029.8, however, regulates the distance to a decision point within a room or space used for assembly seating where a single access row of seating is provided to a location where a patron would have two choices for a way out of the space.

**1029.8.1 Path through adjacent row.** Where one of the two paths of travel is across the *aisle* through a row of seats to another *aisle*, there shall be not more than 24 seats between the two *aisles*, and the minimum clear width between rows

for the row between the two *aisles* shall be 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row between *aisles*.

**Exception:** For *smoke-protected assembly seating* there shall be not more than 40 seats between the two *aisles* and the minimum clear width shall be 12 inches (305 mm) plus 0.3 inch (7.6 mm) for each additional seat.

❖ In establishing the point where the occupants of a row served by a single access aisle have two distinct paths of travel, the code allows one of those paths to be through the rows of an adjacent seating area or section. This requirement increases the row widths for the single-access seating section and the adjacent dual-access seating section. This allows the occupants to either travel down the single access aisle or readily traverse the oversized row widths to gain access to a second means of egress (see Commentary Figure 1029.8.1). This exception allows a greater number of seats spaced with a minimum clearance of 12 inches (305 mm) for smoke-protected assembly seating that complies with Sections 1029.6.2 through 1029.6.2.3 or Section 1029.6.3. For the base width requirements for single- and dual-access rows, see the commentary to Sections 1029.12.2 through 1029.12.2.2.

**1029.9 Assembly aisles are required.** Every occupied portion of any building, room or space used for assembly purposes that contains seats, tables, displays, similar fixtures or equipment shall be provided with *aisles* leading to *exits* or *exit access doorways* in accordance with this section.

❖ This section requires that each assembly space have designated aisles. For aisle accessway requirements, see Section 1029.10. For aisles in other occupancies, see Section 1018.

**1029.9.1 Minimum aisle width.** The minimum clear width for *aisles* shall comply with one of the following:

1. Forty-eight inches (1219 mm) for stepped *aisles* having seating on each side.

**Exception:** Thirty-six inches (914 mm) where the stepped *aisles* serve less than 50 seats.

2. Thirty-six inches (914 mm) for stepped *aisles* having seating on only one side.

**Exception:** Twenty-three inches (584 mm) between a stepped *aisle handrail* and seating where a stepped *aisle* does not serve more than five rows on one side.

3. Twenty-three inches (584 mm) between a stepped *aisle handrail* or *guard* and seating where the stepped *aisle* is subdivided by a mid-*aisle handrail*.

4. Forty-two inches (1067 mm) for level or ramped *aisles* having seating on both sides.

**Exceptions:**

1. Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.
2. Thirty inches (762 mm) where the *aisle* does not serve more than 14 seats.
5. Thirty-six inches (914 mm) for level or ramped *aisles* having seating on only one side.

**Exception:** For other than ramped *aisles* that serve as part of an *accessible route*, 30 inches (762 mm) where the ramped *aisle* does not serve more than 14 seats.

❖ The clear widths of aisles established by the formulas given in Section 1029.6 must not be less than the minimum width requirements of this section. The development of minimum width requirements is based on the association of aisle capacity with the path of exit travel as influenced by the different features of aisle construction. The purpose is to create an aisle system that would provide an even flow of occupant egress. The minimum width of the aisles is also based on an anticipated movement of people in two directions.

Items 1, 2 and 3 deal with stepped aisles. Items 4 and 5 deal with ramped and level aisles. Items 1, 3 and 4 deal with aisles with seating on both sides. Items 2 and 5 deal with aisles with seating on one side. Note that each exception is only applicable to the item directly above. For example, per Item 4, where there is seating on both sides, the minimum ramped or level aisle width is 42 inches (1219 mm),

except where that aisle serves less than 50 seats it can be 36 inches (914 mm) wide (Exception 1) and where that aisle serves less than 15 seats it can be 30 inches (762 mm) wide (Exception 2).

**1029.9.2 Aisle catchment area.** The *aisle* shall provide sufficient capacity for the number of persons accommodated by the catchment area served by the *aisle*. The catchment area served by an *aisle* is that portion of the total space served by that section of the *aisle*. In establishing catchment areas, the assumption shall be made that there is a balanced use of all *means of egress*, with the number of persons in proportion to egress capacity.

❖ The determination of required aisle and aisle accessway width is a function of the occupant load. In calculating the required widths, the assumption is that in a system or network of aisles and aisle accessways serving an occupied area, people will normally exit the area in a way that will distribute the occupant load throughout the system in proportion to the egress capacity of the aisles and aisle accessways. Each aisle and aisle accessway would take its tributary share (catchment area) of the total occupant load (see Commentary Figure 1029.9.2).

In addition to the provisions in this section, the requirement for the capacity of the main exit and other exits must also be considered (see Sections 1029.2 and 1029.3). While this section assumes an equal distribution, Section 1029.2 requires that where the facility has a main exit, the main exit and the access thereto must be capable of handling 50 percent of the occupant load.

**1029.9.3 Converging aisles.** Where *aisles* converge to form a single path of egress travel, the required capacity of that path shall be not less than the combined required capacity of the converging aisles.

❖ Where one or more aisles or aisle accessways meet to form a single path of egress travel, that path must be sized to handle the combined occupant capacity of the converging aisles and aisle accessways (see Commentary Figure 1029.9.3). The reason for this requirement is to maintain the natural pace of travel all the way through the aisle accessways or aisles to the exits and to minimize the queuing of occupants.

This section requires combining the required occupant capacity of converging aisles and aisle accessways, but not necessarily the required widths. For example, if two 48-inch (1219 mm) aisles converge, the result need not be a 96-inch (2438 mm) aisle unless the 48-inch (1219 mm) width of the aisles is required based on the requirements of Section 1029.6 for the actual occupant load served. However, if the 48-inch (1219 mm) width is not based on the occupant load but is required to comply with the minimum aisle width requirements of Section 1029.9.1, the resulting aisle width must be sized for the total occupant load served by the converging aisles, as determined by Section 1029.6, but not less than the minimum widths of Section 1029.9.1.

**MEANS OF EGRESS**

**1029.9.4 Uniform width and capacity.** Those portions of *aisles*, where egress is possible in either of two directions, shall be uniform in minimum width or required capacity.

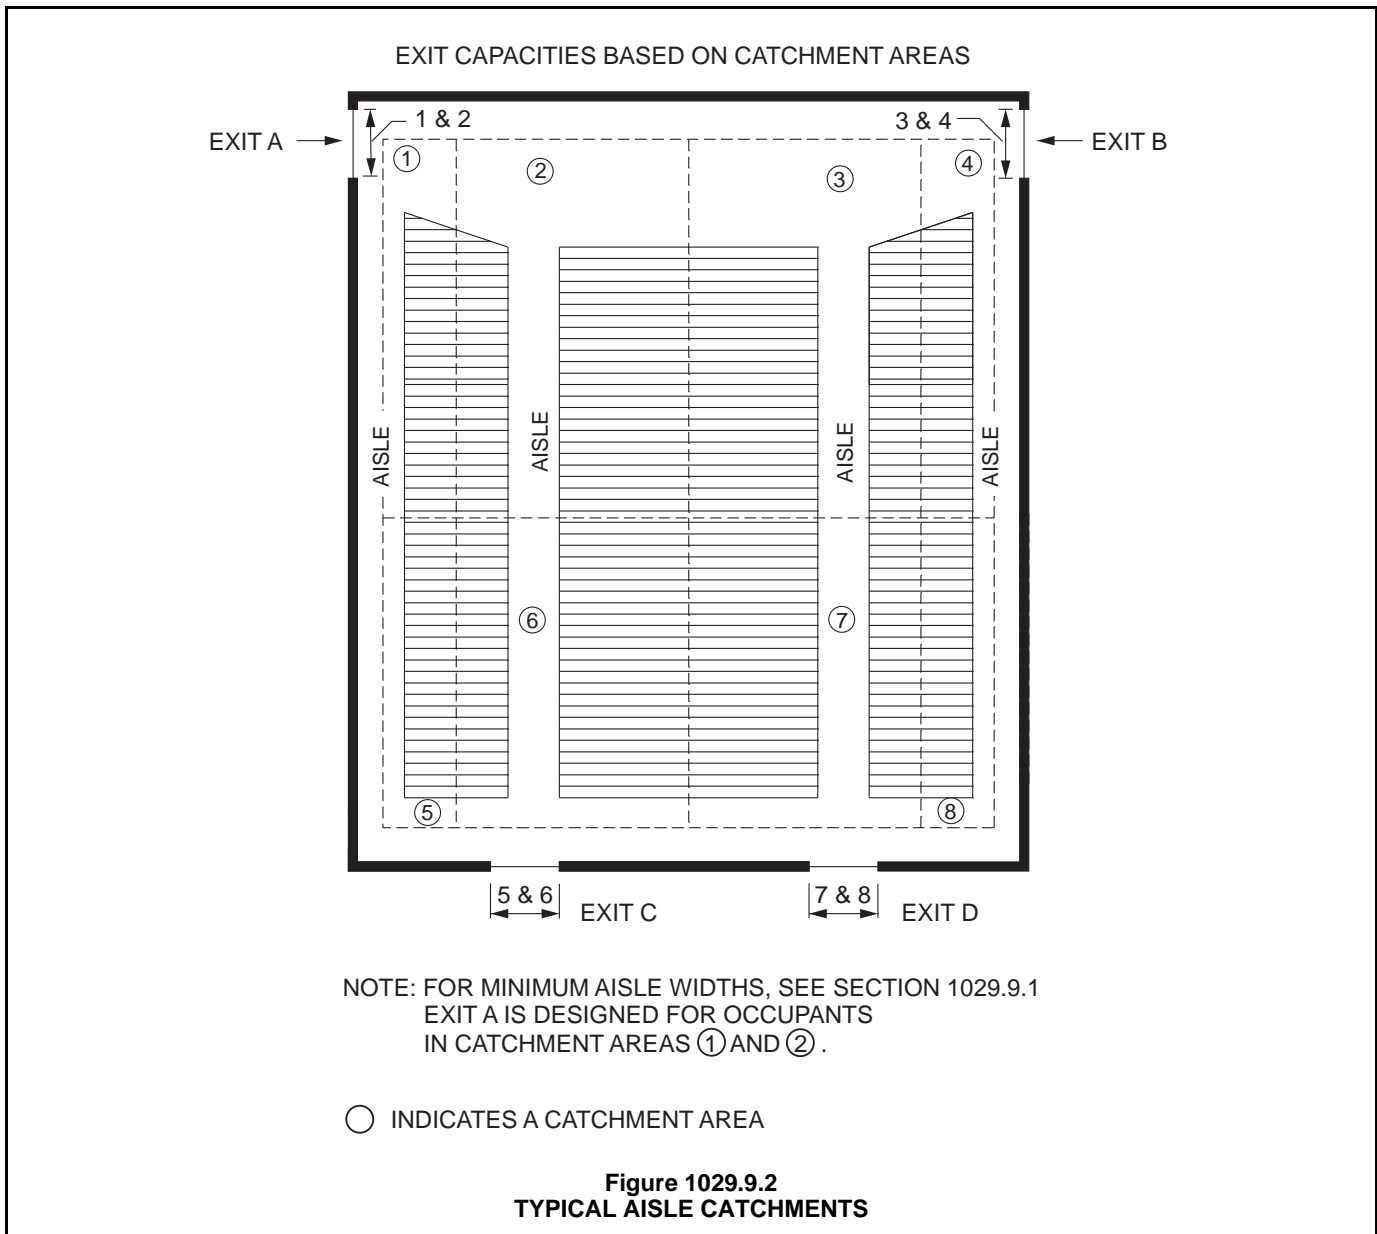

❖ Aisles that connect or lead to opposite exits must, at a minimum, be of uniform width throughout their entire lengths to allow for exit travel in two directions without creating a traffic bottleneck (see Commentary Figure 1029.9.4). They may need to be wider based on Section 1029.9.2 or 1029.9.3.

**1029.9.5 Dead end aisles.** Each end of an *aisle* shall be continuous to a cross *aisle*, foyer, doorway, vomitory, concourse or *stairway* in accordance with Section 1029.9.7 having access to an *exit*.

**Exceptions:**

1. Dead-end *aisles* shall be not greater than 20 feet (6096 mm) in length.

2. Dead-end *aisles* longer than 16 rows are permitted where seats beyond the 16th row dead-end *aisle* are not more than 24 seats from another *aisle*, measured along a row of seats having a minimum clear width of 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row where seats have backrests or beyond 10 where seats are without backrests in the row.
3. For *smoke-protected assembly seating*, the dead end *aisle* length of vertical *aisles* shall not exceed a distance of 21 rows.
4. For *smoke-protected assembly seating*, a longer dead-end *aisle* is permitted where seats beyond the 21-row dead-end *aisle* are not more than 40 seats from another *aisle*, measured along a row of seats having an *aisle* accessway with a minimum clear width of 12 inches (305 mm) plus 0.3 inch (7.6 mm)

for each additional seat above seven in the row where seats have backrests or beyond 10 where seats are without backrests in the row.

- ❖ Both ends of a cross aisle must terminate at either an intersecting aisle, a foyer, a doorway or a vomitory (lane) that gives access to an exit(s). Each exception allows an aisle to have a dead end of limited length. Exceptions 1 and 2 address dead-end aisles in assembly spaces with or without smoke protection. Exceptions 3 and 4 address dead-end aisles only in smoke-protected assembly seating. In accordance with Exception 1, dead-end aisles (similar to corridors and passageways) that terminate at one end of a cross aisle or at a foyer, doorway or vomitory must not be more than 20 feet (6096 mm) in length. The intent of the row width requirements in the exceptions is to provide sufficient clear width between rows of seating to allow the occupants in times of emergency to pass quickly from a dead-end aisle to the aisle at the opposite end.

In Exception 2, the 0.6-inch (15 mm) increase beyond seven seats with backrests is consistent with the minimum width determined in accordance with Section 1029.12.2 for single access rows. The code recognizes that one dead-end aisle may not be usable, thus creating a single access row condition. There is a greater allowance for seating that looks similar to bleacher style seating. This is consistent with ICC 300 (see Section 1029.1.1).

Exceptions 3 and 4 allow longer dead-end aisles for smoke-protected assembly seating that complies with Sections 1029.6.2 through 1029.6.2.3 or Section

1029.6.3 (see Commentary Figure 1026.9.5). In Exception 4, there is a greater allowance for seating that looks similar to bleacher style seating. This is consistent with ICC 300 (see Section 1029.1.1).

The overall purpose of this section is to provide aisle/seating arrangements that would allow the occupants to seek safe and rapid passage to exits in case of fire or other emergency.

**1029.9.6 Aisle measurement.** The clear width for *aisles* shall be measured to walls, edges of seating and tread edges except for permitted projections.

**Exception:** The clear width of *aisles* adjacent to seating at tables shall be permitted to be measured in accordance with Section 1029.12.1.

- ❖ The clear width for stepped, ramped and level aisles is measured consistently with stairways and ramps to ensure a clear width for egress. The exception is dealing with aisles in dining areas and how to measure with loose tables and chairs.

**1029.9.6.1 Assembly aisle obstructions.** There shall not be obstructions in the minimum width or required capacity of *aisles*.

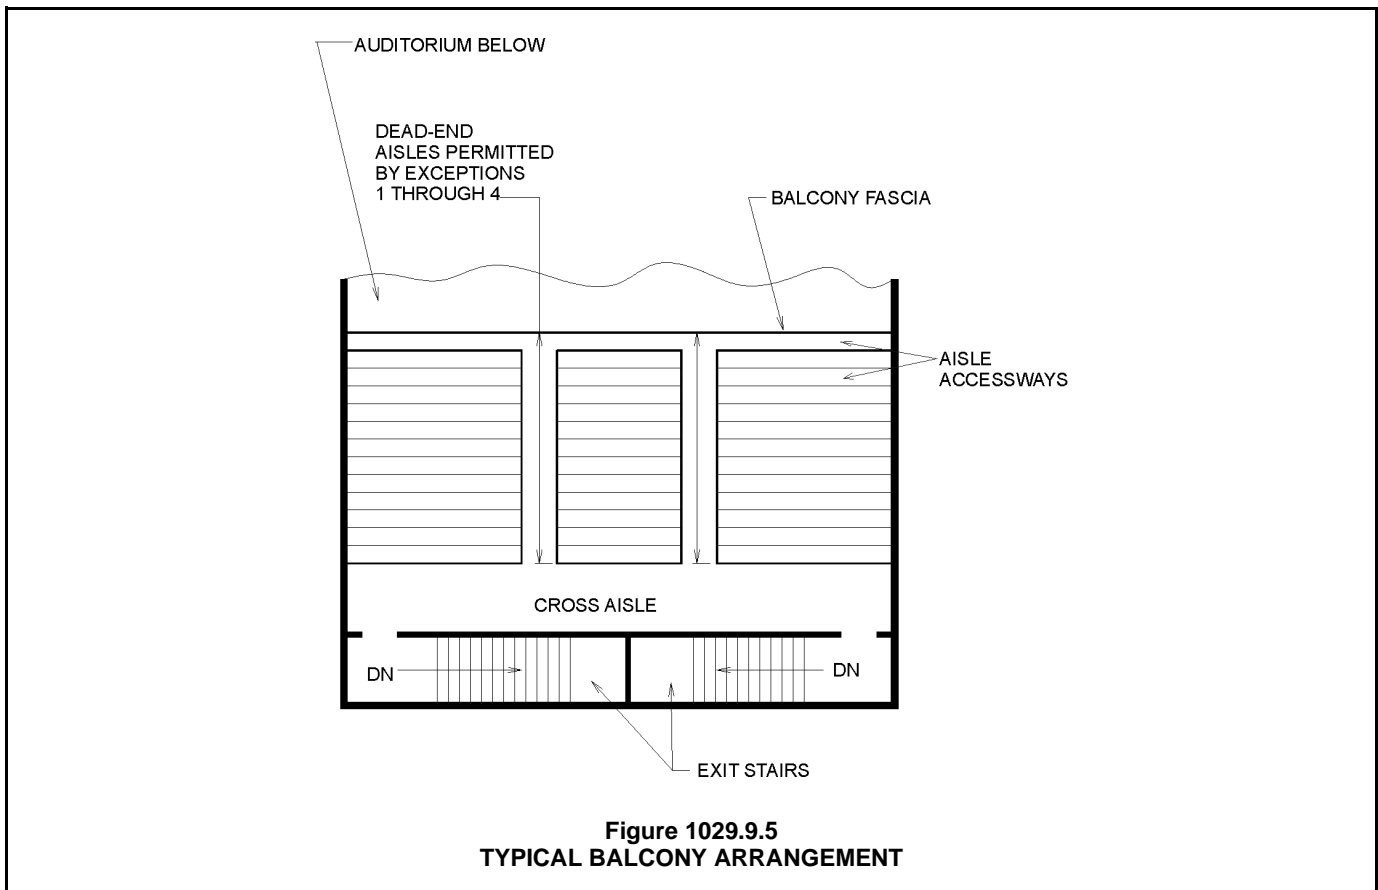

**Exception:** *Handrails* are permitted to project into the required width of stepped *aisles* and ramped *aisles* in accordance with Section 1014.8.

- ❖ Except for handrails, aisles are required to be clear of any obstructions so that the full width is available for egress purposes. Handrails are allowed to project into the required aisle width in the same manner as handrail projections in stairways.

For SI: 1 inch = 25.4 mm.

**Figure 1029.9.3**  
**COMPUTATION OF EXIT PASSAGE FOR CONVERGING AISLES**

**1029.9.7 Stairways connecting to stepped aisles.** A *stairway* that connects a stepped *aisle* to a cross *aisle* or concourse shall be permitted to comply with the assembly *aisle* walking surface requirements of Section 1029.13. Transitions between *stairways* and stepped *aisles* shall comply with Section 1029.10.

- ❖ Stairways that are a direct continuation of a stepped aisle, either at the top or bottom of the stepped aisle, and provide access to a cross aisle, shall be handled the same way as a stepped aisle for treads and risers (see Section 1029.13). For the transitions between the stepped aisle and the stairway, see Section 1029.10. For examples, see Figures 1029.9.7(1) and 1029.9.7(2).

**1029.9.8 Stairways connecting to vomitories.** A *stairway* that connects a vomitory to a cross aisle or concourse shall be permitted to comply with the assembly *aisle* walking surface requirements of Section 1029.13. Transitions between *stairways* and stepped *aisles* shall comply with Section 1029.10.

- ❖ A vomitory is an entrance that pierces the back of a seating bowl of a theater or stadium that allows for entrance into the seating area. Stairways that provide a direct connection between that vomitory and an aisle or concourse shall be handled the same way as a stepped aisle for treads and risers (see Section 1029.13). For the transitions between the stepped aisle and the stairway, see Section 1029.10.

**1029.10 Transitions.** Transitions between *stairways* and stepped *aisles* shall comply with either Section 1029.10.1 or 1029.10.2.

- ❖ Line of sight in assembly seating is an important issue that needs to be balanced with safe egress for people seated in the assembly spaces. In order to maintain line of site, sometime it is necessary to have a transition between stairways and stepped aisles that does not meet the standard tread, riser and land-

ing provisions for stairway. This section replaces the standard landing requirements for stairways with a transition tread/landing.

**1029.10.1 Transitions and stairways that maintain stepped aisle riser and tread dimensions.** Stepped *aisles*, transitions and *stairways* that maintain riser and tread dimensions shall comply with Section 1029.13 as one *exit access* component.

- ❖ Where the treads and risers on the stairway and the treads and risers on the stepped aisle are the same, the whole run can be considered as one long stepped aisle.

**1029.10.2 Transitions to stairways that do not maintain stepped aisle riser and tread dimensions.** Transitions to *stairways* from stepped *aisles* with riser and tread dimensions that differ from the *stairways* shall comply with Sections 1029.10.2.1 through 1029.10.3.

- ❖ Where the stepped aisle and directly connected stairways do not have the same tread and riser dimensions, there are options for the transition between the two sections. This transition is the tread(s) between the stepped aisle and the stairway.

**1029.10.2.1 Stairways and stepped aisles in a straight run.** Transitions where the *stairway* is a straight run from the stepped *aisle* shall have a minimum depth of 22 inches (559 mm) where the treads on the descending side of the transition have greater depth and 30 inches (762 mm) where the treads on the descending side of the transition have lesser depth.

- ❖ Typically, the treads on the stairway will have a smaller depth than the treads at the seating. Assuming that is the case, where the stairway is at the high end of the stepped aisle, a transition tread 22 inches (559 mm) in depth shall be provided between the stairway and the stepped aisle [see Commentary Figure 1029.10.2.1(1)]. Where the stairway is at the low

**Figure 1029.9.7(1)**  
EXAMPLE OF A CONTINUATION OF  
A STEPPED AISLE UP TO A CROSS AISLE

**Figure 1029.9.7(2)**  
EXAMPLE OF A CONTINUATION OF  
A STEPPED AISLE DOWN TO A FLOOR

## MEANS OF EGRESS

end of the stepped aisle, a transition tread a minimum of 30 inches (762 mm) in depth shall be provided between the stepped aisle and the stairway [see Commentary Figure 1029.10.2.1(2)].

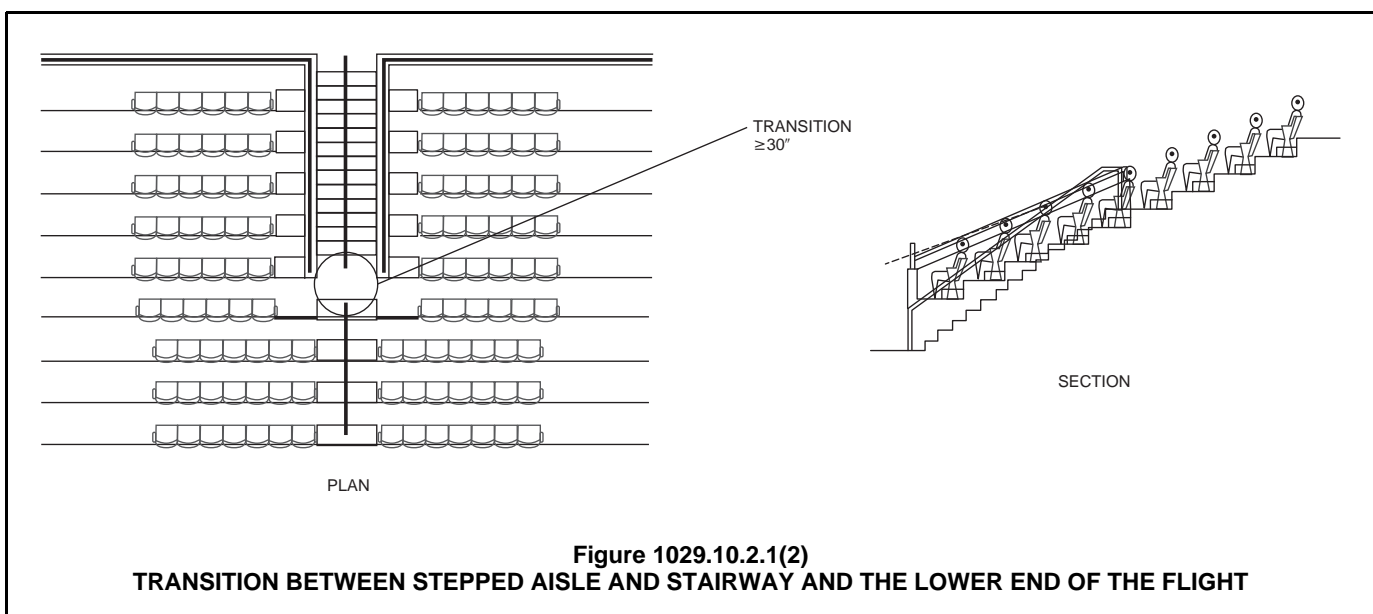

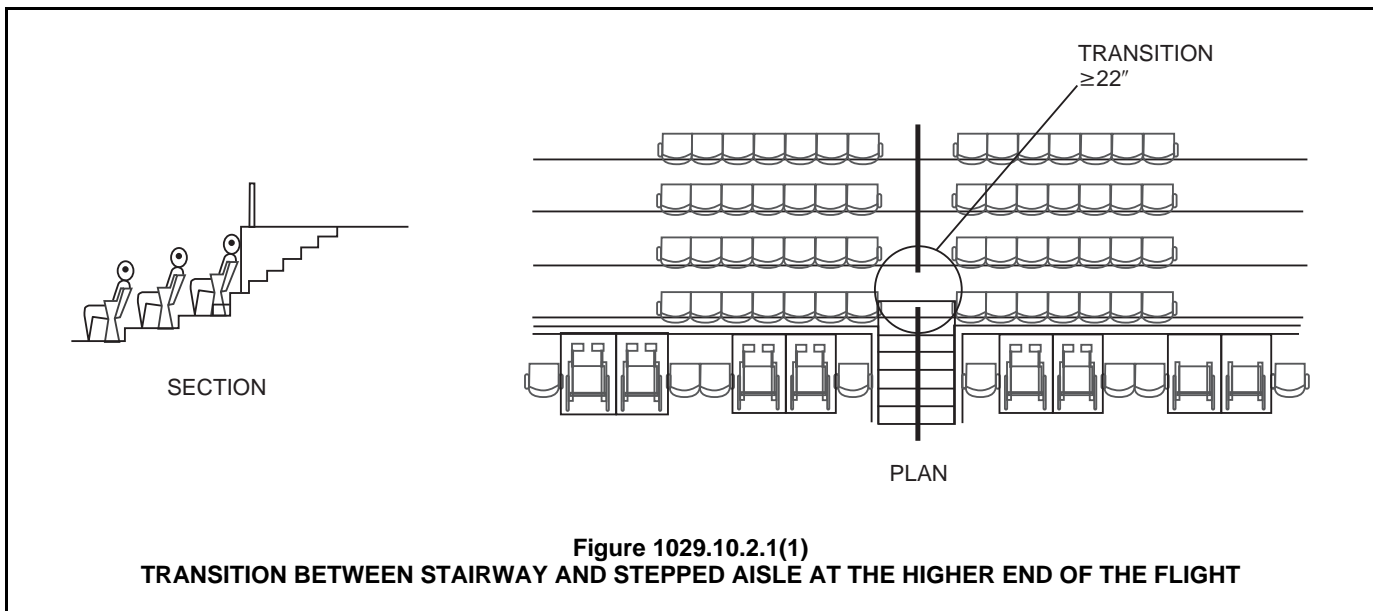

**1029.10.2.2 Stairways and stepped aisles that change direction.** Transitions where the *stairway* changes direction from the stepped *aisle* shall have a minimum depth of 11 inches (280 mm) or the stepped *aisle* tread depth, whichever is greater, between the stepped *aisle* and *stairway*.

❖ Where the stepped aisle takes a turn or takes a turn and becomes a stairway, the aisle width must be maintained (see Sections 1029.6 and 1029.9.1). The transition between the stepped aisle and the turn must continue the tread depth of the stepped aisle, or have a minimum depth of 11 inches (280 mm) to match the stairway treads, whichever is greater.

There may be more than one transition between the stepped aisle and the turn [see Commentary Figures 1029.10.2.2(1) and 1029.10.2.2(2)].

**1029.10.3 Transition marking.** A distinctive marking stripe shall be provided at each *nosing* or leading edge adjacent to the transition. Such stripe shall be not less than 1 inch (25 mm), and not more than 2 inches (51 mm), wide. The edge marking stripe shall be distinctively different from the stepped *aisle* contrasting marking stripe.

❖ At these transitions there may be a change in riser height, even if the tread depth stayed the same. The stripe is to draw attention to the transition to reduce the chance of a trip and fall. This is different from the stripes required for the stepped aisles in Sections 1029.13.2.2.1 and 1029.13.2.3.

**1029.11 Construction.** *Aisles*, stepped *aisles* and ramped *aisles* shall be built of materials consistent with the types permitted for the type of construction of the building.

**Exception:** Wood *handrails* shall be permitted for all types of construction.

❖ The construction materials permitted for stepped, ramped and level aisles are consistent with stairways and ramps.

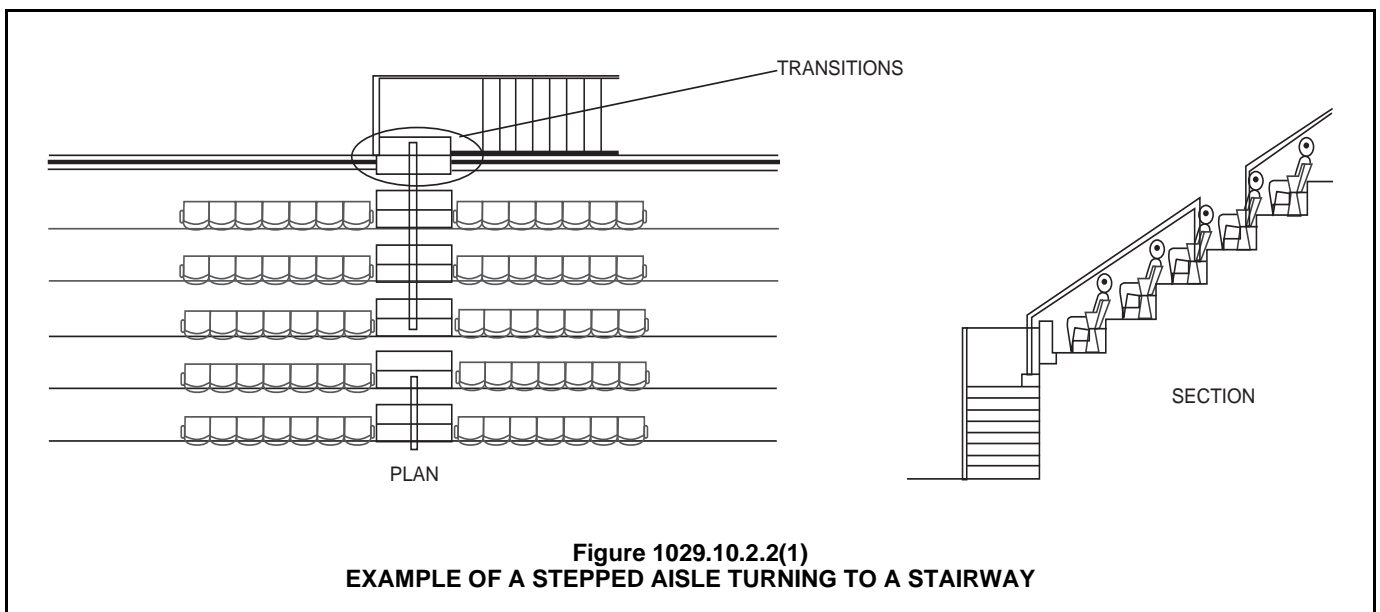

**1029.11.1 Walking surface.** The surface of *aisles*, stepped *aisles* and ramped *aisles* shall be of slip-resistant materials that are securely attached. The surface for stepped *aisles* shall comply with Section 1011.7.1.

❖ It is the intent of this section that for walking surfaces, stepped aisles will be addressed similar to stairways

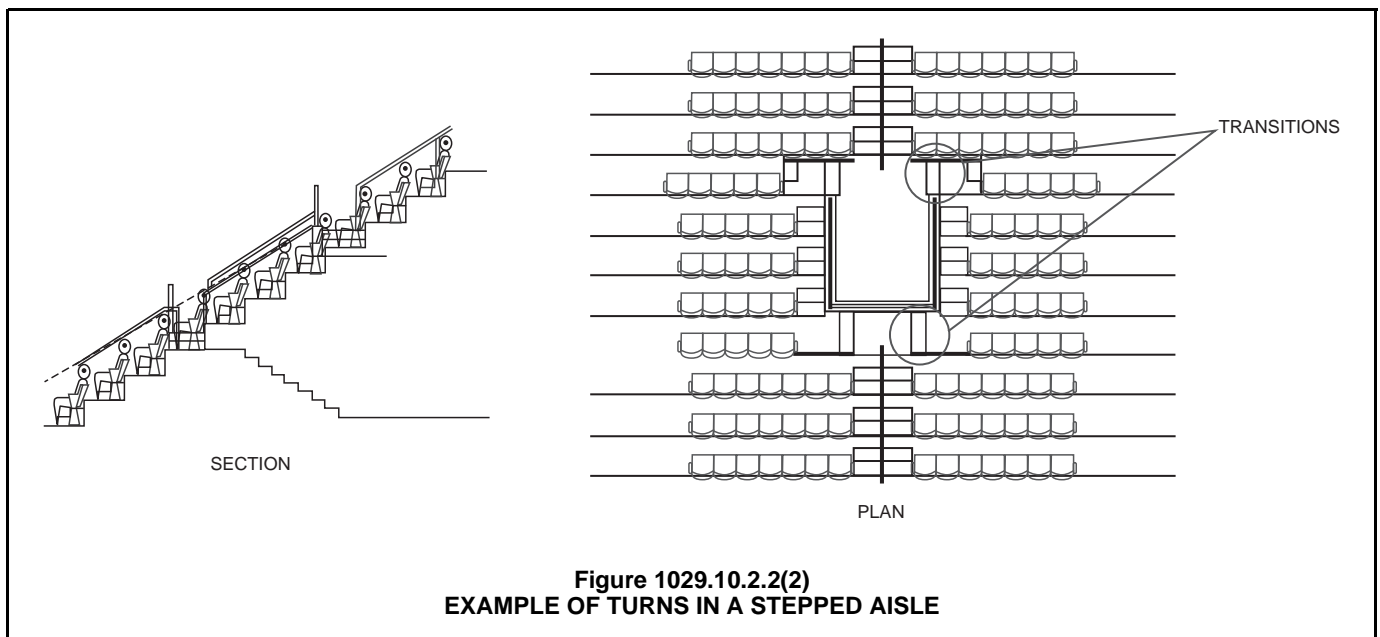

(Section 1011.7.1), level aisles the same as floors (Section 1003.4) and ramped aisles the same as ramps (Section 1012.7.1). See the commentary for these sections.

**1029.11.2 Outdoor conditions.** Outdoor *aisles*, stepped *aisles* and ramped *aisles* shall be designed so that water will not accumulate on the walking surface.

❖ Where stepped, ramped and level aisles are located in an outdoor situation, there is the same concern for the accumulation of ice and snow as there would be for exterior stairways or ramps. See Sections 1011.7.2 and 1012.7.2 regarding maximum slope to allow for drainage and when grated walking surfaces are permitted.

**Figure 1029.10.2.2(1)**  
**EXAMPLE OF A STEPPED AISLE TURNING TO A STAIRWAY**

**Figure 1029.10.2.2(2)**  
**EXAMPLE OF TURNS IN A STEPPED AISLE**

## MEANS OF EGRESS

**1029.12 Aisle accessways.** *Aisle accessways* for seating at tables shall comply with Section 1029.12.1. *Aisle accessways* for seating in rows shall comply with Section 1029.12.2.

❖ Aisle accessways are paths for means of egress between rows of seats or between tables. The aisle accessway leads to aisles, which in turn lead toward exits from the space. This is the same idea as moving through a room full of furniture to a corridor to reach an exit. In both situations, the path for means of egress is confined. For aisle accessway requirements in other occupancies, see Section 1018.

**1029.12.1 Seating at tables.** Where seating is located at a table or counter and is adjacent to an *aisle* or *aisle accessway*, the measurement of required clear width of the *aisle* or *aisle accessway* shall be made to a line 19 inches (483 mm) away from and parallel to the edge of the table or counter. The 19-inch (483 mm) distance shall be measured perpendicular to the side of the table or counter. In the case of other side boundaries for *aisles* or *aisle accessways*, the clear width shall be measured to walls, edges of seating and tread edges.

**Exception:** Where tables or counters are served by *fixed seats*, the width of the *aisle* or *aisle accessway* shall be measured from the back of the seat.

❖ Most seating at tables should be adjacent to aisles or aisle accessways. In measuring the width of an aisle or aisle accessway for movable seating, the measurement is taken at a distance of 19 inches (483 mm) perpendicular to the side of the table or counter. This 19-inch (483 mm) space from the edge of the table or counter to the line where the aisle or aisle accessway measurement begins is intended to represent the space occupied by a typical seated occupant. This dimension is also considered to be adequate to accommodate seats with armrests that are too high to fit under the table where fixed seats are used. The aisle width is permitted to be measured

from the back of the seat based on the exception. As indicated in Commentary Figure 1029.12.1, where seating abuts an aisle or aisle accessway, 19 inches (483 mm) must be added to the required aisle or aisle accessway width for seating on only one side and 38 inches (965 mm) for seating on both sides. When seating will not be adjacent to the aisles or aisle passageways, as is the case when tables are at an angle to the aisle or aisle accessway, the measurement may be taken to the edge of the seating, table, counter or tread. Sections 1029.12.1.1 and 1029.12.1.2 address width and travel along aisle accessways. For aisles between tables, see the general requirements for aisles in assembly spaces.

**1029.12.1.1 Aisle accessway capacity and width for seating at tables.** *Aisle accessways* serving arrangements of seating at tables or counters shall comply with the capacity requirements of Section 1005.1 but shall not have less than 12 inches (305 mm) of width plus  $\frac{1}{2}$  inch (12.7 mm) of width for each additional 1 foot (305 mm), or fraction thereof, beyond 12 feet (3658 mm) of *aisle accessway* length measured from the center of the seat farthest from an *aisle*.

**Exception:** Portions of an *aisle accessway* having a length not exceeding 6 feet (1829 mm) and used by a total of not more than four persons.

❖ This section specifies two criteria for the determination of the required width of aisle accessways at tables: the requirements of Section 1005.1 for capacity based on the number of occupants and the option described in this section. The aisle accessway width is to be the wider of the two requirements. The aisle accessway width between tables is determined similarly to the aisle accessway between rows of seats that view an event.

The relationship of tables and seating sometimes results in a situation in which it is difficult to determine which chairs are served by which aisle accessway; therefore, the width of the aisle accessway is a func-

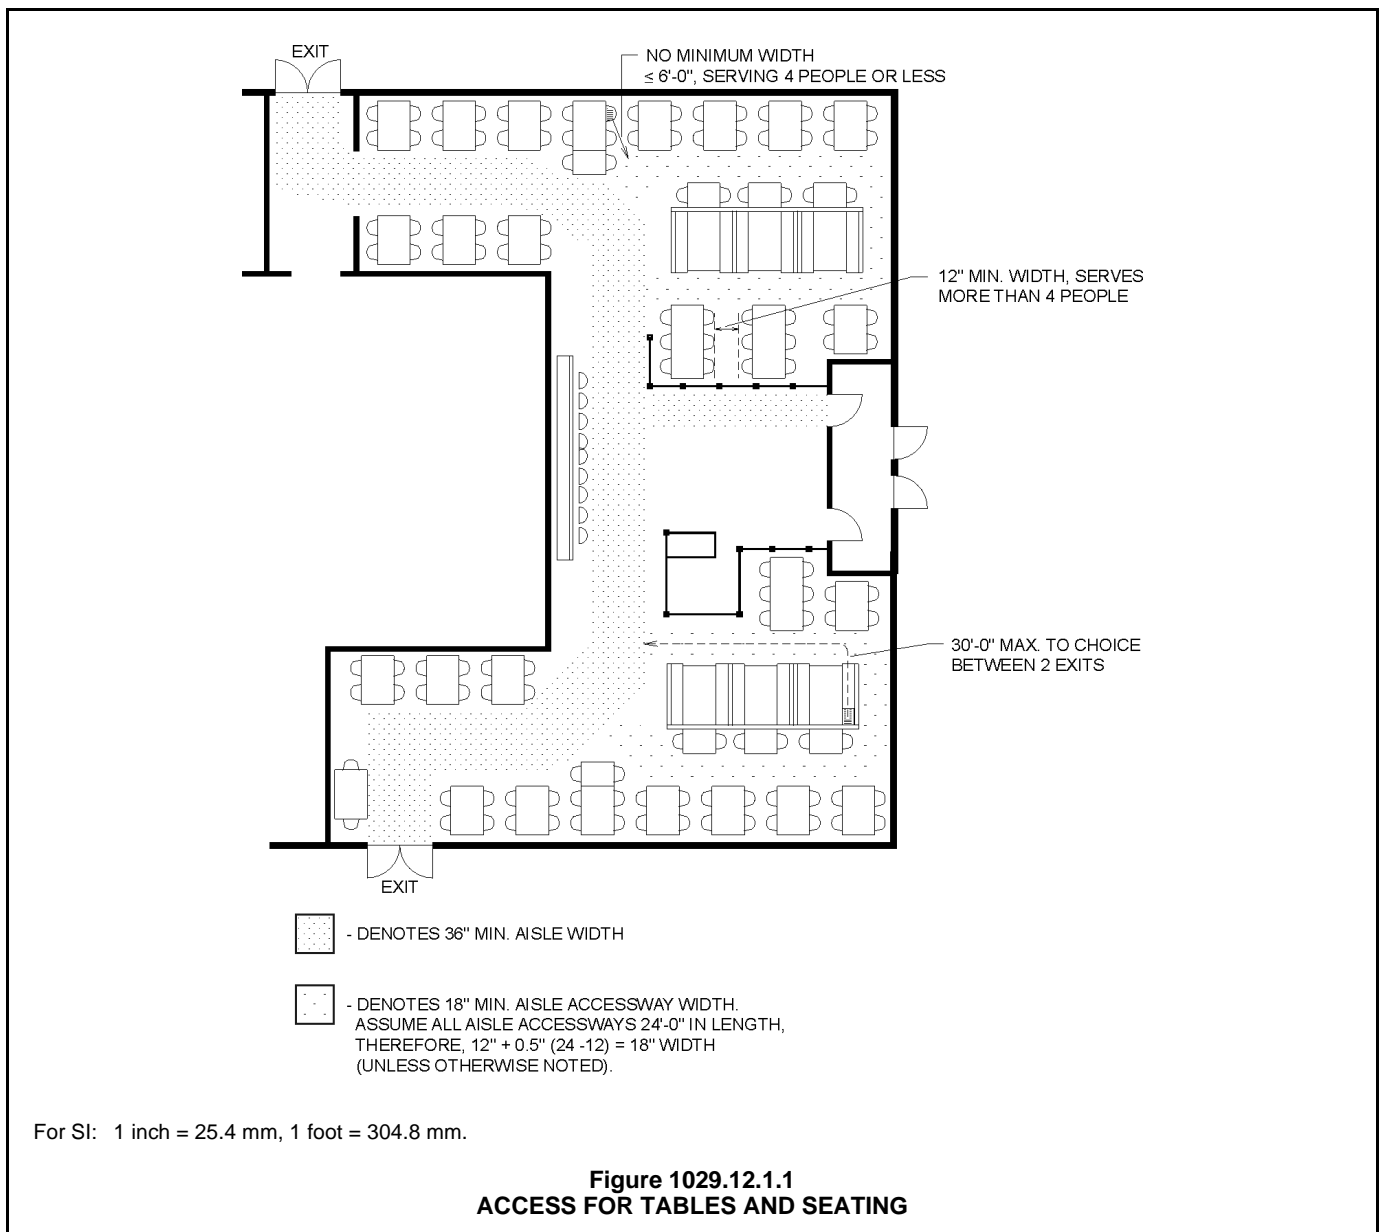

tion of the distance from the aisle. The same minimum 12 inches (305 mm) is used and is increased 1/2 inch (12.7 mm) for each additional foot of travel beyond 12 feet (3658 mm).

Recognizing that the normal use of table and chair seating will require some clearance for access and service, the exception eliminates the minimum width criteria if the distance to the aisle [or an aisle accessway of at least 12 inches (305 mm)] is less than 6 feet (1829 mm) and the number of people served is not more than four. Therefore, the first 6 feet (1829 mm) are not required to meet any minimum width criteria. After the first 6 feet (1829 mm), the requirements for an aisle accessway will apply. The length of the aisle accessway is then restricted by Section 1029.12.1.2. When the maximum length of the aisle accessway is reached, an aisle, corridor or exit access door must be provided (see Commentary Figure 1029.12.1.1).

**1029.12.1.2 Seating at table aisle accessway length.** The length of travel along the *aisle accessway* shall not exceed 30 feet (9144 mm) from any seat to the point where a person has a choice of two or more paths of egress travel to separate exits.

❖ At some point in the exit access travel, it is necessary to reach an aisle complying with the minimum widths of Section 1029.9.1. Aisle accessway travel distance for seating at tables is not to exceed 30 feet (9144 mm), which may represent a dead-end condition (see Commentary Figure 1029.12.1.1).

More and more sports facilities are starting to add venues that include dining while watching the sporting event. At this time, the code does not include provisions for dining that occurs in smoke-protected areas.

## MEANS OF EGRESS

**1029.12.2 Clear width of aisle accessways serving seating in rows.** Where seating rows have 14 or fewer seats, the minimum clear *aisle accessway* width shall be not less than 12 inches (305 mm) measured as the clear horizontal distance from the back of the row ahead and the nearest projection of the row behind. Where chairs have automatic or self-rising seats, the measurement shall be made with seats in the raised position. Where any chair in the row does not have an automatic or self-rising seat, the measurements shall be made with the seat in the down position. For seats with folding tablet arms, row spacing shall be determined with the tablet arm in the used position.

**Exception:** For seats with folding tablet arms, row spacing is permitted to be determined with the tablet arm in the stored position where the tablet arm when raised manually to vertical position in one motion automatically returns to the stored position by force of gravity.

❖ The requirements of this section are applicable to theater-type seating arrangements. This includes both “continental” and “traditional” seating arrangements. Theater-type seating is characterized by a number of seats arranged side by side and in rows. In this type of seating arrangement, the potential exists for a large number of occupants to be present in a confined environment where the ability of the occupants to move quickly is limited. In order to egress, people are required to move single file within a narrow row (i.e., aisle accessway) before reaching an aisle; both the aisle or aisle accessway limit movement toward an exit. To provide adequate passage between rows of seats, this section requires that the clear width between the back of a row to the nearest projection of the seating immediately behind must be at least 12 inches (305 mm) [see Commentary Figure 1029.12.2(1)]. Where chairs are manufactured with automatic or self-lifting seats, the minimum width requirement may be measured with the seats in a raised position. Commonly used in college lecture halls, seats with built-in tablet arms are provided so that students can take notes. For an example of a type of tablet arm that complies with the exception,

see Commentary Figure 1029.12.2(2).

When tablet chairs are used, the required width is to be determined with the tablet arm in its usable position. The exception allows for folding tablet arms that fall back into the stored position when a person rises out of the seat. With seats occupied and tablets raised, students egressing en masse down the row would at most encounter one tablet to move out of the way. With these types of arms, the aisle accessway can be measured for the seat or arm as indicated in Commentary Figure 1029.12.2(1).

With respect to self-rising seats, ASTM F851 provides one method of determining acceptability.

**1029.12.2.1 Dual access.** For rows of seating served by *aisles* or doorways at both ends, there shall be not more than 100 seats per row. The minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.3 inch (7.6 mm) for every additional seat beyond 14 seats where seats have backrests or beyond 21 where seats are without backrests.

For SI: 1 inch = 25.4 mm.

**Figure 1029.12.2(2)**  
**EXAMPLE OF FOLDING TABLET ARMS**

For SI: 1 inch = 25.4 mm.

**Figure 1029.12.2(1)**  
**MINIMUM REQUIRED ROW WIDTH CLEARANCE FOR AISLE ACCESSWAYS**

The minimum clear width is not required to exceed 22 inches (559 mm).

**Exception:** For *smoke-protected assembly seating*, the row length limits for a 12-inch-wide (305 mm) *aisle accessway*, beyond which the *aisle accessway* minimum clear width shall be increased, are in Table 1029.12.2.1.

- ❖ Where rows of seating are served by aisles or doorways located at both ends of the path of row travel, the number of seats that may be used in a row may be up to, but not more than, 100 (continental seating) and the minimum required clear width aisle accessway of 12 inches (305 mm) between rows of seats must be increased by 0.3 inch (8 mm) for every additional seat with backrests beyond 14, but not more than a total of 22 inches (559 mm) (see Commentary Figure 1029.12.2.1). The increase for seating without backrests is to allow for bench seating similar to bleacher requirements in ICC 300 (see Section 1029.1.1). For example, in a row of 24 seats, the minimum clear width would compute to 15 inches (381 mm) [12 + (0.3 x 10)]. For a row of 34 seats, a clear width of 18 inches (457 mm) would be required. Increases in the clear width between rows of seats would occur up to a row of 46 seats. From 47 to 100 seats, a maximum clear width between rows of 22 inches (559 mm) would apply.

Since the row is to provide access to an aisle in both directions, the minimum width applies to the entire length of the row aisle accessway.

The exception allows more seats in a row with the minimum 12-inch (305 mm) seat spacing since safe egress time is extended for this condition.

When a second means of egress for occupants of a single access row is possible through an adjacent dual access row, see Section 1029.8.1.

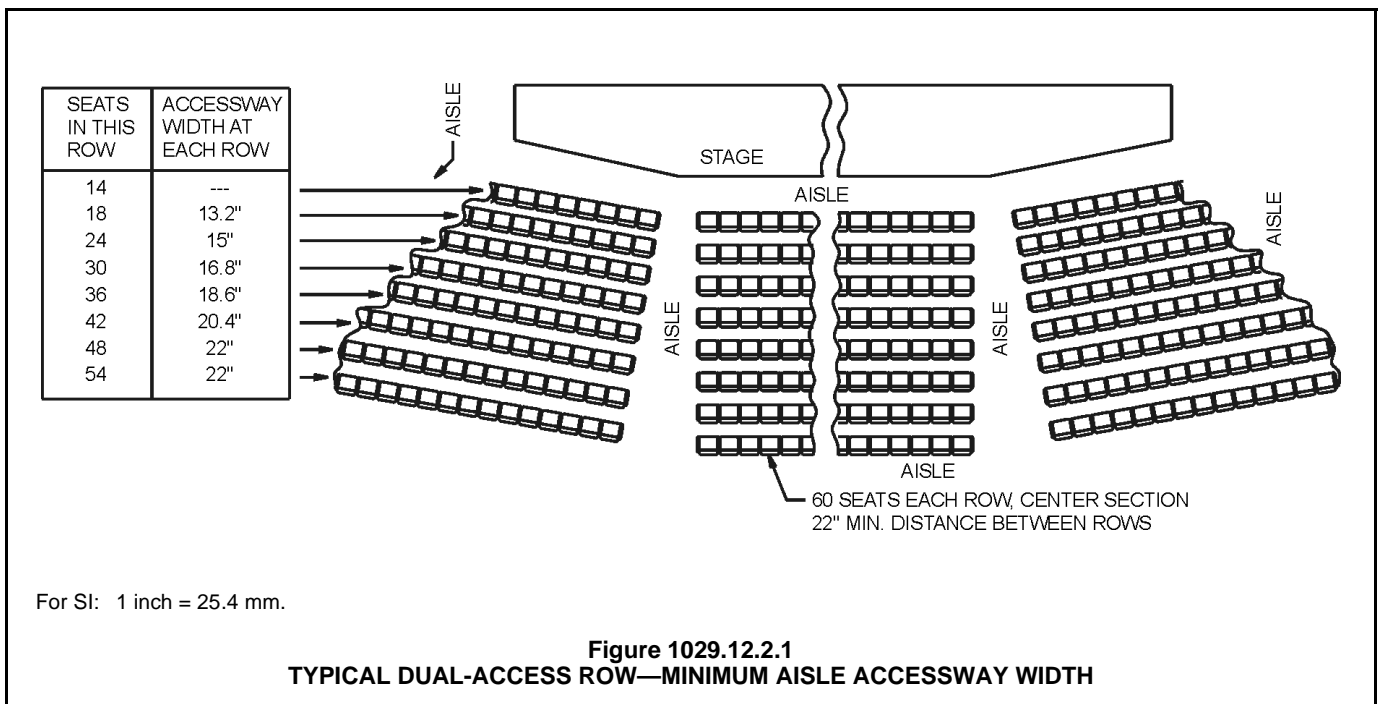

**TABLE 1029.12.2.1.** See page 10-202.

- ❖ Table 1029.10.1 recognizes the increased egress time available in smoke-protected assembly seating areas. Therefore, the table permits greater lengths of rows that have the minimum 12 inches (305 mm) of clear width. When a row exceeds the lengths identified in the table, the row width is to be increased in accordance with Section 1029.12.2.1 [0.3 inch (8 mm) per additional seat] for dual-access rows and Section 1029.12.2.2 [0.6 inch (15 mm) per additional seat] for single-access rows. Column one in this table is based on the total number of seats contained within the assembly space, not the seats per level. The increase for seating without backrests is to allow for bench seating similar to bleacher requirements in ICC 300 (see Section 1029.1.1).

**1029.12.2.2 Single access.** For rows of seating served by an *aisle* or doorway at only one end of the row, the minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.6 inch (15.2 mm) for every additional seat beyond seven seats where seats have backrests or beyond 10 where seats are without backrests. The minimum clear width is not required to exceed 22 inches (559 mm).

**Exception:** For *smoke-protected assembly seating*, the row length limits for a 12-inch-wide (305 mm) *aisle accessway*, beyond which the *aisle accessway* minimum clear width shall be increased, are in Table 1029.12.2.1.

- ❖ Where rows of seating are served by an aisle or doorway at only one end of a row, the minimum clear width of 12 inches (305 mm) between rows of seats must be increased by 0.6 inch (15 mm) for every additional seat beyond seven for seats with backrests, but not more than a total of 22 inches (559 mm) (see Commentary Figure 1029.12.2.2). The increase

**MEANS OF EGRESS**

for seating without backrests is to allow for bench seating similar to bleacher requirements in ICC 300 (see Section 1029.1.1). While this section does not specify the maximum number of seats permitted in a row, the 30-foot (9144 mm) common path of travel limitation (see Section 1029.8) essentially restricts the single-access row to approximately 20 seats, based on an 18-inch (457 mm) width per seat. A row of 12 seats with backrests would compute to a required minimum width of 15 inches [12 + (0.5 x 5)]. Similarly, a row of 17 seats with backrests would require a clear width of 18 inches (457 mm) and so on. Since dual access is not provided, incremental increases would be permitted in the aisle accessway width as shown in Commentary Figure 1029.12.2.2. Incremental increases in the required width would occur up to the maximum number of seats, which is determined by the 30-foot (9144 mm) dead-end limitation.

The reason for increasing the row accessway widths incrementally with increases in the number of seats per row is to provide more efficient passage for the occupants who are using the aisle accessway. As

a practical matter, where dual-access (see Section 1029.12.2.1) and single-access seating arrangements are used together, the largest computed clear width dimension would normally be applied by the designer to both arrangements so that the rows of seats will be in alignment. When a second means of egress for occupants of a single-access row is possible through an adjacent dual access row, see Section 1029.8.1.

**1029.13 Assembly aisle walking surfaces.** Ramped *aisles* shall comply with Sections 1029.13.1 through 1029.13.1.3. Stepped *aisles* shall comply with Sections 1029.13.2 through 1029.13.2.4.

❖ Assembly facilities such as theaters and auditoriums often require sloping or stepped floors to provide seated occupants with preferred sightlines for viewing presentations (for sightlines for wheelchair spaces, see IBC Section 1108.2). Aisles must, therefore, be designed to accommodate the changing elevations of the floor in such a manner that the path of travel will allow occupants to leave the area at a rapid pace with minimal possibilities for stumbling or falling during times of emergency.

**[BE] TABLE 1029.12.2.1  
SMOKE-PROTECTED ASSEMBLY AISLE ACCESSWAYS**

TOTAL NUMBER OF SEATS IN THE SMOKE-PROTECTED ASSEMBLY SEATING	MAXIMUM NUMBER OF SEATS PER ROW PERMITTED TO HAVE A MINIMUM 12-INCH CLEAR WIDTH AISLE ACCESSWAY			
	Aisle or doorway at both ends of row		Aisle or doorway at one end of row only	
	Seats with backrests	Seats without backrests	Seats with backrests	Seats without backrests
Less than 4,000	14	21	7	10
4,000	15	22	7	10
7,000	16	23	8	11
10,000	17	24	8	11
13,000	18	25	9	12
16,000	19	26	9	12
19,000	20	27	10	13
22,000 and greater	21	28	11	14

For SI: 1 inch = 25.4 mm.

**1029.13.1 Ramped aisles.** *Aisles* that are sloped more than one unit vertical in 20 units horizontal (5-percent slope) shall be considered a ramped *aisle*. Ramped *aisles* that serve as part of an *accessible route* in accordance with Sections 1009 and 1108.2 shall have a maximum slope of one unit vertical in 12 units horizontal (8-percent slope). The slope of other ramped *aisles* shall not exceed one unit vertical in 8 units horizontal (12.5-percent slope).

❖ Similar to the definition for ramp in Chapter 2, aisles that slope 1:20 or less are considered sloped aisles, but are not ramps. Note that ramps that serve as part of an accessible route to and from accessible wheelchair spaces (Section 1009 and IBC Section 1108.2) must comply with the more restrictive requirements for ramps in Section 1012. This section requires that aisles with a gradient from 1:20 to 1:8 (12.5 percent slope) must meet the ramped aisle provisions in this section. Aisles with a gradient exceeding one unit vertical and eight units horizontal (12.5-percent slope) must consist of a series of treads and risers that comply with the requirements of stepped aisles in Section 1029.13.2.

**1029.13.1.1 Cross slope.** The slope measured perpendicular to the direction of travel of a ramped *aisle* shall not be steeper than one unit vertical in 48 units horizontal (2-percent slope).

❖ The limitation of one unit vertical in 48 units horizontal on the slope across the direction of travel is to prevent a severe cross slope that would pitch a user to one side (see Commentary Figure 1012.2).

**1029.13.1.2 Landings.** Ramped *aisles* shall have landings in accordance with Sections 1012.6 through 1012.6.5. Landings for ramped *aisles* shall be permitted to overlap required *aisles* or cross *aisles*.

❖ The reference for ramp landings to Sections 1012.6 through 1012.6.5 picks up the requirements for ramps to have a landing at the top and bottom of each run and when ramps change direction. This also includes requirements for landing slope, width and length. This does not pick up the requirement for ramps to have a landing at every 30 inches (762 mm) in rise as indicated in Section 1012.4. This is in consideration of the line of sight requirements for the different venues and the ability to provide a safe and smooth transition between the ramped aisles and the adjacent aisle accessways as patrons move into and out of their rows. A cross aisle or aisle can also serve as the ramp landing as long as it meets the 1:48 maximum slope provisions for landings.

**1029.13.1.3 Edge protection.** Ramped *aisles* shall have edge protection in accordance with Sections 1012.10 and 1012.10.1.

**Exception:** In assembly spaces with *fixed seating*, edge protection is not required on the sides of ramped *aisles* where the ramped *aisles* provide access to the adjacent seating and *aisle accessways*.

❖ Where an aisle has a dropoff on either side, it needs edge protection. In a seating venue, this would typi-

cally be the ramped aisle at the perimeter of the seating. This edge protection can be a wall, a horizontal rail that prevents the passage of a 4-inch (102 mm) sphere between the ramp surface and the rail, or a minimum 4-inch-high (102 mm) curb (see Commentary Figure 1012.10.1). Edge protection is not required between the ramped aisle and adjacent seating, including wheelchair seating spaces, as this could be a tripping hazard for people coming in and out of the rows.

**1029.13.2 Stepped aisles.** *Aisles* with a slope exceeding one unit vertical in eight units horizontal (12.5-percent slope) shall consist of a series of risers and treads that extends across the full width of *aisles* and complies with Sections 1029.13.2.1 through 1029.13.2.4.

❖ What must be recognized here is that stepped aisles are part of the floor construction and are intended to provide horizontal egress. Tread and riser construction for this purpose should not be directly compared to the requirements for treads and risers in conventional stairways that serve as means of vertical egress. Sometimes, because of design considerations, the gradient of an aisle is required to change from a level floor to a ramp and then to steps. In cases where there is no uniformity in the path of travel, occupants tend to be considerably more cautious, particularly in the use of stepped aisles, than they would normally be in the use of conventional stairways.

This section requires aisles with a slope of greater than 1:8 to use steps. Aisles with slopes of greater than 1:20 to 1:8 must comply with provisions for ramped aisles in Section 1029.13.1.

**1029.13.2.1 Treads.** Tread depths shall be not less than 11 inches (279 mm) and shall have dimensional uniformity.

**Exception:** The tolerance between adjacent treads shall not exceed  $\frac{3}{16}$  inch (4.8 mm).

❖ Depths of treads are not to be less than 11 inches (279 mm) and uniform throughout each flight, except that a variance of not more than  $\frac{3}{16}$  inch (4.8 mm) is permitted between adjacent treads to accommodate variations in construction. While the minimum tread depth provision is the same as the limiting dimension for treads in interior stairways (see Section 1011.5.2), it rarely applies in the construction of stepped aisles. A more common form of stepped aisle construction is to provide a tread depth equal to the back-to-back distance between rows of seats. This way the treads can be extended across the full length of the row and serve as a supporting platform for the seats. Other arrangements might require two treads between rows of seats, each tread equaling one-half of the depth of the seat row.

In theaters, for example, the back-to-back distance between rows of fixed seats usually ranges somewhere between 3 and 4 feet (914 and 1219 mm), depending on seat style and seat dimensions as well as the ease of passage between the rows (see Com-

## MEANS OF EGRESS

mentary Figure 1029.13.2.1). The selection of single-tread or two-tread construction between rows of seats depends on the gradient and suitable riser height (see Section 1029.13.2.2), as needed for sightlines.

In comparing this section to Section 1029.13.2.2, it is significant to note the emphasis placed on the tread dimension. While not desirable, the code permits riser heights to deviate; however, tread dimensions must not vary beyond the  $\frac{3}{16}$ -inch (4.8 mm) tolerance.

**1029.13.2.2 Risers.** Where the gradient of stepped *aisles* is to be the same as the gradient of adjoining seating areas, the riser height shall be not less than 4 inches (102 mm) nor more than 8 inches (203 mm) and shall be uniform within each *flight*.

### Exceptions:

1. Riser height nonuniformity shall be limited to the extent necessitated by changes in the gradient of the adjoining seating area to maintain adequate sightlines. Where nonuniformities exceed  $\frac{3}{16}$  inch (4.8

mm) between adjacent risers, the exact location of such nonuniformities shall be indicated with a distinctive marking stripe on each tread at the *nosing* or leading edge adjacent to the nonuniform risers. Such stripe shall be not less than 1 inch (25 mm), and not more than 2 inches (51 mm), wide. The edge marking stripe shall be distinctively different from the contrasting marking stripe.

2. Riser heights not exceeding 9 inches (229 mm) shall be permitted where they are necessitated by the slope of the adjacent seating areas to maintain sightlines.

- ❖ In stepped aisles where the gradient of the aisle is the same as the gradient of the adjoining seating area, riser heights are not to be less than 4 inches (102 mm) nor more than 8 inches (203 mm) (see Commentary Figure 1029.13.2.2). For the safety of the occupants, risers should have uniform heights, where possible, throughout each flight. However, nonuniformity of riser heights is permitted in cases where changes to the gradient in the adjoining seating area

are required because of sightlines and other seating layout considerations.

Where variations in height exceed  $\frac{3}{16}$  inch (4.8 mm) between adjacent risers, a distinctive marking stripe between 1 inch (25 mm) and 2 inches (51 mm) wide is to be located on the nosings of each tread as a visual warning to the occupants to be cautious. Frequently, this is done with “runway” lights. Note that this stripe must be different from the tread contrast marking stripes required for transitions in Section 1029.10.3 and the tread stripes in Section 1029.13.2.2.1. All of these stripes must be visible in lighted conditions; therefore, they are not required to comply with the provisions for luminous tread markings in Section 1025.

While the riser height may vary to adjust to sight lines of the associated seating, there is a maximum change for adjacent treads so that there is consistency in the flight (see Section 1029.13.2.2.1).

In comparing this section with Section 1029.13.2.1, it is significant to note the emphasis placed on the tread dimension. While not desirable, the code permits riser heights to deviate; however, Section 1029.13.2.1 does not permit tread dimensions to vary beyond the  $\frac{3}{16}$ -inch (4.8 mm) tolerance.

**1029.13.2.2.1 Construction tolerances.** The tolerance between adjacent risers on a stepped *aisle* that were designed to be equal height shall not exceed  $\frac{3}{16}$  inch (4.8 mm). Where the stepped *aisle* is designed in accordance with Exception 1 of Section 1029.13.2.2, the stepped *aisle* shall be constructed so that each riser of unequal height, determined in the direction of descent, is not more than  $\frac{3}{8}$  inch (9.5 mm) in height different from adjacent risers where stepped *aisle* treads are less than 22 inches (560 mm) in depth and  $\frac{3}{4}$  inch (19.1 mm) in height different from adjacent risers where stepped *aisle* treads are 22 inches (560 mm) or greater in depth.

❖ Where risers in a stepped aisle are consistent, the construction tolerance between adjacent treads allows for a maximum difference of  $\frac{3}{16}$  inch (4.8 mm). Stairways allow for  $\frac{3}{8}$  inch (9.5 mm), but this is for the flight of stairs (see Section 1011.5.4). Where the seating arrangement allows for unequal heights, the difference between adjacent risers is greater for situations with deeper treads. With a tread of 22 inches (560 mm) or greater, most people will be taking more than one step on each tread.

**1029.13.2.3 Tread contrasting marking stripe.** A contrasting marking stripe shall be provided on each tread at the *nos-ing* or leading edge such that the location of each tread is readily apparent when viewed in descent. Such stripe shall be not less than 1 inch (25 mm), and not more than 2 inches (51 mm), wide.

**Exception:** The contrasting marking stripe is permitted to be omitted where tread surfaces are such that the location of each tread is readily apparent when viewed in descent.

❖ The exception provides for the omission of the contrasting marking stripe where the tread is readily

apparent, such as when aisle stair treads are provided with a roughened metal nosing strip or where lighted nosings occur. In this situation, the user is aware of the treads without the marking stripe. This stripe must be different from the marking stripe required for nonuniform risers in Section 1029.13.2.2.1 and the tread contrast marking stripes required for transitions in Section 1029.10.3

These stripes must be visible in lighted conditions; therefore, these stripes are not required to comply with the provisions for luminous tread markings in Section 1025.

**1029.13.2.4 Nosing and profile.** *Nosing* and riser profile shall comply with Sections 1011.5.5 through 1011.5.5.3.

❖ The profiles of treads and risers contribute to stepped aisle safety. The radius or bevel of the nosing eases the otherwise square edge of the tread and prevents irregular chipping and wear that can become a maintenance issue and seriously affect the safe use of the stepped aisles. Since safety considerations for stepped aisles and stairways are the same for nosing and riser profiles, the provisions in stairways are referenced for this requirement.

**1029.14 Seat stability.** In a building, room or space used for assembly purposes, the seats shall be securely fastened to the floor.

**Exceptions:**

1. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating and with 200 or fewer seats, the seats shall not be required to be fastened to the floor.
2. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating, the seats shall not be required to be fastened to the floor.
3. In a building, room or space used for assembly purposes or portions thereof without seating at tables and without ramped or tiered floors for seating and with greater than 200 seats, the seats shall be fastened together in groups of not less than three or the seats shall be securely fastened to the floor.
4. In a building, room or space used for assembly purposes where flexibility of the seating arrangement is an integral part of the design and function of the space and seating is on tiered levels, not more than 200 seats shall not be required to be fastened to the floor. Plans showing seating, tiers and *aisles* shall be submitted for approval.
5. Groups of seats within a building, room or space used for assembly purposes separated from other seating by railings, *guards*, partial height walls or similar barriers with level floors and having not more than 14 seats per group shall not be required to be fastened to the floor.
6. Seats intended for musicians or other performers and separated by railings, *guards*, partial height

## MEANS OF EGRESS

walls or similar barriers shall not be required to be fastened to the floor.

- ❖ The purpose of this section is to require that assembly seating be fastened to the floor where it would be a significant hazard if loose and subject to tipping over. The exceptions allow loose assembly seating for situations where the hazard is lower, such as floors where ramped or tiered seating is not used, where not more than 200 seats are used and for box seating arrangements and where a limited number of seats are within railings, guards or partial height walls.

**1029.15 Handrails.** Ramped *aisles* having a slope exceeding one unit vertical in 15 units horizontal (6.7-percent slope) and stepped *aisles* shall be provided with *handrails* in compliance with Section 1014 located either at one or both sides of the *aisle* or within the *aisle* width.

### Exceptions:

1. *Handrails* are not required for ramped *aisles* with seating on both sides.
  2. *Handrails* are not required where, at the side of the *aisle*, there is a *guard* with a top surface that complies with the graspability requirements of *handrails* in accordance with Section 1014.3.
  3. *Handrail* extensions are not required at the top and bottom of stepped *aisles* and ramped *aisles* to permit crossovers within the *aisles*.
- ❖ For the safety of occupants, handrails must be provided in aisles where ramps exceed a gradient of one unit vertical in 15 units horizontal (6.67-percent slope) (see Commentary Figure 1029.15). All stepped aisles are required to have handrails. Handrails can be on one side, both sides or in the center of the aisle. Typically, handrails are in the center of the aisle when there is seating on both sides or on one side when the aisle is adjacent to the side walls of the room or a guard. While Sections 1011.11 and 1012.8 specify that handrails are required on both sides of stairways or ramps, the exceptions in Sections 1011.1 and

1012.1 and throughout Section 1014 allow for Section 1029.13 to be utilized for handrail location when dealing with stepped aisles, transitions and ramped aisles within assembly seating areas. This would include requiring handrails being within 30 inches (762 mm) (Section 1014.2) of the required stairway width. Safety for aisles with center handrails wider than 60 inches (1524 mm) and side aisles wider than 30 inches (762 mm) is specifically addressed with the capacity increases in Sections 1029.6.1 and 1029.6.2. What the reference to Section 1014 will require are the provisions for handrail height, graspability and fittings. Continuity, extensions, clearance and projections are more specifically addressed in Section 1029.9.1, this section and subsequent subsections.

Exception 1 omits the handrail requirements where ramped aisles are steeper, but the seats on both sides of the aisle effectively reduce the fall hazard.

Exception 2 allows handrails to be omitted where there is a guard at the side of the ramped or stepped aisle with a top rail that complies with the requirements for handrail graspability (see Section 1014.3). Note that the guard must meet the height and opening requirements specified in Section 1015 or 1029.16, as applicable.

While Section 1029.15.1 allows for discontinuous handrails, and Exception 3 (as well as Section 1014.6, Exception 2) exempts handrail extensions where they could block access to the seating, the handrail must extend the full run of the aisle stair. Stopping the handrail short of the bottom riser flight (except where permitted for mid-aisle handrails by Section 1029.15.3) would be considered a code violation. Handrails along the wall adjacent to stepped aisles or ramps should include the handrail extensions where feasible.

**1029.15.1 Discontinuous handrails.** Where there is seating on both sides of the *aisle*, the mid-aisle *handrails* shall be discontinuous with gaps or breaks at intervals not exceeding five rows to facilitate access to seating and to permit crossing

from one side of the *aisle* to the other. These gaps or breaks shall have a clear width of not less than 22 inches (559 mm) and not greater than 36 inches (914 mm), measured horizontally, and the mid-aisle *handrail* shall have rounded terminations or bends.

- ❖ Where aisles have seating on both sides, handrails may be located at the sides of the aisles, but are typically located in the center of the aisle. (Handrails on both sides of a stepped aisle will typically either block access to the aisle accessways or not be able to meet the gap requirements. Transitions per Section 1029.10 can have handrails on both sides or mid-width.) The width of each section of the subdivided aisle between the handrail and the edge of seating is to be not less than 23 inches (584 mm) measured to the handrail centerline (see Section 1029.9.1, Item 3).

For reasons of life safety in fire situations and also as a practical matter in the efficient use of the facility, a handrail down the middle of an aisle should not be continuous along its entire length. Crossovers must be provided by means of gaps or breaks in the handrail installation. Such openings must not be less than 22 inches (559 mm) or more than 36 inches (914 mm) wide, and must be provided at intervals not exceeding the distance of five rows of seats (see Commentary Figure 1029.15.1). All handrail terminations should be designed to have rounded ends or bends to avoid possible injury to the occupants (see Commentary Figure 1029.15).

**1029.15.2 Handrail termination.** *Handrails* located on the side of stepped *aisles* shall return to a wall, *guard* or the walking surface or shall be continuous to the *handrail* of an adjacent stepped *aisle flight*.

- ❖ The purpose of return requirements at handrail ends is to prevent a person from catching an article of clothing or satchel straps or from being injured by falling on the extended end of a handrail. When a handrail is on a wall adjacent to a stepped aisle, it can return the same as a handrail on a stairway.

**1029.15.3 Mid-aisle termination.** Mid-aisle *handrails* shall not extend beyond the lowest riser and shall terminate within 18 inches (381 mm), measured horizontally, from the lowest riser. *Handrail* extensions are not required.

**Exception:** Mid-aisle *handrails* shall be permitted to extend beyond the lowest riser where the *handrail* extensions do not obstruct the width of the cross *aisle*.

- ❖ The intent is to clarify how far a mid-aisle handrail can stop from the bottom of a stepped aisle and still allow for a person to get past the front of the rail to enter the first row of seating. Since the purpose of a handrail is to arrest a fall or provide stability for someone moving up or down the stepped aisle, the handrails should also not start so far back that someone could not reach the handrail from the cross aisle, or have to let go too soon before they get to the cross aisle. The intent of the exception is to allow for a mid-aisle handrail to have a bottom extension if it will not block the

cross aisle. However, if a designer wants to not have a handrail extension in order to provide access to the front row of raised seats, the handrail must extend to at least 18 inches (381 mm) from the nosing of the bottom riser.

**1029.15.4 Rails.** Where mid-aisle *handrails* are provided in stepped *aisles*, there shall be an additional rail located approximately 12 inches (305 mm) below the *handrail*. The rail shall be adequate in strength and attachment in accordance with Section 1607.8.1.2.

- ❖ Handrail installations down the middle of an aisle must be constructed with intermediate rails located 12 inches (305 mm) below and parallel to main handrails. The rail below the handrail is to stop people from going under the handrail or swinging on the handrail (see Commentary Figure 1029.15). The lower rail is not intended to meet all handrail provisions for graspability; however, it does have to meet the same strength criteria as a handrail.

**1029.16 Assembly guards.** *Guards* adjacent to seating in a building, room or space used for assembly purposes shall be provided where required by Section 1015 and shall be constructed in accordance with Section 1015 except where provided in accordance with Sections 1029.16.1 through 1029.16.4. At *bleachers, grandstands* and *folding and telescopic seating*, *guards* must be provided where required by ICC 300 and Section 1029.16.1.

❖ This section establishes the scope of the guard provisions within assembly seating. Depending on the event, the sightline constraints can be for a wide viewing angle. For example, to see the entire football field, a person may have to look right and left. Good design will establish a balance between safety and sight issues that will need to be evaluated on a case-by-case basis.

Some situations unique to assembly make it necessary to strike a balance between safety requirements and line of sight issues. Section 1029.16.1 addresses the guards around the outside edge of a seating area, such as a bleacher or tiered seating arrangement that is on each side of a high-school football field, or along the first- and third-base lines at a baseball field. The perimeter guards are required for assembly seating addressed in Section 1029 and seating covered by ICC 300. The purpose of Section 1029.16.2 is to provide for occupant safety with guards along elevated cross aisles, typically in aisles that occupants use to move side to side across the seating bowl. If there is only an aisle accessway between the seats and the guard, typically found at the front of a balcony or raised section, then Section 1029.16.3 is applicable. If the aisle is moving down through the seating toward a dropoff, then Section 1029.16.4 is applicable.

**1029.16.1 Perimeter guards.** Perimeter *guards* shall be provided where the footboards or walking surface of seating facilities are more than 30 inches (762 mm) above the floor or grade below. Where the seatboards are adjacent to the perimeter, *guard* height shall be 42 inches (1067 mm) high minimum, measured from the seatboard. Where the seats are self-rising, *guard* height shall be 42 inches (1067 mm) high minimum, measured from the floor surface. Where there is an *aisle* between the seating and the perimeter, the *guard* height shall be measured in accordance with Section 1015.2.

**Exceptions:**

1. *Guards* that impact sightlines shall be permitted to comply with Section 1029.16.3.
  2. *Bleachers, grandstands* and *folding and telescopic seating* shall not be required to have perimeter *guards* where the seating is located adjacent to a wall and the space between the wall and the seating is less than 4 inches (102 mm).
- ❖ The intent of perimeter guards is to address the risk of falling from the side and back of a seating area. This question is applicable for bleacher, grandstands and folding and telescopic seating addressed in ICC 300 and other assembly seating arrangements.

ICC 300 requires guards with 4-inch openings where the floor surface has an adjacent 30-inch dropoff (ICC 300, Section 408). The dropoff is measured from the floor rather than the seatboard because the ICC 300 committee did not believe it was appropriate to require guards in a two- or three-row bleacher system. For fixed seats and benches, the height for perimeter guards is measured from the seatboard, to address when people stand on the seats. Where seats are self-rising, the guard height would be measured from the floor. Self-rising seats have backs and are very difficult to stand on.

Exception 1 is to allow for the limited situation where guards at the sides of the seating may affect the line of sight in wide venues.

Exception 2 will permit bleacher systems constructed inside the building to use the building walls as perimeter guards if the opening between the bleacher and the wall is less than the opening permitted for guards.

**1029.16.2 Cross aisles.** Cross *aisles* located more than 30 inches (762 mm) above the floor or grade below shall have *guards* in accordance with Section 1015.

Where an elevation change of 30 inches (762 mm) or less occurs between a cross *aisle* and the adjacent floor or grade below, *guards* not less than 26 inches (660 mm) above the *aisle* floor shall be provided.

**Exception:** Where the backs of seats on the front of the cross *aisle* project 24 inches (610 mm) or more above the adjacent floor of the *aisle*, a *guard* need not be provided.

❖ The purpose of this section is to provide for occupant safety with guards along elevated cross aisles. The minimum height of the guard is a function of the cross-aisle elevation above the adjacent floor or grade below [i.e., 42 inches (1067 mm) high with more than a 30-inch (762 mm) dropoff and 26 inches (660 mm) high with a 30-inch (762 mm) or less dropoff]. When the seatbacks adjacent to cross aisles are a minimum of 24 inches (610 mm) above the floor level of the cross aisle, they will serve as the guard (see Commentary Figure 1029.16.3 for an illustration of the requirements in this section).

**1029.16.3 Sightline-constrained guard heights.** Unless subject to the requirements of Section 1029.16.4, a fascia or railing system in accordance with the *guard* requirements of Section 1015 and having a minimum height of 26 inches (660 mm) shall be provided where the floor or footboard elevation is more than 30 inches (762 mm) above the floor or grade below and the fascia or railing would otherwise interfere with the sightlines of immediately adjacent seating.

❖ The purpose of this section is to provide for occupant safety with guards along elevated seating for areas other than cross aisles, such as the front of a raised area or balcony level. The seats would only have an access aisle between the seat and the dropoff.

This section specifies a height of 26 inches (660 mm) for guards along fascias. The guard height and the dropoff are measured from the floor or footboard.

This is to provide a reasonable degree of safety while improving sightlines for persons seated immediately behind a fascia or balcony edge. The guard opening configuration must comply with Section 1015.3 (see Commentary Figure 1029.16.3 for an illustration of the requirements in this section).

**1029.16.4 Guards at the end of aisles.** A fascia or railing system complying with the *guard* requirements of Section 1015 shall be provided for the full width of the *aisle* where the foot of the *aisle* is more than 30 inches (762 mm) above the floor or grade below. The fascia or railing shall be a minimum of 36 inches (914 mm) high and shall provide a minimum 42 inches (1067 mm) measured diagonally between the top of the rail and the *nosing* of the nearest tread.

❖ This section applies only where the foot end of aisles (the lower end) is greater than 30 inches (762 mm) above the adjacent floor or grade below. This typically occurs where aisles move down through rows of seating to the front edge of a balcony or raised seating area. The guard must satisfy both of the specified height requirements to provide safety for persons at the end of the aisle in case someone trips moving down the stepped or ramped aisle. The 36-inch (914 mm) minimum height is measured from the floor vertically to the top of the guard. The minimum 42-inch (1067 mm) diagonal dimension from the nosing of the nearest stair tread to the top of the fascia or guard provides sufficient height to arrest a fall from the nearest aisle riser (see Commentary Figure

1029.16.3 for an illustration of the requirements in this section). The end result could be a guard with a vertical height of more than 36 inches (914 mm).

**SECTION 1030  
EMERGENCY ESCAPE AND RESCUE**

**1030.1 General.** In addition to the *means of egress* required by this chapter, provisions shall be made for *emergency escape and rescue openings* in Group R-2 occupancies in accordance with Tables 1006.3.2(1) and 1006.3.2(2) and Group R-3 occupancies. *Basements* and sleeping rooms below the fourth story above *grade plane* shall have at least one exterior *emergency escape and rescue opening* in accordance with this section. Where *basements* contain one or more sleeping rooms, *emergency escape and rescue openings* shall be required in each sleeping room, but shall not be required in adjoining areas of the *basement*. Such openings shall open directly into a *public way* or to a *yard* or *court* that opens to a *public way*.

**Exceptions:**

1. *Basements* with a ceiling height of less than 80 inches (2032 mm) shall not be required to have *emergency escape and rescue openings*.
2. *Emergency escape and rescue openings* are not required from *basements* or sleeping rooms that have an *exit door* or *exit access door* that opens directly into a *public way* or to a *yard, court* or exterior exit balcony that opens to a *public way*.

3. *Basements without habitable spaces* and having not more than 200 square feet (18.6 m<sup>2</sup>) in floor area shall not be required to have *emergency escape and rescue openings*.

- ❖ Emergency escape and rescue openings (EERO) are required in single-exit residential buildings where occupants may be sleeping during a potential fire buildup (Groups R-2, R-3 and R-4). Group R-2 apartment buildings permitted to have a single exit from a story are required to have EERO by Table 1006.3.2(1), Note a. Group R-2 congregate residences permitted to have a single exit are required to have an EERO by Table 1006.3.2(2), Note a. All Group R-4 congregate residences would also be required to have EERO because Group R-4 follows Group R-3 provisions unless specifically mentioned otherwise (IBC Section 310.6).

All basements and each bedroom/sleeping room are to be provided with an exterior window or door that meets the minimum size requirements and is operable for emergency escape by methods that are obvious and clearly understood by all users. Sleeping rooms four stories or more above grade are not required to be so equipped, since fire service access at that height, as well as escape through such an opening, may not be practical or reliable. Since single-exit apartment buildings are limited to three stories and most Group R-3 and R-4 buildings are two or three stories, this limit is not applicable very often. Section 1018.3 limits Groups R-3 and R-4 to four stories where using a single open exit access stairway.

The provision for basements is in recognition that they typically have only a single means of egress without alternative routes through standard windows. Many times a basement is finished at a later time; therefore, as a safety precaution; at least one EERO is required in every basement. If bedrooms are provided within the basement, the location and number of EERO are determined by the bedrooms.

It is important to note that this window is only an element of escape and is not part of the means of egress required from the story unless it is a door conforming to normal egress requirements.

Exceptions 1 and 3 are intended to exempt basements that would not be likely to be finished as living space, and thus have sleeping rooms in them.

The intent of Exception 2 is to permit sleeping rooms with a door that has direct access to an exterior-type environment, such as a street or exit balcony, to not have an EERO. The open atmosphere of the escape route would increase the likelihood that the means of egress would be available even with the delayed response time for sleeping residents. This would also exempt walk-out basements that did not include bedrooms.

**1030.2 Minimum size.** *Emergency escape and rescue openings* shall have a minimum net clear opening of 5.7 square feet (0.53 m<sup>2</sup>).

**Exception:** The minimum net clear opening for grade-floor *emergency escape and rescue openings* shall be 5 square feet (0.46 m<sup>2</sup>).

- ❖ The dimensional criteria of the openings are intended to permit fire service personnel (in full protective clothing with a breathing apparatus) to enter from a ladder, as well as permit occupants to escape. The net clear opening area and minimum dimensions are intended to provide a clear opening through which an occupant can pass to escape the building or a fire fighter can pass to enter the building for rescue or fire suppression activities. Since the emergency escape windows must be usable to all occupants, including children and guests, the required opening dimensions must be achieved by the normal operation of the window from the inside (e.g., sliding, swinging or lifting the sash). It is impractical to assume that all occupants can operate a window that requires a special sequence of operations to achieve the required opening size. While most occupants are familiar with the normal operation by which to open the window, children and guests are frequently unfamiliar with any special procedures that may be necessary to remove or tilt the sashes. The time spent in comprehending the special operation unnecessarily delays egress from the bedroom and could lead to panic and further confusion. Thus, windows that achieve the required opening dimensions only through operations such as the removal of sashes or mullions are not permitted. It should be noted that the minimum area cannot be achieved by using both the minimum height and minimum width specified in Section 1030.2.1 (see Commentary Figure 1030.2).

**1030.2.1 Minimum dimensions.** The minimum net clear opening height dimension shall be 24 inches (610 mm). The minimum net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

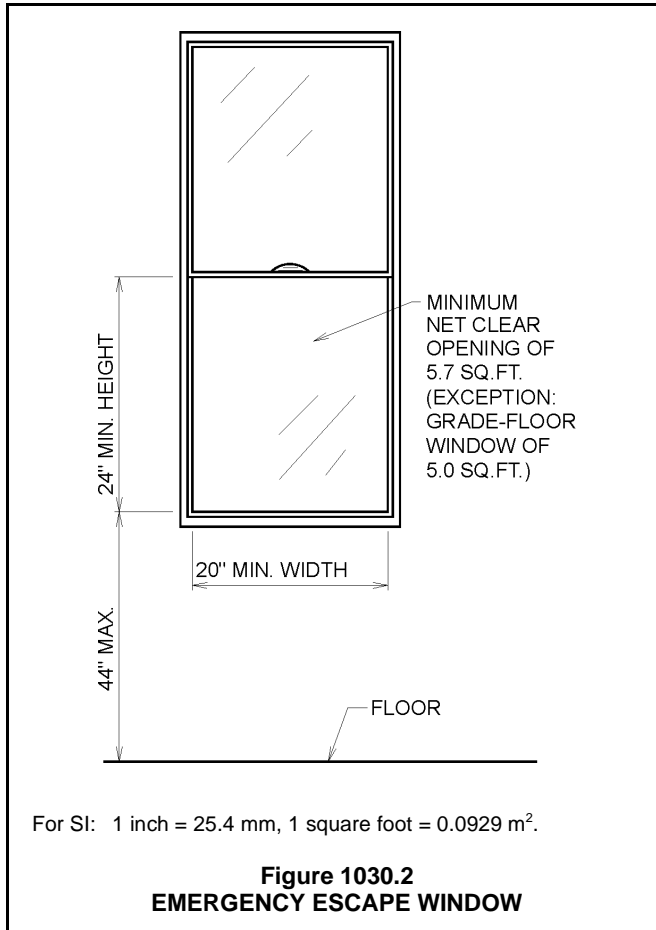

- ❖ Note that both the minimum dimensions in this section and the minimum area requirements in Section 1030.2 apply. Thus, a grade-floor window that is only 24 inches (610 mm) in height must be 30 inches (762 mm) wide to meet the 5-square-foot (0.46 m<sup>2</sup>) area requirement of Section 1030.2 for grade-floor window (see Commentary Figure 1030.2).

**1030.3 Maximum height from floor.** *Emergency escape and rescue openings* shall have the bottom of the clear opening not greater than 44 inches (1118 mm) measured from the floor.

- ❖ This section limits the height of the bottom of the clear opening to 44 inches (1118 mm) or less such

that it can be used effectively as an emergency escape (see Commentary Figure 1030.2).

Windows in Group R-2, R-3 and R-4 dwelling units may also have to meet window-opening limitations because of concerns about child falls (see Section 1015.8). Only some of the window opening-control devices will also work for emergency escape and rescue openings.

**1030.4 Operational constraints.** *Emergency escape and rescue openings* shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are permitted to be placed over *emergency escape and rescue openings* provided the minimum net clear opening size complies with Section 1030.2 and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the *emergency escape and rescue opening*. Where such bars, grilles, grates or similar devices are installed in existing buildings, *smoke alarms* shall be installed in accordance with Section 907.2.11 regardless of the valuation of the *alteration*.

❖ If security grilles, decorations or similar devices are installed on escape windows, such items must be readily removable to permit occupant escape without the use of any tools, keys or a force greater than that required for the normal operation of the window. This would include any window fall-prevention devices and

window opening-control devices required by Section 1013.8.

Where bars, grilles, grates or other devices that prevent full operation of the window are placed over the emergency escape and rescue opening, it is important that they are easily removable. Thus, the requirements for ease of operation are the same as required for windows.

Windows in Group R-2, R-3 and R-4 dwelling units may also have to meet window opening limitations because of concerns about child falls (see Section 1015.8). Only some of the window opening-control devices will also work for emergency escape and rescue openings.

Where smoke alarms are not already provided and when items that could possibly slow the opening of emergency escape and rescue windows are installed in existing buildings, smoke alarms must also be installed. Smoke alarms are necessary to provide advance warning of a fire for safety purposes.

**1030.5 Window wells.** An *emergency escape and rescue opening* with a finished sill height below the adjacent ground level shall be provided with a window well in accordance with Sections 1030.5.1 and 1030.5.2.

❖ Emergency escape and rescue openings that are partially or completely below grade need to have window wells so that they can be used effectively (see Commentary Figure 1030.5).

**1030.5.1 Minimum size.** The minimum horizontal area of the window well shall be 9 square feet (0.84 m<sup>2</sup>), with a minimum dimension of 36 inches (914 mm). The area of the window well shall allow the *emergency escape and rescue opening* to be fully opened.

❖ This section specifies the size of the window well that is needed for a rescue person in full protective clothing and breathing apparatus to use the rescue opening. The required 9 square feet (0.84 m<sup>2</sup>) is the size of the window well. Thus, the window well must project away from the plane of the window at least 3 feet (914 mm), and the required dimension in the plane of the window along the wall is also 3 feet (914 mm) (see Commentary Figure 1030.5).

**1030.5.2 Ladders or steps.** Window wells with a vertical depth of more than 44 inches (1118 mm) shall be equipped with an *approved* permanently affixed ladder or steps. Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center (o.c.) vertically for the full height of the window well. The ladder or steps shall not encroach into the required dimensions of the window well by more than 6 inches (152 mm). The ladder or steps shall not be obstructed by the *emergency escape and rescue opening*. Ladders or steps required by this section are exempt from the *stairway* requirements of Section 1011.

❖ This section specifies that a ladder or steps be provided for ease of getting into and out of window wells that are more than 44 inches (1118 mm) deep.

## MEANS OF EGRESS

Usually, ladder rungs are embedded in the wall of the window well. The 44-inch (1118 mm) dimension is the depth of the window well, not the distance from the bottom of the window well to grade. Thus, if the floor of a window well is 40 inches (1016 mm) below grade, but the wall of the window well projects above grade by 6 inches (152 mm), steps or a ladder are required since the vertical depth is 46 inches (1168 mm).

It is important that the ladder not obstruct the operation of the emergency escape window (see Commentary Figure 1030.5).

### SECTION 1031

#### MAINTENANCE OF THE MEANS OF EGRESS

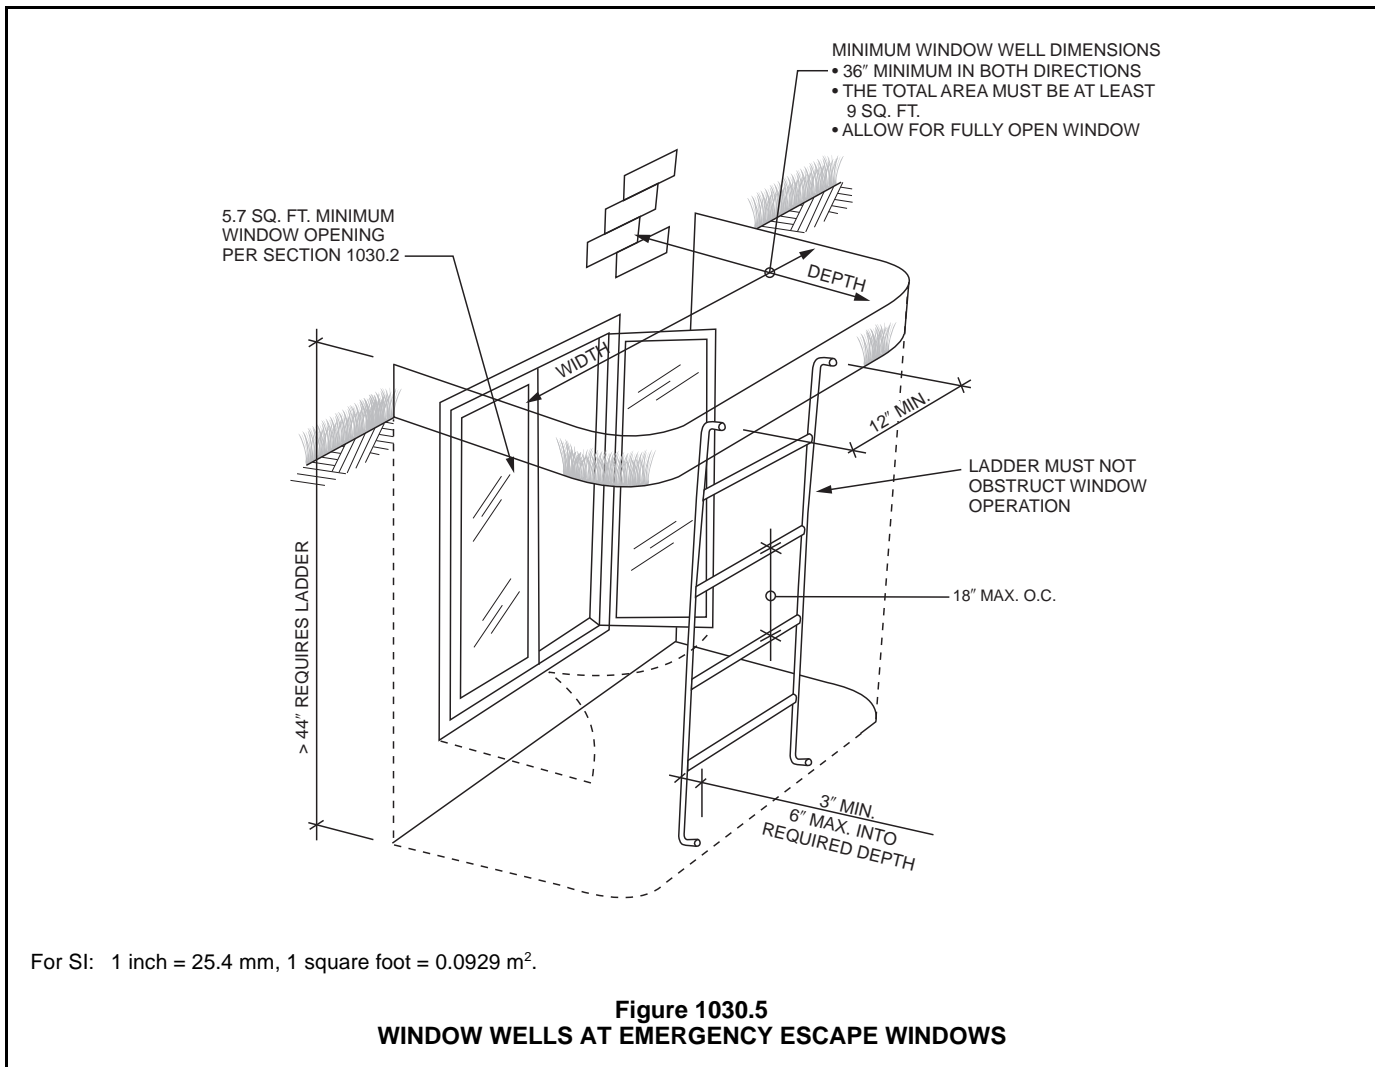

**1031.1 General.** The *means of egress* for buildings or portions thereof shall be maintained in accordance with this section.

❖ This section introduces the provisions for the maintenance of the means of egress in all buildings and structures.

**1031.2 Reliability.** Required *exit accesses*, *exits* and *exit discharges* shall be continuously maintained free from obstructions or impediments to full instant use in the case of fire or other emergency when the building area served by the *means of egress* is occupied. An *exit* or *exit passageway* shall not be used for any purpose that interferes with a *means of egress*.

❖ It is important for safety that the pathway from any point in a building to the exit discharge be kept clear so that occupants can exit the building at any time without obstructions in the egress path. Such obstructions could include storage in the means of egress, which is specifically regulated by IBC Section 315.3.2. Similarly, handrails, stair treads, flooring materials, door hardware and other fixtures and finishes must be maintained in such a way as to prevent them from becoming hazards themselves.

The last sentence of this section provides correlation with Sections 1022.1, 1023.1 and 1024.1, which, in new buildings, prohibit the use of exits, interior exit stairway and ramp enclosures and exit passageway enclosures, respectively, for any purpose other than

a means of egress. However, it is important that an exit, interior exit stairway or ramp enclosure or an exit passageway not be used for any purpose other than as a means of egress throughout the life of the building, not just when the building is built. For example, there is a tendency to use stairway enclosures for storage, furniture, vending machines, copy machines, displays and similar purposes. Such a situation can obstruct the path of exit travel. Further, if the contents consist of combustible materials or ignition sources, the use of the stairway as a means of egress may be jeopardized, creating a hazard to life safety. Note, however, that the restriction is not limited to situations where the contents are combustible because of the potential for obstruction and the inherent difficulties in limiting the materials to noncombustibles (see also commentary, Sections 1022.1, 1023.1 and 1024.1).

It is not the intent of this requirement to prohibit occupants from using the stairway exit passageway as a circulation route during normal operation.

**1031.2.1 Security devices and egress locks.** Security devices affecting *means of egress* shall be subject to approval of the *fire code official*. Security devices and locking arrangements in the means of egress that restrict, control, or delay egress shall be installed and maintained as required by this chapter.

❖ In our society, security is an ever-growing concern, and often the solutions to enhancing the security of buildings conflict with the life-safety concerns of building and fire codes. This section gives the fire code official an important measure of control over the installation or modification of security devices that could adversely effect the egress system of a building. See the commentary to Section 1008 for specifics on the different security hardware options permitted.

While this section focuses on physical impediments or obstructions to exit use, there are also security devices that emit smoke, mist or other confusing or debilitating media that could obscure exits, temporarily disable innocent occupants or result in mistaken false alarms (from passersby seeing the smoke or mist and thinking the building is on fire), which could affect fire fighter egress and safety. See the commentary to IBC Section 316.5 for a discussion of such devices.

**1031.3 Obstructions.** A *means of egress* shall be free from obstructions that would prevent its use, including the accumulation of snow and ice.

❖ Blocked exits are among the most common egress problems. Obstructions, impediments and storage or placement of articles in a manner that prevents access to or reduces the effective width of egress elements are prohibited. Such impediments may be movable or fixed. Maintenance of safe egress conditions implies keeping exits free of storage, decorations or debris that obstruct access or visibility. Complex egress paths may also violate the intent of

this requirement by confusing or obscuring the path of travel. When inspecting, extra care should be taken to follow the egress path occupants must take in the event of an emergency from a number of points in the same manner. Holding open an egress door, thus giving fire unimpeded access to the path of egress, may pose an even greater hazard than blocking an exit.

Accumulations of snow and ice could prevent timely exiting from the building in the case of fire or other emergencies. Generally, if the exit is used regularly, the exit doorway area is kept free of ice and snow. Where a required exit is not used regularly, it may be necessary to protect the exit doorway area from the accumulation of ice and snow, either by construction of overhangs or enclosures, heated slabs or, when approved by the fire code official, by a reliable snow removal program that is aggressively enforced.

**1030.3.1 Group I-2.** In Group I-2, the required clear width for aisles, corridors and ramps that are part of the required means of egress shall comply with Section 1020.2. The facility shall have a plan to maintain the required clear width during emergency situations.

**Exception:** In areas required for bed movement, equipment shall be permitted in the required width where all the following provisions are met:

1. The equipment is low hazard and wheeled.
2. The equipment does not reduce the effective clear width for the means of egress to less than 5 feet (1525 mm).
3. The equipment is limited to:
  - 3.1 Equipment and carts in use;
  - 3.2 Medical emergency equipment;
  - 3.3 Infection control carts; and
  - 3.4 Patient lift and transportation equipment.
4. Medical emergency equipment and patient lift and transportation equipment, when not in use, is required to be located on one side of the corridor.
5. The equipment is limited in number to a maximum of one per patient sleeping room or patient care room within each smoke compartment.

❖ This is a procedural requirement. In a Group I-2 occupancy where beds are moved, the minimum corridor width is 8 feet. It is recognized that certain movable pieces of equipment will be present in the corridor during normal operations of the patient care units. This section limits the types and number of such pieces of equipment and the restrictions the equipment may impose on the means of egress. During emergencies, facilities must have an emergency management plan addressing the steps that must be taken by the facility and responding staff to ensure that the required 8-foot-wide corridor is kept clear of movable obstructions (see IBC Sections 404 and 405). The terminology is consistent with NFPA 101.

**[B] 1031.4 Exit signs.** *Exit* signs shall be installed and maintained in accordance with Section 1011. Decorations, furnishings, equipment or adjacent signage that impairs the visibility of *exit* signs, creates confusion or prevents identification of the *exit* shall not be allowed.

❖ The scoping provisions of Section 1001.1 restrict the applicability of Section 1013 to new construction. This section provides needed application of the provisions of Section 1013 to existing buildings as well. Exit signs are intended to stand out from their immediate background. Clutter and obstructions in the form of drapes, decorations, partitions and other signs may distract attention from properly placed exit signs. Careful attention should be paid to how occupants will view the sign from where they must begin the egress sequence. Certain lighting conditions can obscure the direct viewing and ready identification of exit signs.

**1031.5 Nonexit identification.** Where a door is adjacent to, constructed similar to and can be confused with a *means of egress* door, that door shall be identified with an *approved* sign that identifies the room name or use of the room.

❖ Many times doors have the appearance of being exit doors but do not lead to an egress path. In many cases, these doors only open into rooms with no other way out. In such cases, this section requires that the door be provided with “non-exit” door signage to warn occupants that it is not part of the means of egress. The exact name or use of the room should be indicated, such as “storage,” “mechanical room,” “electrical room” or similar verbiage. Note that this section is not specifically included in the new construction requirements for a building because it is difficult to determine potentially confusing non-exit doors during the plan review process. It is intended for use by the fire code official during maintenance inspections when the confusion becomes apparent.

**1031.6 Finishes, furnishings and decorations.** *Means of egress* doors shall be maintained in such a manner as to be distinguishable from the adjacent construction and finishes such that the doors are easily recognizable as doors. Furnishings, decorations or other objects shall not be placed so as to obstruct *exits*, access thereto, egress therefrom, or visibility thereof. Hangings and draperies shall not be placed over *exit* doors or otherwise be located to conceal or obstruct an *exit*. Mirrors shall not be placed on *exit* doors. Mirrors shall not be placed in or adjacent to any *exit* in such a manner as to confuse the direction of exit.

❖ Similar to Section 1010.1, this section establishes that existing egress doors need to be easily recognizable for immediate use in emergency situations throughout the life of the building. Thus, the code specifies that doors are not to be hidden in such a manner that a person would have trouble seeing where to egress. Displays, furnishings, finishes and decorations are frequently intended to create a mood or atmosphere; however, they often make familiar places confusing even to those who normally occupy

them. Bright lights, vivid colors, mirrors and hanging material may significantly reduce contrast, impede visibility or confuse direction. It is not uncommon for a building owner to refinish the interior of an occupancy and paint or otherwise apply a matching finish to a door and the surrounding wall, making the door indistinguishable. This commonly occurs with murals that are painted on walls of corridors.

Tables, chairs, display cases, coat racks and similar movable objects placed in corridors or aisles may reduce required egress capacity or may require substantial effort to remove or negotiate quickly. Anything that slows egress may also impede access, particularly to fire fighters who may be called to rescue occupants or fight the fire. Similarly, anything that obscures the visibility of exit signs is prohibited by Section 1031.4.

**1031.7 Emergency escape and rescue openings.** Required *emergency escape and rescue openings* shall be maintained in accordance with the code in effect at the time of construction, and the following: Required *emergency escape and rescue openings* shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are allowed to be placed over *emergency escape and rescue openings* provided the minimum net clear opening size complies with the code that was in effect at the time of construction and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the *emergency escape and rescue opening*.

❖ In new construction, Section 1030.1 requires that in Group R-2 buildings with a single exit or in Group R-3 and R-4 dwellings, every sleeping room below the fourth story must have at least one operable window or exterior door approved for emergency escape or rescue. This section provides the necessary maintenance and utilization requirements for emergency escape openings.

Maintenance requirements are provided to increase the reliability of the emergency escape elements. Included are allowances to provide the emergency escape elements with security devices that retain the usability of the window or door while allowing a measure of security for the building occupants from intruders. Note that these provisions are applicable only to emergency escape openings required by the applicable building code in force when the building was constructed, in accordance with Section 1104.1.

The same blocking, locking and maintenance restrictions that apply to egress doors apply to emergency escape windows and doors. These egress components are frequently found blocked by furniture, fans and window air conditioners, especially in residential sleeping rooms. Inspections of other means of egress elements should include a look at basement escape windows and doors as well. Mechanical parts of exterior doors and windows are particularly susceptible to wear and tear and should

be the subject of frequent inspections and periodic preventive maintenance. Hinges must swing and handles must turn at all times so that they are ready to function when needed.

Since the emergency escape windows must be usable to all occupants, including children and guests, the required opening dimensions must be achieved by the normal operation of the window from the inside (e.g., sliding, swinging or lifting the sash). It is impractical to assume that all occupants can operate a window requiring a special sequence of operations to achieve the mandated opening size. While most occupants are familiar with the normal operation by which to open the window, children and guests are frequently unfamiliar with special procedures necessary to remove the sashes. The time spent in comprehending the special operation unnecessarily delays egress from the bedroom and could lead to panic and further confusion; thus, windows that achieve the required opening dimensions only by performing operations such as the removal of sashes or mullions are not permitted.

Not only are security devices or accessories frequently added to emergency escape windows to prevent entry, but too often the windows themselves are replaced with others that provide inadequate clearance or improper locking arrangements. Security grille designs are available to deter entry without compromising egress. Security bars, grilles or screens placed over emergency escape windows must also be releasable or removable from the inside without the use of a key, tool or force greater than what is required for normal operation of the window.

**1031.8 Inspection, testing and maintenance.** All two-way communication systems for *areas of refuge* shall be inspected and tested on a yearly basis to verify that all components are operational. When required, the tests shall be conducted in the presence of the *fire code official*. Records of inspection, testing and maintenance shall be maintained.

❖ Since these components are part of the fire protection features of a building, two-way communications systems should be tested in order to verify their operation. Communication is paramount for the occupant using the area of refuge; therefore, it is reasonable to verify the operation of the communication system just as is done for any other fire protection equipment. Many of these systems utilize an “acknowledge” light, and yearly testing would help to eliminate a potential failure of the communication system for something as critical, yet unassuming, as a burned-out bulb. See the commentary to Sections 1009.6.5 and 1009.8 for further discussion of these systems.

**1031.9 Floor identification signs.** The floor identification signs required by Sections 1023.9 and 1104.24 shall be maintained in an *approved* manner.

❖ This section provides correlation with Sections 1023.9 and 1104.24. The requirement for the maintenance

of signs designating floor levels in interior stairway exit enclosures has equal importance in existing buildings. See the commentary to Section 1023.9 for further discussion of these signs.

# Chapter 11: Construction Requirements for Existing Buildings

## General Comments

This chapter first appeared in the 2009 edition of the code, as Chapter 46. It brings many of the retroactive existing building fire protection and life safety requirements previously found in Chapters 7, 9 and 10 to one location for a more convenient and user-friendly enforcement tool. Requirements for premises identification of buildings remain in Chapter 5 and the existing building interior finish requirements remain in Chapter 8.

Excluding the general provisions and definitions, Chapter 11 is divided into four sections. Section 1103 addresses fire safety requirements for existing buildings. This includes protection of vertical openings in shafts and openings for escalators. Section 1103 also contains provisions requiring automatic sprinkler, standpipe, and fire alarm and detection systems in existing buildings. Section 1104 specifies the minimum means of egress requirements for existing buildings and is based on the provisions previously found in Section 1027. Section 1105 establishes construction require-

ments for existing Group I-2 occupancies. Section 1106 sets forth the requirements for fire department access to outdoor storage of tires, which is retroactive to any existing storage conditions.

Note that Section 1101.4 provides a level of reasonableness for enforcement of this chapter. It is not intended that existing conditions be immediately fixed, rather a process and timeline is worked through with the owner.

## Purpose

The purposes of this chapter are to provide minimum construction requirements for existing buildings and to provide them in one place. Many newer buildings may already meet these requirements and no further action will be necessary. Those that do not meet these minimal construction requirements will need to address those deficiencies. It should be noted that interior finishes for existing buildings are dealt with separately in Chapter 8.

---

## SECTION 1101 GENERAL

**1101.1 Scope.** The provisions of this chapter shall apply to existing buildings constructed prior to the adoption of this code.

❖ This section introduces Chapter 11 and indicates that it is applicable to all buildings constructed prior to the code's date of adoption.

**1101.2 Intent.** The intent of this chapter is to provide a minimum degree of fire and life safety to persons occupying existing buildings by providing minimum construction requirements where such existing buildings do not comply with the minimum requirements of the *International Building Code*.

❖ This chapter provides a single location for such requirements. Included is a quick-reference table (see Table 1103.1) to determine if there may be any requirements that would be applicable as the inspector is conducting the inspection. Each of the provisions in the code that refers to retroactive requirements now has a reference to this chapter.

Historically, there has been confusion as to when the construction provisions of Section 102.1 could be applied to an existing building. It has been said that in every case the fire code official must declare a "dis-

tingent hazard"; however, this is not correct. There are specific construction requirements for existing buildings provided by International Code Council® (ICC®) membership to address distinct hazards. Since the determination of a hazard is already accomplished, it is not necessary for the fire code official to repeat the process. Therefore, all of the requirements in Chapter 11 will apply to existing buildings.

Section 102.1, Item 3, also indicates that the retroactive construction provisions referred to are located in Chapter 11, thus clarifying which provisions in the code are actually construction provisions that should be applied to an existing building. Since only the provisions listed in this chapter would apply to an existing facility, all of the other construction provisions in the code apply to new construction. However, as has always been the case, the code official can still exercise judgment and declare a distinct hazard under Section 102.1, Item 4, for other items or operations not addressed in Chapter 11. See the commentary to Section 102.1 for further information.

Section 1104.1 makes it clear that existing buildings must still comply with the code under which the building was built or the minimum egress requirements in Section 1104, whichever is more restrictive.

In this fashion, a building will not be allowed to reduce the egress system protection or design from the original approval. Section 1104 is not as restrictive as requirements for new construction and allows for the continued use of existing buildings when the egress is at an acceptable standard, but not in complete compliance with the *International Building Code*® (IBC®).

**1101.3 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7 and the *International Building Code*.

❖ See the commentary to Section 105.7 and IBC Section 105.

**1101.4 Owner notification.** When a building is found to be in noncompliance with this chapter, the *fire code official* shall duly notify the *owner* of the building. Upon receipt of such notice, the *owner* shall, subject to the following time limits, take necessary actions to comply with the provisions of this chapter.

❖ See the commentary to Sections 109.3 and 109.3.2.

**1101.4.1 Construction documents.** *Construction documents* necessary to comply with this chapter shall be completed and submitted within a time schedule *approved* by the *fire code official*.

❖ See the commentary to Section 105.4 and its subsections.

**1101.4.2 Completion of work.** Work necessary to comply with this chapter shall be completed within a time schedule *approved* by the *fire code official*.

❖ See the commentary to Section 105.3.1 and IBC Section 105.3.2.

**1101.4.3 Extension of time.** The *fire code official* is authorized to grant necessary extensions of time when it can be shown that the specified time periods are not physically practical or pose an undue hardship. The granting of an extension of time for compliance shall be based on the showing of good cause and subject to the filing of an acceptable systematic plan of correction with the *fire code official*.

❖ See the commentary to Section 105.3.2.

## SECTION 1102 DEFINITIONS

**1102.1 Definitions.** The following terms are defined in Chapter 2:

**DUTCH DOOR.**

**EXISTING.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

## SECTION 1103 FIRE SAFETY REQUIREMENTS FOR EXISTING BUILDINGS

**1103.1 Required construction.** Existing buildings shall comply with not less than the minimum provisions specified in Table 1103.1 and as further enumerated in Sections 1103.2 through 1103.10.

The provisions of this chapter shall not be construed to allow the elimination of *fire protection systems* or a reduction in the level of fire safety provided in buildings constructed in accordance with previously adopted codes.

### Exceptions:

1. Where a change in fire-resistance rating has been approved in accordance with Section 803.6 of the *International Existing Building Code*.
2. Group U occupancies.

❖ This section reinforces the provisions of Section 1101.1 and points to the table that provides a tabular summary of the requirements of this chapter and how they apply to the various occupancy groups. With respect to existing fire protection systems, this section reinforces the provisions of Section 901.4, which emphasizes the principle that systems installed and maintained in compliance with the codes and standards in effect at the time they were placed in service must remain operational at the same level at all times.

The first exception recognizes an allowance provided in the *International Existing Building Code*® (IEBC®). Section 803.6 of the IEBC allows reductions in fire-resistance-rated construction if an automatic sprinkler system is added to a building. These reductions are required to be consistent with what is required in the IBC and also include extensive documentation and approval from the code official.

The second exception correlates with Table 1103.1, which does not include provisions for Group U occupancies (as defined in Section 202 and IBC Section 312), which are generally miscellaneous structures that do not pose the same life safety hazard as occupancies that are not classified in Group U.

**1103.1.1 Historic buildings.** Facilities designated as historic buildings shall develop a fire protection plan in accordance with NFPA 914. The fire protection plans shall comply with the maintenance and availability provisions in Sections 404.3 and 404.4.

❖ Section 102.6 generally does not require compliance with the code for historic buildings. However, that same section states that such buildings have a fire protection plan as required by this section. This plan will provide minimal ongoing safety for the occupants. This section also references back to the maintenance and availability requirements found in Chapter 4 to make sure the plans remain current and available to occupants and code officials.

TABLE 1103.1  
OCCUPANCY AND USE REQUIREMENTS<sup>a</sup>

SECTION	USE			OCCUPANCY CLASSIFICATION

1103.9	R	—	—	—	—	—	—	—	—	—	—	—	R	R	—	R	—	R	R	R	R	—	
1104	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	
1105	—	—	—	—	—	—	—	—	—	—	—	—	—	R	—	—	—	—	—	—	—	—	
1106	—	—	—	—	—	—	—	—	—	—	—	—	—	R	—	—	—	—	—	—	—	—	

a. Existing buildings shall comply with the sections identified as “Required” (R) based on occupancy classification or use, or both, whichever is applicable.  
 b. Only applies to Group I-2 Condition 2 as established by the adopting ordinance.  
 c. Only applies to Group A-2 occupancies.  
 R = The building is required to comply.

**1103.2 Emergency responder radio coverage in existing buildings.** Existing buildings that do not have approved radio coverage for emergency responders within the building, based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building, shall be equipped with such coverage according to one of the following:

1. Where an existing wired communication system cannot be repaired or is being replaced, or where not approved in accordance with Section 510.1, Exception 1.
2. Within a time frame established by the adopting authority.

**Exception:** Where it is determined by the fire code official that the radio coverage system is not needed.

❖ This section specifies the requirements for emergency responder radio coverage in existing buildings. When radio coverage is not adequate, Section 510.1, Exception 1, allows for the installation of a wired communication system. However, in existing buildings that have such a system or may have taken that exception, in the event the wired communication system becomes inoperative and cannot be repaired or is undergoing extended repair or replacement, this section allows the fire code official to require the installation of an acceptable system.

Where an existing building is determined to have inadequate radio coverage based on the requirements of Section 510.4, Item 2 of this section allows the fire code official to establish a time frame for compliance with Section 510.1. There are times when prior to construction it will be difficult to confidently assure that radio coverage will not be affected by the building itself. That is the reason these requirements are also applicable to existing facilities.

**1103.3 Existing elevators.** Existing elevators, escalators and moving walks shall comply with the requirements of Sections 1103.3.1 and 1103.3.2.

❖ The following two sections provide retroactive requirements that apply to existing elevators and, to a certain extent, escalators and moving walkways. Note that Section 607 also deals with the ongoing operation and maintenance of elevators in buildings. That section also has requirements related to fire service keys.

**1103.3.1 Elevators, escalators and moving walks.** Existing elevators, escalators and moving walks in Group I-2 Condition 2 occupancies shall comply with ASME A17.3.

❖ This section is specific to Group I-2 Condition 2 occupancies (hospitals). Not only are existing elevators required to comply with ASME A17.3, but escalators and moving walks must also comply. Note that Section 3001.2 of the IBC would require ongoing maintenance of all elevators and conveying systems. This section specifies compliance with ASME A17.3, *Safety Code for Existing Elevators and Escalators*, for such maintenance.

The healthcare industry has historically been

required to comply with regulations set forth by accreditation and certification agencies, such as The Joint Commission. ASME A17.3 has been referenced by guidelines adopted by The Joint Commission for over a decade and this requirement provides correlation of the code with the mandated healthcare industry standard.

The reference to ASME A17.3 requires that existing elevators, escalators, moving walks and their related operating equipment in Group I-2 Condition 2 occupancies comply with a minimum level of safety. Because the occupants of these types of facilities are often incapable of self-preservation, it is essential to provide ASME-mandated features for occupant safety including escalator and moving walk emergency stop buttons and automatic skirt obstruction stop features.

**1103.3.2 Elevator emergency operation.** Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

**Exceptions:**

1. Buildings without occupied floors located more than 55 feet (16 764 mm) above or 25 feet (7620 mm) below the lowest level of fire department vehicle access where protected at the elevator shaft openings with additional fire doors in accordance with Section 716.5 of the *International Building Code* and where all of the following conditions are met:
  - 1.1 The doors shall be provided with vision panels of approved fire protection-rated glazing so located as to furnish clear vision of the approach to the elevator. Such glazing shall not exceed 100 square inches (0.065 m<sup>2</sup>) in area.
  - 1.2 The doors shall be held open but be automatic-closing by activation of a fire alarm initiating device installed in accordance with the requirements of NFPA 72 as for Phase I Emergency Recall Operation, and shall be located at each floor served by the elevator; in the associated elevator machine room, control space, or control room; and in the elevator hoistway, where sprinklers are located in those hoistways.
  - 1.3 The doors, when closed, shall have signs visible from the approach area stating: **WHEN THESE DOORS ARE CLOSED OR IN FIRE EMERGENCY, DO NOT USE ELEVATOR. USE EXIT STAIRWAYS.**
2. Buildings without occupied floors located more than 55 feet (16 764 mm) above or 25 feet (7620 mm) below the lowest level of fire department vehicle access where provided with *automatic sprinkler systems* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

3. Freight elevators in buildings provided with both *automatic sprinkler systems* installed in accordance with Section 903.3.1.1 or 903.3.1.2 and not less than one ASME 17.3-compliant elevator serving the same floors.

Elimination of previously installed Phase I emergency recall or Phase II emergency in-car systems shall not be permitted.

- ❖ This section establishes requirements for existing elevators. Existing elevators that travel 25 feet (7620 mm) or more above or below the main level must, as a minimum, be equipped with emergency operation capabilities that comply with ASME A17.3. New elevator installations are held to more restrictive guidelines for increased cost effectiveness and must have both emergency recall (Phase I) and emergency in-car operation (Phase II) to comply with ASME A17.1 for any amount of travel distance, as required by Section 607.1. The ASME standards are safety codes for elevators and escalators: ASME A17.3 for existing elevators and ASME A17.1 for new elevator installations. Automatic fire detection devices provided for Phase I emergency recall operation must be installed in accordance with Section 907.3.3.

There are several exceptions based on the expense of providing Phase I recall and Phase II emergency operation for existing elevators. ASME A17.3, Rule 211.3 (Firefighters' Service—Automatic Elevators) states, "All automatic (nondesignated attendant) operation elevators having a travel of 25 ft (7.62 m) or more above or below the designated level shall conform to the requirements of this Rule."

These changes are needed because of the excessive expense of compliance for many of these retrofits. Application of the mandatory Phase I and Phase II retrofits required by A17.3 triggers complete replacement of the elevator machinery at costs running into the hundreds of thousands of dollars. What is a relatively inexpensive fire safety feature in a new elevator installation can be unreasonably onerous when applied to existing elevators. It is therefore reasonable to codify alternate methods for building owners to meet the intent of the codes. It is important to note that the 25-foot travel threshold for an ASME A17.3 emergency operation retrofit is not mitigated by occupant load; number of stories; elevator use; building fire or smoke compartment conditions; the presence of sprinklers; or any building-specific operational firefighting considerations. For elevators installed prior to the adoption of newer elevator emergency operations features, many existing three-story buildings require retrofits; elevators in nonatmospherically segregated spaces such as low-rise atriums require retrofits; vintage freight elevators, regardless of maintenance condition or the ability of building occupants to access them, require retrofits. The problem of inflexible compliance options is magnified by the division of professional jurisdictions because elevator authorities typically do not have the expertise to

assess fire risk on a total building basis; hence there is a need for the code to scope retroactive fire safety provisions.

By allowing for more affordable or effective alternatives to the Phase I and Phase II retrofits, less opposition should exist to adoption of ASME A17.3 and its other retroactive safety requirements such as safety bulkheads for hydraulic elevators and door restrictors, thereby enhancing overall elevator safety.

The intents of Phase I emergency recall are to prevent elevator users from being discharged at a floor that is engaged in a fire; to prevent occupants from accessing an elevator during a fire; and, in a detected fire condition, to return the elevator car to a designated floor for fire-fighter access for operations and rescue.

The intent of Phase II emergency in-car operation is to provide fire fighters the ability to operate the elevator for fire-fighting operations.

Exception 1 meets the intent of the code by:

- Providing an additional fire door, with a vision panel, between elevator occupants and a fire engaged floor. This protects occupants from car and hoistway doors automatically opening directly to a fire event. The vision panel lets occupants view fire risk and select another floor to travel to for egress. This door provides an additional barrier to smoke and water contamination of the hoistway and improves building compartmentation.
- Providing additional signs on the added door immediately at the elevator opening telling building occupants to not use the elevator when the door is closed. In other words, if you can read the sign you shouldn't use the elevator.
- Recognizing that common fire-fighting operations policy requires fire fighters to use the stairs to address any fire on the sixth floor or lower in a building; meaning that in low-rise buildings immediate fire-fighter access to the elevators is not as critical. The sixth floor of a building typically corresponds to the code's definition of a high-rise building as one with "an occupied floor located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access." This is broadly recognized as the elevation at which a compromise is achieved between the inherent hazard of using an elevator in a structural fire response and the need to respond in a timely way to the fire.

Exception 1 also tacitly acknowledges that these are not elevators that were ever "intended to serve the needs of emergency personnel for fire-fighting or rescue purposes," as the charging section states.

Locations of fire alarm-initiating devices used to initiate door closing are identical to those used to initiate Phase I operations via reference to NFPA 72 by ASME A17.3.

Exception 2 recognizes that there is no docu-

mented loss of life while in an elevator during a structural fire in a building protected with automatic fire sprinklers. It is reasonable that if an owner has already provided superior fire safety features in an existing building he or she will not be required to retrofit expensive fire safety features of limited value.

For buildings within the scope of the exception that are not already equipped with an automatic sprinkler system, Exception 2 provides an incentive to provide fire sprinklers.

The references to Sections 903.3.1.1 and 903.3.1.2 mean that only a fire sprinkler system installed in accordance with the appropriate technical standard will permit relaxation of the Phase I and Phase II emergency operations requirements.

Fifty-five feet was selected as the upper limit for the floor height of buildings for a couple of reasons. It was suggested that a height limit of roughly four stories would be preferable when considering response factors associated with ascertaining elevator occupant locations and conditions. Since 55 feet is the elevation at which automatic sprinkler protection is triggered, and since it roughly corresponds to four stories, it is offered as a suitable threshold.

Exception 3 recognizes that buildings having another elevator equipped with Phase I and Phase II emergency operations already meet the intent of Phase II fire-fighter operations provisions. The fire sprinkler requirement and the limited passenger use of freight elevators means that the likelihood of life loss in the freight elevator is very low. For buildings without fire sprinklers, this provision provides an incentive to install fire sprinkler systems.

The final paragraph of this section clarifies that previously installed Phase I emergency recall and Phase II emergency in-car operations are not to be removed.

**1103.4 Vertical openings.** Interior vertical openings, including but not limited to *stairways*, elevator hoistways, service and utility shafts, that connect two or more stories of a building, shall be enclosed or protected as specified in Sections 1103.4.1 through 1103.4.10.

❖ Vertical openings that are not properly protected can act as a chimney for smoke, hot gases and products of combustion. Unprotected floor openings have been a major contributing factor in many large loss-of-life fires. This section retroactively requires the enclosure of vertical openings between floors with approved fire barriers. The intent is to increase the level of safety in all buildings by enclosing unprotected floor openings and, thus, removing the avenue for unimpeded fire and smoke spread. In particular, the code is intended to ensure that means of egress in existing multiple-story buildings are given a reasonable level of protection.

Vertical communication between floors (including stairways, escalator openings, elevator hoistways, trash and laundry chutes, and other types of building service and mechanical shafts) can contribute significantly to fire and smoke spread because of “stack

effect” (see Commentary Figure 1103.4). This section and Sections 1103.4.1 through 1103.4.7 require that interior shafts be enclosed with fire barriers of the fire-resistance rating indicated. These assemblies must be constructed and protected as required by the IBC. The allowance for sprinklers in the various sections recognizes the value of automatic sprinkler systems conforming to Section 903.3.1.1 (NFPA 13 system) or 903.3.1.2 (NFPA 13R system), as applicable.

**1103.4.1 Group I-2 and I-3 occupancies.** In Group I-2 and I-3 occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

**Exceptions:**

1. In Group I-2, unenclosed vertical openings not exceeding two connected stories and not concealed within the building construction shall be permitted as follows:
  - 1.1. The unenclosed vertical openings shall be separated from other unenclosed vertical openings serving other floors by a smoke barrier.
  - 1.2. The unenclosed vertical openings shall be separated from corridors by smoke partitions.
  - 1.3. The unenclosed vertical openings shall be separated from other fire or smoke compartments on the same floors by a smoke barrier.

- 1.4. On other than the lowest level, the unenclosed vertical openings shall not serve as a required means of egress.
- 2. In Group I-2, atriums connecting three or more stories shall not require 1-hour fire-resistance-rated construction where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3, and all of the following conditions are met:
  - 2.1. For other than existing approved atriums with a smoke control system, where the atrium was constructed and is maintained in accordance with the code in effect at the time the atrium was created, the atrium shall have a smoke control system that is in compliance with Section 909.
  - 2.2. Glass walls forming a smoke partition or a glass-block wall assembly shall be permitted when in compliance with Condition 2.2.1 or 2.2.2.
    - 2.2.1. Glass walls forming a smoke partition shall be permitted where all of the following conditions are met:
      - 2.2.1.1. Automatic sprinklers are provided along both sides of the separation wall and doors, or on the room side only if there is not a walkway or occupied space on the atrium side.
      - 2.2.1.2. The sprinklers shall be not more than 12 inches (305 mm) away from the face of the glass and at intervals along the glass of not greater than 72 inches (1829 mm).
      - 2.2.1.3. Windows in the glass wall shall be non-operating type.
      - 2.2.1.4. The glass wall and windows shall be installed in a gasketed frame in a manner that the framing system deflects without breaking (loading) the glass before the sprinkler system operates.
      - 2.2.1.5. The sprinkler system shall be designed so

that the entire surface of the glass is wet upon activation of the sprinkler system with-out obstruction.

2.2.2. A fire barrier is not required where a glass-block wall assembly complying with Section 2110 of the *International Building Code* and having a 3/4-hour fire protection rating is provided.

2.3. Where doors are provided in the glass wall, they shall be either self-closing or automatic-closing and shall be constructed to resist the passage of smoke.

3. In Group I-3 occupancies, exit *stairways* or ramps and *exit access stairways* or *ramps* constructed in accordance with Section 408 in the *International Building Code*.

- ❖ This section specifically addresses vertical openings only for Group I-2 and I-3 occupancies. In nursing homes, hospitals and jails, the first response to a fire is to defend in place or move residents, patients or detainees to an adjacent smoke compartment. To maintain the separation needed to limit the spread of smoke, an increased level of protection is required. There are three exceptions to the requirement for 1-hour enclosure of vertical openings (for vertical openings in other occupancies, see Section 1103.4.8).
  - Exceptions 1 and 2 are applicable for Group I-2 occupancies (nursing homes and hospitals). The intent of Exceptions 1 and 2 is to more appropriately address floor openings in existing construction. Without these exceptions, the IBC would allow construction of a floor opening without a 1-hour fire barrier in certain specific cases. This also impacts all historical non-rated floor openings that have been reviewed, approved and maintained. Unrated vertical openings had been allowed in hospitals and nursing homes previously. Atriums have been installed with various types of smoke venting and removal systems over the past few decades. These exceptions attempt, while maintaining an appropriate level of protection, to address general requirements that have been broadly used throughout older editions of the building codes. These exceptions are consistent with federal regulations governing hospitals and nursing homes. It should be remembered that these provisions are retroactive. They apply regardless of whether an alteration is to be undertaken.
  - Exception 3 provides consistency with Exception 1 to Section 1023.2, which allows interior exit stairways in Group I-3 occupancies to be in accordance with Section 408.3.8 of the IBC. Being able to see into and out of a stairway enclosure is an important security feature.

**1103.4.2 Three to five stories.** In other than Group I-2 and I-3 occupancies, interior vertical openings connecting three to five stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2.

**Exceptions:**

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages.
3. Vertical opening protection for escalators shall be in accordance with Section 1103.4.5, 1103.4.6 or 1103.4.7.
4. *Exit access stairways* and *ramps* shall be in accordance with Section 1103.4.8.

❖ See the commentary to Section 1103.4. The exceptions are consistent with the exceptions to the shaft enclosure requirements of the IBC. Exception 1 exempts single-family dwellings and small congregate residences from vertical opening enclosures because of occupant familiarity with the premises and the relatively small occupant load. Exception 2 recognizes that it would be impractical and unnecessary to enclose shafts in parking occupancies where open ramps are a fundamental design element. Exception 3 addresses escalator openings and refers to the applicable code sections that apply. Exception 4 recognizes that exit access stairways and ramps have various allowances that would not require enclosure. These allowances are consistent with Chapters 7 of the IBC and 10 (see Section 1103.4.8).

**1103.4.3 More than five stories.** In other than Group I-2 and I-3 occupancies, interior vertical openings connecting more than five stories shall be protected by 1-hour fire-resistance-rated construction.

**Exceptions:**

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages.
3. Vertical opening protection for escalators shall be in accordance with Section 1103.4.5, 1103.4.6 or 1103.4.7.
4. *Exit access stairways* and *ramps* shall be in accordance with Section 1103.4.8.

❖ See the commentary to Section 1103.4. The exceptions are consistent with the exceptions to the shaft enclosure requirements of the IBC. Exception 1 exempts single-family dwellings and small congregate residences from vertical opening enclosures because of occupant familiarity with the premises and the relatively small occupant load. Exception 2 recognizes that it would be impractical and unnecessary to enclose shafts in parking occupancies where open

ramps are a fundamental design element. Exception 3 addresses escalator openings and refers to the applicable code sections that apply. Exception 4 recognizes that exit access stairways and ramps have various allowances that would not require enclosure. These allowances are consistent with Chapters 7 of the IBC and 10 (see Section 1103.4.8).

**1103.4.4 Atriums and covered malls.** In other than Group I-2 and I-3 occupancies, interior vertical openings in a covered mall building or a building with an atrium shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2.

**Exceptions:**

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages.
3. *Exit access stairways* and *ramps* shall be in accordance with Section 1103.4.8.

❖ See the commentary to Section 1103.4. The exceptions are consistent with the allowances for atrium and mall enclosure requirements of the IBC. Exception 1 exempts single-family dwellings and small congregate residences from vertical opening enclosures because of occupant familiarity with the premises and the relatively small occupant load. Exception 2 recognizes that it would be impractical and unnecessary to enclose shafts in parking occupancies where open ramps are a fundamental design element. Exception 3 recognizes that exit access stairways and ramps have various allowances that would not require enclosure. These allowances are consistent with Chapters 7 and 10 of the IBC and IBC Sections 402 and 404. Escalators within a mall are addressed in Sections 1103.4.5, 1103.4.6 and 1103.4.7 (see Section 1103.4.8).

**1103.4.5 Escalators in Group B and M occupancies.** In Group B and M occupancies, escalators creating vertical openings connecting any number of stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* in accordance with Section 903.3.1.1 installed throughout the building, with a draft curtain and closely spaced sprinklers around the escalator opening.

❖ This section addresses escalator openings in Group B and M occupancies and provides the option of either enclosing the vertical opening with 1-hour construction or equipping the building throughout with an NFPA 13 sprinkler system with the vertical opening protected by draft curtains and closely spaced sprinklers. Section 8.15.4.2 of NFPA 13 provides specifications on the construction and installation of the draft curtains (“draftstops” in NFPA 13) and Section 8.15.4.3 provides installation criteria for the automatic sprinklers for protecting the opening. There is no limit to the number of stories connected by vertical openings protected by either option in this section. IBC

Section 712.1.3 contains similar, but more stringent, requirements for escalator openings in new buildings.

**1103.4.6 Escalators connecting four or fewer stories.** In other than Group B and M occupancies, escalators creating vertical openings connecting four or fewer stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 shall be installed throughout the building, and a draft curtain with closely spaced sprinklers shall be installed around the escalator opening.

❖ In other than Group B and M occupancies, escalators creating vertical openings connecting four or fewer stories shall either be protected by 1-hour fire-resistance-rated construction or an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 shall be installed throughout the building and a draft curtain with closely spaced sprinklers shall be installed around the escalator opening.

This section addresses escalator openings connecting a maximum of four stories in other than Group B and M occupancies. Similar to Section 1103.4.5, it provides the option of either enclosing the vertical opening with 1-hour construction or equipping the building throughout with an NFPA 13 or 13R sprinkler system with the vertical opening protected by draft curtains and closely spaced sprinklers. Section 8.15.4.2 of NFPA 13 provides specifications on the construction and installation of the draft curtains (“draftstops” in NFPA 13) and Section 8.15.4.3 provides installation criteria for the automatic sprinklers for protecting the opening also see commentary, Section 1103.4. IBC Section 712.1.3.1 contains similar, but more stringent, requirements for escalator openings in new buildings.

**1103.4.7 Escalators connecting more than four stories.** In other than Group B and M occupancies, escalators creating vertical openings connecting five or more stories shall be protected by 1-hour fire-resistance-rated construction.

❖ This section addresses escalator openings connecting five stories or more in other than Group B and M occupancies and provides no option to enclosing the vertical opening with 1-hour construction (see commentary, Section 1103.4). IBC Section 712.1.3 contains similar, but more stringent, requirements for escalator openings in new buildings.

**1103.4.8 Occupancies other than Group I-2 and I-3.** In other than Group I-2 and I-3 occupancies, floor openings containing *exit access stairways* or *ramps* that do not comply with one of the conditions listed in this section shall be protected by 1-hour fire-resistance-rated construction.

1. *Exit access stairways* and *ramps* that serve, or atmospherically communicate between, only two stories. Such interconnected stories shall not be open to other stories.
2. In Group R-1, R-2 or R-3 occupancies, *exit access stairways* and *ramps* connecting four stories or less serving and contained within an individual *dwelling unit* or *sleeping unit* or live/work unit.

3. *Exit access stairways* and *ramps* in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, where the area of the vertical opening between stories does not exceed twice the horizontal projected area of the *stairway* or *ramp*, and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13. In other than Group B and M occupancies, this provision is limited to openings that do not connect more than four stories.

4. *Exit access stairways* and *ramps* within an atrium complying with the provisions of Section 404 of the *International Building Code*.

5. *Exit access stairways* and *ramps* in open parking garages that serve only the parking garage.

6. *Exit access stairways* and *ramps* serving open-air seating complying with the exit access travel distance requirements of Section 1029.7 of the *International Building Code*.

7. *Exit access stairways* and *ramps* serving the balcony, gallery or press box and the main assembly floor in occupancies such as theaters, places of religious worship, auditoriums and sports facilities.

❖ Vertical openings in Group I-2 and I-3 occupancies are specifically addressed in Section 1103.4.1. This section addresses vertical openings in other occupancies. There are many provisions for new construction in Chapter 10 that permit exit access stair floor openings without a fire rated enclosure. Without this section, many of these permitted floor openings would be required to be fire rated by this chapter. In addition, a building constructed under this code in full compliance with Chapter 10 would be in violation of Sections 1103.4 through 1103.4.7 upon issuance of the certificate of occupancy if these allowances were not provided. Clearly it was not the intent for Chapter 11 to contradict Chapter 10. This section notes all of the current conditions that allow an unenclosed exit access stair or ramp. All of these conditions originate from Section 1019. It is important to note that this section and these conditions only apply to exit access stairways and ramps. This section does not apply to exit stairways. Exit stairways are not exempted from enclosure.

**1103.4.9 Waste and linen chutes.** In Group I-2 occupancies, existing waste and linen chutes shall comply with Sections 1103.4.9.1 through 1103.4.9.5.

❖ This section is intended to clarify the allowable use and construction of chutes and incinerators in Group I-2 occupancies (hospitals and nursing homes). These items are used as integral parts of the operation of a healthcare facility, especially the waste or linen chutes. Some incinerators are still in use, but the requirements found in Sections 1103.4.9.1 through 1103.4.9.5 seek to separate them from other vertical openings, especially a trash chute, by requiring a separate discharge room from the incinerator.

Waste and linen chutes in other occupancies are addressed in Section 1103.4.8.

**1103.4.9.1 Enclosure.** Chutes shall be enclosed with 1-hour fire-resistance-rated construction. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1 hour.

❖ At minimum, chutes must be enclosed with 1-hour fire-resistance-rated construction. This is consistent with Section 713.4 of the IBC for shaft enclosures for chutes connecting three stories or less. Openings other than chute access doors addressed in Section 1103.4.9.2 must meet IBC Section 716 requirements.

**1103.4.9.2 Chute intakes.** Chute intakes shall comply with Section 1103.4.9.2.1 or 1103.4.9.2.2.

❖ This section focuses on where chutes can be accessed throughout a building. There are two configurations addressed. The first, in Section 1103.4.9.2.1, addresses access from the corridor. Section 1103.4.9.2.2 then addresses chute intakes accessed from a chute intake room.

**1103.4.9.2.1 Chute intake direct from corridor.** Where intake to chutes is direct from a *corridor*, the intake opening shall be equipped with a chute-intake door in accordance with Section 716 of the *International Building Code* and having a fire protection rating of not less than 1 hour.

❖ In facilities that predate current requirements, some chute doors open into corridors. As it is not practical to reconstruct such chutes to meet modern standards, this section aims to directly address that situation by defining requirements for the chutes' safe maintenance. This configuration has a more direct effect on the safety of the occupants than those chute intakes addressed in Section 1103.4.9.2.2. Therefore, the opening must be in accordance with Section 716 of the IBC and be rated for at least 1 hour.

**1103.4.9.2.2 Chute intake via a chute-intake room.** Where the intake to chutes is accessed through a chute-intake room, the room shall be enclosed with 1-hour fire-resistance-rated construction. Opening protectives for the intake room shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 3/4 hour. Opening protective for the chute enclosure shall be in accordance with Section 1103.4.9.1.

❖ This configuration provides a layer of protection to the building occupants by first entering a room that is protected with 1-hour fire-resistance-rated construction. The door rating is only required to be 3/4 hour versus 1 hour as required in Section 1103.4.9.2.1. The door for the chute intake itself would still be required to be 1 hour.

**1103.4.9.3 Automatic sprinkler system.** Chutes shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.2.11.2.

❖ This section would retroactively require compliance with Section 903.2.11.2 for sprinkler placement within the chute.

**1103.4.9.4 Chute discharge rooms.** Chutes shall terminate in a dedicated chute discharge room. Such rooms shall be separated from the remainder of the building by not less than 1-hour fire-resistance-rated construction. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1 hour.

❖ This section provides minimal requirements for protection of the chute discharge room. This provides a minimal separation requirement for existing chute discharge rooms. This is consistent with the requirements in Section 713.13.4 of the IBC for shafts connecting three stories or less in new construction. The rating of the door must also be 1 hour.

**1103.4.9.5 Chute discharge protection.** Chute discharges shall be equipped with a self-closing or automatic-closing opening protective in accordance with Section 716 of the *International Building Code* and having a fire protection rating of not less than 1 hour.

❖ This section requires that the chute discharge room continue the protection of the enclosure through opening protection. The discharge must also have a 1-hour fire protection rating and be self or automatically closing. This is consistent with the requirement of IBC Section 713.13.4 that the opening protection have the same rating as the enclosure. The opening must also be self closing or automatic closing.

**1103.4.10 Flue-fed incinerators.** Existing flue-fed incinerator rooms and associated flue shafts shall be protected with 1-hour fire-resistance-rated construction and shall not have other vertical openings connected with the space other than the associated flue. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1 hour.

❖ Because of regulation from the EPA and other entities, flue-fed incinerators are frequently found abandoned or otherwise unused in existing buildings. This requirement is intended to separate and protect any potential hazard of inactive incinerator systems from the rest of the building.

**1103.5 Sprinkler systems.** An *automatic sprinkler system* shall be provided in existing buildings in accordance with Sections 1103.5.1 through 1103.5.3.

❖ This section introduces the retroactive sprinkler requirements of Sections 1103.5.1 through 1103.5.3.

**1103.5.1 Group I-2.** In Group I-2, an *automatic sprinkler system* shall be provided in accordance with Section 1105.8.

❖ This section is merely a pointer to the sprinkler requirements for Group I-2 occupancies found in Section 1105.8. Section 1105.8 requires an automatic sprinkler system to be retroactively installed in Group I-2 occupancies from the story containing the Group I-2 to the level of exit discharge. This requirement is less restrictive than what is found in Section 1103.5.2.

**1103.5.2 Group I-2 Condition 2.** In addition to the requirements of Section 1103.5.2, existing buildings of Group I-2

Condition 2 occupancy shall be equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. The *automatic sprinkler system* shall be installed as established by the adopting ordinance.

❖ This section is specific to hospitals and is more restrictive than the requirements of Sections 1103.5.1 and 1105.8. Instead of requiring the installation of an automatic sprinkler system from the story containing the Group I-2 Condition 2 occupancy to the level of exit discharge, this section requires the building to be equipped throughout with an automatic sprinkler system. This requirement, however, is based on the adopting ordinance establishing a date by which the automatic sprinkler system will be installed. Sprinkler systems are a vital safety system that protects building systems and components.

To ensure continuous operation in healthcare facilities, the installation of automatic sprinkler systems needs to be carefully planned so as to not adversely affect patient health. Accessing and exposing ceiling spaces can create conditions leading to infection and possibly death to patients with compromised immune systems. In many situations, hospitals may not be able to appropriately retrofit the installation of a fire suppression system; in those situations, a time frame is needed to replace facilities. The period for adoption of this proposed requirement has been left to the local authority having jurisdiction. Coordinating the timeframe for adoption with federal requirements is recommended. It is currently anticipated that the Centers for Medicaid and Medicare (the federal authority having jurisdiction) will require retroactive installation of automatic sprinkler systems in hospitals by the year 2021. However, the exact time frame was uncertain at the time of development of this requirement. Facilities will require lead time to meet this standard without adversely affecting the health of patients and disrupting patient care. These are the same factors that a jurisdiction should consider when choosing a date for adoption.

It should be also clear that this change is a separate measure that must be taken in addition to the current requirement. It is not intended to allow a facility to have a time frame for installing the current requirement (although jurisdictions may choose to do this). Nor is it intended to imply that the entire building containing a hospital should install an automatic sprinkler system immediately. At a minimum, a 3-year time frame is recommended for implementation of this requirement. This considers the process planning, capital approval, regulatory approval, design and installation of the sprinkler system. The capital-planning piece of a large-scale initiative such as a building-wide sprinkler system, normally spans multiple fiscal years.

**1103.5.3 Pyroxylin plastics.** An *automatic sprinkler system* shall be provided throughout existing buildings where cellulose nitrate film or pyroxylin plastics are manufactured, stored or handled in quantities exceeding 100 pounds (45 kg). Vaults located within buildings for the storage of raw pyrox-

ylin shall be protected with an *approved automatic sprinkler system* capable of discharging 1.66 gallons per minute per square foot (68 L/min/m<sup>2</sup>) over the area of the vault.

❖ This section requires an approved automatic fire-extinguishing system in existing buildings used for the manufacture and storage of pyroxylin plastics. Cellulose nitrate (pyroxylin) plastics pose unusual and substantial fire risks. Pyroxylin plastics are the most dangerous and unstable of all plastic compounds. The chemically bound oxygen in their structure permits them to burn vigorously in the absence of atmospheric oxygen. Although these compounds produce approximately the same amount of energy as paper when they burn, pyroxylin plastics burn at a rate as much as 15 times greater than comparable common combustibles. When burning, these materials release highly flammable and toxic combustion byproducts. Consequently, cellulose nitrate fires are very difficult to control. Although this section specifies a sprinkler threshold quantity of 100 pounds (45 kg), the need for additional fire protection should be considered for pyroxylin plastics in any amount.

Although the code includes cellulose nitrate “film” in its requirements, cellulose nitrate motion picture film has not been used in the United States since the 1950s. All motion picture film produced since that time is what is typically called “safety film.” Consequently, the only application for this section relative to motion picture film is where it may be used in laboratories or storage vaults that are dedicated to film restoration and archives. The protection of these facilities is addressed in Sections 306.2 and 6504.2.

Even though this section would permit an approved fire-extinguishing system in existing structures containing pyroxylin plastics, vaults must be protected by an approved automatic sprinkler system with a density of 1.66 gpm/ft<sup>2</sup> (68 L/min/m<sup>2</sup>) over the entire area of the vault. The high sprinkler density recognizes the need to immerse the pyroxylin plastics in water to counteract the vigorous burn rate of these materials.

Note that in Table 1103.1, on the row for Section 1103.5.3, an “R” appears for all occupancy groups. In previous editions of the code, this table row reflected the rationale of the table’s author of “anticipating” (guessing) where pyroxylin plastics might be used or found when, in actuality, it could be applicable to any or all occupancy groups. Even the text of this section does not list specific occupancies. Therefore, an “R” now appears in all occupancy group cells on the Section 1103.5.3 row.

**1103.6 Standpipes.** Existing structures shall be equipped with standpipes installed in accordance with Section 905 where required in Sections 1103.6.1 and 1103.6.2. The *fire code official* is authorized to approve the installation of manual standpipe systems to achieve compliance with this section where the responding fire department is capable of providing the required hose flow at the highest standpipe outlet.

❖ This section recognizes that some existing buildings do not have a standpipe system and introduces the

minimum requirements for existing buildings. In place of a standpipe system that has a water supply capable of supplying the system demand automatically, this section would permit the fire code official to approve the use of a manual standpipe system in an existing building if adequate hose flow is available when the fire department charges the system. The standpipe system may be either a manual dry or a manual wet system.

**1103.6.1 Existing multiple-story buildings.** Existing buildings with occupied floors located more than 50 feet (15 240 mm) above the lowest level of fire department access or more than 50 feet (15 240 mm) below the highest level of fire department access shall be equipped with standpipes.

❖ Although it would be inappropriate to require a standpipe system in an existing building to be designed based on the requirements of Section 905.3 for new construction, this section establishes a maximum height limitation for existing buildings regardless of occupancy beyond which a standpipe is required. The system is to be installed in accordance with Section 905. Many existing buildings may also not be equipped with an automatic sprinkler system. This section will, at least, provide some means of manual fire suppression in buildings where exterior fire department access is limited.

**1103.6.2 Existing helistops and heliports.** Existing buildings with a rooftop helistop or heliport located more than 30 feet (9144 mm) above the lowest level of fire department access to the roof level on which the helistop or heliport is located shall be equipped with standpipes in accordance with Section 2007.5.

❖ A heliport or helistop on a new or existing building is a distinct hazard that can involve flammable fuels and combustible cargo and present an immediate rescue situation. In the event of an emergency, rapid deployment of hand hose lines will be necessary to attack a resulting fire, effectuate rescue and to protect exposures and the remainder of the building. This section specifies that when existing buildings have a helistop or heliport on a rooftop location more than 30 feet (9144 mm) above the lowest level of fire department vehicle access, a standpipe system is required throughout the building, not just a hose connection at the roof level. This is critical in fire-fighting operations because, many times, the connection below the rooftop level may be needed to gain access to the roof. If the only connection is on the roof, it is of no use if the fire fighters cannot get to it. Additionally, a heliport includes fueling operations. It is entirely possible for a spill to not only affect the rooftop, but also floors below as the liquid fuel spreads. The standpipe system will again be utilized in these situations. Note that this section refers to Section 2007.5 for design and standpipe hose connection location for the rooftop heliport or helistop. See the commentary to Sections 905.3.6 and 2007.5 for further information.

**1103.7 Fire alarm systems.** An *approved* fire alarm system shall be installed in existing buildings and structures in accordance with Sections 1103.7.1 through 1103.7.7 and provide occupant notification in accordance with Section 907.5 unless other requirements are provided by other sections of this code.

**Exception:** Occupancies with an existing, previously *approved* fire alarm system.

❖ This section specifies the occupancy conditions when an approved fire alarm system is retroactively required in an existing building. These systems must, upon activation, provide occupant notification throughout the area protected by the system unless other alternative provisions, such as an emergency voice/alarm communication system, are allowed.

The exception recognizes the infeasibility of requiring existing, previously approved fire alarm systems to conform to current code requirements. The existing fire alarm system must be adequately tested and maintained in accordance with Section 901.6 and shown not to create a hazard.

A common concern in the application of the exception is in the scoping of the condition. Where the building is in use and continues in use as it was before, the exception is quite clear that no modifications are required if the existing system has been previously approved, regardless of how long ago that may have been. If there is an addition to the building, the addition must meet the requirements for new work and tie into the existing system if the existing system is capable of adequately handling the new devices. The addition is only adding devices and does not require the existing system to be upgraded.

If the building is altered, the alarm system must be altered in accordance with its original installation. For example, if the existing system does not include visual notification devices and the alteration includes remodeling to existing toilet rooms, there is no requirement for installing visual devices in the remodeled toilet rooms. If, on the other hand, the existing system is not capable of receiving new devices or relocated existing devices, then the replacement of the existing panel must be considered since the altered system would be less effective than before the alteration.

**1103.7.1 Group E.** A fire alarm system shall be installed in existing Group E occupancies in accordance with Section 907.2.3.

**Exceptions:**

1. A manual fire alarm system is not required in a building with a maximum area of 1,000 square feet (93 m<sup>2</sup>) that contains a single classroom and is located not closer than 50 feet (15 240 mm) from another building.
2. A manual fire alarm system is not required in Group E occupancies with an *occupant load* less than 50.

❖ Group E occupancies are limited to educational purposes through the 12th grade. Because of the typical age and maturity of the occupants, more time may be needed to safely evacuate the building. The require-

ment for retroactive installation of, at least, a fire alarm system recognizes that many existing, previously approved nonsprinklered educational facilities would most likely require sprinklers under current code provisions (see Section 903.2.3).

Although not limited to this use condition, Exception 1 recognizes the current use of mobile trailer-type facilities on site as additional educational classroom facilities. This exception does not exempt the main building, but it would exempt these auxiliary buildings of limited size that do not present an exposure hazard because of the required separation distance.

Exception 2 would exempt small day care centers that serve children older than 2 years of age, a small Sunday school classroom at a church or similar limited educational use areas (see commentary, Section 907.2.3).

**1103.7.2 Group I-1.** An automatic fire alarm system shall be installed in existing Group I-1 facilities in accordance with Section 907.2.6.1.

**Exception:** Where each sleeping room has a *means of egress* door opening directly to an exterior egress balcony that leads directly to the *exits* in accordance with Section 1021, and the building is not more than three stories in height.

❖ Group I-1 facilities are assumed to have more than 16 occupants who, because of their age, mental disability or other reasons, must live in a supervised environment 24 hours a day. This section would require existing Group I-1 occupancies to have an approved fire alarm system as required by Section 907.2.6.1.

The exception recognizes the increased degree of life safety resulting from having direct access to the exterior from the sleeping rooms. The occupants are not forced to evacuate through the interior of the building during a potential fire. The exterior egress balconies must be sufficiently open to the atmosphere and constructed to minimize the accumulation of smoke and toxic gases.

**1103.7.3 Group I-2.** In Group I-2, an automatic fire alarm system shall be installed in accordance with Section 1105.9.

❖ This section is simply a pointer to the specific requirements for Group I-2 occupancies found in Section 1105. Section 1105.9 addresses the need for a fire alarm system. See the commentary to Section 1105.9.

**1103.7.4 Group I-3.** An automatic and manual fire alarm system shall be installed in existing Group I-3 occupancies in accordance with Section 907.2.6.3.

❖ Because occupants may be restrained, leading to difficulties in evacuating, an approved fire alarm system is required in existing Group I-3 occupancies. The system must comply with Section 907.2.6.3 (see commentary, Section 907.2.6.3).

**1103.7.5 Group R-1.** A fire alarm system and smoke alarms shall be installed in existing Group R-1 occupancies in accordance with Sections 1103.7.5.1 through 1103.7.5.2.1.

❖ This section introduces the retroactive fire alarm system and smoke alarm requirements for Group R-1 transient occupancies such as hotels, motels, and boarding houses.

**1103.7.5.1 Group R-1 hotel and motel manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-1 hotels and motels more than three stories or with more than 20 *sleeping units*.

**Exceptions:**

1. Buildings less than two stories in height where all *sleeping units*, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each *sleeping unit* has direct access to a *public way*, *egress court* or yard.

2. Manual fire alarm boxes are not required throughout the building where the following conditions are met:

2.1. The building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2.

2.2. The notification appliances will activate upon sprinkler water flow.

2.3. Not less than one manual fire alarm box is installed at an *approved* location.

❖ This section specifies the conditions when a fire alarm system is required in existing Group R-1 hotels and motels. The two main criteria are independent of each other in that a fire alarm system is required if the building is more than three stories above grade, regardless of the number of sleeping units, or contains 20 sleeping units, regardless of the number of stories. Occupants of these types of Group R-1 facilities are assumed to be more transient than the occupants of Group R-1 boarding and rooming houses regulated by Section 907.2.8.

Exception 1 recognizes the increased level of life safety afforded by adequate compartmentation using 1-hour fire-resistance-rated construction between sleeping units and direct exterior access for egress.

Exception 2 does not omit fire alarm systems but, rather, permits them to be initiated automatically by sprinkler system water flow switches in lieu of manual fire alarm boxes. The sprinkler system is to be equipped with local audible alarms that can be heard throughout the building and at least one manual fire alarm box installed at an approved location.

The exceptions do not affect the independent provision in Section 1103.8 for single- or multiple-station smoke alarms.

**1103.7.5.1.1 Group R-1 hotel and motel automatic smoke detection system.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-1 hotels

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

and motels throughout all interior *corridors* serving sleeping rooms not equipped with an *approved*, supervised sprinkler system installed in accordance with Section 903.

**Exception:** An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *sleeping units* and where each sleeping unit has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an *exit*.

- ❖ This section requires an automatic smoke detection system within interior corridors serving unsprinklered sleeping rooms. Such systems make use of smoke detectors for alarm initiation, in accordance with Section 907.4.3, with one exception.

The exception provides that automatic smoke detection is not required in motels and hotels that do not have interior corridors and in which sleeping units have a door opening directly to an exterior exit access that leads directly to the exits. The intent of the exception is that the exit access from the sleeping unit door be exterior and not require reentering the building prior to entering the exit. Since the exit access is outside, the need for detectors other than in sleeping units is greatly reduced. Unlike Exception 1 to Section 1103.7.5.1, exit balconies and exterior stairs serving sleeping units are allowed.

**1103.7.5.2 Group R-1 boarding and rooming houses manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-1 boarding and rooming houses.

**Exception:** Buildings less than two stories in height where all *sleeping units*, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each *sleeping unit* has direct access to a *public way*, *egress court* or *yard*.

- ❖ Group R-1 boarding and rooming houses are still assumed to be transient residential occupancies even though the functional use of a boarding and rooming house is different from that of a typical hotel or motel. Boarding and rooming houses tend to have more extended living arrangements and border on being classified as Group R-2 facilities. For this reason, this section requires Group R-1 boarding and rooming houses to be equipped with a manual fire alarm system regardless of the height of the building or number of sleeping rooms.

The exception recognizes the increased level of life safety afforded by adequate compartmentation using 1-hour fire-resistance-rated construction between sleeping units and direct exterior access for egress.

**1103.7.5.2.1 Group R-1 boarding and rooming houses automatic smoke detection system.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-1 boarding and rooming houses throughout all interior *corridors* serving *sleeping units* not equipped with

an *approved*, supervised sprinkler system installed in accordance with Section 903.

**Exception:** Buildings equipped with single-station smoke alarms meeting or exceeding the requirements of Section 907.2.11.1 and where the fire alarm system includes not less than one manual fire alarm box per floor arranged to initiate the alarm.

- ❖ This section requires an automatic smoke detection system within interior corridors serving unsprinklered sleeping rooms. Such systems make use of smoke detectors for alarm initiation, in accordance with Section 907.4.3, with one exception.

The exception provides that automatic fire detectors are not required in boarding and rooming houses where single-station smoke alarms complying with the minimum requirements of Section 907.2.11.1 and at least one manual fire alarm box per floor are installed. The single-station smoke alarms give the desired early warning notification to occupants and the manual fire alarm box is an additional means to activate the occupant notification system.

**1103.7.6 Group R-2.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-2 occupancies more than three stories in height or with more than 16 *dwelling* or *sleeping units*.

### Exceptions:

1. Where each living unit is separated from other contiguous living units by *fire barriers* having a *fire-resistance rating* of not less than  $\frac{3}{4}$  hour, and where each living unit has either its own independent *exit* or its own independent stairway or ramp discharging at grade.
2. A separate fire alarm system is not required in buildings that are equipped throughout with an *approved* supervised *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2 and having a local alarm to notify all occupants.
3. A fire alarm system is not required in buildings that do not have interior *corridors* serving *dwelling units* and are protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, provided that *dwelling units* either have a *means of egress* door opening directly to an exterior *exit access* that leads directly to the *exits* or are served by open-ended *corridors* designed in accordance with Section 1027.6, Exception 3.
4. A fire alarm system is not required in buildings that do not have interior *corridors* serving *dwelling units*, do not exceed three stories in height and comply with both of the following:
  - 4.1. Each *dwelling unit* is separated from other contiguous *dwelling units* by *fire barriers*

having a *fire-resistance rating* of not less than  $\frac{3}{4}$  hour.

- 4.2. Each *dwelling unit* is provided with hard-wired, interconnected smoke alarms as required for new construction in Section 907.2.11.

- ❖ This section specifies the conditions when a manual fire alarm system is required in existing Group R-2 apartment buildings based on height or the number of dwelling or sleeping units. Occupants of Group R-2 facilities tend to be more permanent than those in Group R-1 facilities.

Exception 1 recognizes the increased degree of life safety afforded by compartmentation using fire-resistance-rated construction and independent means of egress (see Section 907.2.9).

As indicated in Exception 2, existing buildings that are fully sprinklered in accordance with NFPA 13 or 13R do not need a manual fire alarm system if local alarms will sound upon activation of the sprinkler system. The exception essentially eliminates the need for manual fire alarm boxes if evacuation alarms can still be heard throughout the building upon sprinkler system water flow. Other alarm-initiating devices would similarly not be required if the water flow device will initiate the appropriate alarm. This exception does not affect the independent provision in Section 907.2.11.

Exception 3 mirrors Section 907.2.9, Exception 3, and recognizes the superior fire record of sprinklered multiple-family occupancies by allowing omission of a fire alarm system when a building is fully sprinklered, has no interior egress corridors and provides direct exterior egress from each dwelling unit. Note that in such buildings, rated fire separations are still required between units.

Exception 4 provides a reasonable alternative to retrofitting a manual fire alarm system in existing Group R-2 occupancy buildings not exceeding three stories in height and having exits that lead directly to the outside. Fire risk in apartments tends to be greatest for occupants inside the dwelling unit where a fire originates, and money spent to retrofit firesafety equipment in apartments is better spent within dwelling units, as opposed to common areas.

Countless existing apartment buildings have only a single smoke alarm in the common area. The code does not require retrofitting sleeping rooms with smoke alarms when such alarms weren't required at the time of construction. The lack of smoke alarms in bedrooms, and particularly the lack of interconnecting alarm signals, increases the risk of injury or death in a unit of fire origin and other units that experience smoke infiltration. An additional consequence may be delayed recognition of a fire event, which increases the risk of harm to other building occupants and may delay notification of the fire department. This exception also requires minimal separation from other units.

**1103.7.7 Group R-4.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in existing Group R-4 residential care/assisted living facilities in accordance with Section 907.2.10.1.

**Exceptions:**

1. Where there are interconnected smoke alarms meeting the requirements of Section 907.2.11 and there is not less than one manual fire alarm box per floor arranged to continuously sound the smoke alarms.
2. Other manually activated, continuously sounding alarms *approved by the fire code official*.

- ❖ Existing Group R-4 residential care/assisted living facilities must have a manual fire alarm system. Group R-4 residential care/assisted living facilities are defined in Section 202 as residential occupancies with more than five, but not more than 16, occupants living in a supervised environment.

Exception 1 allows the omission of the fire alarm system if installed interconnected smoke alarms can be manually activated by at least one manual fire alarm box on each floor.

Exception 2 allows the fire code official to approve alternative means of manually activating the alarms in place of a manual fire alarm box.

**1103.8 Single- and multiple-station smoke alarms.** Single- and multiple-station smoke alarms shall be installed in existing Group I-1 and R occupancies in accordance with Sections 1103.8.1 through 1103.8.3.

- ❖ This section introduces the requirements for the installation of smoke alarms in existing Group I-1 and R occupancies. These requirements recognize the benefit of installing smoke alarms in existing structures, but provide several exceptions for buildings that are not undergoing substantial renovations. These provisions also correlate with Section 704.2 of the *International Property Maintenance Code*® (IPMC®) for single- or multiple-station smoke alarm requirements for existing Group R dwellings.

**1103.8.1 Where required.** Existing Group I-1 and R occupancies shall be provided with single-station smoke alarms in accordance with Section 907.2.11. Interconnection and power sources shall be in accordance with Sections 1103.8.2 and 1103.8.3, respectively.

**Exceptions:**

1. Where the code that was in effect at the time of construction required smoke alarms and smoke alarms complying with those requirements are already provided.
2. Where smoke alarms have been installed in occupancies and dwellings that were not required to have them at the time of construction, additional smoke alarms shall not be required provided that the existing smoke alarms comply with requirements that were in effect at the time of installation.

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

3. Where smoke detectors connected to a fire alarm system have been installed as a substitute for smoke alarms.
- ❖ This section requires that Group I-1 and R occupancies be provided with single-station smoke alarms where they are not already provided. Reference is made to the new building requirements of Section 907.2.11 for the primary requirements; however, interconnection and power supply are more specifically addressed for existing buildings in Sections 1103.8.2 and 1103.8.3. Therefore, the basic requirement is that smoke alarms need to be provided in all locations required by Section 907.2.11, but several modified requirements related to interconnection of alarms and power supply are provided, recognizing the impracticality of such installations in existing conditions. Three exceptions are also provided to address possible scenarios where smoke alarms have already been installed but the installation does not meet the current code requirements, recognizing that the intent of the code is to permit existing smoke alarm installations to continue unchanged where they meet the code that was in effect at the time they were installed.

Exception 1 indicates that smoke alarms installed and maintained in accordance with the applicable code at the time of construction can continue unchanged. Exception 2 indicates that smoke alarms that were not required by the code at the time of construction, but were later installed can continue when they meet the requirements of the applicable code at the time of installation. Exception 3 indicates that smoke detectors connected to a fire alarm system may be used in lieu of smoke alarms.

In summary, this section requires the installation of smoke alarms in Group I-1 and R occupancies that do not currently have any smoke alarms. It does not require compliance with the current smoke alarm requirements if the building already has smoke alarms meeting requirements that were applicable when they were installed. The focus here is not to have the owner replace or revise his or her smoke alarms any time the code requirements for new construction change.

**1103.8.2 Interconnection.** Where more than one smoke alarm is required to be installed within an individual *dwelling* or *sleeping unit*, the smoke alarms shall be interconnected in such a manner that the activation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm. The alarm shall be clearly audible in all bedrooms over background noise levels with all intervening doors closed.

### Exceptions:

1. Interconnection is not required in buildings that are not undergoing *alterations*, repairs or construction of any kind.

2. Smoke alarms in existing areas are not required to be interconnected where *alterations* or repairs do not result in the removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or *basement* available that could provide access for interconnection without the removal of interior finishes.

- ❖ This section, like Section 907.2.11.5, requires that when multiple-station smoke alarms are present, they are to be interconnected and be audible over background noises. This section also includes language that would allow listed wireless alarms to substitute for wired interconnection of the smoke alarms in both new and existing construction, making it clear that listed wireless systems comply with the code. Historically, while some code officials have not recognized wireless interconnection of smoke alarms as meeting the code requirement for interconnection, most have accepted them as their use has proliferated and their reliability shown. See the commentary to Section 907.2.11.5 for further information on interconnection.

Exception 1 does not require interconnection where the building is not undergoing any construction or repairs. Exception 2 clarifies to what extent the building must be undergoing construction before interconnection is required. Generally, the exceptions try to be reasonable based on the practicality of such installations; therefore, unless areas such as attics or crawl spaces can still be utilized while the interior finishes are being removed (e.g., drywall removed, exposing the studs), interconnection would not be required. Such renovations may only be limited to portions of a structure; therefore, complete interconnection may not be practical or possible. The intent is that additional walls, etc., should not be removed solely to interconnect the smoke alarms. Battery-powered alarms, as allowed by Section 1103.8.3, may be required to be interconnected when a building is not supplied by a commercial power source.

**1103.8.3 Power source.** Single-station smoke alarms shall receive their primary power from the building wiring provided that such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery backup shall be connected to an emergency electrical system. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

### Exceptions:

1. Smoke alarms are permitted to be solely battery operated in existing buildings where construction is not taking place.
2. Smoke alarms are permitted to be solely battery operated in buildings that are not served from a commercial power source.
3. Smoke alarms are permitted to be solely battery operated in existing areas of buildings undergoing

*alterations* or repairs that do not result in the removal of interior walls or ceiling finishes exposing the structure, unless there is an attic, crawl space or *basement* available that could provide access for building wiring without the removal of interior finishes.

- ❖ This section requires both a primary power supply from the building wiring, as well as a supervised battery backup. Wiring must be permanent and supplied from a circuit that is properly overcurrent-protected, but without any on-off switching capability. Currently, there are some smoke alarms on the market that have an integral visual alarm notification component (a strobe light) that do not have a built-in battery for the strobe. Thus, if the power for the building fails, the smoke detection and audible signal of the device may still operate, but the strobe will not. It is critical for rooms that may house those with hearing impairments and are equipped with these smoke alarms that the strobe be as reliable as the audible signal element. This section resolves that concern by requiring such smoke alarms to be connected to an emergency electrical system for the required backup power in accordance with Section 604.

This section is very similar to Section 907.2.11.2. The primary differences are the exceptions.

Exception 1 allows the use of batteries as the sole power source if no construction or related repairs are occurring in the building.

Exception 2 allows the use of batteries as the sole power source if there is no other power source available (i.e., the building is without an electric utility connection).

Exception 3 clarifies to what extent the building must be undergoing construction before connection to the building wiring is required. Generally, the exceptions try to be reasonable based on the practicality of such installations; therefore, unless areas such as attics or crawl spaces can be utilized for interstitial access for wiring while the interior finishes are being removed (e.g., drywall removed, exposing the studs), connection to the building wiring would not be required. Such renovations may only be limited to portions of a structure; therefore, adding permanent wiring may not be practical or possible. The intent is that additional walls, etc., should not be removed solely to connect the smoke alarms to the building wiring.

**1103.9 Carbon monoxide alarms.** Existing Group I-1, I-2, I-4 and R occupancies shall be equipped with carbon monoxide alarms in accordance with Section 915, except that the carbon monoxide alarms shall be allowed to be solely battery operated.

- ❖ This section requires CO alarms in accordance with the requirements of Section 915. Section 915 provides very specific requirements on placement. However, these CO alarms for existing buildings are permitted to be battery powered. This recognizes the need for such protection and the practicality of provid-

ing it in existing buildings. Also note that Section 915 addresses Group E occupancies. This section does not address Group E occupancies. See the commentary to Section 915 for more detail on alarm requirements and placement.

**1103.10 Medical gases.** Medical gases stored and transferred in health-care-related facilities shall be in accordance with Chapter 53.

- ❖ This section requires compliance with Chapter 53 compressed gases when medical gases are stored and transferred in existing healthcare related facilities. This will address several different types of occupancies including Group I-2 and ambulatory care facilities but can also address facilities such as a small dentist office. It was considered necessary to make sure that all existing facilities comply with these requirements to meet CMS guidelines. A general reference was made since the medical gas requirements of Section 5306 are only one aspect of the regulation of compressed gases.

## SECTION 1104

### MEANS OF EGRESS FOR EXISTING BUILDINGS

**1104.1 General.** *Means of egress* in existing buildings shall comply with the minimum egress requirements where specified in Table 1103.1 as further enumerated in Sections 1104.2 through 1104.25, and the building code that applied at the time of construction. Where the provisions of this chapter conflict with the building code that applied at the time of construction, the most restrictive provision shall apply. Existing buildings that were not required to comply with a building code at the time of construction shall comply with the minimum egress requirements where specified in Table 1103.1 as further enumerated in Sections 1104.2 through 1104.25.

- ❖ The primary concept of this section is to require existing buildings to comply with the specific means of egress requirements for new buildings except as modified by this section. Where an item is specifically addressed by Section 1104, the requirements of this section are intended to be special allowances for existing buildings to not fully meet the requirements for new buildings in Sections 1003 through 1030.

For example, the guard height requirements in Section 1104.6 include exceptions for the guard height requirement for new buildings in Section 1015.2. The requirements for existing buildings in Section 1104 are intended to be the same or less stringent than the comparable provisions for new buildings in Sections 1003 through 1030.

This section applies to most existing buildings. However, where a building has been built to meet the requirements of the building code in effect at the time of construction and, in the opinion of the fire code official, the means of egress is not hazardous, the building would meet the intent of this section. As such, none of the specific requirements in this section would apply.

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

In the absence of any evidence of compliance with a building code at the time the building was constructed, all provisions of Sections 1104.1 through 1104.25 apply. See Chapter 14 of the IEBC for a performance-based compliance alternative analysis regimen for existing buildings, especially Sections 1401.6.11 through 1401.6.15, which deal with the means of egress analysis. Chapter 19 of the ICC *Performance Code*<sup>®</sup> (ICC PC<sup>®</sup>) also provides a performance approach to means of egress evaluation.

**1104.2 Elevators, escalators and moving walks.** Elevators, escalators and moving walks shall not be used as a component of a required *means of egress*.

**Exceptions:**

1. Elevators used as an *accessible means of egress* where allowed by Section 1009.4.
2. Previously *approved* elevators, escalators and moving walks in existing buildings.

❖ This section is the same as Section 1003.7, except Exception 2 is added. Thus, an escalator or moving walk could be used as part of the required means of egress in an existing building if it had been previously approved by the fire code official.

**1104.3 Exit sign illumination.** Exit signs shall be internally or externally illuminated. The face of an exit sign illuminated from an external source shall have an intensity of not less than 5 footcandles (54 lux). Internally illuminated signs shall provide equivalent luminance and be *listed* for the purpose.

**Exception:** *Approved* self-luminous signs that provide evenly illuminated letters shall have a minimum luminance of 0.06 foot-lamberts (0.21 cd/m<sup>2</sup>).

❖ This section is the same as Section 1013.3 for new buildings, except that Section 1013.3 includes an exception to illumination for tactile signs. The same exception should apply for existing buildings.

**1104.4 Power source.** Where emergency illumination is required in Section 1104.5, exit signs shall be visible under emergency illumination conditions.

**Exception:** *Approved* signs that provide continuous illumination independent of external power sources are not required to be connected to an emergency electrical system.

❖ This section requires that exit signs serving the occupancies listed in Section 1104.5 be illuminated during the use of emergency power for the means of egress. The comparable section for new buildings is Section 1013.6.3. Exit signs for all new building occupancies must be illuminated at all times and have an emergency power source.

**1104.5 Illumination emergency power.** Where *means of egress* illumination is provided, the power supply for *means of egress* illumination shall normally be provided by the premises' electrical supply. In the event of power supply fail-

ure, illumination shall be automatically provided from an emergency system for the following occupancies where such occupancies require two or more *means of egress*:

1. Group A having 50 or more occupants.

**Exception:** Assembly occupancies used exclusively as a place of worship and having an *occupant load* of less than 300.

2. Group B buildings three or more stories in height, buildings with 100 or more occupants above or below a *level of exit discharge* serving the occupants or buildings with 1,000 or more total occupants.
3. Group E in interior *exit access* and *exit stairways* and *ramps, corridors*, windowless areas with student occupancy, shops and laboratories.
4. Group F having more than 100 occupants.

**Exception:** Buildings used only during daylight hours and that are provided with windows for natural light in accordance with the *International Building Code*.

5. Group I.
6. Group M.

**Exception:** Buildings less than 3,000 square feet (279 m<sup>2</sup>) in gross sales area on one story only, excluding mezzanines.

7. Group R-1.

**Exception:** Where each *sleeping unit* has direct access to the outside of the building at grade.

8. Group R-2.

**Exception:** Where each *dwelling unit* or *sleeping unit* has direct access to the outside of the building at grade.

9. Group R-4.

**Exception:** Where each *sleeping unit* has direct access to the outside of the building at ground level.

❖ Section 1008.3 requires emergency power for emergency egress lighting in all new buildings along aisles, corridors and stairways leading through or from spaces where two or more means of egress are required. This section requires emergency power for emergency egress lighting only for the listed occupancy conditions for existing buildings.

**1104.5.1 Emergency power duration and installation.** Emergency power for *means of egress* illumination shall be provided in accordance with Section 604. In other than Group I-2, emergency power shall be provided for not less than 60 minutes for systems requiring emergency power. In Group I-2, essential electrical systems shall comply with Sections 1105.5.1 and 1105.5.2.

❖ A 90-minute emergency power duration for emergency egress lighting is required by Section 1008.3 for new buildings. The emergency power system for

emergency egress lighting in existing buildings in other than Group I-2 occupancies, however, is to provide power for at least 60 minutes. This duration is consistent with Section 1104.1 and with the new building requirements of at least one of the legacy building codes. In Group I-2 occupancies, a reference is made to the specific requirements found in Section 1105. More specifically, Section 1105.5.1 requires 90 minutes of power for emergency egress lighting and exit signs. Section 1105.5.2 requires that essential electrical power complies with NFPA 99, which covers a much wider use of emergency power needed in hospitals. See the commentary to Sections 1105.5.1 and 1105.5.2.

**1104.6 Guards.** Guards complying with this section shall be provided at the open sides of *means of egress* that are more than 30 inches (762 mm) above the floor or grade below.

❖ Where guards are required in this section, the requirements are the same as in Section 1015 for new buildings (see commentary, Section 1015.1). Sections 1104.6.1 and 1104.6.2 do provide allowances for the height and opening limitations that are less than required for new construction.

**1104.6.1 Height of guards.** Guards shall form a protective barrier not less than 42 inches (1067 mm) high.

**Exceptions:**

1. Existing guards on the open side of exit access and exit *stairways* and *ramps* shall be not less than 30 inches (760 mm) high.
2. Existing *guards* within *dwelling units* shall be not less than 36 inches (910 mm) high.
3. Existing *guards* in assembly seating areas.

❖ Guard height in new construction is typically 42 inches (1067 mm) minimum. In the legacy codes, there were allowances for guards to have the top rail at the height required for handrails when the guard was along a stairway or ramp (except for Group E). Exception 1 is in recognition of that allowance. Exceptions 2 and 3 are in recognition of the lower guard heights allowed within dwelling units (Section 1015.3 Exceptions 1, 2 and 3) and with assembly seating (Section 1029.16) for new construction.

**1104.6.2 Opening limitations.** Open *guards* shall have balusters or ornamental patterns such that a 6-inch-diameter (152 mm) sphere cannot pass through any opening up to a height of 34 inches (864 mm).

**Exceptions:**

1. At elevated walking surfaces for access to, and use of, electrical, mechanical or plumbing systems or equipment, guards shall have balusters or be of solid materials such that a sphere with a diameter of 21 inches (533 mm) cannot pass through any opening.
2. In occupancies in Group I-3, F, H or S, the clear distance between intermediate rails measured at right

angles to the rails shall not exceed 21 inches (533 mm).

3. *Approved* existing open guards.

❖ Generally, this section allows maximum openings of 6 inches (152 mm) versus the maximum openings of 4 inches (102 mm) allowed by Section 1015.4. Exception 1 mirrors Section 1015.4, Exception 3, and Exception 2 mirrors Section 1015.4, Exception 4.

**1104.7 Size of doors.** The minimum width of each door opening shall be sufficient for the *occupant load* thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). In ambulatory care facilities, doors serving as *means of egress* from patient treatment rooms or patient sleeping rooms shall provide a clear width of not less than 32 inches (813 mm). In Group I-2, *means of egress* doors where used for the movement of beds shall provide a clear width not less than 41½ inches (1054 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. The height of door openings shall be not less than 80 inches (2032 mm).

**Exceptions:**

1. The minimum and maximum width shall not apply to door openings that are not part of the required *means of egress* in occupancies in Groups R-2 and R-3.
2. Door openings to storage closets less than 10 square feet (0.93 m<sup>2</sup>) in area shall not be limited by the minimum width.
3. Width of door leaves in revolving doors that comply with Section 1010.1.1 shall not be limited.
4. Door openings within a *dwelling unit* shall be not less than 78 inches (1981 mm) in height.
5. Exterior door openings in *dwelling units*, other than the required *exit* door, shall be not less than 76 inches (1930 mm) in height.
6. *Exit access* doors serving a room not larger than 70 square feet (6.5 m<sup>2</sup>) shall be not less than 24 inches (610 mm) in door width.
7. Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the floor.

❖ Generally, this section requires doors to be at least 28 inches (711 mm) wide versus the minimum width of 32 inches (813 mm) for new construction in Section 1010.1.1. The 32-inch clear width for patient treatment or sleeping within ambulatory care facilities is based on the nature of the activities within the space. In Group I-2 occupancies, the need to move patients in beds requires a width of 41½ inches, consistent with new construction requirements. Other doors within ambulatory care facilities and Group I-2 occupancies could use the 28-inch width allowance.

The other provisions and exceptions in this section are the same as those in Section 1010.1.1 for new construction. Exceptions 2, 8, 9 and 10 of Section 1010.1.1 are not included in this section. Exception 2 is not needed since these provisions for existing buildings only require a 28-inch-wide (711 mm) door. Exception 8 relates to accessibility requirements that are not intended to be retroactively applied except within the context of the IEBC. Exceptions 9 and 10 are newer exceptions that have not been addressed in these retroactive provisions.

**1104.8 Opening force for doors.** The opening force for interior side-swinging doors without closers shall not exceed a 5-pound (22 N) force. The opening forces do not apply to the force required to retract latch bolts or disengage other devices that hold the door in a closed position. For other side-swinging, sliding and folding doors, the door latch shall release when subjected to a force of not more than 15 pounds (66 N). The door shall be set in motion when subjected to a force not exceeding 30 pounds (133 N). The door shall swing to a full-open position when subjected to a force of not more than 50 pounds (222 N). Forces shall be applied to the latch side.

❖ This section is similar to Section 1010.1.3. The allowance for fire doors to have a greater opening force in new construction has a broader context in this section, which allows for all doors with closers to not meet the 5-pound opening force. The maximum door-operating force in this section is less restrictive than that required in Section 1010.1.3 for new construction.

**1104.9 Revolving doors.** Revolving doors shall comply with the following:

1. A revolving door shall not be located within 10 feet (3048 mm) of the foot or top of *stairways* or escalators. A dispersal area shall be provided between the *stairways* or escalators and the revolving doors.
2. The revolutions per minute for a revolving door shall not exceed those shown in Table 1104.9.
3. Each revolving door shall have a conforming side-hinged swinging door in the same wall as the revolving door and within 10 feet (3048 mm).

**Exceptions:**

1. A revolving door is permitted to be used without an adjacent swinging door for street-floor elevator lobbies provided a stairway, escalator or door from other parts of the building does not discharge through the lobby and the lobby does not have any occupancy or use other than as a means of travel between elevators and a street.
  2. Existing revolving doors where the number of revolving doors does not exceed the number of swinging doors within 20 feet (6096 mm).
- ❖ This section is comparable with Section 1010.1.4.1 for new buildings. The capability of collapsing to a width of 36 inches (914 mm) in Condition 2 of Section

1010.1.4.1 for new construction does not apply to existing revolving doors. The two exceptions in this section are not allowed for new construction.

**TABLE 1104.9  
REVOLVING DOOR SPEEDS**

INSIDE DIAMETER (feet-inches)	POWER-DRIVEN-TYPE SPEED CONTROL (rpm)	MANUAL-TYPE SPEED CONTROL (rpm)
6-6	11	12
7-0	10	11
7-6	9	11
8-0	9	10
8-6	8	9
9-0	8	9
9-6	7	8
10-0	7	8

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

❖ Table 1008.1.4.1 for new construction has a wider range of door sizes and often has a slower maximum speed allowance than this table.

**1104.9.1 Egress component.** A revolving door used as a component of a *means of egress* shall comply with Section 1104.9 and all of the following conditions:

1. Revolving doors shall not be given credit for more than 50 percent of the required egress capacity.
2. Each revolving door shall be credited with not more than a 50-person capacity.
3. Revolving doors shall be capable of being collapsed when a force of not more than 130 pounds (578 N) is applied within 3 inches (76 mm) of the outer edge of a wing.

❖ This section is similar to Section 1014.1.4.1.1 for new construction.

**1104.10 Stair dimensions for existing stairways.** Existing *stairways* in buildings shall be permitted to remain if the rise does not exceed 8 1/4 inches (210 mm) and the run is not less than 9 inches (229 mm). Existing *stairways* can be rebuilt.

**Exception:** Other *stairways* approved by the *fire code official*.

❖ This section includes a much less stringent criterion for stairway treads and risers than that in Section 1011.5.2. This section also allows existing stairways to be rebuilt. The tread and riser dimensions of the rebuilt stairway have additional allowances in Section 1104.10.1.

**1104.10.1 Dimensions for replacement stairways.** The replacement of an existing *stairway* in a structure shall not be required to comply with the new *stairway* requirements of Section 1009 where the existing space and construction will not allow a reduction in pitch or slope.

❖ This section is consistent with Section 403.1 of the IEBC. The intent of this section is that where an existing stairway was built with a steeper rise/run ratio

than permitted in the current code, the stairway can be replaced with the existing configuration. Enlarging the opening to achieve the current rise/run ratio and headroom would be considered technically infeasible. The principle is that not allowing for this option could result in stairways that were not maintained because they could not be brought up to current codes.

**1104.11 Winders.** Existing winders shall be allowed to remain in use if they have a minimum tread depth of 6 inches (152 mm) and a minimum tread depth of 9 inches (229 mm) at a point 12 inches (305 mm) from the narrowest edge.

❖ In new construction, winders are only permitted within dwelling units and along curved or spiral stairways (Sections 1011.5.3, 1011.9 and 1011.10). The tread size allowances for existing stairways are smaller than permitted for curved stairways.

**1104.12 Curved stairways.** Existing curved *stairways* shall be allowed to continue in use, provided the minimum depth of tread is 10 inches (254 mm) and the smallest radius shall be not less than twice the width of the *stairway*.

❖ For other than certain residential occupancies, this section has fewer requirements than Section 1011.9 for new construction. The relaxed requirements of the exception of Section 1011.9 apply to Group R-3 occupancies and individual dwelling units in Group R-2 occupancies.

**1104.13 Stairway handrails.** *Stairways* shall have *handrails* on at least one side. *Handrails* shall be located so that all portions of the *stairway* width required for egress capacity are within 44 inches (1118 mm) of a *handrail*.

**Exception:** *Aisle stairs* provided with a center *handrail* are not required to have additional *handrails*.

❖ Handrails are required on both sides, with certain exceptions, for new construction compared to the requirement for one side in this section. The 44-inch (1118 mm) dimension in this section is an increase from the 30-inch (762 mm) dimension in Section 1014.9 for new construction. Handrails for assembly occupancies in new construction are covered in Section 1029.15. See Section 1014 for handrail requirements for new construction.

**1104.13.1 Height.** *Handrail* height, measured above *stair* tread nosings, shall be uniform, not less than 30 inches (762 mm) and not more than 42 inches (1067 mm).

❖ The allowable range of handrail height installation in this section is broader than the 34 inches (834 mm) up to 38 inches (965 mm) allowed for new construction in Section 1014.2. This is in recognition of previous allowances for the handrail to be the top rail of a guard. This is still permitted for new construction in assembly seating (see Section 1029.15, Exception 2).

**1104.14 Slope of ramps.** *Ramp* runs utilized as part of a *means of egress* shall have a running slope not steeper than one unit vertical in 10 units horizontal (10-percent slope).

The slope of other *ramps* shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

❖ The slope of means of egress ramps for new construction in Section 1012.2 is a maximum of 1:12. The steeper ramps of 1:8 slope in assembly aisles, as permitted by Section 1029.13 for new construction, should also apply to existing construction.

**1104.15 Width of ramps.** Existing *ramps* are permitted to have a minimum width of 30 inches (762 mm) but not less than the width required for the number of occupants served as determined by Section 1005.1. In Group I-2, *ramps* serving as a *means of egress* and used for the movement of patients in beds shall comply with Section 1105.5.4.

❖ Ramps for new construction in Section 1012.5.1 are required to have a minimum clear width of 36 inches (914 mm) between handrails compared to the 30-inch (762 mm) minimum ramp width requirement in this section (see commentary, Section 1012.5.1). This section also references the more specific requirements for Group I-2 occupancies in Section 1105.5.4. The minimum width required by that section is 48 inches. See the commentary to Section 1105.5.4.

**1104.16 Fire escape stairways.** Fire escape *stairways* shall comply with Sections 1104.16.1 through 1104.16.7.

❖ This section and the referenced sections provide detailed requirements for fire escape stairways. Fire escape stairways are allowed as a required means of egress only in an existing building, according to Section 405 of the IEBC. Sections 1104.16.1 through 1104.16.7 of the code are similar to Sections 405.1 through 405.5 of the IEBC.

**1104.16.1 Existing means of egress.** Fire escape *stairways* shall be permitted in existing buildings but shall not constitute more than 50 percent of the required *exit* capacity.

❖ Fire escapes are limited to serving 50 percent of the required exit capacity because they have minimum usability and are not appropriate for use by persons with limited physical capability.

**1104.16.2 Protection of openings.** Openings within 10 feet (3048 mm) of fire escape *stairways* shall be protected by opening protectives having a minimum  $\frac{3}{4}$ -hour *fire protection rating*.

**Exception:** In buildings equipped throughout with an *approved automatic sprinkler system*, opening protection is not required.

❖ It is important that openings in the vicinity of a fire escape are protected so that the fire escape will be usable during a fire. The exception for a sprinkler system takes into account the control of the fire by the sprinkler system.

**1104.16.3 Dimensions.** Fire escape *stairways* shall meet the minimum width, capacity, riser height and tread depth as specified in Section 1104.10.

❖ The riser height and tread depth requirement is the same as for existing stairways. The limits are speci-

fied in Section 1104.10; however, the minimum width and occupant capacity are not specified.

**1104.16.4 Access.** Access to a fire escape *stairway* from a *corridor* shall not be through an intervening room. Access to a fire escape *stairway* shall be from a door or window meeting the criteria of Section 1005.1. Access to a fire escape *stairway* shall be directly to a balcony, landing or platform. These shall not be higher than the floor or window sill level and not lower than 8 inches (203 mm) below the floor level or 18 inches (457 mm) below the window sill.

❖ This section establishes the arrangement of the fire escape to the building so that the fire escape can be easily reached. Access is not permitted through a room because the room could pose an unacceptable hazard or be locked. The elevation limits of the exterior landing, balcony or platform are to make the fire escape easily accessible.

**1104.16.5 Materials and strength.** Components of fire escape *stairways* shall be constructed of noncombustible materials. Fire escape *stairways* and balconies shall support the dead load plus a live load of not less than 100 pounds per square foot (4.78 kN/m<sup>2</sup>). Fire escape *stairways* and balconies shall be provided with a top and intermediate *handrail* on each side.

❖ The noncombustible construction requirement is so that the fire escape will be available for use during a fire. The loading of 100 pounds per square foot (psf) (4.78 kN/m<sup>2</sup>) anticipates that a number of persons will be using the fire escape at the same time. To verify the ongoing viability of fire escape stairways, Section 1104.16.5.1 requires tests or field surveys to validate the capacity.

**1104.16.5.1 Examination.** Fire escape *stairways* and balconies shall be examined for structural adequacy and safety in accordance with Section 1104.16.5 by a registered design professional or others acceptable to the *fire code official* every 5 years, or as required by the *fire code official*. An inspection report shall be submitted to the *fire code official* after such examination.

❖ Fire escape stairways are typically prohibited in new construction but do constitute a means of egress component in many existing, multistory buildings. Neither the IBC nor the code contain a specific definition as to what actually constitutes fire escape stairways, and in previous editions of the codes no frequency for their inspection was established. This section establishes an inspection frequency for fire escape stairways and balconies erected on existing buildings. By design, fire escape stairways present a concern to code officials because the stairways, ladders, balconies and mechanical fasteners are commonly constructed of carbon or galvanized steel, which will rust, and this reduces their strength if they are not properly maintained. The evaluation is necessary to confirm that this exterior stairway egress component satisfies a minimum design load requirement prescribed in Section 1104.16.5; is properly maintained; and available for service in the event of an

emergency that requires the occupants to egress the building.

Unless otherwise specified by the fire code official, an inspection of fire escape stairways and their balconies is required every 5 years to verify compliance with the structural requirements of Section 1104.16.5. The individual evaluating fire escapes is required to be a registered design professional as defined in Chapter 2 or an individual approved by the fire code official, and a report of the inspection must be provided to the fire code official.

**1104.16.6 Termination.** The lowest balcony shall not be more than 18 feet (5486 mm) from the ground. Fire escape *stairways* shall extend to the ground or be provided with counterbalanced *stairs* reaching the ground.

**Exception:** For fire escape *stairways* serving 10 or fewer occupants, an *approved* fire escape ladder is allowed to serve as the termination.

❖ This section controls the elevation of the lowest fire escape balcony. For fire escapes that serve 10 or fewer people, a ladder from the lowest balcony to the ground is permitted. In all other cases, the lower balcony is to be served by fire escape stairways. The counterbalance keeps the fire escape stairway up and off ground level when not in use.

**1104.16.7 Maintenance.** Fire escape *stairways* shall be kept clear and unobstructed at all times and shall be maintained in good working order.

❖ This section prohibits using the fire escape for outdoor storage or any other activity that could block its full and instant use. Fire escapes must be kept in good condition so they will be available for use (also see Section 1031.7).

**1104.17 Corridor construction.** Corridors serving an occupant load greater than 30 and the openings therein shall provide an effective barrier to resist the movement of smoke. Transoms, louvers, doors and other openings shall be kept closed or be self-closing. In Group I-2, corridors in areas housing patient sleeping or care rooms shall comply with Section 1105.4.

**Exceptions:**

1. *Corridors* in occupancies other than in Group H, that are equipped throughout with an *approved automatic sprinkler system*.
2. *Corridors* in occupancies in Group E where each room utilized for instruction or assembly has not less than one-half of the required *means of egress* doors opening directly to the exterior of the building at ground level.
3. *Corridors* that are in accordance with the *International Building Code*.

❖ This section relates to Section 1020.1 for new construction. This section requires the corridors to be an effective barrier to resist the movement of smoke. Section 1020.1 for new construction requires that corridors have a fire-resistance rating. Generally, solid

walls and doors that would resist smoke migration are the focus of this section. The walls or doors need not have a fire-resistance rating.

A pointer is provided to the requirements for Group I-2 occupancies in areas where such occupancies contain patient sleeping and care. Section 1105.4 provides specific requirements related to the separation requirements, allowable openings. See the commentary to Section 1105.4.

**1104.17.1 Corridor openings.** Openings in *corridor* walls shall comply with the requirements of the *International Building Code*.

**Exceptions:**

1. Where 20-minute fire door assemblies are required, solid wood doors not less than 1.75 inches (44 mm) thick or insulated steel doors are allowed.
  2. Openings protected with fixed wire glass set in steel frames.
  3. Openings covered with 0.5-inch (12.7 mm) gypsum wallboard or 0.75-inch (19.1 mm) plywood on the room side.
  4. Opening protection is not required where the building is equipped throughout with an *approved automatic sprinkler system*.
- ❖ This section makes reference to the IBC requirements for corridor openings. Section 1020.1 specifies that corridors required to be fire-resistance rated are to be constructed according to Section 708 of the IBC for fire partitions. Section 708.6 of the IBC refers to Section 716 of the IBC for protected openings in smoke partitions. Thus, Section 716 of the IBC applies to existing buildings where a fire-resistance-rated corridor would be required for new construction, except where one of the exceptions in this section applies. The exceptions in this section provide a number of practical alternatives for existing buildings.

**1104.18 Dead end corridors.** Where more than one exit or exit access doorway is required, the *exit access* shall be arranged such that dead ends do not exceed the limits specified in Table 1104.18. In Group I-2, in smoke compartments containing patient sleeping rooms and treatment rooms, dead end *corridors* shall be in accordance with Section 1105.5.6.

**Exception:** A dead-end passageway or *corridor* shall not be limited in length where the length of the dead-end passageway or *corridor* is less than 2.5 times the least width of the dead-end passageway or *corridor*.

- ❖ This section references Table 1104.18 for the dead-end corridor limits for existing buildings. The dead-end limit for new construction is in Section 1020.4. That section includes the same exception that is in this section for existing buildings. Dead-end corridors are not a concern for conditions where the exception is satisfied because travel is not limited to a single path. Generally, the dead-end travel limits in Table 1104.18 are more liberal than those in Section 1020.4 for new construction. Note that Table 1104.18 refers

to Section 1105.5.6 for Group I-2 occupancies with regard to dead-end corridor limits.

**TABLE 1104.18.** See page 11-24.

- ❖ This table contains the existing building limits for common path of travel, dead-end limit and travel distance limits. See the commentary to Sections 1104.18, 1104.19 and 1104.20 for a discussion regarding the table.

**1104.19 Exit access travel distance.** *Exits* shall be located so that the maximum length of exit access travel, measured from the most remote point to an *approved exit* along the natural and unobstructed path of egress travel, does not exceed the distances given in Table 1104.18.

- ❖ This section references Table 1104.18 for the exit access travel distance limits for existing buildings. The travel distance limits for new construction are in Section 1017.1. Generally, the travel distance limits in Table 1104.18 for existing construction are the same as those in Table 1017.2 for new construction, except for Group H and I occupancies.

**1104.20 Common path of egress travel.** The *common path of egress travel* shall not exceed the distances given in Table 1104.18.

- ❖ This section refers to Table 1104.18 for the common path of egress travel for existing buildings. The common path of egress travel limits for new construction are in Section 1006.2.1. Generally, the limits in Table 1104.18 for existing construction are the same as in Section 1006.2.1 for new construction.

**1104.21 Stairway discharge identification.** An interior *exit stairway* or *ramp* that continues below its *level of exit discharge* shall be arranged and marked to make the direction of egress to a *public way* readily identifiable.

**Exception:** *Stairways* that continue one-half story beyond their *levels of exit discharge* need not be provided with barriers where the *exit discharge* is obvious.

- ❖ The requirements of this section are less stringent than the discharge identification requirements for new construction in Section 1023.8. The new construction provisions require that a barrier be placed within the stairway to prevent persons from unintentionally continuing into the levels below the exit discharge. The exception in this section is also not included in the requirements for new construction.

**1104.22 Exterior stairway protection.** *Exterior exit stairways* shall be separated from the interior of the building as required in Section 1027.6. Openings shall be limited to those necessary for egress from normally occupied spaces.

**Exceptions:**

1. Separation from the interior of the building is not required for buildings that are two stories or less above grade where the *level of exit discharge* serving such occupancies is the first story above grade.
2. Separation from the interior of the building is not required where the exterior *stairway* is served by an

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

exterior balcony that connects two remote exterior stairways or other approved exits, with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be not less than 50 percent of the height of the enclosing wall, with the top of the opening not less than 7 feet (2134 mm) above the top of the balcony.

3. Separation from the interior of the building is not required for an exterior stairway located in a building or structure that is permitted to have unenclosed interior stairways in accordance with Section 1023.

4. Separation from the open-ended corridors of the building is not required for exterior stairways provided that:

4.1. The open-ended corridors comply with Section 1020.

4.2. The open-ended corridors are connected on each end to an exterior exit stairway complying with Section 1027.

4.3. At any location in an open-ended corridor where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3 m<sup>2</sup>) or an exterior stairway shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

❖ The exterior stairway requirements of this section are similar to those for new construction in Section 1027.1, except for Exception 1. Exception 1 in this section applies to all two-story buildings where the level of the exit discharge is the first story above

**TABLE 1104.18  
COMMON PATH, DEAD-END AND TRAVEL DISTANCE LIMITS (by occupancy)**

OCCUPANCY	COMMON PATH LIMIT		DEAD-END LIMIT		TRAVEL DISTANCE LIMIT	
	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)
Group A	20/75 <sup>a</sup>	20/75 <sup>a</sup>	20 <sup>b</sup>	20 <sup>b</sup>	200	250
Group B <sup>h</sup>	75	100	50	50	200	300
Group E	75	75	20	50	200	250
Group F-1, S-1 <sup>d, h</sup>	75	100	50	50	200	250
Group F-2, S-2 <sup>d, h</sup>	75	100	50	50	300	400
Group H-1	25	25	0	0	75	75
Group H-2	50	100	0	0	75	100
Group H-3	50	100	20	20	100	150
Group H-4	75	75	20	20	150	175

Group I-1	75	75	20	50	200	250
Group I-2	Notes e, g	Notes e, g	Note f	Note f	150	200 <sup>c</sup>
Group I-3	100	100	NR	NR	150 <sup>c</sup>	200 <sup>c</sup>
Group I-4 (Day care centers)	NR	NR	20	20	200	250
Group M (Covered or open mall)	75	100	50	50	200	400
Group M (Mercantile)	75	100	50	50	200	250
Group R-1 (Hotels)	75	75	50	50	200	250
Group R-2 (Apartments)	75	125	50	50	200	250
Group R-3 (One- and two-family)	NR	NR	NR	NR	NR	NR
Group R-4 (Residential care/assisted living)	NR	NR	NR	NR	NR	NR
Group U <sup>h</sup>	75	100	20	50	300	400

NR = No requirements.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m<sup>2</sup>.

a. 20 feet for common path serving 50 or more persons; 75 feet for common path serving less than 50 persons.

b. See Section 1029.9.5 for dead-end aisles in Group A occupancies.

c. This dimension is for the total travel distance, assuming incremental portions have fully utilized their allowable maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.

d. See the *International Building Code* for special requirements on spacing of doors in aircraft hangars.

e. In Group I-2, separation of exit access doors within a care recipient sleeping room, or any suite that includes care recipient sleeping rooms, shall comply with Section 1105.5.7.

f. In Group I-2, in smoke compartments containing care recipient sleeping rooms and treatment rooms, dead-end corridors shall comply with Section 1105.5.6.

g. In Group I-2 Condition 2, care recipient sleeping rooms, or any suite that includes care recipient sleeping rooms, shall comply with Section 1105.6.

h. Where a tenant space in Group B, S and U occupancies has an occupant load of not more than 30, the length of a common path of egress travel shall not be more than 100 feet.

grade. In new buildings, Group R-1 and R-2 occupancies would not be allowed to apply this exception. Exception 3 has been deleted from the new construction requirements. Exception 4 does not have requirements for the building to be sprinklered or a reference to Section 1023.7 for exterior walls.

**1104.23 Minimum aisle width.** The minimum clear width of *aisles* shall be:

1. Forty-two inches (1067 mm) for aisle stairs having seating on each side.

**Exception:** Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

2. Thirty-six inches (914 mm) for stepped *aisles* having seating on only one side.

**Exceptions:**

1. Thirty inches (760 mm) for catchment areas serving not more than 60 seats.
2. Twenty-three inches (584 mm) between a stepped aisle *handrail* and seating where an *aisle* does not serve more than five rows on one side.

3. Twenty inches (508 mm) between a stepped *aisle handrail* or *guard* and seating where the *aisle* is subdivided by the *handrail*.

4. Forty-two inches (1067 mm) for level or ramped *aisles* having seating on both sides.

**Exception:** Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

5. Thirty-six inches (914 mm) for level or ramped *aisles* having seating on only one side.

**Exception:** Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

6. In Group I-2, where *aisles* are used for movement of patients in beds, *aisles* shall comply with Section 1105.5.8.

❖ Items 1 through 5 in this section primarily provide the minimum aisle widths for assembly seating. Similar requirements for new construction are in Section 1029.9.1. Several of the exceptions in this section allow for narrower aisles than permitted in Section 1029.9.1; thus, the requirements for existing buildings are less stringent than those for new construction. Item 6 of this section is a pointer to the specific aisle requirements for Group I-2 occupancies where aisles are used for movement of people. See the commentary to Section 1105.5.8.

**1104.24 Stairway floor number signs.** Existing *stairways* shall be marked in accordance with Section 1023.9.

❖ This section requires that existing stairs be marked in the same manner as new stairways (see commentary, Section 1023.9). The signage includes important information for people evacuating the building as well emergency responders.

**1104.25 Egress path markings.** Existing high-rise buildings of Group A, B, E, I, M and R-1 occupancies shall be provided with luminous *egress* path markings in accordance with Section 1025.

**Exception:** Open, unenclosed stairwells in historic buildings designated as historic under a state or local historic preservation program.

❖ This section requires that luminous exit path markings be provided in existing buildings on the same basis as in new buildings to facilitate rapid egress and assist in full building evacuation. The text is based on Recommendations 17 and 18 of the National Institute of Standards and Technology's (NIST) report on the World Trade Center (WTC) tragedy. In New York City, after the first bombing of the WTC, requirements were instituted to require exit path markings in vertical exit enclosures in new and existing buildings. This section is taken directly from those requirements.

The marking requirement is only applicable to those buildings that have occupied floors exceeding 75 feet (22 860 mm) above the lowest level of fire department vehicle access. The cost impact on existing buildings is minor when considering the life safety benefit. Therefore, it is logical and affordable to provide existing high-rise buildings with the same protections afforded new high-rise structures.

Historically, code requirements for high-rise buildings were written under the assumption that the building would be evacuated floor by floor. In most instances, in a building with a full suppression system, only the floor where the fire is located and the floors immediately above and below would be evacuated. Acts of terrorism and accidental incidents, such as power failures, have made it necessary to consider design for full building evacuation that is as rapid as possible. This may be made necessary in response to events both within and outside the building. This provision is intended to facilitate the most rapid possible full building evacuation. See the commentary to Section 1025 for a more complete discussion of luminous egress path markings.

The exception takes into account the aesthetics and possible natural light in an open, unenclosed stairway in a historic building. Also, since the requirement is only applicable to high-rise buildings, the requirement would have limited application in historic structures.

## SECTION 1105 CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

**1105.1 General.** Existing Group I-2 shall meet all of the following requirements:

1. The minimum fire safety requirements in Section 1103.
2. The minimum mean of egress requirements in Section 1104.

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

3. The additional egress and construction requirements in Section 1105.

Where the provisions of this chapter conflict with the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

❖ This section provides minimum requirements for existing Group I-2 occupancies. The intent is to increase the minimum safety requirements because of the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. These provisions align with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are provided to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements reflect consideration of the minimum previously approved construction methods and provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials. In addition, these provisions are consistent with current national standards used by the federal government, providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

Several sources were reviewed to determine what the appropriate minimum bar should be, including the current building and fire codes, current CMS guidelines, and previous versions of the model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these requirements were both necessary and achievable.

This particular section provides scoping for these provisions. Areas in hospitals and nursing homes not in patient care areas will use the general provisions in Sections 1103 and 1104. More restrictive provisions for hospitals or nursing homes are listed in Section 1105. As stated in the general comments at the beginning of this chapter and the commentary to Sections 1101.2 and 1103.5.2, where the buildings must upgrade, consideration of allowable time frames and procedures will need to be worked out between the authority having jurisdiction and those responsible for repairs and alterations in the nursing homes and hospitals.

**1105.2 Construction.** Group I-2 Condition 2 shall not be located on a floor level higher than the floor level limitation in Table 1105.2 based on the type of construction.

❖ Section 1105.2 is a retroactive limitation for the allowable height based on construction type because it is a

key component of the regulatory approval for a health care facility. While most, if not all, existing hospitals were built to comply with these minimum construction requirements, many were built using methods that predated the current construction type matrix. The allowance for the occupancies, as stipulated in Table 1105.2, are less than that for new construction and are consistent with what is currently mandated for licensure for healthcare facilities.

**1105.3 Incidental uses in existing Group I-2.** Incidental uses associated with and located within existing single-occupancy or mixed-occupancy Group I-2 buildings and that generally pose a greater level of risk to such occupancies shall comply with the provisions of Sections 1105.3.1 through 1105.3.3.2.1. Incidental uses in Group I-2 occupancies are limited to those listed in Table 1105.3.

❖ Incidental use area provisions are applicable to new construction in Section 509 of the IBC; however, similar provisions are needed for existing Group I-2 occupancies since the hazards posed by such rooms or spaces are no different for existing buildings than for new. Section 1105.3 and Table 1105.3 are very similar to and based upon IBC Section 509 and Table 509, except that references to occupancies other than Group I-2 are not included. The basic requirements proposed for incidental uses in existing healthcare occupancies rely on the provisions of the IBC for specifics of construction and protection. Sections 1105.3.1 through 1105.3.3.2.1 are based on IBC Sections 509.2 through 509.4.2.1. These provisions will provide correlation with not only the IBC but also with the operational and CMS program standards for existing Group I-2 occupancies.

This specific section establishes the scope of Section 1105.3 and its applicability to Group I-2 occupancies. Incidental uses are rooms or areas that constitute special hazards or risks to life safety that are not typically addressed by the provisions for the occupancy group in which they occur, even though such rooms or areas may functionally be an extension of the primary use. Only those rooms or areas indicated in Table 1105 are to be regulated as incidental uses. Incidental uses can be located within both single-occupancy and mixed-occupancy buildings. The concern is that those areas designated as incidental uses pose a risk to the remainder of the building, and as such, some degree of protection is required. The nature of these incidental uses is such that they are small areas not frequented by building occupants, in which a fire could get underway and go unnoticed for a longer time than in a more frequently occupied part of the building.

**1105.3.1 Occupancy classification.** Incidental uses shall not be individually classified in accordance with Section 302.1 of the *International Building Code*. Incidental uses shall be included in the building occupancies within which they are located.

❖ Consistent with the IBC, this section expressly states that incidental uses are not considered as separate

and distinct occupancy classifications but, rather, are classified the same as the occupancies in which they are located. As an example, a waste and linen collection room in a hospital would be classified as a portion of the Group I-2 occupancy even though it may present a level of hazard more akin to a Group S-1 occupancy.

**1105.3.2 Area limitations.** Incidental uses shall not occupy more than 10 percent of the building area of the story in which they are located.

❖ The proposed floor area limitation of 10 percent for incidental uses emphasizes the ancillary nature of such rooms and areas and correlates with the IBC. Each incidental use would be limited to a maximum floor area of 10 percent of the floor area of the story in which it is located. Where there are two or more tenants located on the same story, the 10-percent limitation is based on the floor area of each individual tenant space rather than that of the entire story. The application of the limit on a tenant-by-tenant basis is consistent with the concept of incidental uses typically being ancillary only to a portion of the building (i.e., the specific tenant occupancy).

**1105.3.3 Separation and protection.** The incidental uses listed in Table 1105.3 shall be separated from the remainder

of the building or equipped with an *automatic sprinkler system*, or both, in accordance with the provisions of that table.

❖ In addition to identifying those rooms or areas that warrant regulation as incidental uses, Table 1105.3 also indicates the required degree of protection or separation. The requirements identified in Table 1105.3 vary depending on the incidental use. In some cases, a specific type of separation and/or protection is required, while in others there is an option.

**1105.3.3.1 Separation.** Where Table 1105.3 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building in accordance with Section 509.4.1 of the *International Building Code*.

❖ Where a fire-resistance rated separation would be required, the incidental use would need to be separated from other portions of the building in accordance with assemblies complying with the IBC.

**1105.3.3.2 Protection.** Where Table 1105.3 permits an *automatic sprinkler system* without a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building by construction capable of resisting the passage of smoke in accordance with Section 509.4.2 of the *International Building Code*.

❖ In this section, where Table 1105.1 would allow protection by an automatic sprinkler system without a

**TABLE 1105.2

VB	Note b	P	NP	NP	NP
	Note c	NP	NP	NP	NP

P = Permitted; NP = Not permitted.

a. Floor level shall be counted based on the number of stories above grade.

b. The building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

c. The building is equipped with an automatic sprinkler system in accordance with Section 1105.8.

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

fire-resistance-rated separation, the construction enclosing the incidental use would still need to resist the passage of smoke. Construction details for resisting the passage of smoke are provided in the IBC. Note that this requirement is not specifying a smoke partition. The smoke partition requirements in IBC Section 710 are specific requirements that must be directly referenced.

**1105.3.3.2.1 Protection limitation.** Except as otherwise specified in Table 1105.2 for certain incidental uses, where an *automatic sprinkler system* is provided in accordance with Table 1105.3, only the space occupied by the incidental use need be equipped with such a system.

❖ This section makes it clear that the sprinkler systems stipulated in Table 1105.3 would be required for the incidental use area only.

**1105.4 Corridor construction.** In Group I-2, in areas housing patient sleeping or care rooms, *corridor* walls and the opening protectives therein shall provide a barrier designed to resist the passage of smoke in accordance with Sections 1105.4.1 through 1105.4.7.

❖ The focus of this section is specifically for corridor construction in patient care and sleeping room areas in Group I-2 occupancies. The construction of corridors is intended to provide protection that will resist the passage of smoke. The provisions address the type of materials required, fire resistance rating requirements, opening protection and corridor wall continuity.

Existing corridor construction should primarily be evaluated for its ability to resist or limit the transfer of smoke, regardless of the code at the time of construction. This is consistent with the defend-in-place scenario for patient protection during a fire event (see Section 405). Corridor walls, even if they were built 60 years ago, should be regularly assessed to confirm that they minimize the transfer of smoke. This section describes some criteria by which this can be assessed.

**1105.4.1 Materials.** The walls shall be of materials permitted by the building type of construction.

❖ This section simply requires that the materials used to construct the corridors be consistent with the type of construction. If it is a noncombustible construction (Type I or II), the walls must be constructed in accordance with Table 601 of the IBC unless Section 603 of the IBC provides any exceptions.

**1105.4.2 Fire-resistance rating.** Unless required elsewhere in this code, corridor walls are not required to have a fire-resistance rating.

❖ The key with corridor walls is more about the resistance of the passage of smoke and less about the fire resistance. This section clarifies that these walls are not required to be fire-resistance rated unless another requirement, such as for a smoke barrier or incidental use area separation, would prompt such fire-resistance rating.

**TABLE 1105.3  
INCIDENTAL USES IN EXISTING GROUP I-2 OCCUPANCIES**

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input	1 hour or provide automatic sprinkler system
Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic sprinkler system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen fuel gas rooms, not classified as Group H	2 hours
Incinerator rooms	2 hours and provide automatic sprinkler system
Paint shops not classified as Group H	2 hours; or 1 hour and provide automatic sprinkler system
Laboratories and vocational shops, not classified as Group H	1 hour or provide automatic sprinkler system
Laundry rooms over 100 square feet	1 hour or provide automatic sprinkler system
Patient rooms equipped with padded surfaces	1 hour or provide automatic sprinkler system
Physical plant maintenance shops	1 hour or provide automatic sprinkler system
Waste and linen collection rooms with containers with total volume of 10 cubic feet or greater	1 hour or provide automatic sprinkler system
Storage rooms greater than 100 square feet	1 hour or provide automatic sprinkler system
Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons for flooded lead-acid, nickel cadmium or VRLA, or more than 1,000 pounds for lithium-ion and lithium metal polymer used for facility standby power, emergency power or uninterruptible power supplies	2 hours

For SI: 1 square foot = 0.0929 m<sup>2</sup>, 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

**1105.4.3 Corridor wall continuity.** *Corridor* walls shall extend from the top of the foundation or floor below to one of the following:

1. The underside of the floor or roof sheathing, deck or slab above.
  2. The underside of a ceiling above where the ceiling membrane is constructed to limit the passage of smoke.
  3. The underside of a lay-in ceiling system where the ceiling system is constructed to limit the passage of smoke and where the ceiling tiles weigh not less than 1 pound per square foot (4.88 kg/m<sup>2</sup>) of tile.
- ❖ As discussed in Section 1105.4.2, providing a barrier is the key to corridor effectiveness. Section 1105.4.2 does not require a fire-resistance rating for existing corridors, but the separation that the corridor provides needs to be continuous to a point where the separated spaces are protected. This section provides three solutions to achieve this. The first focuses simply on extending all the way to the floor or roof sheathing, deck or slab above. The other options allow the separation to stop at the finished ceiling. The conditions of ending the separation at the ceiling membrane are conditioned on the ceiling being able to resist the passage of smoke. In the case of lay-in ceilings they must also meet the minimum weight requirement to increase the likelihood that they will stay in place.

**1105.4.4 Openings in corridor walls.** Openings in *corridor* walls shall provide protection in accordance with 1105.4.4.1 through 1105.4.4.3.

❖ Openings in corridor walls present the largest failures of such separations. This section addresses both windows and doors located in corridor walls. Again, these provisions are intended to address the condition of existing walls and may not be consistent with new construction.

**1105.4.4.1 Windows.** Windows in *corridor* walls shall be sealed to limit the passage of smoke, or the window shall be automatic-closing upon detection of smoke, or the window opening shall be protected by an automatic closing device that closes upon detection of smoke.

**Exception:** In smoke compartments not containing patient sleeping rooms, pass-through windows or similar openings shall be permitted in accordance with Section 1105.4.4.3.

❖ Windows must effectively employ one of the three following methods to resist the passage of smoke:

- Proper sealing.
- Automatic closing on detection of smoke (smoke detection system).
- Automatic closing by automatic closing device (single-station smoke detector).

The exception addresses lower risk areas where no patient sleeping rooms are present.

**1105.4.4.2 Doors.** Doors in *corridor* walls shall comply with Sections 1105.4.4.2.1 through 1105.4.4.2.3.

❖ This section addresses various different issues related to doors in corridor walls. These provisions provide some basic safety while providing flexibility in existing hospitals. As with the other provisions, these requirements and allowances are consistent with federal compliance requirements.

**1105.4.4.2.1 Louvers.** Doors in *corridor* walls shall not include louvers, transfer grills or similar openings.

**Exception:** Doors shall be permitted to have louvers, transfer grills or similar openings at toilet rooms or bathrooms; storage rooms that do not contain storage of flammable or combustible material; and storage rooms that are not required to be separated as incidental uses.

❖ Louvers, transfer grilles or similar openings present an increased risk of smoke passing into protected spaces. Therefore, these openings are generally prohibited. The exception addresses spaces where passage of smoke presents a reduced risk as such spaces are not typically occupied or their occupancy is limited.

**1105.4.4.2.2 Corridor doors.** Doors in *corridor* walls shall limit the transfer of smoke by complying with the following:

1. Doors shall be constructed of not less than 1<sup>3</sup>/<sub>4</sub> inch-thick (44 mm) solid bonded-core wood or capable of resisting fire not less than 1/3 hour.

**Exception:** Corridor doors in buildings equipped throughout with an automatic sprinkler system.

2. Frames for side-hinged swinging doors shall have stops on the sides and top to limit transfer of smoke.
3. Where provided, vision panels in doors shall be a fixed glass window assembly installed to limit the passage of smoke. Existing wired glass panels with steel frames shall be permitted to remain in place.
4. Door undercuts shall not exceed 1 inch (25 mm).
5. Doors shall be positive latching with devices that resist not less than 5 pounds (22.2 N). Roller latches are prohibited.
6. Mail slots or similar openings shall be permitted in accordance with Section 1105.4.4.3.

❖ This section provides the list of necessary requirements that existing doors in corridors must meet. Often the criteria provide some allowances not given for new construction. All criteria must be addressed if applicable.

Item 1 requires a door to be of substantial construction in nonsprinklered buildings. Either a 1/3-hour fire-rated door is required or an equivalent door is prescribed. The exception allows no rating for the door in buildings equipped throughout with an automatic sprinkler system.

Item 2 requires frames to have stops on the sides and top to minimize the transfer of smoke on swinging doors.

Item 3 addresses vision panels. This item allows wired glass panels in steel frames to continue to be used where they would not be allowed in new construction.

Item 4 minimizes door undercuts to 1 inch to prevent additional smoke passage.

Item 5 addresses how such doors are required to latch. Roller latches are prohibited as they may be compromised during a fire event and lead to the door opening.

Item 6 is consistent with Section 1105.4.4.3 and allows mail slots or similar openings under certain conditions for doors in corridors.

**1105.4.4.2.3 Dutch doors.** Where provided, dutch doors shall comply with Section 1105.4.4.2.2. In addition, dutch doors shall be equipped with latching devices on either the top or bottom leaf to allow leaves to latch together. The space between the leaves shall be protected with devices such as astragals to limit the passage of smoke.

❖ Dutch doors have been used in health care facilities for many years for various necessary operational reasons. While the IBC does not specifically speak of dutch doors, their use is not prohibited but must meet the requirements contained in IBC Section 407.3, including positive latching and limiting the transfer of smoke. This section provides clarity for existing installations by giving specific guidance on the minimum acceptable requirements, including positive latching and smoke transfer, for their use in corridor walls. A definition is provided in Section 202 for further clarity.

**1105.4.4.2.4 Self- or automatic-closing doors.** Where self- or automatic-closing doors are required, closers shall be maintained in operational condition.

❖ This section is provided to make sure that self- or automatic-closing doors continue to be operational. If automatic-closing doors that are no longer operational are propped open, the function of the corridor is reduced. It is important to note that this section does not require self-closing or automatic-closing doors; it is simply requiring that they be maintained.

**1105.4.4.3 Openings in corridor walls and doors.** In other than smoke compartments containing patient sleeping rooms, mail slots, pass-through windows or similar openings shall not be required to be protected where the aggregate area of the openings between the *corridor* and a room are not greater than 80 square inches (51 613 mm<sup>2</sup>) and are located with the top edge of any opening not higher than 48 inches above the floor.

❖ This section is essentially an exception for existing mail slot, pass-through and similar openings that are commonly found in hospitals. These are needed for privacy, medication security and other operational needs. The restrictions on their location are consistent with federal requirements.

**1105.4.5 Penetrations.** The space around penetrating items shall be filled with an *approved* material to limit the passage of smoke.

❖ Penetrations, though smaller than door and window openings, can create locations for smoke to pass through and must be addressed. Group I-2 occupancies often have many pipes penetrating walls that must be addressed. Many smaller openings can lead to a larger overall area of smoke passage.

**1105.4.6 Joints.** Joints shall be filled with an *approved* material to limit the passage of smoke.

❖ Similar to penetrations, joints that are formed at the intersections of walls and floor/ceiling assemblies and roof assemblies can create other avenues of smoke passage. If not addressed, these small openings can lead to a hazard during building fires.

**1105.4.7 Ducts and air transfer openings.** The space around a duct penetrating a smoke partition shall be filled with an *approved* material to limit the passage of smoke. Air transfer openings in smoke partitions shall be provided with a smoke damper complying with Section 717.3.2.2 of the *International Building Code*.

**Exception:** Where the installation of a smoke damper will interfere with the operation of a required smoke control system in accordance with Section 909, approved alternative protection shall be utilized.

❖ Anytime a duct penetrates a wall, the space around the duct must be minimally protected to prevent smoke passage during fire. Group I-2 occupancies may have complex HVAC systems that can lead to a multitude of ducts passing through walls. Air transfer openings through corridor walls need to be protected with smoke dampers in accordance with IBC Section 717.3.2.2 unless such dampers will affect the performance of a smoke control system.

**1105.5 Means of egress.** In addition to the *means of egress* requirements in Section 1104, Group I-2 facilities shall meet the *means of egress* requirements in Section 1105.5.1 through 1105.5.8.

❖ These provisions are intended to provide minimal means of egress requirements specific to Group I-2 occupancies, where these occupancies work on a defend-in-place strategy and the needs are unique. Sections 1105.5.1 through 1105.5.8 address a variety of issues, such as exit signs, emergency illumination, door size, corridor width, dead ends and exit separation.

**1105.5.1 Exit signs and emergency illumination.** The power system for exit signs and emergency illumination for the *means of egress* shall provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator.

❖ Existing hospitals must provide 90 minutes of power for exit signs and emergency illumination. However,

this power can be provided via storage batteries where this would not be permitted by Exception 2 to Section 1013.6.3 for new buildings.

**1105.5.2 Emergency power for operational needs.** The essential electrical system shall be capable of supplying services in accordance with NFPA 99.

❖ This section takes the provisions of Section 1104.5.1 further by adding requirements from and references to NFPA 99. Similar to Section 604.3, it requires facility owners or operators to analyze the hazards in their particular region and prepare accordingly.

**1105.5.3 Size of door.** Means of egress doors used for the movement of patients in beds shall provide a minimum clear width of 41½ inches (1054 mm). The height of the door opening shall be not less than 80 inches (2032 mm).

**Exceptions:**

1. Door closers and door stops shall be permitted to be 78 inches (1981 mm) minimum above the floor.
2. In Group I-2 Condition 1, existing means of egress doors used for the movement of patients in beds that provide a minimum clear width of 32 inches (813 mm) shall be permitted to remain.

❖ This section is consistent with Section 1104.7. It follows the format and requirements of Section 1010.1.1. There are two exceptions that allow the door closers and door stops to not meet the door-opening height. This is a reasonable allowance for existing buildings and is consistent with Exception 5 to Section 1010.1.1, which allows door-opening heights in dwelling units and sleeping units to be 78 inches. The second exception provides flexibility to Group I-2 Condition 1 occupancies such as nursing homes, which do not depend upon these door widths being available as frequently for bed movement.

**1105.5.4 Ramps.** In areas where *ramps* are used for movement of patients in beds, the clear width of the *ramp* shall be not less than 48 inches (1219 mm).

❖ This section, which is referenced from Section 1104.15, provides the width necessary for ramps in Group I-2 occupancies where beds are being moved. Section 1104.15 only requires a 30-inch width.

**1105.5.5 Corridor width.** In areas where *corridors* are used for movement of patients in beds, the clear width of the *corridor* shall be not less than 48 inches (1219 mm).

❖ This section is consistent with the width required for ramps in Section 1105.5.4 and is focused on the width required for the movement of beds. The requirement of 48 inches clear width is less restrictive than that required of new construction in Section 1020.2. New Group I-2 occupancies are required a 96-inch clear width.

**1105.5.6 Dead-end corridors.** In smoke compartments containing patient sleeping rooms and treatment rooms, dead-end

*corridors* shall not exceed 30 feet (9144 mm) unless approved by the *fire code official*.

❖ The dead-end corridor requirements are specific to Group I-2 occupancies. Typically in new construction the dead-end corridor would be limited to 20 feet. This provides more flexibility but is consistent with the CMS requirements.

**1105.5.7 Separation of exit access doors.** Patient sleeping rooms, or any suite that includes patient sleeping rooms, of more than 1,000 square feet (92.9 m<sup>2</sup>) shall have not less than two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors.

❖ This requirement addresses the need for exit separation in larger patient sleeping rooms and suites. Once they become large enough, the need for two exits becomes more important. This section is less restrictive than Section 1007.1.1 by only requiring ⅓ the diagonal of the space versus ½. This requirement may result in the need for an additional exit access door in such spaces.

**1105.5.8 Aisles.** In areas where *aisles* are used for movement of patients in beds, the clear width of the *aisle* shall be not less than 48 inches (1219 mm).

❖ This requirement is consistent with the widths established for ramps and corridors in Sections 1105.5.4 and 1105.5.5, respectively. Again, this width is associated with areas where bed movement will occur.

**1105.6 Smoke compartments.** Smoke compartments shall be provided in existing Group I-2 Condition 2, in accordance with Sections 1105.6.1 through 1105.6.4.

❖ Smoke compartments are a key component of the defend-in-place strategy, a strategy where occupants are protected from fire without relocation, used in healthcare facilities to limit the movement of smoke. These compartments act as safe locations for patients by preventing the spread of smoke. Through compartmentalization, patients may remain safely in their rooms as fire suppression systems and fire responders extinguish the fire. Under severe fire conditions that threaten the immediate compartment area, patients may be evacuated horizontally to the safety of an adjacent compartment on the same floor. Being able to do this is critical since, because of the health status of many patients, their evacuation from the building might put them in danger. The proper design, construction and application of smoke compartments will provide added protection, buy valuable time and save lives of critically ill patients before a total evacuation may become necessary.

These requirements are provided to assist code officials and surveyors during the ongoing regular inspection of hospital facilities. These inspections are required by federal laws for certification and reim-

bursement. These requirements consider the minimum previously approved construction methods. This is consistent with the federal requirements to which these facilities are currently held. Sections 1105.6.1 through 1105.6.6 provide all the necessary elements for existing facilities.

**1105.6.1 Design.** Smoke barriers shall be provided to subdivide each story used for patients sleeping with an occupant load of more than 30 patients into not fewer than two smoke compartments.

❖ The defend-in-place concept is a basic minimum level of safety for these facilities. Every facility should be equipped with at least two smoke compartments for temporary relocation of patients. This section addresses acceptable configurations of smoke barrier walls and smoke barriers in existing hospitals for each story with sleeping rooms accommodating 30 or more patients.

**1105.6.1.1 Refuge areas.** Refuge areas shall be provided within each smoke compartment. The size of the refuge area shall accommodate the occupants and care recipients from the adjoining smoke compartment. Where a smoke compartment is adjoined by two or more smoke compartments, the minimum area of the refuge area shall accommodate the largest occupant load of the adjoining compartments.

The size of the refuge area shall provide the following:

1. Not less than 30 net square feet (2.8 m<sup>2</sup>) for each care recipient confined to a bed or stretcher.
2. Not less than 15 square feet (1.4 m<sup>2</sup>) for each resident in a Group I-2 using mobility assistance devices.
3. Not less than 6 square feet (0.56 m<sup>2</sup>) for each occupant not addressed in Items 1 and 2.

Areas of spaces permitted to be included in the calculation of the refuge area are *corridors*, sleeping areas, treatment rooms, lounge or dining areas and other low-hazard areas.

❖ This section addresses adequate sizing of refuge areas. IBC Section 407.5.1 also includes requirements for sizing refuge areas. Otherwise, the provisions are fairly consistent.

**1105.6.2 Smoke barriers.** Smoke barriers shall be constructed in accordance with Section 709 of the *International Building Code*.

**Exceptions:**

1. Existing smoke barriers are permitted to remain where the existing smoke barrier has a minimum fire-resistance rating of 1/2 hour.
2. Smoke barriers shall be permitted to terminate at an atrium enclosure in accordance with Section 404.6 of the *International Building Code*.

❖ Generally, compliance with the IBC is required for smoke barriers. However, the intent of the first exception is to bring noncompliant smoke barriers to at least 1/2-hour fire-resistance rating. Previously approved smoke barriers are not intended to be

reduced to 1/2 hour. Chapter 7 requires maintenance of approved construction. The second exception addresses termination of the smoke barrier. Typically, smoke barriers are required to terminate at outside walls.

**1105.6.3 Opening protectives.** Openings in smoke barriers shall be protected in accordance with Section 716 of the *International Building Code*. Opening protectives shall have a minimum fire-protection-rating of 1/3 hour.

**Exception:** Existing wired glass vision panels in doors shall be permitted to remain.

❖ This section addresses doors in smoke barriers in existing Group I-2 occupancies. This section requires compliance as applicable with Section 716. The rating of doors is required to be a minimum of 20 minutes. Openings in doors with wired glass are permitted to remain.

**1105.6.4 Penetrations.** Penetrations of smoke barriers shall comply with the *International Building Code*.

**Exception:** Approved existing materials and methods of construction.

❖ Penetrations, as with corridor construction, can be numerous and lead to smoke movement from one smoke compartment to another. This section requires that such penetrations be dealt with in accordance with the IBC. Sealing penetrations is a reasonable requirement to increase patient safety. There is some flexibility provided if such penetrations have already been addressed to the satisfaction of the fire code official.

**1105.6.5 Joints.** Joints made in or between smoke barriers shall comply with the *International Building Code*.

**Exception:** Approved existing materials and methods of construction.

❖ Joints formed by the intersection of smoke barriers and floor/ceiling and roof assemblies can often create gaps where smoke can spread. This simply requires compliance with the IBC to protect those joints. Similar to Section 1105.6.4 addressing penetrations, there is some flexibility provided if such joints have already been addressed to the satisfaction of the fire code official.

**1105.6.6 Duct and air transfer openings.** Penetrations in a smoke barrier by duct and air transfer openings shall comply with Section 717 of the *International Building Code*.

**Exception:** Where existing duct and air transfer openings in smoke barriers exist without smoke dampers, they shall be permitted to remain. Any changes to existing smoke dampers shall be submitted for review and approved in accordance with Section 717 of the *International Building Code*.

❖ Similar to penetrations and joints, where ducts and air transfer openings penetrate a smoke barrier they must be sealed in accordance with the IBC. IBC Section 717.5.5 requires a smoke damper unless Exception 2 to that section is met. Exception 2 to Section

717.5.5 recognizes a fully ducted system in a building equipped throughout with an automatic sprinkler system. See the commentary to IBC Section 717.5.5. The application of that exception is limited to Group I-2 Condition 2 occupancies.

The exception to this section recognizes that existing duct and air transfer openings may be permitted to remain without smoke dampers. Any modification of existing smoke dampers would have to go through the normal process for making an alteration to existing construction. The exception is not intended to allow the removal of existing smoke dampers but instead allow the continuance of existing conditions that did not require them.

**1105.7 Group I-2 care suites.** Care suites in existing Group I-2 Condition 2 occupancies shall comply with Sections 407.4.3 through 407.4.3.6.2 of the *International Building Code*.

❖ This proposal defines the requirements for care suites (both sleeping and nonsleeping) that are an integral design concept for many areas within a hospital. Typical uses include intensive care units, operating rooms, emergency departments and imaging departments. The suites allow for better and safer care than non-suite options. These provisions deal with common paths of travel, separation of exit access doors, and number of doors passed through (i.e., previously intervening rooms) in suites. See the commentary to Sections 407.4.3 through 407.4.3.6.2 of the IBC.

**1105.8 Group I-2 automatic sprinkler system.** An *automatic sprinkler system* installed in accordance with Section 903.3.1.1 shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the *level of exit discharge*.

❖ This section requires that an automatic sprinkler system be provided on the floor containing the Group I-2 occupancy and all floors between that level and the level of exit discharge. This is a general requirement for all Group I-2 occupancies. Automatic sprinkler protection of existing Group I-2 occupancies is of critical importance due to the nature of the occupants. In Group I-2 occupancies, the occupants are, by definition, considered not capable of self-preservation. The evacuation difficulties associated with these occupants create the need to incorporate a defend-in-place philosophy of fire protection in occupancies in Group I-2. For this reason, all such existing occupancies are to be protected with an automatic sprinkler system.

This is an especially important requirement for nursing homes. An NFPA report, *Facilities that Care for the Aged Including Nursing Homes and Residential Board and Care*, states, "The death rate per 1,000 fires was 82 percent lower when automatic suppression systems were present." The report further states,

"Residents of these facilities are particularly vulnerable. The risk increases with increasing age. Consequently, the aged are considered a high-risk population. Institutional facilities that care for older adults must work diligently to prevent fires and to train staff and to equip the property (e.g., active systems) for effective response should a fire occur."

Note that Section 1103.5.3 requires an automatic sprinkler system be installed throughout the entire building containing a group I-2 Condition 2 occupancy. See the commentary to Section 1103.5.3 for more discussion on the intended application of that section.

**1105.9 Group I-2 automatic fire alarm system.** An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2.

**Exception:** Manual fire alarm boxes in patient sleeping areas shall not be required at *exits* if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 are not exceeded.

❖ Because care recipients may be incapable of self-evacuation and thus would rely on staff for assistance, an approved fire alarm system is required in existing Group I-2 occupancies. The system must comply with Section 907.2.6.2 (see commentary, Section 907.2.6.2). Note that Section 1105.8 requires sprinkler protection in existing Group I-2 occupancies and that the requirements of this section are in addition thereto. This provision is not intended to override the allowances for "private mode" in Section 907.2.6.2. Typical audible and visible alarms could be a detriment in some areas of a hospital, such as where patients are undergoing procedures.

**1105.10 Essential electrical systems.** Essential electrical systems in Group I-2 Condition 2 occupancies shall be in accordance with Sections 1105.10.1 and 1105.10.2.

❖ Both requirements within Sections 1105.10.1 and 1105.10.2 are specific to Group I-2 Condition 2 occupancies. This section addresses the requirements related to the needs of essential power and the reassessment to ensure that current installations will still meet the needs of the hospitals they support.

**1105.10.1 Where required.** In Group I-2 Condition 2 occupancies where life support is being provided, an essential electrical system shall be provided in accordance with NFPA 99.

❖ This section requires existing Group I-2 Condition 2 occupancies to provide essential electrical systems where life support is being provided. This section would require any buildings that would not be addressed by CMS but have similar risks to provide these necessary power resources. Buildings that are already approved through CMS are required to provide essential power.

## CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

**1105.10.2 Installation and duration.** In Group I-2 Condition 2 occupancies, the installation and duration of operation of existing essential electrical systems shall be based on a hazard vulnerability analysis conducted in accordance with NFPA 99.

❖ This section requires a reassessment of the essential electrical systems based on a hazard vulnerability analysis to make sure that the systems meet the needs of the facilities for emergencies. This requirement would apply whether or not the facility is being altered or has been damaged. If “substantial improvement” of the building occurs, per the IBC and IEBC definition, ASCE 24 would require this analysis. The flood provision section addresses such concerns as the location of equipment in a flood plain.

### SECTION 1106 REQUIREMENTS FOR OUTDOOR OPERATIONS

**1106.1 Tire storage yards.** Existing tire storage yards shall be provided with fire apparatus access roads in accordance with Sections 1106.1.1 and 1106.1.2.

❖ This section introduces the fire apparatus access provisions that follow.

**1106.1.1 Access to piles.** Access roadways shall be within 150 feet (45 720 mm) of any point in the storage yard where storage piles are located not less than 20 feet (6096 mm) from any storage pile.

❖ See the commentary to Section 3406.2.

**1106.1.2 Location within piles.** Fire apparatus access roads shall be located within all pile clearances identified in Section 3405.4 and within all fire breaks required in Section 3405.5.

❖ See the commentary to Sections 3405.4 and 3405.5.

# Valuable Guides to Changes in the 2015 I-Codes®

**NEW!**

**FULL COLOR! HUNDREDS OF PHOTOS AND ILLUSTRATIONS!**

## SIGNIFICANT CHANGES TO THE 2015 INTERNATIONAL CODES®

Practical resources that offer a comprehensive analysis of the critical changes made between the 2012 and 2015 editions of the codes. Authored by ICC code experts, these useful tools are “must-have” guides to the many important changes in the 2015 International Codes.

**SIGNIFICANT CHANGES TO THE IBC, 2015 EDITION**  
#7024S15

**SIGNIFICANT CHANGES TO THE IRC, 2015 EDITION**  
#7101S15

**SIGNIFICANT CHANGES TO THE IFC, 2015 EDITION**  
#7404S15

**SIGNIFICANT CHANGES TO THE IPC/IMC/IFGC, 2015 EDITION**  
#7202S15

Changes are identified then followed by in-depth discussion of how the change affects real world application. Photos, tables and illustrations further clarify application.

**ICC** INTERNATIONAL  
CODE  
COUNCIL®

People Helping People Build a Safer World®

# The International Code Council's Training and Education Department

Industry professionals look to ICC to provide the critical knowledge and experiences necessary to excel in today's challenging world. ICC's educational programs cover a broad spectrum of code and construction related topics, offering some of the highest quality instruction direct from the source.

## INSTITUTES

*Acquire Skills, Share Experiences, Earn CEUs*

ICC's training institutes offer a comprehensive education experience and a great way to earn much needed CEUs. Learn best practices from the leading experts in the field, build your network of professional contacts and share experiences. Institutes are held across the country throughout the year. To see the full schedule go to [www.iccsafe.org/training](http://www.iccsafe.org/training).

## HIRE ICC TO TEACH

*Bring ICC On-Site and Earn CEUs*

Give your group the confidence they need to meet tough challenges head-on so they can reach their full potential. ICC's course catalog contains a wide variety of educational topics that are available for contract at a location of your choice. Customized training is also available to fit your needs. For our full course catalogue go to [www.iccsafe.org/hireicc](http://www.iccsafe.org/hireicc).

## ICC ONLINE CAMPUS

*Earn CEUs at Your Own Pace*

Online courses offer access to a comprehensive training and education portal, providing you with an effective and convenient tool to enhance your professional skills. Courses are available anytime for 99 days following registration. Go to [www.iccsafe.org/onlinecampus](http://www.iccsafe.org/onlinecampus) for our full offerings.

For more information about ICC's Training please contact us at  
**888-ICC-SAFE (422-7233) ext. 33818** or email us at [icctraining@iccsafe.org](mailto:icctraining@iccsafe.org).

# Get Connected with the Best Code Resources and Member Benefits in the Industry

As a building professional, being connected to a Member-driven association that offers exclusive I-Code resources and training can play a vital role in building your career. No other building code association offers you more I-Code resources to help enhance your code knowledge and your career than the International Code Council® (ICC®).

## *Become an ICC Member now to take advantage of:*

- Free code opinions from I-Codes experts
- Free I-Code book(s) or download to new Members\*
- Discounts on I-Code resources, training and certification renewal
- Free access to employment opportunities in the ICC Career Center, including posting jobs
- Free benefits - Governmental Members: Your staff can receive free ICC benefits too\*
- Great opportunities to network at ICC events
- ***Savings of up to 25% on code books & Training materials***

***Get connected now!*** Visit our Member page at [www.iccsafe.org/membership](http://www.iccsafe.org/membership) or call 1-888-ICC-SAFE (422-7233), ext. 33804 to join or learn more today!

\*Some restrictions apply. Speak with an ICC Member Services Representative for details.

## 2015 I-Code Essentials

This helpful series uses a straightforward, focused approach to explore code requirements with non-code language, allowing readers to gain confidence in their understanding of the material. Each book is an invaluable companion guide to the 2015 IBC, IRC, IFC or IECC for both new and experienced code users.

- Detailed full-color illustrations enhance comprehension of code provisions
- A focused, concise approach facilitates understanding of the essential code provisions
- References to corresponding code sections provide added value as companion guides to the 2015 I-Codes
- Glossary of code and construction terms clarifies their meaning in the context of the code

### A. BUILDING CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL BUILDING CODE

Explores those code provisions essential to understanding the application of the IBC in an easy-to-read format. The user-friendly approach of the text simplifies critical concepts so users can achieve a more complete understanding of the code's intent. Full-color illustrations, examples and simplified tables assist the reader in visualizing the code requirements. This up-to-date, step-by-step guide's topic organization reflects the intent of the IBC and facilitates understanding and application of the code provisions.

SOFT COVER #4031S15

PDF DOWNLOAD #8950P596

### B. RESIDENTIAL CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL RESIDENTIAL CODE

Explains those code provisions essential to understanding the application of the IRC to the most commonly encountered building practices. The information is presented in a user-friendly manner with an emphasis on technical accuracy and clear non-code language. Full-color illustrations, examples and simplified tables assist the reader in visualizing the code requirements.

### C. FIRE CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL FIRE CODE

Focuses on the essential provisions of the IFC for controlling ignition sources and fire hazards, fire department access to buildings, building uses and processes, fire protection and life safety systems, special processes and uses and hazardous materials.

SOFT COVER #4431S15

PDF DOWNLOAD #8950P59

### D. ENERGY CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL ENERGY CONSERVATION CODE®

Designed to provide a straightforward, easy-to-read companion guide to the IECC for both beginning and experienced code users. The text provides accurate information on critical energy code applications in the office and in the field for residential and commercial construction. The focused coverage examines those code provisions essential to understanding the application of the IECC to the most commonly encountered building practices and discusses the reasons behind the requirements.

# PREFACE

The principal purpose of the Commentary is to provide a basic volume of knowledge and facts relating to building construction as it pertains to the regulations set forth in the 2015 *International Fire Code*. The person who is serious about effectively designing, constructing and regulating buildings and structures will find the Commentary to be a reliable data source and reference to almost all components of the built environment.

As a follow-up to the *International Fire Code*, we offer a companion document, the *International Fire Code Commentary—Volume II*. Volume II covers Chapters 20 through 80 and Appendices A through M of the 2015 *International Fire Code*. The basic appeal of the Commentary is thus: it provides in a small package and at reasonable cost thorough coverage of many issues likely to be dealt with when using the *International Fire Code* — and then supplements that coverage with historical and technical background. Reference lists, information sources and bibliographies are also included.

Throughout all of this, effort has been made to keep the vast quantity of material accessible and its method of presentation useful. With a comprehensive yet concise summary of each section, the Commentary provides a convenient reference for regulations applicable to the construction of buildings and structures. In the chapters that follow, discussions focus on the full meaning and implications of the code text. Guidelines suggest the most effective method of application, and the consequences of not adhering to the code text. Illustrations are provided to aid understanding; they do not necessarily illustrate the only methods of achieving code compliance.

The format of the Commentary includes the full text of each section, table and figure in the code, followed immediately by the commentary applicable to that text. At the time of printing, the Commentary reflects the most up-to-date text of the 2015 *International Fire Code*. Each section's narrative includes a statement of its objective and intent, and usually includes a discussion about why the requirement commands the conditions set forth. Code text and commentary text are easily distinguished from each other. All code text is shown as it appears in the *International Fire Code*, and all commentary is indented below the code text and begins with the symbol ❖.

Readers should note that the Commentary is to be used in conjunction with the *International Fire Code* and not as a substitute for the code. The Commentary is advisory only; the code official alone possesses the authority and responsibility for interpreting the code.

Comments and recommendations are encouraged, for through your input, we can improve future editions. Please direct your comments to the Codes and Standards Development Department at the Chicago District Office.

The International Code Council would like to extend its thanks to the following individuals for their contributions to the technical content of this commentary:

Jeff Hugo  
Elley Klausbruckner

## Arrangement and Format of the 2015 IFC

Before applying the requirements of the IFC it is beneficial to understand its arrangement and format. The IFC, like other codes published by the International Code Council, is arranged and organized to follow sequential steps that generally occur during a plan review or inspection. The 2015 IFC is organized into seven Parts as illustrated in the tables below. Each Part represents a broad subject matter and includes the chapters that logically fit under the subject matter of each Part. It is also foreseeable that additional chapters will need to be added in the future as regulations for new processes or operations are developed. Accordingly, the reorganization was designed to accommodate such future chapters by providing reserved (unused) chapters in several of the Parts. This will allow the subject matter parts to be conveniently and logically expanded without requiring a major renumbering of the IFC chapters.

<b>2015 ORGANIZATION OF THE IFC</b>	
<b>Parts and Chapters</b>	<b>Subject Matter</b>
Part I – Chapters 1 and 2	Administrative and definitions
Part II – Chapters 3 and 4	General safety provisions
Part III – Chapters 5 through 11	Building and equipment design features
Part III – Chapters 12 through 19	Reserved for future use
Part IV – Chapters 20 through 37	Special occupancies and operations
Part IV – Chapters 38 through 49	Reserved for future use
Part V – Chapters 50 through 67	Hazardous materials
Part V – Chapters 68 through 79	Reserved for future use
Part VI – Chapter 80	Referenced standards
Part VII – Appendices A through M	Adoptable and informational appendices

The IFC requirements for fire-resistive construction, interior finish, fire protection systems, means of egress and construction safeguards are directly correlated to the chapters containing parallel requirements in the IBC, as follows:

<b>IFC Chapter</b>	<b>Subject</b>
7	Fire and smoke protection features
8	Interior finish, decorative materials and furnishings
9	Fire protection systems
10	Means of egress
33	Fire safety during construction and demolition

# LEGISLATION

The *International Codes* are designed and promulgated to be adopted by reference by legislative action. Jurisdictions wishing to adopt the 2015 *International Fire Code Commentary* as an enforceable set of regulations for the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises should ensure that certain factual information is included in the adopting legislation at the time adoption is being considered by the appropriate governmental body. The following sample adoption legislation addresses several key elements, including the information required for insertion into the code text.

## SAMPLE LEGISLATION FOR ADOPTION OF THE *INTERNATIONAL FIRE CODE* ORDINANCE NO. \_\_\_\_\_

A[N] [ORDINANCE/STATUTE/REGULATION] of the [NAME OF JURISDICTION] adopting the 2015 edition of the *International Fire Code*, regulating and governing the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises in the [NAME OF JURISDICTION]; providing for the issuance of permits and collection of fees therefor; repealing [ORDINANCE/STATUTE/REGULATION] No. \_\_\_\_\_ of the [NAME OF JURISDICTION] and all other ordinances or parts of laws in conflict therewith.

The [GOVERNING BODY] of the [NAME OF JURISDICTION] does ordain as follows:

**Section 1.** That a certain document, three (3) copies of which are on file in the office of the [TITLE OF JURISDICTION'S KEEPER OF RECORDS] of [NAME OF JURISDICTION], being marked and designated as the *International Fire Code*, 2015 edition, including Appendix Chapters [FILL IN THE APPENDIX CHAPTERS BEING ADOPTED] (see *International Fire Code* Section 101.2.1, 2015 edition), as published by the International Code Council, be and is hereby adopted as the Fire Code of the [NAME OF JURISDICTION], in the State of [STATE NAME] regulating and governing the safeguarding of life and property from fire and explosion hazards arising from the storage, handling and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises as herein provided; providing for the issuance of permits and collection of fees therefor; and each and all of the regulations, provisions, penalties, conditions and terms of said Fire Code on file in the office of the [NAME OF JURISDICTION] are hereby referred to, adopted, and made a part hereof, as if fully set out in this legislation, with the additions, insertions, deletions and changes, if any, prescribed in Section 2 of this ordinance.

**Section 2.** That the following sections are hereby revised:

Section 101.1. Insert: [NAME OF JURISDICTION]

Section 109.4. Insert: [OFFENSE, DOLLAR AMOUNT, NUMBER OF DAYS]

Section 111.4. Insert: [DOLLAR AMOUNT IN TWO LOCATIONS]

**Section 3.** That the geographic limits referred to in certain sections of the 2015 *International Fire Code* are hereby established as follows:

Section 5704.2.9.6.1 (geographic limits in which the storage of Class I and Class II liquids in above-ground tanks outside of buildings is prohibited): [JURISDICTION TO SPECIFY]

Section 5706.2.4.4 (geographic limits in which the storage of Class I and Class II liquids in above-ground tanks is prohibited): [JURISDICTION TO SPECIFY]

Section 5806.2 (geographic limits in which the storage of flammable cryogenic fluids in stationary containers is prohibited): [JURISDICTION TO SPECIFY]

Section 6104.2 (geographic limits in which the storage of liquefied petroleum gas is restricted for the protection of heavily populated or congested areas): [JURISDICTION TO SPECIFY]

**Section 4.** That [ORDINANCE/STATUTE/REGULATION] No. \_\_\_\_\_ of [NAME OF JURISDICTION] entitled [FILL IN HERE THE COMPLETE TITLE OF THE LEGISLATION OR LAWS IN EFFECT AT THE PRESENT TIME SO THAT THEY WILL BE REPEALED BY SPECIFIC REFERENCE] and all other ordinances or parts of laws in conflict herewith are hereby repealed.

**Section 5.** That if any section, subsection, sentence, clause or phrase of this legislation is, for any reason, held to be unconstitutional, such decision shall not affect the validity of the remaining portions of this ordinance. The [GOVERNING BODY] hereby declares that it would have passed this law, and each section, subsection, clause or phrase thereof, irrespective of the fact that any one or more sections, subsections, sentences, clauses and phrases be declared unconstitutional.

**Section 6.** That nothing in this legislation or in the Fire Code hereby adopted shall be construed to affect any suit or proceeding impending in any court, or any rights acquired, or liability incurred, or any cause or causes of action acquired or existing, under any act or ordinance hereby repealed as cited in Section 4 of this law; nor shall any just or legal right or remedy of any character be lost, impaired or affected by this legislation.

**Section 7.** That the [JURISDICTION'S KEEPER OF RECORDS] is hereby ordered and directed to cause this legislation to be published. (An additional provision may be required to direct the number of times the legislation is to be published and to specify that it is to be in a newspaper in general circulation. Posting may also be required.)

**Section 8.** That this law and the rules, regulations, provisions, requirements, orders and matters established and adopted hereby shall take effect and be in full force and effect [TIME PERIOD] from and after the date of its final passage and adoption.

# TABLE OF CONTENTS

*Part IV—Special Occupancies and Operations* ..... 20-1

**CHAPTER 20 AVIATION FACILITIES** ..... 20-1 – 20-18

**CHAPTER 21 DRY CLEANING** ..... 21-1 – 21-12

**CHAPTER 22 COMBUSTIBLE DUST-PRODUCING OPERATIONS** ..... 22-1 – 22-4

**CHAPTER 23 MOTOR FUEL-DISPENSING FACILITIES AND REPAIR GARAGES** ..... 23-1 – 23-44

**CHAPTER 24 FLAMMABLE FINISHES** ..... 24-1 – 24-36

RETROACTIVE AUTOMATIC SPRINKLER REQUIREMENT ..... M-1 – M-2**

**INDEX ..... INDEX-1 – INDEX-32**

## Part IV—Special Occupancies and Operations

# Chapter 20: Aviation Facilities

### General Comments

Safe and efficient operation of airports, heliports and aircraft service facilities requires a comprehensive understanding of fire safety and aviation activities. The principal nonflight operational hazards associated with aviation involve fuel, facilities and operations. Conflicts have developed in recent years between airport security and life safety requirements because of an increased concern about air piracy and terrorism. The Federal Aviation Administration (FAA) regulates airport and air carrier security operations. These regulations strictly limit access to the air operations area. Unauthorized individuals must be prevented from entering air operations areas during all operating conditions, including emergencies in the terminal building. Concurrently, airport designs have traditionally included large unconfined

areas for the movement of people and their belongings. Because most contemporary passenger terminal buildings resemble covered malls, Section 402 of the *International Building Code*® (IBC®) permits passenger transportation terminals to comply with the requirements for a covered mall building and, in fact, includes them in the definition of “Covered mall building.”

### Purpose

Chapter 20 specifies minimum requirements for the fire-safe operation of airports, heliports and helistops. Safe use of flammable and combustible liquids during fueling and maintenance operations is emphasized. Availability of portable Class B:C-rated fire extinguishers for prompt control or suppression of incipient fires is required.

---

### SECTION 2001 GENERAL

**2001.1 Scope.** Airports, heliports, helistops and aircraft hangars shall be in accordance with this chapter.

❖ This chapter discusses fire and life safety in the ground environment modes. These modes include aircraft maintenance, aircraft refueling, aircraft hangars, helistops and heliports.

**2001.2 Regulations not covered.** Regulations not specifically contained herein pertaining to airports, aircraft maintenance, aircraft hangars and appurtenant operations shall be in accordance with nationally recognized standards.

❖ If a regulation is not addressed in this chapter, one must go to a recognized standard for the regulation. Ground operations must be conducted in accordance with recognized standards.

**2001.3 Permits.** For permits to operate aircraft-refueling vehicles, application of flammable or combustible finishes and hot work, see Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued (see commentary, Section 105.6 for a general

discussion of operations requiring a permit). The three operations listed in this section pose possible fire hazards because an ignition source close to them would create a hazardous situation. The operations must be reviewed for safety concerns and requirements.

### SECTION 2002 DEFINITIONS

**2002.1 Definitions.** The following terms are defined in Chapter 2:

**AIRCRAFT OPERATION AREA (AOA).**

**AIRPORT.**

**HELIPORT.**

**HELISTOP.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

**SECTION 2003  
GENERAL PRECAUTIONS**

**2003.1 Sources of ignition.** Open flames, flame-producing devices and other sources of ignition shall not be permitted in a hangar, except in *approved* locations or in any location within 50 feet (15 240 mm) of an aircraft-fueling operation.

❖ Smoking and carrying any open-flame device within 50 feet (15 240 mm) of any fueling operation is prohibited because of flammable vapors that are likely to be present during fueling operations. Electrical equipment on aircraft is usually not approved for use in hazardous (classified) locations, and disconnection of electrical devices often produces sparks, possibly igniting flammable vapor-air mixtures. Consequently, fueling operations must be discontinued before connecting or disconnecting these devices.

**2003.2 Smoking.** Smoking shall be prohibited in aircraft-refueling vehicles, aircraft hangars and aircraft operation areas used for cleaning, paint removal, painting operations or fueling. “No Smoking” signs shall be provided in accordance with Section 310.

**Exception:** Designated and *approved* smoking areas.

❖ An aircraft hangar is simply a building that provides weather protection and shop space during aircraft maintenance and storage. In the maintenance process, many hazards are present. Smoking is prohibited in all areas where an aircraft is located because of the potential presence of fuel vapors. The exception gives the fire code official the authority to evaluate and approve designated smoking areas.

**2003.3 Housekeeping.** The aircraft operation area (AOA) and related areas shall be kept free from combustible debris at all times.

❖ Housekeeping should be a daily practice. The level of fire safety is greatly improved when areas are kept clean and neat. Make sure that all generated waste is removed from the building and safely disposed of each day. Additionally, keeping the areas in which aircraft operate free from debris reduces the likelihood of foreign object damage (FOD) to aircraft engines that could result in engine damage or catastrophic engine failure.

**2003.4 Fire department access.** Fire apparatus access roads shall be provided and maintained in accordance with Chapter 5. Fire apparatus access roads and aircraft parking positions shall be designed in a manner so as to preclude the possibility of fire vehicles traveling under any portion of a parked aircraft.

❖ Access by emergency vehicles is an important factor. Fire apparatus access roads must be wide enough, well-marked and unobstructed in accordance with Section 503. The access roads should also be arranged so there is no confusion over where emergency vehicles are to go in the event of a fire or rescue emergency in a building, on a runway or in an aircraft. Space between aircraft must be large

enough to allow emergency response equipment access to buildings and the aircraft.

**2003.5 Dispensing of flammable and combustible liquids.** The dispensing, transferring and storage of flammable and *combustible liquids* shall be in accordance with this chapter and Chapter 57. Aircraft motor vehicle fuel-dispensing facilities shall be in accordance with Chapter 23.

❖ Section 2006 gives guidelines for dispensing fuel into an aircraft. Section 5706 also gives guidelines for dispensing flammable and combustible liquids. Chapter 23 applies when small general aviation-type aircraft and airport service vehicles are brought to a fueling station instead of being fueled from a vehicle. See the commentary to Section 202 for the definition of “Aircraft motor-vehicle fuel-dispensing facility.”

**2003.6 Combustible storage.** Combustible materials stored in aircraft hangars shall be stored in *approved* locations and containers.

❖ Combustible materials storage is to be confined to cutoff rooms or approved metal containers with tight-fitting, self-closing or automatic-closing lids to limit the fuel load readily exposed within the hangar. Approved containers provided for oily rags and similar wastes are to be supplied throughout service areas and emptied every day. Combustible materials should be removed from the building as soon as possible.

**2003.7 Hazardous material storage.** Hazardous materials shall be stored in accordance with Chapter 50.

❖ Chapter 50 contains the requirements for storing hazardous materials. Requirements in Chapters 51 through 67 also apply to specific materials.

**SECTION 2004  
AIRCRAFT MAINTENANCE**

**2004.1 Transferring flammable and combustible liquids.** Flammable and *combustible liquids* shall not be dispensed into or removed from a container, tank, vehicle or aircraft except in *approved* locations.

❖ Due to hazards presented by aviation fuels, as discussed in Section 2006, it is necessary that all storage, transfer or dispensing of flammable and combustible liquids be completed outside of and away from structures. This includes the emptying of fuel tanks and the rooftop refueling of helicopters. The large, undivided areas of aircraft hangars coupled with the dollar value of a single aircraft present an unusually high value at risk of loss due to a single fire incident, thus reinforcing the need for the strict regulation of fuels. Dispensing systems generally involve the transfer of liquid from fixed piping systems, drums or 5-gallon (19 L) cans into smaller end-use containers. Because the release of some vapor is practically unavoidable, dispensing must take place in designated areas.

**2004.2 Application of flammable and combustible liquid finishes.** The application of flammable or Class II *combustible liquid* finishes is prohibited unless both of the following conditions are met:

1. The application of the liquid finish is accomplished in an *approved* location.
  2. The application methods and procedures are in accordance with Chapter 24.
- ❖ Application of flammable finishes must comply with Chapter 24. Most exterior aircraft painting is performed using spray apparatus, frequently in aircraft hangars. Usually, control of ignition sources, ventilation and the considerable volume of aircraft hangars is relied on to minimize the hazards typically associated with spraying in more confined areas where vapor-air mixtures can rapidly create an explosive mixture. Small parts and subassemblies should be removed and painted in approved spray booths or areas complying with the requirements of Chapter 24. Exterior painting should not be performed in aircraft hangars not protected throughout by approved automatic fire suppression systems. If systems are inoperable, exterior spray painting is not permitted; only interior painting using water-based products is permitted. Like small exterior parts and subassemblies, application of flammable finishes to removable interior components should be limited to approved spray booths or spray rooms.

**2004.3 Cleaning parts.** Class IA flammable liquids shall not be used to clean aircraft, aircraft parts or aircraft engines. Cleaning with other flammable and *combustible liquids* shall be in accordance with Section 5705.3.6.

- ❖ Class I flammable liquids with flash points below 100°F (38°C) must not be used for cleaning that typically liberates large quantities of flammable vapor and may leave a flammable residue that is easily ignited. Removable parts should be cleaned in approved parts-cleaning machines already tested and labeled for such a purpose. The hazards associated with cleaning an aircraft, aircraft parts and aircraft engines with Class IA flammable liquids are fires and explosions, potentially causing damaged property and loss of life. Section 5005.3.6 gives requirements for cleaning with Class I, II and IIIA liquids.

**2004.4 Spills.** Sections 2004.4.1 through 2004.4.3 shall apply to spills of flammable and *combustible liquids* and other hazardous materials. Fuel spill control shall also comply with Section 2006.11.

- ❖ The following procedures should be adhered to in the event a spill occurs. The specific requirements for fuel spill prevention are found in Section 2006.11.

**2004.4.1 Cessation of work.** Activities in the affected area not related to the mitigation of the spill shall cease until the

spilled material has been removed or the hazard has been mitigated.

- ❖ All ongoing activity must stop in the area of a spill until the spill has been cleaned up and removed, since those ongoing activities may cause an ignition to occur. The area should be clear of all hazards before work is resumed.

**2004.4.2 Vehicle movement.** Aircraft or other vehicles shall not be moved through the spill area until the spilled material has been removed or the hazard has been mitigated.

- ❖ The movement of vehicles may create an ignition source for the flammable liquids that spilled. Stopping all movement of vehicles reduces the possibility of a fire or an explosion significantly.

**2004.4.3 Mitigation.** Spills shall be reported, documented and mitigated in accordance with the provisions of this chapter and Section 5003.3.

- ❖ Any fuel spill, whatever the amount, must be reported to the proper authorities and documented to record the spill details and what was done to clean up the spill. Chapter 50 gives specific procedures for handling a spill.

**2004.5 Running engines.** Aircraft engines shall not be run in aircraft hangars except in *approved* engine test areas.

- ❖ An approved engine test area should have proper ventilation, engine noise control and be separated from other areas of operation. Running engines could create ignition sources that could cause fire or explosions, as well as ventilation and noise hazards for the surrounding employees.

**2004.6 Open flame.** Repairing of aircraft requiring the use of open flames, spark-producing devices or the heating of parts above 500°F (260°C) shall only be done outdoors or in an area complying with the provisions of the *International Building Code* for a Group F-1 occupancy.

- ❖ No heat-producing, welding, cutting or blow-torch devices should be used inside hangars. Their use is restricted to areas that meet the requirements of a Group F-1 occupancy in the *International Mechanical Code*® (IMC®). Flare pots and other open-flame lights are also included in this category.

**2004.7 Other aircraft maintenance.** Maintenance, repairs, modifications, or construction performed upon aircraft not addressed elsewhere in this code shall be conducted in accordance with NFPA 410.

- ❖ Aircraft maintenance is often a hazardous procedure due to the inherent hazards of aircraft. NFPA 410 specifies minimum safety requirements to be performed during specific maintenance operations such as fuel or oxygen system maintenance, aircraft cleaning and hazardous operations such as defueling. It provides additional fire-safety requirements to sup-

plement the procedures already regulated by this chapter, as well as additional fire protection requirements for other specified procedures not regulated by this chapter. See the commentary to Section 102.7 for information on the proper application of referenced standards.

**SECTION 2005  
PORTABLE FIRE EXTINGUISHERS**

**2005.1 General.** Portable fire extinguishers suitable for flammable or *combustible liquid* and electrical-type fires shall be provided as specified in Sections 2005.2 through 2005.6 and Section 906. Extinguishers required by this section shall be inspected and maintained in accordance with Section 906.

❖ Portable fire extinguishers (PFEs) must be approved for use on Class B and C fires. Placement and distribution of PFEs should conform to NFPA 10, NFPA 407 and Section 906 of the code. Generally, PFEs are required in the immediate vicinity of all flammable and combustible liquid storage; use and dispensing; welding and cutting; spray finishing and other maintenance operations, as well as on aircraft fueler and service vehicles.

It should be noted that Sections 2005.2, 2005.4, 2005.5 and 2005.6 specifically require B:C-rated PFEs on vehicles and in locations that are in close proximity to aircraft. This is because it has been reported by the National Safety Council that A:B:C-rated PFE chemicals pose a severe aircraft damage problem. While A:B:C-rated PFEs generally have an excellent fire-fighting capability and track record, the monoammonium-phosphate chemical extinguishing agent is highly corrosive to aluminum. This agent will melt and flow when it comes into contact with heated surfaces and, once it comes into contact with hot aluminum and works its way into the structural joints and crevices, it cannot be flushed out as the B:C dry-chemical agents can. Cleanup following use of an A:B:C-rated PFE on an aircraft could require disassembly of the aircraft to remove every remnant of the chemical to prevent hidden corrosion damage that could lead to structural failure.

**2005.2 On towing vehicles.** Vehicles used for towing aircraft shall be equipped with not less than one *listed* portable fire extinguisher complying with Section 906 and having a minimum rating of 20-B:C.

❖ Tow motors and other towing vehicles must be equipped with a PFE that is readily available if a fire occurs away from a service, maintenance or boarding area.

**2005.3 On welding apparatus.** Welding apparatus shall be equipped with not less than one *listed* portable fire extinguisher complying with Section 906 and having a minimum rating of 2-A:20-B:C.

❖ Consistent with Section 3504.2.6, a PFE is required on all welding apparatus so that it is readily available

during welding or cutting operations outside a welding or cutting shop area.

**2005.4 On aircraft fuel-servicing tank vehicles.** Aircraft fuel-servicing tank vehicles shall be equipped with not less than two *listed* portable fire extinguishers complying with Section 906, each having a minimum rating of 20-B:C. A portable fire extinguisher shall be readily accessible from either side of the vehicle.

❖ Fuel-servicing tank vehicles for aircraft must have a PFE on each side of the vehicle. Both extinguishers must be easily accessible and not be obstructed. Each PFE must be effective for the extinguishment of a flammable liquid fire and also be effective for energized electrical components (see Commentary Figure 2006.3 – note the PFE on each side of the rear bumper).

**2005.5 On hydrant fuel-servicing vehicles.** Hydrant fuel-servicing vehicles shall be equipped with not less than one *listed* portable fire extinguisher complying with Section 906, and having a minimum rating of 20-B:C.

❖ Hydrant fuel-servicing vehicles must be equipped with one PFE that is effective for the extinguishment of a flammable liquid fire and is also effective for energized electrical components.

**2005.6 At fuel-dispensing stations.** Portable fire extinguishers at fuel-dispensing stations shall be located such that pumps or dispensers are not more than 75 feet (22 860 mm) from one such extinguisher. Fire extinguishers shall be provided as follows:

1. Where the open-hose discharge capacity of the fueling system is not more than 200 gallons per minute (13 L/s), not less than two *listed* portable fire extinguishers complying with Section 906 and having a minimum rating of 20-B:C shall be provided.
2. Where the open-hose discharge capacity of the fueling system is more than 200 gallons per minute (13 L/s) but not more than 350 gallons per minute (22 L/s), not less than one *listed* wheeled extinguisher complying with Section 906 and having a minimum extinguishing rating of 80-B:C, and a minimum agent capacity of 125 pounds (57 kg), shall be provided.
3. Where the open-hose discharge capacity of the fueling system is more than 350 gallons per minute (22 L/s), not less than two *listed* wheeled extinguishers complying with Section 906 and having a minimum rating of 80-B:C each, and a minimum capacity agent of 125 pounds (57 kg) of each, shall be provided.

❖ This section requires PFEs with ratings based on the anticipated discharge rate of a broken or ruptured fuel hose. NFPA 407 contains requirements for the inspection and maintenance of an aircraft fueling hose, including daily pre-use inspection and removal from service of obviously defective hoses. Despite these inspections, however, hoses and fittings can and do fail for a variety of reasons (e.g., unnoticed physical damage, coupling and fitting failure, over-pressure rupture, etc.), resulting in a flailing hose,

“open butt” discharge of fuel under the full pressure of the fueling system. Such uncontrolled fuel discharge could flow under the aircraft; fueling vehicles; passenger stairs or ramps; baggage-handling equipment or in close proximity to building openings. If a hose were to rupture on top of an aircraft wing or a flailing hose were to spray fuel on vehicles, baggage carts, etc., the resulting hazard would increase beyond a simple spill fire. The large amount of property damage and potential for loss of life requires that sufficient PFEs of an adequate size be located in the fueling area. (Note: the PFEs required by this section are in addition to others required on vehicles that may be present in the fuel area.)

Considerations in locating PFEs during fueling operations include placing them out and upwind of the fuel-dispensing site and potential spill area, as well as within the access travel distance specified in NFPA 10 for extra-hazard locations. When two PFEs are required, they should be located close enough to each other so NFPA 10 access travel distances are not exceeded and a spill incident does not prevent access to or use of both appliances.

FAA regulations and NFPA 407 require refueling personnel to receive PFE and fire safety training. Annex A of NFPA 407 recommends that such training include live-fire exercises. Training should be adequately detailed so that supervisors are capable of properly indoctrinating their subordinates in fire safety essentials. Topics covered in the training program should include electrical bonding and grounding; maintenance of aircraft egress; emergency shutdown of fuel-servicing equipment; notification of emergency forces; and supporting emergency operations.

The low flow rate in Item 1 requires that at least two 20-B:C hand-held PFEs are provided. It also assumes that the trained personnel available will be able to handle the relatively small anticipated spill. Such PFEs typically discharge for up to ± 25 seconds for distances up to ± 20 feet (± 6096 mm).

Item 2 states that a ruptured hose discharging up to 350 gallons per minute (gpm) (1325 L/m) creates a potentially larger spill area and a more challenging fire for first-aid appliances. The higher “B” rating requires a quantity of extinguishing agent, usually dry chemical, that likely exceeds 50 pounds (28 kg), depending on the agent. Accordingly, a wheeled PFE will enable a single operator more mobility in moving the PFE for fire attack. The size of the wheeled unit, in addition to its longer discharge hose, allows the operator a greater agent discharge time, a higher agent flow rate, a greater agent discharge distance and more mobility in the hazardous area. The potential for such large fuel discharges increases the extinguishing requirements. For the same reasons discussed under Item 2, a minimum of two wheeled units are required to allow a more aggressive fire attack.

**2005.7 Fire extinguisher access.** Portable fire extinguishers required by this chapter shall be accessible at all times. Where necessary, provisions shall be made to clear accumulations of snow, ice and other forms of weather-induced obstructions.

- ❖ Unobstructed access to PFEs is essential. In colder climates, snow and ice may block access and must be removed because fire can occur at any time.

**2005.7.1 Cabinets.** Cabinets and enclosed compartments used to house portable fire extinguishers shall be clearly marked with the words FIRE EXTINGUISHER in letters not less than 2 inches (51 mm) high. Cabinets and compartments shall be readily accessible at all times.

- ❖ In an emergency, people can panic and become confused. Labeling cabinets where PFEs are housed with letters 2 inches high (51 mm) (often in red) makes the PFEs easier to locate.

**2005.8 Reporting use.** Use of a fire extinguisher under any circumstances shall be reported to the manager of the airport and the *fire code official* immediately after use.

- ❖ The fire code official is responsible for the investigation of fires within the jurisdiction and for maintaining records thereof. Likewise, the airport manager is responsible for all activities and events within the airport. Both persons must be notified of extinguisher use so the circumstances of the event can be investigated and appropriate follow-up procedures initiated to mitigate the hazard that resulted in the incident. Discharged PFEs must be promptly replaced with serviceable units.

## SECTION 2006 AIRCRAFT FUELING

**2006.1 Aircraft motor vehicle fuel-dispensing facilities.** Aircraft motor vehicle fuel-dispensing facilities shall be in accordance with Chapter 23.

- ❖ Requirements for fuel-dispensing stations for aircraft motor vehicles are found in Chapter 23. This provision addresses the dispensing of fuel into small general aviation-type aircraft at stationary fuel-dispensing facilities that use equipment similar to that used at automotive service stations rather than fuel hydrants or fuel tanker trucks that are used on larger aircraft. See the commentary to Section 202 for the definition of “Aircraft motor vehicle fuel-dispensing facility.”

**2006.2 Airport fuel systems.** Airport fuel systems shall be designed and constructed in accordance with NFPA 407.

- ❖ Aviation fuels present a wide range of hazards. The fuel, ambient temperature, control of ignition sources, drainage, availability of fire protection equipment and the experience and training of fuel-service personnel have the greatest influence over the outcome of fueling accidents. Consequently, this section references

NFPA 407, specifying requirements for the design and operation of fueling installations, vehicles and procedures.

At normal ambient temperatures, the kerosene-grade fuels are not readily ignitable, which may explain their popularity. When spilled on a warm aircraft apron, however, kerosene-grade fuels can be readily heated above their flash points. Once ignited, most aviation fuels exhibit relatively similar burning characteristics (see Commentary Figure 2006.2 for information on common aviation fuels).

Fuel spills are relatively uncommon occurrences compared to the daily number of refuelings that occur. Most fuel spills occur as the result of a slow or faulty internal shutoff valve that causes overfilling of the tank, resulting in fuel escaping through the tank vent point. To prevent or minimize such accidents, fuel shutoffs and fail-safe, self-closing valves should be exercised and inspected regularly. In addition, faulty valves and equipment should be removed from service and repaired or replaced immediately. All spills must be promptly reported to airport fire-fighting personnel and investigated to determine their cause. The most common ignition source in liquid fuel spills is static electricity. The kerosene and kerosene-gasoline blends are more electrostatically active than AVGAS, and transfer operations may generate con-

siderable amounts of static electricity; therefore, prior to most fueling operations both the aircraft and refueler shall be independently grounded and then bonded to one another either by the filling hose or a separate bonding line (see commentary, Section 2006.5.2 and its subsections for further information).

**2006.3 Construction of aircraft-fueling vehicles and accessories.** Aircraft-fueling vehicles shall comply with this section and shall be designed and constructed in accordance with NFPA 407.

❖ The following sections apply to vehicles operated for refueling aircraft. The sections address transfer apparatus, pumps, dispensing, electrical equipment, venting and smoking. The design and construction of the vehicle tanks, trailers, piping, exhaust system, lighting, venting and safe operating procedures parallel those in NFPA 407, Chapter 2 (see Commentary Figure 2006.3).

**2006.3.1 Transfer apparatus.** Aircraft-fueling vehicles shall be equipped and maintained with an *approved* transfer apparatus.

❖ The transfer apparatus installed on the fuel-servicing vehicle must be approved and tested for transferring fuel into an aircraft. All sections involved in a flammable liquid feed system should be constructed and located to minimize a fire hazard.

	Gasoline	Kerosene Grades	Blends of Kerosene and Gasoline
Commercial Designation	AVGAS	JET A, JET A-1	JET B
Military Designation		JP-5, JP-6, JP-8	JP-4
<b>Characteristics</b>			
Freezing Point	-76°F	-49 to -58°F	-60°F
Vapor Pressure	5.5 to 7.0 psi	0.1 psi	2.0 to 3.0 psi
Flash Point (Closed-cup Method @ MSL)	-50°F	95 to 145°F	-10 to +30°F
Flash Point (Air-saturation Method)	-75 to -85°F	None	-60°F
Flammable Range			
Lower	1.5%	0.74%	1.16%
Upper	7.6%	5.32%	7.63%
Temperature Range	-50 to +30°F	95 to 165°F	-10 to +100°F
Auto-ignition Temperature	825 to 960°F	440 to 475°F	470 to 480°F
Boiling Points			
Initial	110°F	325°F	135°F
End	325°F	450°F	485°F
Pool Rate of Flame Spread	700 to 800 feet per minute	≤ 100 feet per minute	700 to 800 feet per minute

Source: Brennenman, J.J. *Industrial Fire Hazards Handbook*.  
For SI; 1 foot per minute = 0.00508 m/s, °C = [(°F) - 32]/1.8.

**Figure 2006.2**  
**PHYSICAL AND FLAMMABILITY CHARACTERISTICS OF AVIATION FUELS**

**Figure 2006.3  
AIRCRAFT-FUELING VEHICLE**

**2006.3.1.1 Internal combustion type.** Where such transfer apparatus is operated by an individual unit of the internal-combustion-motor type, such power unit shall be located as remotely as practicable from pumps, piping, meters, air eliminators, water separators, hose reels and similar equipment, and shall be housed in a separate compartment from any of the aforementioned items. The fuel tank in connection therewith shall be suitably designed and installed, and the maximum fuel capacity shall not exceed 5 gallons (19 L) where the tank is installed on the engine. The exhaust pipe, muffler and tail pipe shall be shielded.

- ❖ Isolation of an internal combustion engine from the fuel transfer system helps to control possible ignition sources. The ignition sources need to be shielded and equipment should be housed in separate compartments.

**2006.3.1.2 Gear operated.** Where operated by gears or chains, the gears, chains, shafts, bearings, housing and all parts thereof shall be of an *approved* design and shall be installed and maintained in an *approved* manner.

- ❖ The gears and other associated parts should be covered and protected from damage, whether the damage comes from environmental or mechanical sources. The design must be approved for the function. Maintenance should be scheduled to provide consistent and proper operation.

**2006.3.1.3 Vibration isolation.** Flexible connections for the purpose of eliminating vibration are allowed if the material used therein is designed, installed and maintained in an *approved* manner, provided such connections do not exceed 24 inches (610 mm) in length.

- ❖ Because hoses are the weak point in any system and they are necessary for flexible connections, they should be kept as short as possible. Hose length must not exceed 24 inches (610 mm).

**2006.3.2 Pumps.** Pumps of a positive-displacement type shall be provided with a bypass relief valve set at a pressure

of not more than 35 percent in excess of the normal working pressure of such unit. Such units shall be equipped and maintained with a pressure gauge on the discharge side of the pump.

- ❖ A relief valve is needed on positive-displacement pumps to prevent high-pressure damage or an explosion within the fuel feed system. At 35 percent over the normal operating pressure the relief valve will allow the excess pressure to escape, thus preventing a dangerous situation. A pressure gauge also allows monitoring of pump operation to detect overpressure conditions.

**2006.3.3 Dispensing hoses and nozzles.** Hoses shall be designed for the transferring of hydrocarbon liquids and shall not be any longer than necessary to provide efficient fuel transfer operations. Hoses shall be equipped with an *approved* shutoff nozzle. Fuel-transfer nozzles shall be self-closing and designed to be actuated by hand pressure only. Notches and other devices shall not be used for holding a nozzle valve handle in the open position. Nozzles shall be equipped with a bonding cable complete with proper attachment for aircraft to be serviced.

- ❖ Nozzles having notches for holding a nozzle valve handle in the open position create the risk of an overflow/spill situation if the handle sticks in the open position. The shutoff nozzle also aids in the prevention of an overflow/spill situation. Bonding the nozzle to the aircraft helps to dissipate static electricity that is generated in the fueling operation.

**2006.3.4 Protection of electrical equipment.** Electric wiring, switches, lights and other sources of ignition, where located in a compartment housing piping, pumps, air eliminators, water separators, hose reels or similar equipment, shall be enclosed in a vapor-tight housing. Electrical motors located in such a compartment shall be of a type *approved* for use as specified in NFPA 70.

- ❖ Because electrical equipment can be a serious sparking source, precautions must be taken to eliminate this potential ignition source and fire hazard.

**2006.3.5 Venting of equipment compartments.** Compartments housing piping, pumps, air eliminators, water separators, hose reels and similar equipment shall be adequately ventilated at floor level or within the floor itself.

- ❖ Venting compartments housing this equipment provide both dilution air to keep possible air-vapor mixtures below the flammable range and airflow for dissipation of any vapors present.

**2006.3.6 Accessory equipment.** Ladders, hose reels and similar accessory equipment shall be of an *approved* type and constructed substantially as follows:

1. Ladders constructed of noncombustible material are allowed to be used with or attached to aircraft-fueling vehicles, provided the manner of attachment or use of such ladders is *approved* and does not constitute an additional fire or accident hazard in the operation of such fueling vehicles.

## AVIATION FACILITIES

2. Hose reels used in connection with fueling vehicles shall be constructed of noncombustible materials and shall be provided with a packing gland or other device that will preclude fuel leakage between reels and fuel manifolds.

❖ Ladders made of noncombustible materials and that are securely attached help eliminate a potential spark ignition source, and limit the possibility of falling equipment breaking a component of the fuel system.

Hose reels constructed of noncombustible material help eliminate the possibility of an ignition source causing a fire hazard. The installation of a packing gland or other device helps eliminate the possibility of a fuel leak causing a fire hazard.

**2006.3.7 Electrical bonding provisions.** Transfer apparatus shall be metallicly interconnected with tanks, chassis, axles and springs of aircraft-fueling vehicles.

❖ Fuel transfer vehicles must be bonded together as a unit. This helps to eliminate the electrostatic charge created by flowing fuel through pipes and hoses.

**2006.3.7.1 Bonding cables.** Aircraft-fueling vehicles shall be provided and maintained with a substantial heavy-duty electrical cable of sufficient length to be bonded to the aircraft to be serviced. Such cable shall be metallicly connected to the transfer apparatus or chassis of the aircraft-fueling vehicle on one end and shall be provided with a suitable metal clamp on the other end, to be fixed to the aircraft.

❖ The fueling vehicle and the aircraft must be bonded together with a cable before making any fueling connection to the aircraft. This provides a conductive path to equalize the electrostatic charge between the fueling vehicle and the aircraft.

**2006.3.7.2 Bonding cable protection.** The bonding cable shall be bare or have a transparent protective sleeve and be stored on a reel or in a compartment provided for no other purpose. It shall be carried in such a manner that it will not be subjected to sharp kinks or accidental breakage under conditions of general use.

❖ Bonding cable that is worn, frayed or kinked cannot make good contact or provide a continuous path to eliminate the electrostatic charge. Bonding cables require special care in storage and handling.

**2006.3.8 Smoking.** Smoking in aircraft-fueling vehicles is prohibited. Signs to this effect shall be conspicuously posted in the driver's compartment of all fueling vehicles.

❖ Because flammable vapors being discharged during refueling can accumulate in closed areas, such as the driver's compartment of the fueling vehicle, smoking in that compartment is strictly prohibited. Signs must

be posted conspicuously in the driver's compartment as a warning.

**2006.3.9 Smoking equipment.** Smoking equipment such as cigarette lighters and ash trays shall not be provided in aircraft-fueling vehicles.

❖ Because smoking is prohibited in fueling vehicles, the elimination of cigarette lighters and ashtrays reinforces this regulation.

**2006.4 Operation, maintenance and use of aircraft-fueling vehicles.** The operation, maintenance and use of aircraft-fueling vehicles shall be in accordance with Sections 2006.4.1 through 2006.4.4 and other applicable provisions of this chapter.

❖ Fuel-servicing equipment must comply with the requirements of the following sections and must be maintained in safe operating condition. Leaking or malfunctioning equipment must be removed from service.

**2006.4.1 Proper maintenance.** Aircraft-fueling vehicles and all related equipment shall be properly maintained and kept in good repair. Accumulations of oil, grease, fuel and other flammable or combustible materials is prohibited. Maintenance and servicing of such equipment shall be accomplished in *approved* areas.

❖ Fueling vehicles should be inspected every day. The accumulation of oil, grease or any other material creates a fire hazard if it is ignited by an ignition source. A clean, well-maintained fueling vehicle is a high priority in the line of fire-hazard prevention. The cleaning should take place in an area constructed and approved for such a task.

**2006.4.2 Vehicle integrity.** Tanks, pipes, hoses, valves and other fuel delivery equipment shall be maintained leak free at all times.

❖ All fuel delivery equipment should be checked every day for leaks. If a leak occurs, the probability of a fire occurring increases.

**2006.4.3 Removal from service.** Aircraft-fueling vehicles and related equipment that are in violation of Section 2006.4.1 or 2006.4.2 shall be immediately defueled and removed from service and shall not be returned to service until proper repairs have been made.

❖ Whenever a problem is discovered with the vehicle, tank, pipes, hoses, valves or any equipment related to aircraft fueling, the vehicle must be taken out of service immediately and repaired. Having a vehicle in service that is not working properly increases the potential for a fire.

**2006.4.4 Operators.** Aircraft-fueling vehicles that are operated by a person, firm or corporation other than the permittee or the permittee's authorized employee shall be provided with a legible sign visible from outside the vehicle showing the name of the person, firm or corporation operating such unit.

- ❖ A change in the operator, firm or corporation from the permit holder of a fueling vehicle requires notification. In addition to verbal or written communication, a sign that can be read from outside the vehicle must be posted on or in the vehicle notifying observers that a different person or organization is performing the procedure.

**2006.5 Fueling and defueling.** Aircraft-fueling and defueling operations shall be in accordance with Sections 2006.5.1 through 2006.5.5.

- ❖ This section covers the requirements for positioning and bonding the fueling vehicle. It also covers the requirements for training fuel transfer personnel and their responsibilities.

**2006.5.1 Positioning of aircraft-fueling vehicles.** Aircraft-fueling vehicles shall not be located, parked or permitted to stand in a position where such unit would obstruct egress from an aircraft should a fire occur during fuel-transfer operations. Aircraft-fueling vehicles shall not be located, parked or permitted to stand under any portion of an aircraft.

**Exception:** Aircraft-fueling vehicles shall be allowed to be located under aircraft wings during underwing fueling of turbine-engine powered aircraft.

- ❖ Safety of crew and passengers is always the highest priority. Fuel-service vehicles must not be positioned under any part of an aircraft and must always be in a location that leaves aircraft egress paths free of obstruction (see commentary, Section 2006.9, Item 4). The exception, applicable only to jet aircraft, recognizes that a number of factors, including the size of the aircraft, the location of fuel inlets and the length of hose on the tank truck, will dictate where aircraft fueling vehicles are necessarily located.

**2006.5.1.1 Fueling vehicle egress.** A clear path shall be maintained for aircraft-fueling vehicles to provide for prompt and timely egress from the fueling area.

- ❖ The requirement for a clear and unobstructed path in and out of the fueling area calls for cooperation between refueling crews and other ground support personnel to make sure the path exists. This allows for a safe, timely and efficient fueling operation.

**2006.5.1.2 Aircraft vent openings.** A clear space of not less than 10 feet (3048 mm) shall be maintained between aircraft fuel-system vent openings and any part or portion of an aircraft-fueling vehicle.

- ❖ Fuel vapors are released from fuel-system vent openings. The 10-foot (3048 mm) radius gives a distance sufficient for vapor dissipation.

**2006.5.1.3 Parking.** Prior to leaving the cab, the aircraft-fueling vehicle operator shall ensure that the parking brake has been set. Not less than two chock blocks not less than 5 inches by 5 inches by 12 inches (127 mm by 127 mm by 305 mm) in size and dished to fit the contour of the tires shall be utilized and positioned in such a manner as to preclude movement of the vehicle in any direction.

- ❖ This requirement for securing the fueling vehicle is an important safety consideration. Even a slight grade or dishing of the pavement could cause an unsecured vehicle to roll far enough to strain the fueling link into leaking, disconnecting or breaking, which would create the possibility of a spill and a hazardous situation.

**2006.5.2 Electrical bonding.** Aircraft-fueling vehicles shall be electrically bonded to the aircraft being fueled or defueled. Bonding connections shall be made prior to making fueling connections and shall not be disconnected until the fuel-transfer operations are completed and the fueling connections have been removed.

Where a hydrant service vehicle or cart is used for fueling, the hydrant coupler shall be connected to the hydrant system prior to bonding the fueling equipment to the aircraft.

- ❖ Bonding increases the likelihood that the receiving tank (aircraft or vehicle) and the fueling/defueling equipment have the same electrical potential and provides a path for the charges in all parts of the fueling system to neutralize. The bonding of the fuel vehicle and aircraft must be completed before any fuel is moved and must remain in place until after the fueling operation is complete.

**2006.5.2.1 Conductive hose.** In addition to the bonding cable required by Section 2006.5.2, conductive hose shall be used for all fueling operations.

- ❖ The use of conductive hose helps to prevent electrostatic discharge. It is not a substitute for required bonding.

**2006.5.2.2 Bonding conductors on transfer nozzles.** Transfer nozzles shall be equipped with *approved* bonding conductors that shall be clipped or otherwise positively engaged with the bonding attachment provided on the aircraft adjacent to the fuel tank cap prior to removal of the cap.

**Exception:** In the case of overwing fueling where no appropriate bonding attachment adjacent to the fuel fill port has been provided on the aircraft, the fueling operator shall touch the fuel tank cap with the nozzle spout prior to removal of the cap. The nozzle shall be kept in contact with the fill port until fueling is completed.

- ❖ This procedure provides a conductive path for equalizing the potential electrostatic charge between the aircraft and the transfer nozzle. Even if a clip or engaging mechanism is not provided, contact with the fill port must be maintained until the fueling process is complete.

**2006.5.2.3 Funnels.** Where required, metal funnels are allowed to be used during fueling operations. Direct contact

## AVIATION FACILITIES

between the fueling receptacle, the funnel and the fueling nozzle shall be maintained during the fueling operation.

- ❖ Prevention of potential sparks that produce ignition sources for fires is the objective for keeping metal funnels in direct contact with fueling nozzles and receptacles at all times.

**2006.5.3 Training.** Aircraft-fueling vehicles shall be attended and operated only by persons instructed in methods of proper use and operation and who are qualified to use such fueling vehicles in accordance with minimum safety requirements.

- ❖ Only personnel trained in the proper and safe operation of the equipment, emergency controls and emergency procedures are allowed to fuel or defuel aircraft.

**2006.5.3.1 Fueling hazards.** Fuel-servicing personnel shall know and understand the hazards associated with each type of fuel dispensed by the airport fueling-system operator.

- ❖ Personnel performing fueling or defueling procedures must be familiar with every hazard that is involved with each and every fuel that is dispensed.

**2006.5.3.2 Fire safety training.** Employees of fuel agents who fuel aircraft, accept fuel shipments or otherwise handle fuel shall receive *approved* fire safety training.

- ❖ Employees must be trained in and be aware of fire safety rules and precautions involving fuel-servicing processes. Training must be in areas involving vehicle integrity and placement; bonding of vehicles; aircraft; hose connections; valves; and fuel-process equipment. The training must be an approved in-depth program that is recognized by airport authorities.

**2006.5.3.2.1 Fire extinguisher training.** Fuel-servicing personnel shall receive *approved* training in the operation of fire-extinguishing equipment.

- ❖ Employees involved in fuel servicing must have adequate training with extinguishers to use them effectively in the event of an emergency (see commentary, Section 2005.6 for further information).

**2006.5.3.2.2 Records.** The airport fueling-system operator shall maintain records of all training administered to its employees.

- ❖ Training must be documented and records kept on premises for verification, if requested, that the personnel have received the proper training.

**2006.5.4 Transfer personnel.** During fuel-transfer operations, a qualified person shall be in control of each transfer nozzle and another qualified person shall be in immediate control of the fuel-pumping equipment to shut off or otherwise control the flow of fuel from the time fueling operations are begun until they are completed.

### Exceptions:

1. For underwing refueling, the person stationed at the point of fuel intake is not required.

2. For overwing refueling, the person stationed at the fuel pumping equipment shall not be required where the person at the fuel dispensing device is within 75 feet (22 800 mm) of the emergency shutoff device; is not on the wing of the aircraft and has a clear and unencumbered path to the fuel pumping equipment; and the fuel dispensing line does not exceed 50 feet (15 240 mm) in length.

The fueling operator shall monitor the panel of the fueling equipment and the aircraft control panel during pressure fueling or shall monitor the fill port during overwing fueling.

- ❖ Two qualified trained individuals must perform fuel transfer procedures. One individual controls the nozzles. The other individual must be in the control area for flow monitoring and control; and immediate shutdown of fuel flow in case of an emergency (overflow, spill, fire, etc.). The exception for underwing fueling is appropriate because underwing operations require a liquid-tight connection that does not require constant monitoring to ensure freedom from spills and overflows. The four items that must be met in the overwing refueling process are meant for quick response in case a problem occurs. The individual must be completely alert to the fueling process and free from distractions if alone.

**2006.5.5 Fuel flow control.** Fuel flow-control valves shall be operable only by the direct hand pressure of the operator. Removal of the operator's hand pressure shall cause an immediate cessation of the flow of fuel.

- ❖ Deadman controls should be designed so that the operator, while wearing gloves, can hold them for the time required to complete the operation.

**2006.6 Emergency fuel shutoff.** Emergency fuel shutoff controls and procedures shall comply with Sections 2006.6.1 through 2006.6.4.

- ❖ The following sections address emergency fuel shutoff accessibility, fire department notification, determining cause if shutoff activates and testing procedures.

**2006.6.1 Accessibility.** Emergency fuel shutoff controls shall be readily accessible at all times when the fueling system is being operated.

- ❖ Emergency controls must be unobstructed whenever the fueling system is operating. Time should not be wasted having to move objects or material blocking access to the controls before fueling operations can be shut down in an emergency.

**2006.6.2 Notification of the fire department.** The fueling-system operator shall establish a procedure by which the fire department will be notified in the event of an activation of an emergency fuel shutoff control.

- ❖ A plan must be developed for notifying the fire department. The plan should be in a written format and reviewed with trained and certified employees in advance of fueling operations. Notification of the fire

department will have emergency responders on their way immediately in case fire or rescue operations are required.

**2006.6.3 Determining cause.** Prior to reestablishment of normal fuel flow, the cause of fuel shutoff conditions shall be determined and corrected.

❖ If for any reason the flow of fuel is discontinued by the emergency shutoff systems during fueling operations, the cause of the activation must be determined and the problem fixed before fuel flow is started again. Fuel flow may not be restarted if the cause of the shutdown is not determined. If fuel flow were restarted, the problem may occur again and more serious problems could develop.

**2006.6.4 Testing.** Emergency fuel shutoff devices shall be operationally tested at intervals not exceeding three months. The fueling-system operator shall maintain testing records.

❖ Testing of the emergency fuel shutoff devices increases the likelihood that the devices will function properly. Although three-month intervals are the maximum allowed, the test may be performed more frequently if desired. Records are required for documentation that the tests were performed. If an accident occurs, these records will be a great asset for verification that the devices were tested and operational.

**2006.7 Protection of hoses.** Before an aircraft-fueling vehicle is moved, fuel transfer hoses shall be properly placed on the *approved* reel or in the compartment provided, or stored on the top decking of the fueling vehicle if proper height rail is provided for security and protection of such equipment. Fuel-transfer hose shall not be looped or draped over any part of the fueling vehicle, except as herein provided. Fuel-transfer hose shall not be dragged when such fueling vehicle is moved from one fueling position to another.

❖ Accidents or fires may occur if hoses are not properly stored and handled. Sparks caused by metal nozzles or hose ends/couplings striking pavement when hoses are dragged from one area to another are a serious potential ignition source. Also, the hoses are least likely to be damaged if stored in proper locations.

**2006.8 Loading and unloading.** Aircraft-fueling vehicles shall be loaded only at an *approved* loading rack. Such loading racks shall be in accordance with Section 5706.5.1.12.

**Exceptions:**

1. Aircraft-refueling units are allowed to be loaded from the fuel tanks of an aircraft during defueling operations.
2. Fuel transfer between tank vehicles is allowed to be performed in accordance with Section 5706.6 when the operation is not less than 200 feet (60 960 mm) from an aircraft.

The fuel cargo of such units shall be unloaded only by *approved* transfer apparatus into the fuel tanks of aircraft, underground storage tanks or *approved* gravity storage tanks.

❖ Section 5706.5.1.12 addresses requirements for loading racks. Loading racks, platforms and stairs must be constructed of noncombustible materials. Buildings for pumps and buildings that shelter personnel can be part of the loading rack. The area within 25 feet (7620 mm) of a loading platform shall be electrically classified in accordance with Table 5703.1.1.

Transfer of fuel from one tank vehicle to another and from aircraft to vehicle is allowable using approved methods and procedures. At times, loading and unloading fuel from aircraft and refueling units is necessary when taking units out of service and when defueling an aircraft while preparing for maintenance or repair.

An aircraft refueling unit is normally loaded either for refueling an aircraft or for storage. Fuel must not be unloaded into any other type tank, structure or vehicle.

**2006.9 Passengers.** Passenger traffic is allowed during the time fuel transfer operations are in progress, provided the following provisions are strictly enforced by the *owner* of the aircraft or the *owner's* authorized employee:

1. Smoking and producing an open flame in the cabin of the aircraft or the outside thereof within 50 feet (15 240 mm) of such aircraft shall be prohibited.

A qualified employee of the aircraft *owner* shall be responsible for seeing that the passengers are not allowed to smoke when remaining aboard the aircraft or while going across the ramp from the gate to such aircraft, or vice versa.

2. Passengers shall not be permitted to linger about the plane, but shall proceed directly between the loading gate and the aircraft.
3. Passenger loading stands or walkways shall be left in loading position until all fuel transfer operations are completed.
4. Fuel transfer operations shall not be performed on the main *exit* side of any aircraft containing passengers except when the *owner* of such aircraft or a capable and qualified employee of such *owner* remains inside the aircraft to direct and assist the escape of such passengers through regular and emergency *exits* in the event fire should occur during fuel transfer operations.

❖ Special precautions must be taken to protect passengers during fueling operations. If passengers are permitted on or around the aircraft during refueling operations, an employee of the airline or a representative of the airport authority must remain on board and the specified precautions must be taken.

Aircraft fueling, servicing, baggage and cargo loading, movement and passenger boarding are generally conducted in and around the passenger terminal building on the aircraft apron. Aircraft refueling is often accomplished by special refueling vehicles acting like mobile gas stations, transferring fuel directly from their tanks to aircraft fuel tanks. Aircraft fuel tanks are usually topped off after each flight, unless they are making scheduled stops on a multistop flight.

Terminal building discharge to the aircraft apron is not permitted by FAA regulations; however, egress from the aircraft to the apron in the event of a fire or other emergency is permitted. Passengers and unauthorized personnel must be immediately accounted for and escorted from the aircraft operation area.

The terminal building is not required to be separated from the aircraft apron by fire-resistance-rated construction; however, it is considered good practice to take reasonable steps to prevent fire from fueling accidents or other mishaps. Portable fire extinguishers are required on the aircraft apron in accordance with Section 2005.

In Item 1, smoking and open flames are prohibited within and around the aircraft during refueling operations because of the potential for fuel vapors being present. The “No Smoking” signs located in the aircraft cabin must remain illuminated while the aircraft is parked at the gate during refueling operations.

Item 2 requires that deplaning passengers must proceed directly to the terminal and may not remain on the aircraft apron during refueling operations, cargo loading or other similar service functions in order to avoid potential injury.

In Item 3, egress stairways and passageways must remain connected or intact during refueling operations. These stairways and ramps are the primary exit if an emergency occurs during aircraft refueling operations.

Item 4 recognizes that maintenance and fueling operations represent the most serious fire safety concerns at airports and heliports. Fueling represents perhaps the greatest risk because it is commonly conducted near passenger and cargo handling areas and buildings, while maintenance operations are confined to hangars or designated outside maintenance areas. Fueling operations are to be conducted in a manner that avoids locating the refueler on the primary exit side of the aircraft. Airline employees or airport authorities are responsible for directing and assisting egress in the event of an emergency and must direct passengers to exits away from the fueling operation (see commentary, Section 2006.5.1).

**2006.10 Sources of ignition.** Smoking and producing open flames within 50 feet (15 240 mm) of a point where fuel is being transferred shall be prohibited. Electrical and motor-driven devices shall not be connected to or disconnected from an aircraft at any time fueling operations are in progress on such aircraft.

- ❖ The 50-foot (15 240 mm) distance is considered a safe distance from the fuel transfer operation for dis-

sipation of any escaping vapors. Prohibiting open flames and smoking eliminates a prime ignition source (examples of open flame devices are lighted cigarettes, cigars, pipes, cigarette lighters, etc.). Because disconnection or connection of any electrical or motor-driven device could create a spark, these activities are not allowed during refueling.

**2006.11 Fuel spill prevention and procedures.** Fuel spill prevention and the procedures for handling spills shall comply with Sections 2006.11.1 through 2006.11.7.

- ❖ The following sections address equipment maintenance, fuel nozzles, fueling drums, fuel spill procedures, fire department notification and prohibited procedures for multiple fuel deliveries.

**2006.11.1 Fuel-service equipment maintenance.** Aircraft fuel-servicing equipment shall be maintained and kept free from leaks. Fuel-servicing equipment that malfunctions or leaks shall not be continued in service.

- ❖ Fuel-service equipment must not be used unless it is in proper repair and free of possible cracks, frays or breaks that could cause leaks. Defective equipment must be taken out of service and repaired.

**2006.11.2 Transporting fuel nozzles.** Fuel nozzles shall be carried utilizing appropriate handles. Dragging fuel nozzles along the ground shall be prohibited.

- ❖ An ignition source may be produced by dragging the nozzle. Using the appropriate handling devices eliminates both sparking and nozzle damage.

**2006.11.3 Drum fueling.** Fueling from drums or other containers having a capacity greater than 5 gallons (19 L) shall be accomplished with the use of an *approved* pump.

- ❖ The use of an approved pump for transferring fuel from drums with capacity in excess of 5 gallons (19 L) greatly reduces the possibility of spills.

**2006.11.4 Fuel spill procedures.** The fueling-system operator shall establish procedures to follow in the event of a fuel spill. These procedures shall be comprehensive and shall provide for all of the following:

1. Upon observation of a fuel spill, the aircraft-fueling operator shall immediately stop the delivery of fuel by releasing hand pressure from the fuel flow-control valve.
  2. Failure of the fuel control valve to stop the continued spillage of fuel shall be cause for the activation of the appropriate emergency fuel shutoff device.
  3. A supervisor for the fueling-system operator shall respond to the fuel spill area immediately.
- ❖ Safety and emergency procedures must be in place, and personnel must be trained on these procedures. Should a spill occur, the person operating the fuel delivery hose must immediately release hand pressure to stop fuel flow. If this action does not shut off fuel flow, the emergency shutoff device must be activated.

Fuel system supervisors and operators must be trained in the procedures they must follow in case of

a fuel spill. Supervisors must respond if a spill occurs and assist in containment and cleanup if necessary.

**2006.11.5 Notification of the fire department.** The fire department shall be notified of any fuel spill that is considered a hazard to people or property or which meets one or more of the following criteria:

1. Any dimension of the spill is greater than 10 feet (3048 mm).
2. The spill area is greater than 50 square feet (4.65 m<sup>2</sup>).
3. The fuel flow is continuous in nature.

❖ Three criteria are given for determining when the fire department must be notified. Any amount of spill exceeding those criteria causes great concern and must be considered a fire hazard. The fire department must be notified because people and property are at risk if a spill ignites and causes explosion and fire.

**2006.11.6 Investigation required.** An investigation shall be conducted by the fueling-system operator of all spills requiring notification of the fire department. The investigation shall provide conclusive proof of the cause and verification of the appropriate use of emergency procedures. Where it is determined that corrective measures are necessary to prevent future incidents of the same nature, they shall be implemented immediately.

❖ Any spill must be investigated to determine the cause and whether the emergency action plan was properly carried out. If corrective measures are needed, they must be implemented immediately. This investigation should be looked upon as positive, potentially leading to a more efficient emergency action plan that could avoid future property damage and loss of life.

**2006.11.7 Multiple fuel delivery vehicles.** Simultaneous delivery of fuel from more than one aircraft-fueling vehicle to a single aircraft-fueling manifold is prohibited unless proper backflow prevention devices are installed to prevent fuel flow into the tank vehicles.

❖ Only one tank vehicle may be connected to any one aircraft-fueling manifold unless a means is provided that prevents fuel from flowing back into the tank vehicle because of a difference in the pumping pressure. Backflow from one tanker to another could result in fuel overflow from the receiving vehicle that would cause a major fuel spill.

**2006.12 Aircraft engines and heaters.** Operation of aircraft onboard engines and combustion heaters shall be terminated prior to commencing fuel service operations and shall remain off until the fuel-servicing operation is completed.

**Exception:** In an emergency, a single jet engine is allowed to be operated during fuel servicing where all of the following conditions are met:

1. The emergency shall have resulted from an onboard failure of the aircraft's auxiliary power unit.

2. Restoration of auxiliary power to the aircraft by ground support services is not available.
3. The engine to be operated is either at the rear of the aircraft or on the opposite side of the aircraft from the fuel service operation.
4. The emergency operation is in accordance with a written procedure *approved* by the *fire code official*.

❖ Operation of any aircraft engines or combustion heaters allows the possibility of an ignition source being produced. Even in the exceptions allowed in an emergency, care must be taken in preventing a possible fire hazard.

**2006.13 Vehicle and equipment restrictions.** During aircraft-fueling operations, only the equipment actively involved in the fueling operation is allowed within 50 feet (15 240 mm) of the aircraft being fueled. Other equipment shall be prohibited in this area until the fueling operation is complete.

**Exception:** Aircraft-fueling operations utilizing single-point refueling with a sealed, mechanically locked fuel line connection and the fuel is not a Class I flammable liquid.

A clear space of not less than 10 feet (3048 mm) shall be maintained between aircraft fuel-system vent openings and any part or portion of aircraft-servicing vehicles or equipment.

❖ To control the number and type of ignition sources to which the fueling operation might be exposed, no equipment, other than the equipment performing aircraft-servicing functions, is permitted within a 50-foot (15 240 mm) radius of the aircraft during the fueling of the aircraft. The space between service vehicles and equipment and the aircraft fuel vent must be no less than 10 feet (3048 mm) when using a single-point sealed mechanically locked fuel line connector.

**2006.13.1 Overwing fueling.** Vehicles or equipment shall not be allowed beneath the trailing edge of the wing when aircraft fueling takes place over the wing and the aircraft fuel-system vents are located on the upper surface of the wing.

❖ Equipment under the trailing edge of the wing could cause a fire hazard if a leak or spill were to occur. The fuel would run off the edge of the wing and the equipment could have an ignition source and cause a fire.

**2006.14 Electrical equipment.** Electrical equipment, including but not limited to, battery chargers, ground or auxiliary power units, fans, compressors or tools, shall not be operated, nor shall they be connected or disconnected from their power source, during fuel service operations.

❖ Even hand lamps used in the fuel-servicing operation must be approved for the proper hazardous location classification. The equipment could produce sparks that could be an ignition source.

## AVIATION FACILITIES

**2006.14.1 Other equipment.** Electrical or other spark-producing equipment shall not be used within 10 feet (3048 mm) of fueling equipment, aircraft fill or vent points, or spill areas unless that equipment is intrinsically safe and *approved* for use in an explosive atmosphere.

- ❖ No equipment that produces a spark during its operation can be used within a 10-foot (3048 mm) radius of the fueling-operational equipment.

**2006.15 Open flames.** Open flames and open-flame devices are prohibited within 50 feet (15 240 mm) of any aircraft fuel-servicing operation or fueling equipment.

- ❖ Blow torches, welding and cutting equipment, and flare pots are a few examples of equipment that are not allowed within 50 feet (15 240 mm) of the fueling equipment or the fueling operation.

**2006.15.1 Other areas.** The *fire code official* is authorized to establish other locations where open flames and open-flame devices are prohibited.

- ❖ Depending on the situation, the fire code official may find other locations in which open flames and open-flame devices must be prohibited. Examples could be exposed flame heaters, portable gasoline or kerosene heaters.

**2006.15.2 Matches and lighters.** Personnel assigned to and engaged in fuel-servicing operations shall not carry matches or lighters on or about their person. Matches or lighters shall be prohibited in, on or about aircraft-fueling equipment.

- ❖ Because matches, lighters and smoking materials are an ignition hazard, these items are prohibited everywhere in the vicinity of aircraft fueling operations.

**2006.16 Lightning procedures.** The *fire code official* is authorized to require the airport authority and the fueling-system operator to establish written procedures to follow when lightning flashes are detected on or near the airport. These procedures shall establish criteria for the suspension and resumption of aircraft-fueling operations.

- ❖ Fuel-servicing procedures must cease when lightning flashes occur at or in the vicinity of the airport. The fueling supervisor and airport authority must establish a written procedure that sets the criteria for stopping and restarting fueling operations.

**2006.17 Fuel-transfer locations.** Aircraft fuel-transfer operations shall be prohibited indoors.

**Exception:** In aircraft hangars built in accordance with the provisions of the *International Building Code* for Group F-1 occupancies, aircraft fuel-transfer operations are allowed where either of the following conditions exist:

1. Necessary to accomplish aircraft fuel-system maintenance operations. Such operations shall be performed in accordance with nationally recognized standards.
  2. The fuel being used has a *flash point* greater than 100°F (37.8°C).
- ❖ Aircraft fueling operations must be performed outdoors to minimize the accumulation of flammable

vapors. The exception allows indoor fueling only under very specific and limited conditions.

**2006.17.1 Position of aircraft.** Aircraft being fueled shall be positioned such that any fuel system vents and other fuel tank openings are not less than:

1. Twenty-five feet (7620 mm) from buildings or structures other than jet bridges; and
2. Fifty feet (15 240 mm) from air intake vents for boiler, heater or incinerator rooms.

- ❖ Maintaining minimum distances between fueling operations and other aircraft or buildings allows any flammable vapors released during fueling to dissipate before encountering any possible ignition sources. These distances also provide protection against ignitable vapor concentrations getting to an ignition source in the event of a fuel spill.

**2006.17.2 Fire equipment access.** Access for fire service equipment to aircraft shall be maintained during fuel-servicing operations.

- ❖ A clear and unobstructed path is required for quick response for fire personnel. A quick response is essential in an emergency; however, an obstacle may create a delay in emergency operations.

**2006.18 Defueling operations.** The requirements for fueling operations contained in this section shall also apply to aircraft defueling operations. Additional procedures shall be established by the fueling-system operator to prevent overfilling of the tank vehicle used in the defueling operation.

- ❖ Transferring of fuel from an aircraft through a hose to a tank vehicle is generally the same process as fueling. The same requirements apply to defueling as to fuel servicing an aircraft. Operators must establish procedures and safeguards for prevention of overfilling the tank vehicle, which is a hazard when defueling.

**2006.19 Maintenance of aircraft-fueling hose.** Aircraft-fueling hoses shall be maintained in accordance with Sections 2006.19.1 through 2006.19.4.

- ❖ The following sections address the maintenance of aircraft fueling hose in terms of the frequency of inspections, recognizing damaged hose and repairing the hose before placing it back in service.

**2006.19.1 Inspections.** Hoses used to fuel or defuel aircraft shall be inspected periodically to ensure their serviceability and suitability for continued service. The fuel-service operator shall maintain records of all tests and inspections performed on fueling hoses. Hoses found to be defective or otherwise damaged shall be immediately removed from service.

- ❖ Regular inspections of fueling equipment are essential to maintaining serviceable systems. Records of these inspections are required to document inspection results. Damaged or defective items must be removed from service immediately for repair or replacement.

**2006.19.1.1 Daily inspection.** Each hose shall be inspected daily. This inspection shall include a complete visual scan of the exterior for evidence of damage, blistering or leakage. Each coupling shall be inspected for evidence of leaks, slip-page or misalignment.

- ❖ Daily hose inspections are essential for prevention of leaks. Even minor damage to a hose, coupling, nozzle or other system part can lead to safety hazards.

**2006.19.1.2 Monthly inspection.** A more thorough inspection, including pressure testing, shall be accomplished for each hose on a monthly basis. This inspection shall include examination of the fuel delivery inlet screen for rubber particles, which indicates problems with the hose lining.

- ❖ During the monthly inspection, the hose again must be extended to its full length of operation. The area within 12 inches (305 mm) of the coupling must be examined for structural weakness by pressing and observing soft spots. Hoses must be pressure tested at operating pressure and observed for ballooning or twisting that would indicate a weakening of the hose carcass. Examination of the fuel inlet screen for rubber particles is a means of checking the condition of hose linings.

**2006.19.2 Damaged hose.** Hose that has been subjected to severe abuse shall be immediately removed from service. Such hoses shall be hydrostatically tested prior to being returned to service.

- ❖ If hose has been subjected to unusual abuse, it must be removed from service immediately as a safety precaution. Such hoses must be hydrostatically tested and inspected. If any soft spots or weakening of the hose is observed, the hose may not be returned to service.

**2006.19.3 Repairing hose.** Hoses are allowed to be repaired by removing the damaged portion and recoupling the undamaged end. When recoupling hoses, only couplings designed and *approved* for the size and type of hose in question shall be used. Hoses repaired in this manner shall be visually inspected and hydrostatically tested prior to being placed back in service.

- ❖ Damaged hoses can be repaired. The damaged portion must be cut off and the undamaged part recoupled. Two lengths from separate hoses may not be joined. To increase the likelihood that the repaired hose is leak tight, only couplings specifically designed for that type and size of hose can be used. Hydrostatic testing of the repaired hose increases efficiency and safety for fueling operations.

**2006.19.4 New hose.** New hose shall be visually inspected prior to being placed into service.

- ❖ Before any new hose assembly can be placed into service, it must be inspected visually for evidence of damage or wear and tear of any kind.

**2006.20 Aircraft fuel-servicing vehicles parking.** Unattended aircraft fuel-servicing vehicles shall be parked in areas that provide for both the unencumbered dispersal of vehicles in the event of an emergency and the control of leakage such

that adjacent buildings and storm drains are not contaminated by leaking fuel.

- ❖ The fuel-servicing vehicles must be positioned so that they can be moved quickly if an emergency occurs. This may not only save the vehicle but also assist in a rapid response to an emergency situation and saving lives. Fuel leaking into storm drains causes not only environmental problems, but also a serious explosion hazard if vapor accumulates in the confines of a drain line.

**2006.20.1 Parking area design.** Parking areas for tank vehicles shall be designed and utilized such that a clearance of 10 feet (3048 mm) is maintained between each parked vehicle for fire department access. In addition, a minimum clearance of 50 feet (15 240 mm) shall be maintained between tank vehicles and parked aircraft and structures other than those used for the maintenance and/or garaging of aircraft fuel-servicing vehicles.

- ❖ This section regulates the design and use of outdoor parking areas for aircraft fueling vehicles. The requirement for a 10-foot (3048 mm) clearance between parked fueling vehicles permits ready access by fire department personnel and equipment in case of an emergency. The fire department may need the area to deploy hose in case of a fire or to walk through the area en route to an investigation of an emergency call. The 50-foot (15 240 mm) clearance requirement is to allow dispersion of flammable vapors in case of a leak before the vapors can enter nearby buildings or parked aircraft, and possibly reach an ignition source inside. Such clearance would not be required for buildings that have been approved by the fire code official in accordance with Section 5706.6.3 for the purpose of garaging or repairing aircraft fuel-servicing vehicles, based on the assumption that such buildings would have ignition sources safeguarded. This clearance also provides a measure of exposure protection for the parked vehicles in the event of a fire in the building or a parked aircraft.

**2006.21 Radar equipment.** Aircraft fuel-servicing operations shall be prohibited while the weather-mapping radar of that aircraft is operating.

Aircraft fuel-servicing or other operations in which flammable liquids, vapors or mists could be present shall not be conducted within 300 feet (91 440 mm) of an operating aircraft surveillance radar.

Aircraft fuel-servicing operations shall not be conducted within 300 feet (91 440 mm) of airport flight traffic surveillance radar equipment.

Aircraft fuel-servicing or other operations in which flammable liquids, vapors or mists could be present shall not be conducted within 100 feet (30 480 mm) of airport ground traffic surveillance radar equipment.

- ❖ The beam of radar equipment has been known to cause flammable vapor-air mixtures to ignite from electrical arcs or sparks from chance resonant (con-

tinuing) conditions. This ability of an arc to ignite flammable vapor-air mixtures depends on the total energy of the arc and the time lapse involved. The key factor in establishing safe distances between fueling operations, storage areas and radar antennas is the peak power output of the radar unit.

**2006.21.1 Direction of radar beams.** The beam from ground radar equipment shall not be directed toward fuel storage or loading racks.

**Exceptions:**

1. Fuel storage and loading racks in excess of 300 feet (91 440 mm) from airport flight traffic surveillance equipment.
  2. Fuel storage and loading racks in excess of 100 feet (30 480 mm) from airport ground traffic surveillance equipment.
- ❖ Ground radar for approach control or traffic pattern surveillance is considered the most hazardous type of radar normally operated at an airport. The beam must not be directed toward fuel storage or loading racks because of the possible ignition sources (sparks, arcs) igniting flammable vapor-air mixtures. The exceptions are based on the arc energy emissions of the radars listed.

**SECTION 2007  
HELISTOPS AND HELIPORTS**

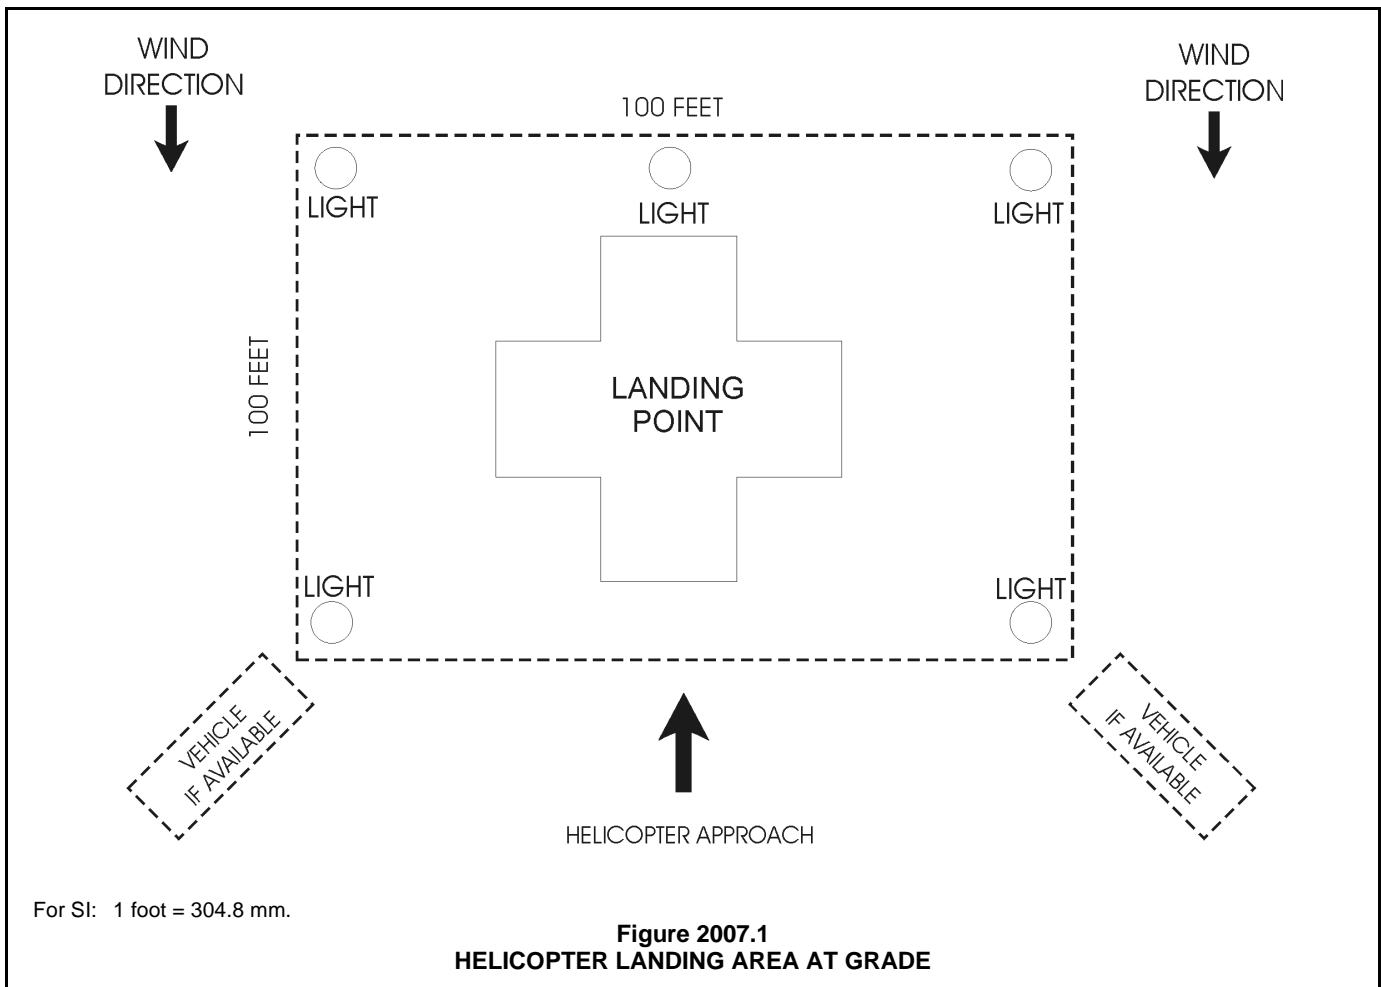

**2007.1 General.** Helistops and heliports shall be maintained in accordance with Sections 2007.2 through 2007.8. Helistops and heliports on buildings shall be constructed in accordance with the *International Building Code*.

❖ The following sections address clearances of the touch-down areas, spillage of liquid fuels, exits, fire protection systems and approval of the FAA. Information for construction and design of heliports can be found in FAA A/C 150/5390-2A, as well as in the IBC (see Commentary Figure 2007.1).

**2007.2 Clearances.** The touchdown area shall be surrounded on all sides by a clear area having minimum average width at roof level of 15 feet (4572 mm) but no width less than 5 feet (1524 mm). The clear area shall be maintained.

❖ Most accidents involving helicopters occur during takeoff and landing procedures, with a significant number occurring at night or in bad weather. The clearance requirements are intended to limit the likelihood of the aircraft colliding with permanent features at the landing site.

**2007.3 Flammable and Class II combustibile liquid spillage.** Landing areas on structures shall be maintained so as to

confine flammable or Class II *combustible liquid* spillage to the landing area itself, and provisions shall be made to drain such spillage away from *exits* or *stairways* serving the helicopter landing area or from a structure housing such *exit* or *stairway*.

❖ Rooftop landing areas must be designed to prevent fuel spills from escaping the landing area and flowing into adjacent or lower building spaces that could contain ignition sources for the fuel vapors. The stairways and exits serving the landing area must also be protected from the effects of fuel spills to afford personnel a safe means of escape from any dangers developing on the landing area. To accomplish this task, some rooftop heliport structure designs drain the pad to the center of the landing area. Although it is not required by the code, such designs often provide some means of separating fuel runoff from storm water. Additionally, drip pans should be provided below the helicopter engine when the aircraft is parked with the engine off.

**2007.4 Exits.** *Exits* and *stairways* shall be maintained in accordance with Section 412.7 of the *International Building Code*.

❖ IBC Section 412.5 refers to Chapter 10 for exit requirements. The section also addresses landing platforms and roof area size and the number of exits required. At least two means of egress must be provided off the landing pad.

**2007.5 Standpipe systems.** A building with a rooftop heli-stop or heliport shall be provided with a Class I or III standpipe system extended to the roof level on which the heli-stop or heliport is located. All portions of the heli-stop and heliport area shall be within 150 feet (45 720 mm) of a 2<sup>1</sup>/<sub>2</sub>-inch (63.5 mm) outlet on the standpipe system.

❖ A heliport is a distinct hazard that will involve flammable fuels. In the event of an emergency, rapid deployment of hand-held hose lines will be necessary to attack a resulting fire, effectuate rescue and protect exposures, as well as the remainder of the building.

Section 905.3.6 and this section require that when a heli-stop or heliport is provided on a rooftop location, a standpipe system is required throughout the building, with a 2<sup>1</sup>/<sub>2</sub>-inch hose connection within 150 feet of all parts of the heli-stop or heliport at the roof level. This is critical in fire-fighting operations because many times the connection below the rooftop level may be needed just to gain access to the roof. If the only hose connection were on the roof, it would be of no use if the fire fighters could not get to it. Since a heliport includes liquid fueling operations, it is entirely possible for a spill to affect not only the rooftop area, but also the floors below as the liquid fuel spreads downward into the building. The standpipe system will again be utilized in these situations.

Class I standpipes serve 2<sup>1</sup>/<sub>2</sub>-inch (63.5 mm) fire hose valves for fire department use. Class III standpipes have both 2<sup>1</sup>/<sub>2</sub>-inch (63.5 mm) valves for fire

department use and 1<sup>1</sup>/<sub>2</sub>-inch (38 mm) fire hose cabinets for use by building occupants.

**2007.6 Foam protection.** Foam fire-protection capabilities shall be provided for rooftop heliports. Such systems shall be designed, installed and maintained in accordance with the applicable provisions of Sections 903, 904 and 905.

❖ A foam fire-extinguishing system must be designed and installed for protection of the rooftop landing pad. Factors considered in the design of the system are aircraft size, effectiveness of agent selected, time required to achieve control and time required to maintain control. Foam discharge rates must also be considered according to the type of foam selected.

**2007.7 Fire extinguishers.** Not less than one portable fire extinguisher having a minimum 80-B:C rating shall be provided for each permanent takeoff and landing area and for the aircraft parking areas. Installation, inspection and maintenance of these extinguishers shall be in accordance with Section 906.

❖ The portable fire extinguisher for the takeoff/landing area must be effective for the extinguishment of a flammable liquid fire and for energized electrical components.

**2007.8 Federal approval.** Before operating helicopters from heli-stops and heliports, approval shall be obtained from the Federal Aviation Administration.

❖ The FAA approves all installations of heliports and heli-stops. Design criteria can be found in FAA A/C 150/5390-2A.

## Bibliography

The following resource material was used in the preparation of the commentary for this chapter of the code:

*Code Changes Resource Collection—2015 International Fire Code*. Washington, DC: International Code Council, 2014.

# Chapter 21: Dry Cleaning

## General Comments

Dry cleaning operations remove dirt, grease and other foreign substances from clothing, rugs, textiles and fabrics with solvents that are not water based, thus it is called “dry.” These methods may involve several techniques, including immersion and agitation, brushing or scouring, or dual-phase processing, which replicate a laundering (soap and water) process using the same equipment. The solvents employed may be flammable or nonflammable and may present certain health hazards. Both the fire code official and fire service personnel should be aware of the health and flammability hazards.

Concerns over flammability hazards and hazardous waste disposal have radically altered the nature of the dry cleaning business in the United States. Most plants currently use nonflammable solvents, such as perchloroethylene (“perc”) or tetrachloroethylene, rather than Stoddard solvent, naphtha, kerosene, gasoline or specially compounded oils, which were favored in previous years. “Perc” had become the solvent of choice for the dry cleaning industry over the years because it is not

only safer and faster, but does a much better job of cleaning, requires small equipment and is safe enough to be used in retail- or public-operated equipment. However, it has fallen into disfavor because of its carcinogenicity (see commentary, Section 2108.2).

Storage of flammable and combustible liquids must comply with the requirements of Chapter 57. Flammable solvent containers and processing equipment must be bonded and grounded during storage, handling and use to prevent buildup of static charges. Solvents must be used only in equipment approved for use with that specific class of solvent.

## Purpose

The provisions of Chapter 21 are intended to reduce hazards associated with use of flammable and combustible dry cleaning solvents. These materials, like all volatile organic chemicals, generate significant quantities of static electricity and are thus readily ignitable. Many flammable and nonflammable dry cleaning solvents also possess health hazards when involved in a fire.

---

## SECTION 2101 GENERAL

**2101.1 Scope.** Dry cleaning plants and their operations shall comply with the requirements of this chapter.

❖ Hazards associated with dry cleaning operations are addressed by the provisions of this chapter. Solvent storage hazards are addressed by Chapter 57.

**2101.2 Permit required.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.6.13 for discussion of specific operational permits for dry cleaning plants and their operation.

## SECTION 2102 DEFINITIONS

**2102.1 Definitions.** The following terms are defined in Chapter 2:

**DRY CLEANING.**

**DRY CLEANING PLANT.**

**DRY CLEANING ROOM.**

**DRY CLEANING SYSTEM.**

**SOLVENT OR LIQUID CLASSIFICATIONS.**

**Class I solvents.**

**Class II solvents.**

**Class IIIA solvents.**

**Class IIIB solvents.**

**Class IV solvents.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper

application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3 or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 2103 CLASSIFICATIONS

**2103.1 Solvent classification.** Dry cleaning solvents shall be classified according to their *flash points* as follows:

1. Class I solvents are liquids having a *flash point* below 100°F (38°C).
  2. Class II solvents are liquids having a *flash point* at or above 100°F (38°C) and below 140°F (60°C).
  3. Class IIIA solvents are liquids having a *flash point* at or above 140°F (60°C) and below 200°F (93°C).
  4. Class IIIB solvents are liquids having a *flash point* at or above 200°F (93°C).
  5. Class IV solvents are liquids classified as nonflammable.
- ❖ In order to establish regulations for mitigating the hazards of dry cleaning, the hazards of dry cleaning solvent must be identified and established. Because the liquid solvents used in dry cleaning operations, other than Class IV solvents, are either flammable or combustible, they are classified using the same criteria as those used to classify flammable and combustible liquids in Chapter 57.

Class I solvents are, by the definition in Chapter 57, flammable liquids because they have a closed-cup flash point of less than 100°F (38°C). The 100°F (38°C) flash point for flammable solvents assumes possible indoor ambient temperature conditions of 100°F (38°C), which means that the solvent could be used at or below its flash point under normal operating conditions in the dry cleaning plant. This solvent classification, however, includes no further subclassifications based on flash point and boiling point as does Chapter 57 for Class I flammable liquids.

Combustible solvents (Classes II and III) differ from flammable solvents in that the closed-cup flash point of all combustible liquids is at or above 100°F (38°C) (see commentary, definition of “Flash point” in Chapter 57). The range of flash point dictates the class of liquid solvent. The flash point range of 100°F (38°C) to 140°F (60°C) for Class II solvents is based on a possible indoor ambient temperature exceeding 100°F (38°C). Only a moderate degree of heating is required to bring the solvent to its flash point in this situation. Class III solvents, which have flash points higher than 140°F (38°C), require a significant heat source in addition to ambient temperature conditions to reach their flash point (see commentary, definition of “Flammable liquid” in Chapter 57).

### 2103.2 Classification of dry cleaning plants and systems.

Dry cleaning plants and systems shall be classified based on the solvents used as follows:

1. Type I—systems using Class I solvents.
2. Type II—systems using Class II solvents.
3. Type III-A—systems using Class IIIA solvents.
4. Type III-B—systems using Class IIIB solvents.
5. Type IV—systems using Class IV solvents in which dry cleaning is not conducted by the public.
6. Type V—systems using Class IV solvents in which dry cleaning is conducted by the public.

Spotting and pretreating operations conducted in accordance with Section 2106 shall not change the type of the dry cleaning plant.

❖ Dry cleaning plants are classified based on the solvents they use and the hazards presented by them.

Type I dry cleaning systems are those systems using a Class I flammable liquid [flash point less than 100°F (38°C)] as a cleaning solvent, such as low flash-point [less than 50°F (10°C)] naphtha. Such plants are prohibited by Section 2104.1.

Type II dry cleaning systems are those systems using a Class II combustible liquid [flash points 100°F (38°C) to 140°F (60°C)] as a cleaning solvent, such as Stoddard solvent. NFPA 32 classifies the entire dry cleaning room of a Type II plant as a Class I, Division 2 hazardous (classified) location.

Type III-A dry cleaning systems are those systems using a Class IIIA combustible liquid as a cleaning solvent [flash point 140°F (60°C) to 200°F (93°C)].

Type III-B dry cleaning systems are those systems using a Class IIIB combustible liquid as a cleaning solvent [flash point greater than 200°F (93°C)], usually specially compounded oils.

Type IV dry cleaning systems are those systems using nonflammable solvents, and dry cleaning is done only by trained operators.

Type V dry cleaning systems are those systems using nonflammable solvent, typically perchloroethylene, and dry cleaning is done by the general public (e.g., at coin-operated laundries).

This section recognizes the practical need to have limited amounts of higher hazard solvents on hand in the plant for spotting and pretreating by not classifying the plant based on the highest hazard solvent that might be present in any quantity. See the commentary to Section 2106 for further information on spotting and pretreating operations.

**2103.2.1 Multiple solvents.** Dry cleaning plants using more than one class of solvent for dry cleaning shall be classified based on the numerically lowest solvent class.

❖ Ventilation, and electrical requirements in particular, vary considerably among various types of dry cleaning plants. Additionally, each type of dry cleaning equipment is designed for the hazards specific to the

solvent used. The greatest hazard determines the appropriate level of protection where a danger of accidental misuse exists.

The more volatile compounds, such as naphtha, Stoddard solvent and oils, may still be found in some specialized industrial dry cleaning plants to remove specific materials from work clothes. Although perchloroethylene and similar safety solvents are not flammable, they do present certain health hazards, especially under fire conditions. Commentary Figure 2103.2.1 lists some of the more common dry cleaning solvents with their physical, flammability and toxicity characteristics.

Perchloroethylene concentrations as low as 300 to 1,100 parts per million (ppm) under normal conditions may cause loss of coordination and impairment, while dizziness, drowsiness or loss of consciousness may result at higher concentrations. Perchloroethylene may also emit highly toxic and irritating fumes in a fire.

**2103.3 Design.** The occupancy classification, design and construction of dry cleaning plants shall comply with the applicable requirements of the *International Building Code*.

❖ This section makes it clear that dry cleaning plants are required to comply with the applicable provisions of the *International Building Code*® (IBC®) for their classification of occupancy, as well as their design and construction.

Dry cleaning operations are classified in Group B based on IBC Section 304.1 where only drop-off/pickup facilities are provided or where self-service dry cleaning is done by the public using Class V systems with Class IV solvents (see Sections 2103.1 and 2103.2 of the code). Nonself-service dry cleaning operations using other than flammable liquids in cleaning or dyeing operations are classified in moderate hazard industrial Group F-1 (see IBC Section 306.2) based on the classification and quantity of dry cleaning solvent used. The Group F-1 occupancy classification for dry cleaning plants is based on IBC Section 307.1, which provides two exceptions to classification in Group H for dry cleaning plants.

The first exception, Exception 4, states that plants utilizing Class IIIA solvents [flash point at or above 140°F (60°C)] in closed, testing laboratory-listed machines are exempt from being classified in Group H, provided that the plant is physically separated from all other portions of the building in which it is located

by 1-hour fire barriers or horizontal assemblies, or both.

The second exception, Exception 5, states that plants utilizing Class IIIB solvents [flash point at or above 200°F (93°C)] that are difficult to ignite are exempt from being classified in Group H without further conditions. Such liquids can be used in open systems, but with due care.

Systems that do not meet the descriptions and exceptions above must be evaluated for possible classification in Group H based upon the type and quantity of solvent in storage use. If a Group H classification is warranted, IBC Section 415.9.3 requires compliance with the applicable provisions of the *International Plumbing Code*® (IPC®), the *International Mechanical Code*® (IMC®) and NFPA 32 for plant construction and system installation. Both NFPA 32 and the IMC specify mechanical exhaust ventilation rates for dry cleaning rooms.

The IPC specifies requirements for sanitary sewers and drains in laundries and where hazardous materials are used or stored.

**SECTION 2104  
GENERAL REQUIREMENTS**

**2104.1 Prohibited use.** Type I dry cleaning plants shall be prohibited. Limited quantities of Class I solvents stored and used in accordance with this section shall not be prohibited in dry cleaning plants.

❖ This section flatly prohibits Class I dry cleaning plants (i.e., those that use Class I flammable liquids) because of the extreme flammability of such liquids. This section also recognizes the practical need to have limited amounts of Class I solvent on hand in the plant for spotting and pretreating, provided that it is stored and used in accordance with Chapter 57. See the commentary to Section 2106 for further information on spotting and pretreating operations.

**2104.2 Building services.** Building services and systems shall be designed, installed and maintained in accordance with this section and Chapter 6.

❖ Electrical and mechanical systems serving the dry cleaning plant must comply with the provisions of Sections 2104.2.1 through 2104.2.4 and the applicable provisions of Chapter 6.

CHEMICAL NAME	FLASH POINT	IGNITION TEMPERATURE	HEALTH <sup>a</sup>	FLAMMABILITY <sup>a</sup>	REACTIVITY <sup>a</sup>
Naptha	28° to 50°F	450°F	1	3	0
Perchloroethylene	None	None	2	0	0
Stoddard solvent	Above 100°F	444°F	0	2	0

For SI: °C = [(°F) - 32]/1.8.

a. Based on NFPA 704.

**Figure 2103.2.1  
CHARACTERISTICS OF DRY CLEANING SOLVENTS**

## DRY CLEANING

**2104.2.1 Ventilation.** Ventilation shall be provided in accordance with Section 502 of the *International Mechanical Code* and DOL 29 CFR Part 1910.1000, where applicable.

❖ This section is intended to provide ventilation in dry cleaning plants that is adequate to protect plant employees and the public from the hazards associated with dry cleaning operations using any of the various classes of dry cleaning solvents, both in approved dry cleaning machines and in spotting and pretreating operations in the open. To achieve this objective, this section requires that mechanical ventilation systems comply with the provisions of IMC Section 502.6. Compliance with the applicable provisions of the Occupational Safety and Health Administration (OSHA) workplace regulations pertaining to air contaminants contained in DOL 29 CFR 1910.1000 is also required.

**2104.2.2 Heating.** In Type II dry cleaning plants, heating shall be by indirect means using steam, hot water or hot oil only.

❖ Open-flame heating appliances, such as unit heaters, must not be located in Type II dry cleaning plants because they could create conditions conducive to the ignition of any fugitive vapors from the Class II dry cleaning solvent used in these plants. Indirect steam, hot water or hot oil heat supplied from appliances located in rooms separated from the Type II dry cleaning plant or in separate buildings are examples of indirect heat methods.

**2104.2.3 Electrical wiring and equipment.** Electrical wiring and equipment in dry cleaning rooms or other locations subject to flammable vapors shall be installed in accordance with NFPA 70.

❖ To reduce the likelihood of a vapor ignition, electrical wiring and equipment located where flammable vapors might be released by malfunctioning equipment, rupture or breakage is typically classified as Class I, Division 1 equipment under the provisions of NFPA 70. This would include rooms or spaces containing closed-system dry cleaning equipment that, under normal conditions, keeps the solvent vapors confined within the equipment. For the same reason, in areas where flammable vapors are present under normal operating conditions, such as in spotting or pretreating areas, using Class I solvents in the open, in tubs or on soaking tables, electrical wiring and equipment must be classified as Class I, Division 1, equipment to meet the requirements of NFPA 70.

**2104.2.4 Bonding and grounding.** Storage tanks, treatment tanks, filters, pumps, piping, ducts, dry cleaning units, stills, tumblers, drying cabinets and other such equipment, where not inherently electrically conductive, shall be bonded together and grounded. Isolated equipment shall be grounded.

❖ Solvent containers and processing equipment during storage, handling and use must be bonded and grounded to prevent buildup of static charges, thus eliminating a common source of ignition for vapors

emitted by flammable and combustible liquid solvents.

## SECTION 2105 OPERATING REQUIREMENTS

**2105.1 General.** The operation of dry cleaning systems shall comply with the requirements of Sections 2105.1.1 through 2105.3.

❖ Section 2105 establishes requirements for the safe operation and maintenance of dry cleaning plants. The fire hazard associated with these plants has diminished significantly in recent years as fire protection, environmental and hazardous waste disposal concerns have caused the industry to move away from the use of flammable and combustible solvents. Poor housekeeping is the primary fire prevention concern these days.

**2105.1.1 Written instructions.** Written instructions covering the proper installation and safe operation and use of equipment and solvent shall be given to the buyer.

❖ This section applies to persons or firms that engage in wholesale or retail sales of dry cleaning equipment. Each piece of equipment sold must be accompanied by written instructions for the installation and operation of the equipment and for the safe storage, handling and use of the dry cleaning solvent for which it is designed.

**2105.1.1.1 Type II, III-A, III-B and IV systems.** In Type II, III-A, III-B and IV dry cleaning systems, machines shall be operated in accordance with the operating instructions furnished by the machinery manufacturer. Employees shall be instructed as to the hazards involved in their departments and in the work they perform.

❖ Safety in dry cleaning operations depends on employees being familiar with not only the dry cleaning machines and their operation as described in the written instructions required by Section 2105.1.1, but also understanding the hazards associated with and the proper methods of storing, handling, dispensing and using dry cleaning solvents within their respective work spaces. This section requires that employees be trained in all aspects of dry cleaning operations.

**2105.1.1.2 Type V systems.** Operating instructions for customer use of Type V dry cleaning systems shall be conspicuously posted in a location near the dry cleaning unit. A telephone number shall be provided for emergency assistance.

❖ Type V dry cleaning systems are operated by the general public rather than by trained employees as are Type II, III-A and III-B systems. Under ideal conditions, such operations should have an attendant to supervise cleaning activities and be available to answer questions on the proper operation of the machines. Most Type V systems, however, are not attended. For this reason, machine operating instruc-

tions must be posted prominently in the machine area where they can be seen readily by patrons. In addition, an emergency phone number must be posted prominently for patron use. Note that this section does not require a public telephone on the premises. With the proliferation of cellular technology, much of the public carries a cell phone that can be used in case of an emergency.

**2105.1.2 Equipment identification.** The manufacturer shall provide nameplates on dry cleaning machines indicating the class of solvent for which each machine is designed.

- ❖ Because dry cleaning machines are designed to be used only with a specific class of solvent, this information must be clearly displayed on a permanent nameplate affixed to the machine so that there can be no question of what solvent may be used in a given machine (also see commentary, Section 2105.1.4).

**2105.1.3 Open systems prohibited.** Dry cleaning by immersion and agitation in open vessels shall be prohibited.

- ❖ Dry cleaning is intended to be a closed-system process, with the cleaning solvent contained within the machinery. Pouring large quantities of combustible solvent into an open container to soak or agitate items being cleaned allows and increases the escape of combustible vapors or, in the case of Type IV systems, noncombustible but toxic vapors, and is, therefore, prohibited. Also see the commentary to Section 2106 for a discussion of spotting and pretreating in the open and special handling provisions that allow limited hand agitation in the open.

**2105.1.4 Prohibited use of solvent.** The use of solvents with a *flash point* below that for which a machine is designed or *listed* shall be prohibited.

- ❖ Dry cleaning equipment is designed and tested for use with specific classifications of solvents. This section mandates that equipment be used only with the class of solvent for which it has been designed. Equipment approved for higher flash-point or nonflammable solvents may not be equipped with many of the inherent safety features required for lower flash-point solvents.

**2105.1.5 Equipment maintenance and housekeeping.** Proper maintenance and operating practices shall be observed in order to prevent the leakage of solvent or the accumulation of lint. The handling of waste material generated by dry cleaning operations and the maintenance of facilities shall comply with the provisions of this section.

- ❖ Safe dry cleaning depends on safe, well-maintained equipment and good housekeeping practices. Because dry cleaning is intended to be a closed-system use, machines must be checked regularly for loose fittings and connections that could allow the leakage of a solvent and its vapors. Also, the lint that accumulates in the cleaning of textile materials must be regularly removed from lint traps and disposed of properly. This section requires that dry cleaning

plants comply with the provisions of Sections 2105.1.5.1 through 2105.1.5.4.

**2105.1.5.1 Floors.** Class I and II liquids shall not be used for cleaning floors.

- ❖ This section prohibits the use of flammable and Class II combustible liquids for cleaning floors in dry cleaning plants for basically the same reasons that open soaking and agitation with solvents are prohibited by Section 2105.1.3: open use will allow flammable vapors to escape and accumulate. This effect is aggravated by the fact that in many instances, dry cleaning plants operate at high ambient temperatures that may be at or above the flash point of Class I or II liquids, thus forming an immediately ignitable mixture in air.

**2105.1.5.2 Filters.** Filter residue and other residues containing solvent shall be handled and disposed of in covered metal containers.

- ❖ The Environmental Protection Agency (EPA) has raised health and safety concerns about dry cleaning workers and people living near dry cleaners. Improper handling and disposal of dry cleaning solvents can pollute outdoor air, soil and water. Dry cleaning and laundry plants that might generate hazardous waste and be subject to Resource Conservation and Recovery Act (RCRA) requirements covering the generation, transportation and management of hazardous waste include: retail dry cleaning stores; industrial and linen supply plants with dry cleaning operations; self-service laundromats with dry cleaning equipment; or other facilities with dry cleaning operations. The volume of hazardous waste produced in these facilities often places them in the EPA category of "small quantity generator." Proper storage and disposal of spent filters and other solvent-containing wastes (empty solvent containers, still residues from solvent distillation and water contaminated with cleaning solvent) as required by this section reduces the potential for the production of solvent vapors and environmental pollution.

**2105.1.5.3 Lint.** Lint and refuse shall be removed from traps daily, deposited in *approved* waste cans, removed from the premises, and disposed of safely. At all other times, traps shall be held securely in place.

- ❖ Lint is finely divided textile fiber sloughed off of articles being cleaned and is generated in large quantities in the dry cleaning process. As with any combustible material, the more finely it is divided, the more surface area of the material is available for ignition and the more readily it will ignite. For this reason, this hazard must be reduced by collection and removal of lint, as well as other combustible waste materials, at least daily, followed by proper disposal.

**2105.1.5.4 Customer areas.** In Type V dry cleaning systems, customer areas shall be kept clean.

- ❖ Coin-operated laundries and dry cleaning establishments are often unattended, which can lead to poor

housekeeping and hazardous conditions that could contribute to the start or spread of a fire. This section requires that reasonable housekeeping procedures be established and executed regularly to reduce this hazard.

**2105.2 Type II systems.** Special operating requirements for Type II dry cleaning systems shall comply with the provisions of Sections 2105.2.1 through 2105.2.3.

- ❖ Sections 2105.2.1 through 2105.2.3 contain operating procedures uniquely applicable to Type II dry cleaning systems because of their use of Class II solvents and the higher relative hazards associated with that use.

**2105.2.1 Inspection of materials.** Materials to be dry cleaned shall be searched thoroughly and foreign materials, including matches and metallic substances, shall be removed.

- ❖ To prevent damage to dry cleaning equipment and eliminate potential sources of ignition, such as matches being ignited or metallic objects striking a spark with dry cleaning machine parts, articles to be dry cleaned must be carefully screened for foreign objects that could create a hazardous condition.

**2105.2.2 Material transfer.** In removing materials from the washer, provisions shall be made for minimizing the dripping of solvent on the floor. Where materials are transferred from a washer to a drain tub, a nonferrous metal drip apron shall be placed so that the apron rests on the drain tub and the cylinder of the washer.

- ❖ To reduce the amount of Class II solvent lost during removal of cleaned articles from the dry cleaning machine, means must be provided to minimize the amount of solvent that drips on the plant floor and evaporates into hazardous vapors in the work space. This section describes one method of preventing solvent drips by placing a drain board between the dry cleaning machine and drain tubs. The drain board must be nonferrous to prevent potential metal-to-metal sparks during the transfer process.

**2105.2.3 Ventilation.** A mechanical ventilation system which is designed to exhaust 1 cubic foot of air per minute for each square foot of floor area [ $0.0058 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] shall be installed in dry cleaning rooms and in drying rooms. The ventilation system shall operate automatically when the dry cleaning equipment is in operation and shall have manual controls at an *approved* location.

- ❖ This section intended to prevent solvent vapors from Type II dry cleaning systems from accumulating to an ignitable concentration in the room in which those appliances are located by providing adequate mechanical ventilation. The prescribed rate of mechanical ventilation will also help prevent the ambient temperature in the room from exceeding the flash point of the solvent being used in the cleaning process. It is not the intent that this system be classified as a “hazardous exhaust system” as addressed

in IMC Section 510; however, consistent with IMC Section 502, this system must be independent of all other exhaust and ventilation systems.

The required ventilation rate of 1 cubic foot per minute (cfm) per square foot [ $0.0058 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of floor area is typical of that required in hazardous material-related areas where fugitive flammable vapors need dilution or removal. Although its exact technical origins remain obscure, it is thought to have been derived from a rule of thumb (possibly from the insurance industry) that established a ventilation requirement in flammable and combustible liquid use areas of six air changes per hour, which has proven to be effective over the years. Although this method provides effective ventilation and hazard reduction, moving that volume of air in industrial or storage buildings with larger-than-average floor-to-floor and floor-to-roof dimensions requires large, costly mechanical equipment installations and creates concerns over energy conservation. To deal with those concerns, a design ceiling height of 10 feet (3048 mm) was assumed in recognition of the fact that solvent vapors will gather at the lowest point in the room. Each square foot of building area, then, would represent 10 cubic feet ( $0.3 \text{ m}^3$ ) and, at the rate of six air changes per hour, 60 cubic feet ( $1.7 \text{ m}^3$ ) of air per hour would be moved, which yields 1 cfm per square foot [ $0.0058 \text{ m}^3/(\text{s} \cdot \text{m}^2)$ ] of room area.

To be effective, the exhaust equipment is required by this section to be interlocked with the dry cleaning equipment so that it operates whenever the dry cleaning equipment operates. Manual controls are also required for additional flexibility and reliability in the event that the mechanical system runs on after the dry cleaning system is shut down. The location of the controls is to be approved by the fire code official.

**2105.3 Type IV and V systems.** Type IV and V dry cleaning systems shall be provided with an automatically activated exhaust ventilation system to maintain a minimum of 100 feet per minute ( $0.51 \text{ m/s}$ ) air velocity through the loading door when the door is opened. Such systems for dry cleaning equipment shall comply with the *International Mechanical Code*.

**Exception:** Dry cleaning units are not required to be provided with exhaust ventilation where an exhaust hood is installed immediately outside of and above the loading door which operates at an airflow rate as follows:

$$Q = 100 \times A_{LD} \quad \text{(Equation 21-1)}$$

where:

$Q$  = flow rate exhausted through the hood, cubic feet per minute ( $\text{m}^3/\text{s}$ ).

$A_{LD}$  = area of the loading door, square feet ( $\text{m}^2$ ).

- ❖ This section is intended to prevent solvent vapors from Type IV and V dry cleaning systems from escaping into the room where the appliances are located by

drawing the required exhaust airflow into the unit through the open door at the minimum velocity of 100 feet per minute (51 m/s). In this way, exposure of employees (in Type IV systems) or the public (in Type V systems) to potentially harmful solvent vapors is minimized. The exhaust capability contemplated by this section is integral with the dry cleaning unit, and its operation must be interlocked with the unit door to automatically start the required exhaust airflow as soon as the unit door is opened. It is not the intent that this system be classified as a “hazardous exhaust system” as addressed in IMC Section 510; however, consistent with IMC Section 502, this system must be independent of all other exhaust and ventilation systems.

The exception is a design alternative to achieve the goal of solvent vapor capture at the door opening through installation of what is often referred to as an “eyebrow hood” located immediately above the dry cleaning unit door opening. This enables the exhaust airflow to sweep across the loading door opening of the machine and capture any escaping solvent vapors. This kind of hood may be integral with the unit or may be an after-market-installed accessory to the unit. In either case, it must be either interlocked with the unit door to automatically start the required exhaust airflow as soon as the unit door is opened or operate continuously whenever the dry cleaning machine is in operation.

Since exhaust hoods are not designed for a constant air velocity in all parts of the hood, such as can be achieved by drawing air into a machine through a loading door opening, exhaust capability for this alternative design calculated in accordance with Equation 21-1 will be expressed as a flow rate rather than a fixed velocity. The fan will be drawing in a large volume of environmental air to achieve the prescribed exhaust airflow across the entire loading door opening. For example, applying the formula to a dry cleaning unit that has a 2-foot-diameter (610 mm) circular loading/unloading door, the exhaust flow rate ( $Q$ ) would be calculated as follows:

$$Q = 100 \times A_{LD}$$

$$A_{LD} = \pi r^2; \text{ where } \pi = 3.14 \text{ and } r = 1, \text{ therefore}$$

$$Q = 100 \times (3.14 \times 1^2)$$

$$Q = 100 \times 3.14$$

$$Q = 314 \text{ cubic feet per minute}$$

It is not the intent that this system be classified as a “hazardous exhaust system” as addressed in IMC Section 510; however, consistent with IMC Section 502.1.3, this system must be independent of all other exhaust and ventilation systems.

## SECTION 2106 SPOTTING AND PRETREATING

**2106.1 General.** Spotting and pretreating operations and equipment shall comply with the provisions of Sections 2106.2 through 2106.5.

- ❖ Spotting and pretreating operations consist of soaking or direct local application of cleaning solvents to articles about to be dry cleaned. These operations focus the solvent’s cleaning power on the removal of more stubborn stains, such as those from grease, oils, makeup, paint, dirt or petroleum products (tar, asphalt sealer, etc). The operations typically take place on spotting tables or in scrubbing tubs in the open in the dry cleaning plant. Compliance with the requirements of Section 2106 will result in an acceptable level of safety for spotting and pretreating operations.

**2106.2 Class I solvents.** The maximum quantity of Class I solvents permitted at any work station shall be 1 gallon (4 L). Spotting or prespotting shall be permitted to be conducted with Class I solvents where they are stored in and dispensed from *approved* safety cans or in sealed DOT-approved metal shipping containers of not more than 1-gallon (4 L) capacity.

- ❖ This section allows up to 1 gallon (4 L) of Class I (flammable) solvent to be stored in its original shipping container or, where used for spotting or prespotting, stored in and dispensed from a safety can complying with UL 30 (see commentary, Sections 5005.1.10 and 5705.2.4).

**2106.2.1 Spotting and prespotting.** Spotting and pre-spotting shall be permitted to be conducted with Class I solvents where dispensed from plastic containers of not more than 1 pint (0.5 L) capacity.

- ❖ This section recognizes the use of U.S. Department of Transportation-approved plastic containers to ship and store chemicals used in dry cleaning plants, including spotting chemicals. Use of such containers is permitted by Section 5704.3.1 of the code and OSHA regulations for the storage of flammable and combustible liquids. Similar provisions also appear in Chapter 5 of NFPA 32. Note that the quantity limitation in this section is well below the use-open maximum allowable quantities (MAQ) for flammable liquids in Table 5003.1.1(1).

**2106.3 Class II and III solvents.** Scouring, brushing, and spotting and pretreating shall be permitted to be conducted with Class II or III solvents. The maximum quantity of Class II or III solvents permitted at any work station shall be 1 gallon (4 L). In other than Group H-2 occupancy, the aggregate quantities of solvents shall not exceed the maximum allowable quantity per control area for use-open system.

- ❖ This section allows Class II or III solvents to be used for spotting or pretreating and limits the quantity of

## DRY CLEANING

solvent that can be in use at a spotting or pretreating work station to 1 gallon (4 L) to reduce the likelihood of an unmanageable solvent spill. Aggregate quantities of spotting or pretreating solvent must not exceed the MAQ for open system use established by Table 5003.1.1(1), including the increases allowed for the sprinkler system required by Section 2108.2.

**2106.3.1 Spotting tables.** Scouring, brushing or spotting tables on which articles are soaked in solvent shall have a liquid-tight top with a curb on all sides not less than 1 inch (25 mm) high. The top of the table shall be pitched to ensure thorough draining to a 1½-inch (38 mm) drain connected to an *approved* container.

❖ To reduce spills of spotting solvents during their open use, surfaces upon which the spotting is done must be designed to catch and route solvent to an approved container (preferably a closed one) for disposal or recycling.

**2106.3.2 Special handling.** Where *approved*, articles that cannot be washed in the usual washing machines are allowed to be cleaned in scrubbing tubs. Scrubbing tubs shall comply with the following:

1. Only Class II or III liquids shall be used.
2. The total amount of solvent used in such open containers shall not exceed 3 gallons (11 L).
3. Scrubbing tubs shall be secured to the floor.
4. Scrubbing tubs shall be provided with permanent 1½-inch (38 mm) drains. Such drain shall be provided with a trap and shall be connected to an *approved* container.

❖ Although dry cleaning by immersion and agitation in open vessels is prohibited by Section 2105.1.3, there are isolated circumstances in which an article that needs dry cleaning cannot be cleaned in the conventional manner in an approved dry cleaning machine. This section establishes minimum safeguards intended to reduce the hazards associated with open cleaning in a scrubbing tub.

The first step in cleaning an article in the open is to secure the approval of the fire code official for the operation. This enables him or her to inspect the area where the open cleaning is to be done to verify that the housekeeping complies with this chapter, that all the safeguards required by this section are in place, that the ventilation requirements of Section 2106.3.3 are met, and that the bonding and grounding required by Section 2106.3.4 are in place.

Although limited use of Class I spotting solvents is allowed by Section 2106.3, this section makes it clear that dry cleaning in the open is limited to only Class II or III solvents because of their higher flash points. To avoid an unmanageable spill while still allowing a workable quantity of solvent in the scrubbing tub, Class II or III solvents are limited to only 3 gallons (11 L) in process, and then only in a tub that is firmly fixed in place by securing it to the floor in an approved manner. Solvents used in open dry cleaning pro-

cesses must be captured in an approved (preferably closed) container for recycling or proper disposal.

**2106.3.3 Ventilation.** Scrubbing tubs, scouring, brushing or spotting operations shall be located such that solvent vapors are captured and exhausted by the ventilating system.

❖ When locating the spotting or pretreating operation within the plant, care must be taken to choose a location that will allow adequate airflow on all sides of the spotting or pretreating equipment to maximize the effectiveness of the exhaust ventilation system required by Section 2105.2.3 in preventing the accumulation of hazardous vapor concentrations.

**2106.3.4 Bonding and grounding.** Metal scouring, brushing and spotting tables and scrubbing tubs shall be permanently and effectively bonded and grounded.

❖ Solvent containers and processing equipment during storage, handling and use must be grounded to prevent buildup of static charges, thus eliminating a common source of ignition for vapors from flammable and combustible liquid solvents.

**2106.4 Type IV systems.** Flammable and combustible liquids used for spotting operations shall be stored in *approved* safety cans or in sealed DOTn-approved shipping containers of not more than 1 gallon (4 L) in capacity. Aggregate amounts shall not exceed 10 gallons (38 L).

❖ Type IV dry cleaning systems are those systems using nonflammable solvents where dry cleaning is done only by trained operators who must be familiar with solvent hazards. Up to an aggregate quantity of 10 gallons (38 L) of Class I, II or III spotting or pretreating solvents is allowed if the solvents comply with the minimum storage safeguard of being stored in their original shipping container or safety cans complying with UL 30 (see commentary, Sections 5005.1.10 and 5705.2.4).

**2106.5 Type V systems.** Spotting operations using flammable or *combustible liquids* are prohibited in Type V dry cleaning systems.

❖ Type V dry cleaning systems are those systems using nonflammable solvents where dry cleaning is done by the general public, such as in coin-operated laundries that may or may not be attended by qualified staff. To prevent exposing the general public to the hazards of spotting or pretreating operations using solvents more hazardous than the nonflammable solvents used in the Type V system itself, and to preclude any action that might violate Section 2105.1.4, this section prohibits spotting and pretreating operations altogether.

## SECTION 2107 DRY CLEANING SYSTEMS

**2107.1 General equipment requirements.** Dry cleaning systems, including dry cleaning units, washing machines, stills, drying cabinets, tumblers and their appurtenances,

including pumps, piping, valves, filters and solvent coolers, shall be installed and maintained in accordance with NFPA 32. The construction of buildings in which such systems are located shall comply with the requirements of this section and the *International Building Code*.

❖ NFPA 32 contains provisions for the prevention and control of fire and explosion hazards incidental to dry cleaning operations for the protection of employees and the public. Likewise, the IBC regulates the construction of dry cleaning plant buildings based on the relative hazards of the occupancies. IBC Chapter 3 classifies dry cleaning pickup/drop-off stations and Type V dry cleaning systems in Occupancy Group B (business) because of their low-hazard nature. Type II, III and IV dry cleaning plants are classified in Occupancy Group F-1 (moderate-hazard factory-industrial) because they include or could include the processing of combustible textiles using combustible solvents and, on a limited basis, flammable liquids for spotting. Certain dry cleaning operations could be classified by the IBC in Group H, depending on the quantity of solvent present and the type of machines used. See the commentary to IBC Section 307.1 for further discussion of exceptions to Group H classifications.

**2107.2 Type II systems.** Type II dry cleaning and solvent tank storage rooms shall not be located below grade or above the lowest floor level of the building and shall comply with Sections 2107.2.1 through 2107.2.3.

**Exception:** Solvent storage tanks installed underground, in vaults or in special enclosures in accordance with Chapter 57.

❖ Type II dry cleaning systems are those systems using a Class II combustible liquid [flash point from 100°F (38°C) to 140°F (60°C)] as a cleaning solvent, sometimes at or above its lowest flash point under normal plant operating conditions. For this reason, this section prohibits the location of these systems and solvent storage at other than the level of fire department access or exit discharge (i.e., other than at grade). Because of the higher relative hazards of these systems and their solvents, locating them above or below the lowest grade floor level could affect rapid egress by employees, as well as rapid access to the system by fire fighters in case of an emergency.

**2107.2.1 Fire-fighting access.** Type II dry cleaning plants shall be located so that access is provided and maintained from one side for fire-fighting and fire control purposes in accordance with Section 503.

❖ The general design of fire apparatus access to buildings is regulated by Section 503. To give fire fighters timely access to the building, this section requires that the building containing the Type II system be accessible on at least one side. This is consistent with the provisions of Section 503.1.1, which allows access on only one side when a building is equipped throughout with an automatic sprinkler system as is required by Section 2108.2 for dry cleaning plants. Fire apparatus access must be kept unobstructed at

all times and comply with the provisions of Section 503.

**2107.2.2 Number of means of egress.** Type II dry cleaning rooms shall have not less than two *means of egress* doors located at opposite ends of the room, not less than one of which shall lead directly to the outside.

❖ The number of exit access doorways required from a room or space is regulated by Section 1015.1. That general section would not require two doors out of a Type II dry cleaning room classified in Occupancy Group F-1 unless it had an occupant load of more than 50 persons; that is, greater than 5,000 square feet (465 m<sup>2</sup>) in area based on 100 square feet (9 m<sup>2</sup>) per person in accordance with Table 1004.1.2. However, this section is specific to Type II dry cleaning rooms and supersedes general Group F egress requirements by requiring two doors out of the room, regardless of occupant load. Note that at least one of the doors must be an exit door that opens directly to the exit discharge or public way outside of the building. All doors must also comply with Section 1022.2.

This section also supersedes the general exit or exit access remoteness requirements of Section 1015.2 by mandating that the two means of egress doors from a Type II dry cleaning room be located at opposite ends of the room, rather than a distance apart equal to one-half the overall diagonal dimension of the room.

**2107.2.3 Spill control and secondary containment.** Curbs, drains or other provisions for spill control and secondary containment shall be provided in accordance with Section 5004.2 to collect solvent leakage and fire protection water and direct it to a safe location.

❖ To prevent the flow of Class II solvents to rooms or spaces adjoining the dry cleaning room, spill control complying with Section 5004.2 is required by this section. Care must be taken in the design of drainage and secondary containment systems to accurately calculate automatic sprinkler design discharge flow rates and fire suppression hand line [typically 1½- or 1¾-inch (38 mm or 44 mm) hose] flows. Note that secondary containment provisions do not include control of the flammable, irritating or toxic vapors given off by the solvent. Care must be taken to minimize exposure to hazardous vapors. Runoff from spills or manual fire suppression activities may result in environmental contamination if not properly controlled (also see commentary, Section 5004.2).

**2107.3 Solvent storage tanks.** Solvent storage tanks for Class II, IIIA and IIIB liquids shall conform to the requirements of Chapter 57 and be located underground or outside, above ground.

**Exception:** As provided in NFPA 32 for inside storage or treatment tanks.

❖ Safe and proper storage of solvents is a paramount concern in the safe operation of a dry cleaning plant or facility. This section requires that combustible sol-

vents be stored in approved tanks located either underground or above ground outside the building, and references Chapter 57 for detailed requirements.

The exception recognizes the provisions contained in NFPA 32 governing the inside storage of solvents. While NFPA 32 allows the unenclosed indoor installation of up to three 1,500-gallon (5678 L) storage or treatment tanks of Class II solvent, it should be noted that, in accordance with the IBC, indoor storage of Class II solvents in excess of the MAQ indicated in IBC Table 307.1(1) would cause the dry cleaning facility to be classified in Group H-3.

### SECTION 2108 FIRE PROTECTION

**2108.1 General.** Where required by this section, *fire protection systems*, devices and equipment shall be installed, inspected, tested and maintained in accordance with Chapter 9.

❖ To control the relative hazards posed by dry cleaning operations, this section requires the installation of a fire protection system and references Chapter 9 for installation and maintenance.

**2108.2 Automatic sprinkler system.** An *automatic sprinkler system* shall be installed in accordance with Section 903.3.1.1 throughout dry cleaning plants containing Type II, Type III-A or Type III-B dry cleaning systems.

**Exceptions:**

1. An *automatic sprinkler system* shall not be required in Type III-A dry cleaning plants where the aggregate quantity of Class III-A solvent in dry cleaning machines and storage does not exceed 330 gallons (1250 L) and dry cleaning machines are equipped with a feature that will accomplish any one of the following:
  - 1.1. Prevent oxygen concentrations from reaching 8 percent or more by volume.
  - 1.2. Keep the temperature of the solvent not less than 30°F (16.7°C) below the flash point.
  - 1.3. Maintain the solvent vapor concentration at a level lower than 25 percent of the lower explosive limit (LEL).
  - 1.4. Utilize equipment *approved* for use in Class I, Division 2 hazardous locations in accordance with NFPA 70.
  - 1.5. Utilize an integrated dry-chemical, clean agent or water-mist automatic fire-extinguishing system designed in accordance with Chapter 9.
2. An *automatic sprinkler system* shall not be required in Type III-B dry cleaning plants where the aggregate quantity of Class III-B solvent in dry cleaning

machines and storage does not exceed 3,300 gallons (12 490 L).

❖ Section 903.2 contains the general “where required” criteria for the installation of automatic sprinklers in buildings. Section 2108.7 is more specific and would require an automatic sprinkler system throughout dry cleaning plants regardless of the size of the fire area. This is related to the hazard of relatively high fire loads coupled with the presence of combustible and possibly flammable liquids. These liquids may be in both open and closed system operations

Several exceptions to the requirement for sprinklers are included in this section of the code in part because several states have banned the use of the nonflammable dry cleaning fluid perchlorethylene or “perc” due to its carcinogenicity which already requires that plant operators purchase new equipment using alternative dry cleaning technology. The ICC voting membership approved the addition of the exceptions because its members felt that having a sprinkler requirement on top of that capital expense would be a business hardship and also because the nationally recognized standard, NFPA 32, already included such exceptions. Exception 1 recognizes that modern Type IIIA dry cleaning machines have intrinsic safety features that can prevent fires from starting within the dry cleaning machine and parallels Section 8.1.2.6 of NFPA 32. It recognizes the lesser relative hazard of plants using higher flash point [140°F to 299°F (60°C to 148.23)] Class IIIA dry cleaning solvents while maintaining a reasonable limit on aggregate solvent quantity and providing needed safety features. Exception 2 parallels Section 8.2.3.4 of NFPA 32 and recognizes the even lesser hazard of Class IIIB solvents having a very high flash point [at or above 200°F (93.33°C)] further decreasing the likelihood of accidental ignition. These exceptions were added to the code rather than relying on a reference to NFPA 32 so the inspector would not have to carry the referenced standard into the field. See also the commentary to Section 2103.3 and IBC Section 307.1, Exceptions 4 and 5 for further information.

**2108.3 Automatic fire-extinguishing systems.** Type II dry cleaning units, washer-extractors, and drying tumblers in Type II dry cleaning plants shall be provided with an *approved* automatic fire-extinguishing system installed and maintained in accordance with Chapter 9.

**Exception:** Where *approved*, a manual steam jet not less than 3/4 inch (19 mm) with a continuously available steam supply at a pressure not less than 15 pounds per square inch gauge (psig) (103 kPa) is allowed to be substituted for the automatic fire-extinguishing system.

❖ Section 2108.2 focuses on the protection of the dry cleaning plant occupants and building. This section requires additional fire protection for dry cleaning

equipment using Class II solvent because of its lower flash point. Automatic fire-extinguishing systems for local, direct application of suppression media in the dry cleaning machinery must be installed in accordance with Section 904. The type of automatic fire-extinguishing system typically used (and required by NFPA 32) in this application is carbon dioxide, installed in accordance with Section 904.8, although approved dry chemical or gaseous-agent systems could also be used.

The exception recognizes the fire-smothering capabilities of steam. Although there is no recognized standard for the design of steam-smothering systems, the fact that steam is usually available in large quantities in dry cleaning plants makes it an inexpensive alternative to the more state-of-the-art fire-extinguishing systems. The design and installation of the steam jet(s) that must be available for personnel to manually use must be reviewed and approved by the fire code official. Because steam poses a serious burn hazard, the system design should minimize personnel exposure to this hazard.

**2108.4 Portable fire extinguishers.** Portable fire extinguishers shall be selected, installed and maintained in accordance with this section and Section 906. A minimum of two, 2-A:10-B:C portable fire extinguishers shall be provided near the doors inside dry cleaning rooms containing Type II, Type III-A and Type III-B dry cleaning systems.

❖ Portable fire extinguishers are intended only for fighting incipient fires. Employees should be trained in the proper selection and use of portable fire extinguishers. Both the extinguisher rating and the travel distance must be consistent with Section 906 and NFPA 10 for the moderate hazards expected in dry cleaning plants. Placing the extinguishers at the doors leading out of rooms containing Type II, III-A and III-B dry cleaning systems will enhance personnel safety by requiring them to travel toward the means of egress door to gain access to an extinguisher in case of a fire. The required size of the extinguisher(s) should give the operator sufficient agent capacity and discharge time to handle the magnitude of incipient fires expected.

# Chapter 22:

## Combustible Dust-Producing Operations

### General Comments

Problems associated with the production and handling of dusts were not widely recognized and understood until the twentieth century. Likewise, the need for adequate protection from dust explosions did not become widely accepted until the latter half of the twentieth century. A relatively incomplete understanding of the theoretical underpinnings of the explosion hazards of dusts is largely responsible for this lag.

The following factors affect the explosion hazards of dusts:

- Chemical composition of the dust.
- Geometry and size of the dust particles.
- Concentration of dust present in suspension (distance between dust particles or the mass of dust particles in a given volume).
- Nature and concentration of the oxidant, usually air.
- Moisture content of both the atmosphere and the dust.
- Minimum required ignition temperature or ignition energy of the dust and amount of time the two are in contact with each other.

Curiously, not all combustible dusts are explosible. The reasons for this are not very well understood. Explosion hazards of dusts are often defined by the lower and upper explosive limits, explosion pressures and explosion rates of various dusts. These values cannot be derived from the thermal properties of the dusts but rather must be determined by measurement. Combustible dusts may produce explosion pressures as great as 150 pounds per square inch gauge (psig) (103 kPa) and explosion pressure rise rates as high as 15,000 pounds per square inch (psi) per second (103 425 kPa).

Dust explosions usually produce flame fronts traveling at rates less than the speed of sound, and are, therefore, classified as deflagrations. High oxidizer concentrations or the presence of flammable gases may, however, produce detonations with shockwaves traveling in excess of the speed of sound preceding the flame front.

Unlike flammable gases and vapors, concentrations of explosive dusts exceeding stoichiometric quantities (the amount of fuel necessary to consume all the available oxidizer) produce more violent explosions up to the point at which dust concentrations approach several times the stoichiometric concentration.

In 1973, K.N. Palmer listed the following explosion protection measures. Formation of explosive dust suspensions is inevitable, and complete elimination of igni-

tion sources cannot be relied on; therefore, implementing a combination of explosion protection strategies is strongly recommended. Such explosion protection measures include ignition prevention, suppression or containment of the primary explosion flame and allowing the explosion to take its full course in a safe manner.

Fire fighters are especially aware of the hazards of dust explosions in grain elevators in rural areas, but may not recognize the potential for dust explosions in a wide variety of other manufacturing operations. Dusts are produced and used in industrial applications ranging from water treatment to semiconductor manufacturing. The explosive force generated by a dust explosion is comparable to flammable vapor and gas explosions.

The following industries are involved in the production or handling of explosible dusts:

- Agricultural, including coffee, cornstarch, cottonseed, sugar and various grains.
- Chemical, including dye.
- Coal mining and use.
- Food (human and animal).
- Metals, including aluminum, magnesium, iron, manganese and various alloys.
- Pharmaceuticals.
- Plastics, including polyethylene resins, styrene polymer resins, epoxy resins and polycarbonate resins.
- Woodworking.

Conditions under which a combustible dust will produce an explosion are quite specific, though they are difficult to quantify. As a result, precautions to prevent dust explosions are often determined by assigning a particular dust to a hazard class. A sample of material is ignited under controlled conditions in a special test apparatus to determine the hazard class of a dust. The results of such tests were reported for common dusts by P. Field in his book *Dust Explosions*, which describes, in tabular form, the explosion data for selected combustible dusts. In each column, values of the table are derived experimentally using a special explosion apparatus. For each property, values are presented to fully describe the explosion characteristics of the given material. Dust hazard classes are expressed as ST-1 through ST-3, with ST-1 being the highest hazard, as portrayed in *The SFPE Handbook of Fire Protection Engineering*.

During the drafting of the code, combustible dust was not included in Table 5003.1.1(1) because of the inherent difficulty in establishing a maximum allowable quan-

tity (MAQ), and for determining if and when the MAQ had been exceeded. An occupancy with combustible dust is classified in Group H-2 in accordance with Section 307.4 of the *International Building Code*<sup>®</sup> (IBC<sup>®</sup>), with the exception of certain woodworking uses classified as Group F-1. Many spaces with combustible dust should be classified in Group H-2. However, others may fall into Group F or S, depending on the specifics of the process. Accordingly, in the 2012 edition of the code, a new row in Table 5003.1.1(1) added combustible dust to the MAQ table, so the code user would not miss this important hazard category. Note q directs the code user to pertinent sections in the code and the IBC to determine if a dust hazard exists by an engineering evaluation. The content of Note q is also included in IBC Section 307.4.

**Purpose**

Awareness and knowledge of the hazards of dusts and powders are less common than of flammable liquids and gases; however, explosions and fires involving dusts and powders are just as hazardous in many industrial settings. The requirements of this chapter seek to reduce the likelihood of dust explosions by managing the hazards of suspensions of ignitable dusts. Ignition source control and good housekeeping practices in occupancies containing dust-producing operations are emphasized.

**SECTION 2201  
GENERAL**

**2201.1 Scope.** The equipment, processes and operations involving dust explosion hazards shall comply with the provisions of this chapter.

- ❖ This chapter details general requirements for the protection of properties and processes from explosions and deflagrations involving combustible dust residues and suspensions.

**2201.2 Permits.** Permits shall be required for *combustible dust*-producing operations as set forth in Section 105.6.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6.6 for discussion of specific combustible dust-producing operations requiring an operational permit.

**SECTION 2202  
DEFINITION**

**2202.1 Definition.** The following term is defined in Chapter 2: **COMBUSTIBLE DUST.**

- ❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated term used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*<sup>®</sup> (I-Code<sup>®</sup>) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

**SECTION 2203  
PRECAUTIONS**

**2203.1 Sources of ignition.** Smoking or the use of heating or other devices employing an open flame, or the use of spark-producing equipment is prohibited in areas where *combustible dust* is generated, stored, manufactured, processed or handled.

- ❖ Smoking is prohibited in areas where dust explosion hazards exist. Welding and cutting must be confined to approved areas and subject to a hot work permit system and prior approval for each operation (see commentary, Chapter 35). Open-flame heating and spark-producing equipment, as well as other heat-producing devices, are prohibited. Torches and other open-flame devices are never to be used to remove accumulations of dust or dust residue. Electrical wiring, lighting and equipment where dust explosion hazards exist should be approved for use in Class II hazardous (classified) locations as regulated in NFPA 70.

**2203.2 Housekeeping.** Accumulation of *combustible dust* shall be kept to a minimum in the interior of buildings. Accumulated *combustible dust* shall be collected by vacuum cleaning or other means that will not place *combustible dust* into suspension in air. Forced air or similar methods shall not be used to remove dust from surfaces.

- ❖ Good housekeeping practices are extremely important in occupancies where combustible dust-producing operations are located. Ideally, minimizing the amount of fugitive combustible dust that accumulates in buildings should be accomplished by fixed equipment, such as physical enclosures for dust-producing machinery, and by approved dust collection systems designed to capture the dust at the point of generation. In its simplest form, a dust collection system can

consist of a shop vacuum cleaner connected to a woodworking machine, such as a table saw. In larger industrial applications, a ducted dust collection system can serve multiple machines or entire production lines. Such systems are considered to be hazardous exhaust systems and should be designed and installed in accordance with the *International Mechanical Code*<sup>®</sup> (IMC<sup>®</sup>).

It is important when removing accumulated combustible dust not to place it into suspension in the air, thus creating the potential for a dust explosion. Accordingly, this section requires that dust be collected by vacuum cleaning equipment or other approved means that will not disturb the accumulated dust. Dust should never be brushed from dust-loaded surfaces or be blown off with compressed air.

**SECTION 2204  
EXPLOSION PROTECTION**

**2204.1 Standards.** The *fire code official* is authorized to enforce applicable provisions of the codes and standards listed in Table 2204.1 to prevent and control dust explosions.

- ❖ Because the pressure exerted by a combustible dust explosion typically ranges from 13 to 89 pounds per square inch (psi) (90 to 614 kPa), it is impractical to construct a building that will withstand such pressures. Therefore, a means of explosion relief or venting must be provided in accordance with Section 911 and the referenced standards. Additional guidance on the relative fire risk associated with various combustible dusts can be found in the referenced standards and the bibliographic material.

**TABLE 2204.1.** See below.

- ❖ Table 2204.1 references nine NFPA standards that detail specific precautions for a wide variety of dust explosion situations covering the broad spectrum of industries involved in dust-producing operations. These standards include the most common dust explosion hazards, and regulations for their prevention. Essentially, each of the referenced standards prescribes reasonable requirements for safety to life

and property from fire and explosion. The standards also minimize the resulting damage should a fire or explosion occur. More specifically, the standards contain requirements for construction, ventilation, explosion venting, equipment, heating devices, dust control, fire protection and supplemental requirements related to electrical wiring and equipment; provisions concerning protection from sparks; cutting and welding; and smoking and signage regulations.

Unusual situations, especially those involving plastics, resins, pharmaceuticals and semiconductor dusts, should be carefully evaluated.

**Bibliography**

The following resource materials were used in the preparation of the commentary for this chapter of the code:

Field, P. *Dust Explosions*. New York: Elsevier, 1982.

Palmer, K. N. *Dust Explosions and Fires*. London, England: Chapman and Hall, 1973.

*Report of Important Dust Explosions: A Record of Dust Explosions in the United States and Canada since 1860*. Fire Record Department, compiler. Boston, MA: National Fire Protection Association, 1957.

**TABLE 2204.1  
EXPLOSION PROTECTION STANDARDS**

STANDARD	SUBJECT
NFPA 61	Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities
NFPA 69	Standard on Explosion Prevention Systems
NFPA 70	National Electrical Code
NFPA 85	Boiler and Combustion System Hazards Code
NFPA 120	Standard for Fire Prevention and Control in Coal Mines
NFPA 484	Standard for Combustible Metals
NFPA 654	Standard for Prevention of Fire and Dust Explosions from the Manufacturing, Processing and Handling of Combustible Particulate Solids
NFPA 655	Standard for the Prevention of Sulfur Fires and Explosions
NFPA 664	Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities

# Chapter 23: Motor Fuel-Dispensing Facilities and Repair Garages

## General Comments

The requirements of this chapter apply to all occupancies that dispense any type of motor fuel and to automotive repair garages.

## Purpose

This chapter contains provisions that regulate the storage and dispensing of liquid or gaseous motor fuels at public and private automotive and marine motor fuel-dispensing facilities, fleet vehicle motor fuel-dispensing facilities, aircraft motor-vehicle fuel-dispensing facilities and repair garages.

---

## SECTION 2301 GENERAL

**2301.1 Scope.** Automotive motor fuel-dispensing facilities, marine motor fuel-dispensing facilities, fleet vehicle motor fuel-dispensing facilities, aircraft motor-vehicle fuel-dispensing facilities and repair garages shall be in accordance with this chapter and the *International Building Code*, *International Fuel Gas Code* and *International Mechanical Code*. Such operations shall include both those that are accessible to the public and private operations.

❖ Generally speaking, if liquid or gaseous motor fuels are dispensed from a storage tank, either above or below ground, into the fuel tank of a motor vehicle, marine craft or general aviation aircraft from fixed, automotive-type equipment, then the operation is within the scope of this chapter. See also the commentary to Section 202 for the definition of “Aircraft motor-vehicle fuel-dispensing facility.”

**2301.2 Permits.** Permits shall be required as set forth in Section 105.6.

❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit. The process also notifies the fire department of the need for prefire planning for the hazardous property.

**2301.3 Construction documents.** *Construction documents* shall be submitted for review and approval prior to the installation or construction of automotive, marine or fleet vehicle motor fuel-dispensing facilities and repair garages in accordance with Section 105.4.

❖ Construction documents, as defined in Section 202, must be drawn to scale with sufficient clarity to be

understood by the fire code official, contractors and owners and must address the requirements of the code. State or local laws may require preparation of the construction documents by a registered design professional. See the commentary to Section 106.1 of the *International Building Code*® (IBC®).

**2301.4 Indoor motor fuel-dispensing facilities.** Motor fuel-dispensing facilities located inside buildings shall comply with the *International Building Code* and NFPA 30A.

❖ Generally speaking, this type of motor fuel-dispensing facility is found at parking garages where space is very limited and is subject to the approval of the fire code official. Chapter 7 of NFPA 30A is, in part, dedicated to the provisions that govern motor fuel-dispensing facilities inside buildings.

**2301.4.1 Protection of floor openings in indoor motor fuel-dispensing facilities.** Where motor fuel-dispensing facilities are located inside buildings and the dispensers are located above spaces within the building, openings beneath dispensers shall be sealed to prevent the flow of leaked fuel to lower building spaces.

❖ Floor openings in the dispensing area must be sealed if located over other spaces and drains, and designed to protect areas below from flammable and combustible liquid spills as well as anticipated water from fire hose streams. Drains are to be equipped with separators in accordance with the *International Plumbing Code*® (IPC®).

**2301.5 Electrical.** Electrical wiring and equipment shall be suitable for the locations in which they are installed and shall comply with Section 605, NFPA 30A and NFPA 70.

❖ Chapter 8 of NFPA 30A addresses electrical equipment at motor fuel-dispensing facilities and is correlated with NFPA 70. Electrical equipment must be approved for the particular hazards anticipated at motor fuel-dispensing facilities and the hazardous

## MOTOR FUEL-DISPENSING FACILITIES AND REPAIR GARAGES

nature of flammable and combustible liquids and gases.

**2301.6 Heat-producing appliances.** Heat-producing appliances shall be suitable for the locations in which they are installed and shall comply with NFPA 30A and the *International Fuel Gas Code* or the *International Mechanical Code*.

❖ Heat-producing appliances are ignition sources. Precautions must be taken when using such appliances around flammable and combustible liquids. NFPA 30A, the *International Mechanical Code*® (IMC®) and the *International Fuel Gas Code*® (IFGC®) all provide requirements for the safe use of these appliances.

### SECTION 2302 DEFINITIONS

**2302.1 Definitions.** The following terms are defined in Chapter 2:

**AIRCRAFT MOTOR-VEHICLE FUEL-DISPENSING FACILITY.**

**ALCOHOL-BLENDED FUELS.**

**AUTOMOTIVE MOTOR FUEL-DISPENSING FACILITY.**

**DISPENSING DEVICE, OVERHEAD TYPE.**

**FLEET VEHICLE MOTOR FUEL-DISPENSING FACILITY.**

**LIQUEFIED NATURAL GAS (LNG).**

**MARINE MOTOR FUEL-DISPENSING FACILITY.**

**REPAIR GARAGE.**

**SELF-SERVICE MOTOR FUEL-DISPENSING FACILITY.**

❖ Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2 or in another *International Code*® (I-Code®) as indicated in Section 201.3, or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

### SECTION 2303 LOCATION OF DISPENSING DEVICES

**2303.1 Location of dispensing devices.** Dispensing devices shall be located as follows:

1. Ten feet (3048 mm) or more from *lot lines*.
2. Ten feet (3048 mm) or more from buildings having combustible exterior wall surfaces or buildings having noncombustible exterior wall surfaces that are not part

of a 1-hour fire-resistance-rated assembly or buildings having combustible overhangs.

**Exception:** Canopies constructed in accordance with the *International Building Code* providing weather protection for the fuel islands.

3. Such that all portions of the vehicle being fueled will be on the premises of the motor fuel-dispensing facility.
  4. Such that the nozzle, when the hose is fully extended, will not reach within 5 feet (1524 mm) of building openings.
  5. Twenty feet (6096 mm) or more from fixed sources of ignition.
- ❖ In order to reduce the likelihood of motor fuels coming into contact with ignition sources or posing a hazard to persons, adjoining property or on-site buildings, this section provides very specific dispenser location requirements in relation to buildings, lot lines and ignition sources.

#### Item 1

Commentary Figure 2303.1(1) shows the relationship of the dispenser to the lot line (see also commentary, Item 5).

#### Item 2

Commentary Figure 2303.1(2) shows the relationship of the dispenser to a building with a combustible exterior.

#### Item 3

Commentary Figure 2303.1(3) shows the location of the vehicle being fueled in relation to the motor fuel-

dispensing facility property lines. Note that this item is a dispenser location requirement or hose length limitation in that neither feature should be such that any portion of a vehicle could be off site while being fueled. In the past, it was not unusual to find dispensing devices installed on the sidewalk or near the curb in front of the motor fuel-dispensing facility so that vehicles could simply pull up to the curb and be fueled. This was especially true for motor fuel-dispensing facilities situated on very small sites. The intent of this requirement is similar to Item 4; that is, to keep the motor fuel from possible contact with off-site ignition sources. It also eliminates the hazard of an off-site vehicle being struck by another vehicle during fueling.

**Item 4**

Commentary Figure 2303.1(4) shows the relationship of the dispenser nozzle to a building opening. The intent of this requirement is similar to Item 3; that is, to keep the motor fuel from possible contact with ignition sources inside the building.

**Item 5**

Commentary Figure 2303.1(5) illustrates the area around a dispenser where fixed sources of ignition are prohibited. In planning and reviewing dispenser locations, the 20-foot (6096 mm) dimension should be correlated with Item 1 to prevent any fixed ignition sources beyond the property line from falling within the 20-foot (6096 mm) area required by this item.

**2303.2 Emergency disconnect switches.** An *approved*, clearly identified and readily accessible emergency disconnect switch shall be provided at an *approved* location to stop the transfer of fuel to the fuel dispensers in the event of a fuel spill or other emergency. The emergency disconnect switch for exterior fuel dispensers shall be located within 100 feet (30 480 mm) of, but not less than 20 feet (6096 mm) from, the fuel dispensers. For interior fuel-dispensing operations, the emergency disconnect switch shall be installed at an *approved* location. Such devices shall be distinctly *labeled* as: EMERGENCY FUEL SHUTOFF. Signs shall be provided in *approved* locations.

❖ This section establishes the requirement for emergency disconnect switches to shut off the flow of fuel in an emergency and specifies where they are to be located for both exterior and interior applications. The emergency disconnect switch must be clearly visible and placed far enough away from the fuel dispenser so that the switch will be easily accessible without entering the fuel spill area, but not so far that it would take too long to get to the switch. The switch location must be prominently indicated by an approved sign and access to the switch must be free of any obstructions, such as displayed merchandise. Commentary Figure 2303.2 illustrates the zone in which the disconnect switch must be located.

**SECTION 2304**  
**DISPENSING OPERATIONS**

**2304.1 Supervision of dispensing.** The dispensing of fuel at motor fuel-dispensing facilities shall be conducted by a qualified attendant or shall be under the supervision of a qualified attendant at all times or shall be in accordance with Section 2304.3.

❖ Motor fuel-dispensing facilities must have a trained, qualified attendant on duty when the facility is open for business, unless the fire code official specifically approves an unattended location.

**2304.2 Attended self-service motor fuel-dispensing facilities.** Attended self-service motor fuel-dispensing facilities shall comply with Sections 2304.2.1 through 2304.2.5. Attended self-service motor fuel-dispensing facilities shall have not less than one qualified attendant on duty while the facility is open for business. The attendant’s primary function shall be to supervise, observe and control the dispensing of fuel. The attendant shall prevent the dispensing of fuel into containers that do not comply with Section 2304.4.1, control sources of ignition, give immediate attention to accidental spills or releases, and be prepared to use fire extinguishers.

❖ An attendant trained in spill control, ignition source control, recognizing approved fuel containers and fire extinguishment is required to be in visual contact with the dispensing operation when the motor fuel-dispensing facility is open for business unless the fire code official has given approval for an unattended self-service facility. The attendant may perform other duties such as those of cashier as long as the attendant can supervise the dispensing operation and has immediate access to emergency shutoff controls. Note that the responsibility of supervision, observation and control of the dispensing operations includes enforcement of the procedures and rules in Sections 2305.6 and 2310.5.

**2304.2.1 Special-type dispensers.** *Approved* special-dispensing devices and systems such as, but not limited to, card- or coin-operated and remote-preset types, are allowed at motor fuel-dispensing facilities provided there is not less than one qualified attendant on duty while the facility is open to the public. Remote preset-type devices shall be set in the “off” position while not in use so that the dispenser cannot be activated without the knowledge of the attendant.

❖ Special dispensing devices that allow the customer to pay at the dispenser have become very popular. This provision requires that the dispenser be maintained in the off position so that the attendant is alerted before the fuel is dispensed and can, therefore, supervise the dispensing operation, making certain that the customer is placing fuel in an approved container and there are no sources of ignition in the area.

**2304.2.2 Emergency controls.** *Approved* emergency controls shall be provided in accordance with Section 2303.2.

❖ A clearly marked emergency fuel shutoff switch must be located no further than 100 feet (30 480 mm) from the dispenser and no closer than 20 feet (6096 mm) to the dispenser. The switch must be readily available to all persons and must cut off power to all dispensers and pumps.

**2304.2.3 Operating instructions.** Dispenser operating instructions shall be conspicuously posted in *approved* locations on every dispenser.

❖ Clearly understandable operating instructions for the use of the dispenser must be posted on the dispenser. The location must be approved by the fire code official. These operating instructions are in addition to the warnings required in Section 2305.6.

**2304.2.4 Obstructions to view.** Dispensing devices shall be in clear view of the attendant at all times. Obstructions shall not be placed between the dispensing area and the attendant.

❖ This provision does not specify a distance the attendant must be from the dispensing operation; however, the attendant must be able to clearly view the entire dispensing area from his or her workstation. In some cases, this is accomplished by closed-circuit television monitoring; however, the fire code official should carefully evaluate the clarity and resolution of the video image to verify that it meets the “clear view” requirement of this section. This section also prohibits the common practice of loading outside areas, including the dispenser islands, with displayed merchandise piled high enough so as to be a visual obstruction to the attendant.

**2304.2.5 Communications.** The attendant shall be able to communicate with persons in the dispensing area at all times. An *approved* method of communicating with the fire department shall be provided for the attendant.

❖ This is a two-part requirement. The first part requires that the attendant has the ability to communicate, for example, via intercom, with the person performing the dispensing. The second part requires the attendant to have some type of communication equipment that will allow him or her to immediately call the fire department in case of an emergency.

**2304.3 Unattended self-service motor fuel-dispensing facilities.** Unattended self-service motor fuel-dispensing facilities shall comply with Sections 2304.3.1 through 2304.3.7.

❖ An unattended self-service motor fuel-dispensing facility is allowed only with the specific approval of the fire code official. He or she should consider the location; exposures; the likelihood of vandalism; and how emergency equipment such as the emergency shut-off switch, portable fire extinguishers and the means of notifying the fire department in case of spill, fire or other emergency is going to be protected.

**2304.3.1 General.** Where *approved*, unattended self-service motor fuel-dispensing facilities are allowed. As a condition of approval, the *owner* or operator shall provide, and be accountable for, daily site visits, regular equipment inspection and maintenance.

❖ It is imperative that the owner/operator designates a responsible person to make daily site visits to the unattended self-service motor fuel-dispensing facility. All emergency equipment must be inspected for proper operation and availability to the customer. Vandalism is a major problem with unattended, self-service motor fuel-dispensing facilities. Vandals will trip the emergency fuel shutoff switch, and remove or discharge the fire-extinguishing equipment. This equipment must be maintained and made available to the person dispensing fuel. Also, a method of documenting the daily visits needs to be established and approved by the fire code official.

**2304.3.2 Dispensers.** Dispensing devices shall comply with Section 2306.7. Dispensing devices operated by the insertion of coins or currency shall not be used unless *approved*.

❖ The intent of this provision is to allow card or key-operated-type dispensers. Coin- or currency-type dispensers are allowed only with the approval of the fire code official.

**2304.3.3 Emergency controls.** *Approved* emergency controls shall be provided in accordance with Section 2303.2. Emergency controls shall be of a type that is only manually resettable.

❖ The emergency controls must be clearly identified and available to the person dispensing fuel. The controls or switch must be located no closer than 20 feet (6096 mm) to the dispenser and no farther than 100 feet (30 480 mm) from the dispenser. The switch must cut off power to all dispensers and pumps and must be manually resettable by the owner/operator. The intent is to prevent anyone from dispensing fuel until the problem has been corrected.

**2304.3.4 Operating instructions.** Dispenser operating instructions shall be conspicuously posted in *approved* locations on every dispenser and shall indicate the location of the emergency controls required by Section 2304.3.3.

❖ It is a special requirement for unattended self-service motor fuel-dispensing facilities that the location of the emergency control switch be included with the dispenser instructions and posted on the dispenser in an *approved* location.

**2304.3.5 Emergency procedures.** An *approved* emergency procedures sign, in addition to the signs required by Section 2305.6, shall be posted in a conspicuous location and shall read:

IN CASE OF FIRE, SPILL OR RELEASE

1. USE EMERGENCY PUMP SHUTOFF

2. REPORT THE ACCIDENT!

FIRE DEPARTMENT TELEPHONE NO. \_\_\_\_\_

FACILITY ADDRESS \_\_\_\_\_

❖ Signs must be clearly posted giving the location of the emergency fuel shutoff switch, the fire department’s telephone number and the motor fuel-dispensing facility address.

It is imperative that the person dispensing fuel at an unattended motor fuel-dispensing facility knows where the emergency control equipment is located. People not familiar with the area may not know the fire department’s telephone number or the address of the motor fuel-dispensing facility; therefore, this information must be included on the sign.

**2304.3.6 Communications.** A telephone not requiring a coin to operate or other *approved*, clearly identified means to notify the fire department shall be provided on the site in a location *approved* by the *fire code official*.

❖ The intent of this section is to provide a means to call the fire department in an emergency without the use

of a coin or phone card. Many jurisdictions with 911 telephone systems have pay phones that do not require the use of a coin or card to dial 911; this type of coin-operated telephone would be allowed.

**2304.3.7 Quantity limits.** Dispensing equipment used at unsupervised locations shall comply with one of the following:

1. Dispensing devices shall be programmed or set to limit uninterrupted fuel delivery to 25 gallons (95 L) and require a manual action to resume delivery.
  2. The amount of fuel being dispensed shall be limited in quantity by a preprogrammed card as *approved*.
- ❖ Limiting the amount of uninterrupted fuel delivered before another action is taken reduces the chances of a major fuel spill in the case of vandalism or equipment failure.

**2304.4 Dispensing into portable containers.** The dispensing of flammable or *combustible liquids* into portable *approved* containers shall comply with Sections 2304.4.1 through 2304.4.3.

❖ This section describes an approved container and states requirements for dispensing fuel into an approved container.

**2304.4.1 Approved containers required.** Class I, II and IIIA liquids shall not be dispensed into a portable container unless such container does not exceed a 6-gallon (22.7 L) capacity, is *listed* or of *approved* material and construction, and has a tight closure with a screwed or spring-loaded cover so designed that the contents can be dispensed without spilling. Liquids shall not be dispensed into portable or cargo tanks.

❖ Approved containers must be easily identified as fuel containers and constructed of materials that will maintain structural stability and resist spills. Flammable and combustible liquids should not be dispensed into portable or cargo tanks using conventional automotive dispensing equipment. If the tank is not properly grounded and the dispenser nozzle is not in contact with the tank, static electricity may build up and discharge between the nozzle and the tank. Note that this section is also intended to prohibit filling of a new class of portable gasoline containers that have entered the marketplace. These cans, some of which hold as much as 14 gallons (53 L) and weigh over 100 pounds (45 kg) when full, often include integrated hoses and dispensing nozzles, yet they do not comply with any Underwriters Laboratories (UL), American Society for Testing and Materials (ASTM) or similar recognized standard. Apparently, these cans are “certified” by the manufacturer as meeting United Nations/U.S. Department of Transportation (UN/DOT) standards for transportation, but it is questionable whether the safety standards required for transportation are adequate for storage and use of these products. For example, there are concerns about the ability of users to safely hoist these containers off of and onto vehicles to avoid static accumulation during filling, and the static charge will be greater than that

experienced with smaller cans because there is more fuel transferred during filling. Given that UL 30, UL 1313 and ASTM F852 or ASTM F976 (the recognized standards for construction of portable gas containers) all limit container capacities to approximately 6 gallons (22.7 L), it makes sense for the code to also reflect this limitation.

**2304.4.2 Nozzle operation.** A hose nozzle valve used for dispensing Class I liquids into a portable container shall be in compliance with Section 2306.7.6 and be manually held open during the dispensing operation.

❖ A listed automatic-closing-type nozzle must be used for dispensing fuel into portable containers. The hold-open device must not be used because the automatic-closing feature may not function properly since it is designed to operate in the neck of an automobile fuel receiver. The fuel tank vent in an automobile terminates in the receiver neck and the blow-back of fuel coming from the vent is what normally triggers the automatic shutoff feature.

**2304.4.3 Location of containers being filled.** Portable containers shall not be filled while located inside the trunk, passenger compartment or truck bed of a vehicle.

❖ Portable fuel containers riding on carpets, mats or pickup truck bed liners can build up a charge of static electricity that could discharge to the dispenser hose nozzle if not properly grounded. In order to dissipate the static charge, the container must be removed from the vehicle and placed on the ground before fueling begins. The nozzle must be in contact with the container before discharging the fuel. See the commentary to Section 2305.6, Warnings 3 and 4, for additional discussion of static electricity.

## SECTION 2305 OPERATIONAL REQUIREMENTS

**2305.1 Tank filling operations for Class I, II or III liquids.** Delivery operations to tanks for Class I, II or III liquids shall comply with Sections 2305.1.1 through 2305.1.3 and the applicable requirements of Chapter 57.

❖ History has shown that most accidents at motor fuel-dispensing facilities occur during the tank-filling operation. The provisions of this section address those operations.

**2305.1.1 Delivery vehicle location.** Where liquid delivery to above-ground storage tanks is accomplished by positive-pressure operation, tank vehicles shall be positioned not less than 25 feet (7620 mm) from tanks receiving Class I liquids and 15 feet (4572 mm) from tanks receiving Class II and IIIA liquids.

❖ Above-ground tanks are usually above the elevation of the fuel delivery truck, and the fuel must be pumped from the truck into the storage tank. The fuel is delivered in large volumes under pressure and most delivery trucks use a power take-off-driven pump that requires the truck engine to be running.

Because of this, the delivery truck and the storage tanks must be separated by the distances indicated so that venting vapors do not find their way to the running engine of the delivery vehicle and ignite.

**2305.1.2 Tank capacity calculation.** The driver, operator or attendant of a tank vehicle shall, before making delivery to a tank, determine the unfilled, available capacity of such tank by an *approved* gauging device.

❖ A gauge stick may be used to determine the quantity of fuel in a tank, but is impractical for use on an above-ground tank because the attendant would have to climb on top of the tank each time. In icy, wet or inclement weather this could be dangerous. It is more practical to install a fuel-level gauge accessible to the delivery operator on an above-ground tank.

After the driver places the delivery truck in position, he or she should record the ullage (i.e., the amount of liquid it would take to fill the tank) and set the delivery up for that amount of fuel. This is the first line of defense to prevent fuel spills (see also Section 5706.6.1.5 of the code).

**2305.1.3 Tank fill connections.** Delivery of flammable liquids to tanks more than 1,000 gallons (3785 L) in capacity shall be made by means of *approved* liquid- and vapor-tight connections between the delivery hose and tank fill pipe. Where tanks are equipped with any type of vapor recovery system, all connections required to be made for the safe and proper functioning of the particular vapor recovery process shall be made. Such connections shall be made liquid and vapor tight and remain connected throughout the unloading process. Vapors shall not be discharged at grade level during delivery.

❖ The delivery of Class I liquid motor fuel to either an above-ground or underground storage tank that exceeds 1,000 gallons (3785 L) in capacity must be through a liquid- and vapor-tight fitting to reduce the potential for the escape of flammable liquid or vapors at the point of connection. These fittings include liquid transfer lines and vapor recovery lines, which are designed to prevent the release of polluting, flammable fuel vapor during transfer. These requirements prohibit the extremely dangerous, but not uncommon, practice of delivery tanker operators not connecting vapor return hoses, thus allowing the vapors displaced during delivery to escape at grade level from the unmade connections. Incidents have been reported where the vapors have traveled to nearby buildings, found an ignition source and exploded (see also commentary, Section 5706.6.1.10).

**2305.2 Equipment maintenance and inspection.** Motor fuel-dispensing facility equipment shall be maintained in proper working order at all times in accordance with Sections 2305.2.1 through 2305.2.5.

❖ The provisions of this section address the requirements for maintaining safety equipment at dispensing operations.

**2305.2.1 Inspections.** Flammable and *combustible liquid* fuel-dispensing and containment equipment shall be periodically

inspected where required by the *fire code official* to verify that the equipment is in proper working order and not subject to leakage. Records of inspections shall be maintained.

❖ This section authorizes the fire code official to require the inspection of equipment on a periodic basis, and identifies that the inspection is to verify the equipment is in proper working order and is not leaking. The importance of the inspections is supported by the requirement for an operational permit in Section 105.6.16, Item 10, for the dispensing of flammable and combustible liquids into motor vehicles. The frequency and nature of the inspections are to be determined by the fire code official. This section also requires that written inspection records be kept. Such records should indicate the date, time and name of the person conducting the inspection or maintenance. These records must be maintained by the owner and should be made available to the fire code official for review when requested. This requirement relieves the fire code official of the administrative burden of maintaining test records.

**2305.2.2 Repairs and service.** The *fire code official* is authorized to require damaged or unsafe containment and dispensing equipment to be repaired or serviced in an *approved* manner.

❖ In conjunction with the inspection process in Section 2305.2.1, this section authorizes the fire code official to require that damaged, worn or leaking equipment be serviced or repaired in an approved manner. Though not specifically required by the section, removal from service of equipment needing repair or replacement would be advisable if its continued use presents an increased hazard to the public or emergency personnel. Examples of conditions that could prompt the need for repair or servicing include, but are not limited to, equipment that shows signs of physical damage, internal and external corrosion, leakage, brittleness, aging or undue wear and tear.

**2305.2.3 Dispensing devices.** Where maintenance to Class I liquid dispensing devices becomes necessary and such maintenance could allow the accidental release or ignition of liquid, the following precautions shall be taken before such maintenance is begun:

1. Only persons knowledgeable in performing the required maintenance shall perform the work.
2. Electrical power to the dispensing device and pump serving the dispenser shall be shut off at the main electrical disconnect panel.
3. The emergency shutoff valve at the dispenser, where installed, shall be closed.
4. Vehicle traffic and unauthorized persons shall be prevented from coming within 12 feet (3658 mm) of the dispensing device.

❖ Dispensers are complex pieces of machinery made up of many listed parts. Certain components of the dispenser are sealed to prevent ignition of fuel

vapors. Therefore, it is imperative that the repair technician be qualified to perform work on the dispenser.

The dispenser and the pump are usually two separate and distinct pieces of equipment. In most cases, the pump is located at the tank, remote from the dispensers, and fuel is supplied under pressure to the dispenser. Therefore, it is imperative that power be disconnected to both the dispenser and the pump before work is begun.

As a safety measure, in case the remote pump kicks on, the dispenser emergency valve must be manually closed. This valve is located below the dispenser in the liquid supply piping. This valve is required in remote pumping systems by Section 2306.7.4.

The separation distance of 12 feet (3658 mm) is intended to keep the public and ignition sources away from possible fuel spills that may occur during the maintenance of dispensing devices.

**2305.2.4 Emergency shutoff valves.** Automatic emergency shutoff valves required by Section 2306.7.4 shall be checked not less than once per year by manually tripping the hold-open linkage.

❖ The emergency shutoff valve, also known as an impact valve, is located in the pit in the island below the dispenser, and consists of a shear section and a fusible link with a spring-loaded valve that must be manually tripped at least annually to verify that it is operable. See the commentary to Section 2306.7.4 for additional discussion of these valves.

**2305.2.5 Leak detectors.** Leak detection devices required by Section 2306.7.7.1 shall be checked and tested not less than annually in accordance with the manufacturer's specifications to ensure proper installation and operation.

❖ In a remote pumping system (where fuel is supplied under pressure to the dispenser) a leak detection device is required on the discharge/pressure side of the pump. The most common area to leak fuel is the piping between the storage tanks and the dispensers. Therefore, it is imperative that the required leak detection equipment be tested annually and maintained in an operable condition.

**2305.3 Spill control.** Provisions shall be made to prevent liquids spilled during dispensing operations from flowing into buildings. Acceptable methods include, but shall not be limited to, grading driveways, raising doorsills or other *approved* means.

❖ This provision is intended to prevent flammable and combustible liquids from entering buildings if a spill occurs. The spill control method must be approved by the fire code official and may be as simple as scoring the concrete pavement adjacent to the dispenser island (similar to highway "rumble strips") to retard the surface flow of spilled fuel.

If the spilled liquid is to be routed to a drain, the drain must be equipped with a sump and an oil-water separator to prevent the fuel from entering the storm drainage system. The oil-water separator must be installed in accordance with the IPC.

**2305.4 Sources of ignition.** Smoking and open flames shall be prohibited in areas where fuel is dispensed. The engines of vehicles being fueled shall be shut off during fueling. Electrical equipment shall be in accordance with NFPA 70.

❖ This provision is intended to control all ignition sources near fuel-dispensing operations. This includes smoking, matches, lighters or any other ignition source. Internal combustion engines must also be shut off during the fueling operation in accordance with Section 2305.6, Item 2. Electrical equipment in close proximity to the fueling operation, including the dispensing equipment, must be in accordance with NFPA 70 and Table 5703.1.1 of the code.

**2305.5 Fire extinguishers.** *Approved* portable fire extinguishers complying with Section 906 with a minimum rating of 2-A:20-B:C shall be provided and located such that an extinguisher is not more than 75 feet (22 860 mm) from pumps, dispensers or storage tank fill-pipe openings.

❖ A person should not have to travel more than 75 feet (22 860 mm) from a fuel dispenser, pump or a fill opening to reach an extinguisher. If the dispenser, pump and fill opening are in close proximity to each other, one extinguisher may satisfy the requirements.

**2305.6 Warning signs.** Warning signs shall be conspicuously posted within sight of each dispenser in the fuel-dispensing area and shall state the following:

1. No smoking.
2. Shut off motor.
3. Discharge your static electricity before fueling by touching a metal surface away from the nozzle.
4. To prevent static charge, do not reenter your vehicle while gasoline is pumping.
5. If a fire starts, do not remove nozzle—back away immediately.
6. It is unlawful and dangerous to dispense gasoline into unapproved containers.
7. No filling of portable containers in or on a motor vehicle. Place container on ground before filling.

❖ The warning sign must be legible and conspicuously posted in the dispensing area. The intent is to notify the dispenser operator of the dangers of each of the enumerated items. Warnings 1 and 2 intend to control the obvious ignition hazards of smoking and operating internal combustion engines in the presence of gasoline vapors.

Warnings 3 and 4 focus on the hazard of static electricity. People generally build up a charge of

static electricity through the friction between their clothing and the car seat while entering, leaving and driving a vehicle, especially in cold, dry weather. If that charge is not dissipated in accordance with Warning 3 prior to fueling the vehicle, it is likely that the static charge will arc the gap between the person's hand and the vehicle fill pipe as they start to remove the fill cap and possibly ignite the vapors. Warning 4 recognizes that even if the Warning 3 precaution is taken, reentering the vehicle while fueling can regenerate a static charge that will, in all likelihood, arc the gap between the driver's hand and the hose nozzle valve or between the vehicle fill pipe and the hose nozzle as the nozzle is being withdrawn and ignite the vapors. Renkes reported in 2006 that, between 1992 and 2006, 166 incidents of static ignition at motor fuel-dispensing facilities were reported to the Petroleum Equipment Institute (PEI) and 34 to the National Highway Traffic Safety Administration (NHTSA). Those incidents resulted in varying levels of damage to vehicles and property and varying degrees of injury to consumers intimate with the ignition scenarios.

In case of fire, Warning 5 cautions the customer not to remove the hose nozzle from the fill pipe, possibly expanding the extent of the fire. Moving away from the fire while at the same time keeping an eye on it is the precaution of choice.

Warning 6 correlates with the provisions for dispensing into approved portable containers in Section 2304.4. Section 2304.4.1 outlines the characteristics of approved portable containers. The intent of this warning is to not allow dispensing into random containers that might be available, such as plastic milk jugs, glass or plastic bottles, open pans, etc.

Warning 7 correlates with Section 2304.4.3 as to removing containers from vehicles and placing them on the ground to dissipate any static electricity buildup prior to fueling (see commentary, Section 2304.4.3).

**2305.7 Control of brush and debris.** Fenced and diked areas surrounding above-ground tanks shall be kept free from vegetation, debris and other material that is not necessary to the proper operation of the tank and piping system.

Weeds, grass, brush, trash and other combustible materials shall be kept not less than 10 feet (3048 mm) from fuel-handling equipment.

- ❖ Above-ground tanks must to be secured and inaccessible to the public. The secured area around the tanks must be kept clean and free of combustibles. The area around dispensers, remote pumps and fill openings must also be kept clean and free of combustibles for a distance of at least 10 feet (3048 mm). The intent is to prevent the accumulation of readily

combustible materials near tanks and equipment that could contribute to a fire in the event of an ignition.

## SECTION 2306 FLAMMABLE AND COMBUSTIBLE LIQUID MOTOR FUEL-DISPENSING FACILITIES

**2306.1 General.** Storage of flammable and *combustible liquids* shall be in accordance with Chapter 57 and Sections 2306.2 through 2306.6.3.

- ❖ The general requirements for storing flammable and combustible liquids are found in Chapter 57. The provisions specific to motor fuel-dispensing facilities are found in this section. Due to the activities in locations such as convenience stores, vehicle traffic and location of most motor fuel-dispensing facilities, the provisions for tank capacities, locations and dispensing equipment are more stringent in this chapter of the code than the general provisions found in Chapter 57. Accordingly, these specific regulations take precedence over the general provisions of Chapter 57.

**2306.2 Method of storage.** *Approved* methods of storage for Class I, II and III liquid fuels at motor fuel-dispensing facilities shall be in accordance with Sections 2306.2.1 through 2306.2.6.

- ❖ These provisions are specifically for motor fuel-dispensing facilities.

**2306.2.1 Underground tanks.** Underground tanks for the storage of Class I, II and IIIA liquid fuels shall comply with Chapter 57.

- ❖ This section relies on Chapter 57, which contains the requirements for the location and installation of underground tanks.

**2306.2.1.1 Inventory control for underground tanks.** Accurate daily inventory records shall be maintained and reconciled on underground fuel storage tanks for indication of possible leakage from tanks and piping. The records shall include records for each product showing daily reconciliation between sales, use, receipts and inventory on hand. Where there is more than one system consisting of tanks serving separate pumps or dispensers for a product, the reconciliation shall be ascertained separately for each tank system. A consistent or accidental loss of product shall be immediately reported to the *fire code official*.

- ❖ In addition to the leak detection requirements of Section 2305.2.5, this section requires another level of scrutiny for underground motor fuel storage tanks in the form of daily, documented reconciliation of inventory versus product sold to help detect leaks in underground tanks and piping. Loss in inventory should be reported immediately to the fire code official (see also Section 5704.2.11.5.1).

**2306.2.2 Above-ground tanks located inside buildings.**

Above-ground tanks for the storage of Class I, II and IIIA liquid fuels are allowed to be located in buildings. Such tanks shall be located in special enclosures complying with Section 2306.2.6, in a liquid storage room or a liquid storage warehouse complying with Chapter 57, or shall be *listed* and *labeled* as protected above-ground tanks in accordance with UL 2085.

❖ This provision is intended to establish requirements for placing an above-ground tank inside a building. The options are:

- A tank in a special enclosure in accordance with Section 2306.2.6.
- A tank inside a liquid storage room in accordance with Section 5704.3.7.
- A tank inside a liquid storage warehouse in accordance with Section 5704.3.8.
- A protected above-ground tank in accordance with UL 2085.

**2306.2.3 Above-ground tanks located outside, above grade.**

Above-ground tanks shall not be used for the storage of Class I, II or III liquid motor fuels, except as provided by this section.

1. Above-ground tanks used for outside, above-grade storage of Class I liquids shall be *listed* and *labeled* as protected above-ground tanks in accordance with UL 2085 and shall be in accordance with Chapter 57. Such tanks shall be located in accordance with Table 2306.2.3.
2. Above-ground tanks used for outside, above-grade storage of Class II or IIIA liquids shall be *listed* and *labeled* as protected above-ground tanks in accordance with UL 2085 and shall be installed in accordance with Chapter 57. Tank locations shall be in accordance with Table 2306.2.3.

**Exception:** Other above-ground tanks that comply with Chapter 57 where *approved* by the *fire code official*.

3. Tanks containing fuels shall not exceed 12,000 gallons (45 420 L) in individual capacity or 48,000 gallons

(181 680 L) in aggregate capacity. Installations with the maximum allowable aggregate capacity shall be separated from other such installations by not less than 100 feet (30 480 mm).

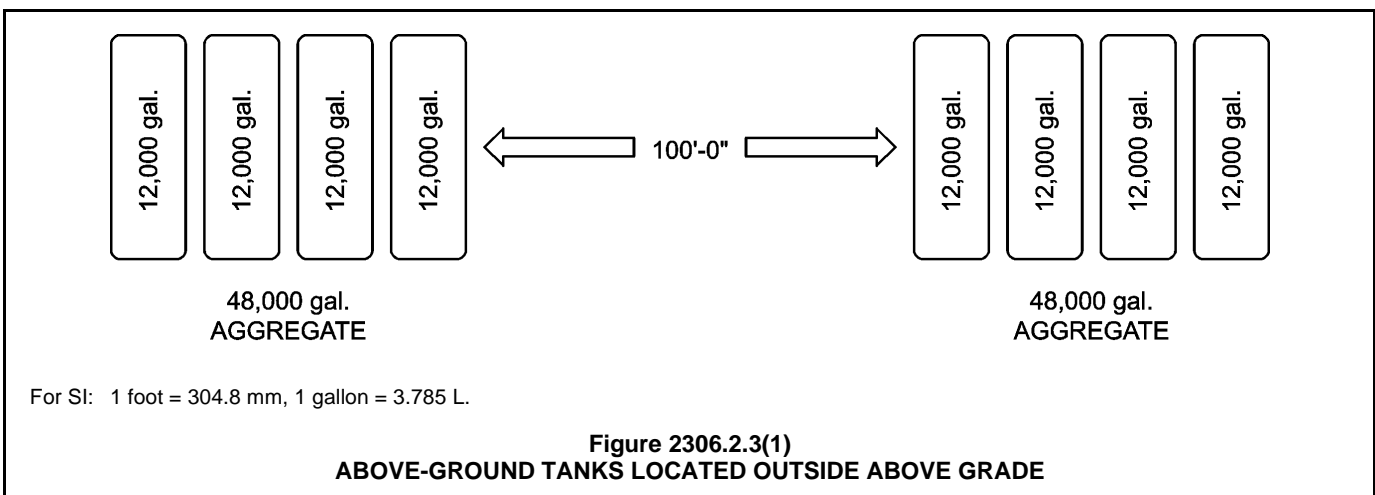

4. Tanks located at farms, construction projects, or rural areas shall comply with Section 5706.2.
5. Above-ground tanks used for outside above-grade storage of Class IIIB liquid motor fuel shall be *listed* and *labeled* in accordance with UL 142 or *listed* and *labeled* as protected above-ground tanks in accordance with UL 2085 and shall be installed in accordance with Chapter 57. Tank locations shall be in accordance with Table 2306.2.3.

❖ This section essentially prohibits the use of above-ground tanks for the storage of motor fuels unless they are in compliance with one of the five listed conditions. Where above-ground storage of flammable liquid motor fuel is desired, the intent of Item 1 is to allow the storage of flammable liquids in protected above-ground tanks only, listed and labeled in accordance with UL 2085 and in compliance with the applicable requirements of Section 5704.2.9.

Item 2 states that Class II or IIIA combustible liquids must be stored in either a UL 2085 protected above-ground tank or other above-ground tanks where approved by the fire code official.

In Item 3, the maximum aggregate capacity is the total capacity of all the individual tanks in one area. A separation distance of at least 100 feet (30 480 mm) must be placed between installations of the maximum aggregate capacities [see Commentary Figure 2306.2.3(1)]. The 100-foot (30 480 mm) separation distance is intended to protect multiple aggregate capacity installations from one another in the event of a fire or other emergency.

Item 4 provides an exception since the provisions of Section 5706.2 pertain to the permanent and temporary storage and dispensing of Class I (gasoline) and Class II (diesel and kerosene) for private use on farms and rural areas and at construction sites, earth-moving projects and gravel pits. See Section 5706.2 for maximum capacities and other provisions, and Sec-

tion 5706.2.4.4 for locations where above-ground tanks are prohibited.

An increasing number of facilities are establishing motor-vehicle fuel-dispensing stations for dispensing B100/B99 biodiesel, a Class IIIB liquid, into motor vehicles. In many cases these fueling stations are not set up as traditional motor fuel-dispensing stations but, rather, they consist of a small stand-alone fuel-dispensing operation using a 500- to 3,000-gallon (1893 to 11 356 L) fuel tank located near a drive-through espresso stand or mini market [see Commentary Figures 2306.2.3(2) and 2306.2.3(3)]. Chapter 23 previously had only minimal requirements for the installation of tanks and fueling operations for dispensing Class IIIB liquids into motor vehicles. This section now addresses the trend of dispensing of Class IIIB liquid motor fuels in a more comprehensive manner by providing, in Item 5, two options for tanks used for Class IIIB motor fuels, i.e., either an unprotected above-ground tank complying with UL 142 or a protected above-ground tank listed and labeled in accordance with UL 2085 and complying with the applicable requirements of Section 5704.2.9 of the code. This will eliminate the heretofore fairly common practice of dispensing Class IIIB motor fuels directly from plastic intermediate bulk container (often termed IBCs) totes (see Chapter 9 of NFPA 30 for information on such containers).

requirements for a protected, above-ground tank of 6,000 gallons (22 710 L) or less in accordance with UL 2085. Commentary Figure 2306.2.3(5) shows the spacing requirements for a protected above-ground tank greater than 6,000 gallons (22 710 L) in accordance with UL 2085. Commentary Figure 2306.2.3(6) shows the spacing requirements for a listed UL 142 above-ground tank regardless of whether it is a double-wall UL 142 tank or a single-wall UL 142 tank inside of a dike.

**TABLE 2306.2.3.** See below.

❖ This table provides the minimum physical separation requirements for above-ground motor fuel storage tanks of all types allowed by Sections 2306.2.3 and 2306.2.4, including those installed in vaults. Commentary Figure 2306.2.3(4) shows the spacing

**TABLE 2306.2.3  
MINIMUM SEPARATION REQUIREMENTS FOR ABOVE-GROUND TANKS**

CLASS OF LIQUID AND TANK TYPE	INDIVIDUAL TANK CAPACITY (gallons)	MINIMUM DISTANCE FROM NEAREST IMPORTANT BUILDING ON SAME PROPERTY (feet)	MINIMUM DISTANCE FROM NEAREST FUEL DISPENSER (feet)	MINIMUM DISTANCE FROM LOT LINE THAT IS OR CAN BE BUILT UPON, INCLUDING THE OPPOSITE SIDE OF A PUBLIC WAY (feet)	MINIMUM DISTANCE FROM NEAREST SIDE OF ANY PUBLIC WAY (feet)	MINIMUM DISTANCE BETWEEN TANKS (feet)
Class I protected above-ground tanks	Less than or equal to 6,000	5	25 <sup>a</sup>	15	5	3
	Greater than 6,000	15	25 <sup>a</sup>	25	15	3
Class II and III protected above-ground tanks	Same as Class I	Same as Class I	Same as Class I <sup>c</sup>	Same as Class I	Same as Class I	Same as Class I
Tanks in vaults	0–20,000	0 <sup>b</sup>	0	0 <sup>b</sup>	0	Separate compartment required for each tank
Other tanks	All	50	50	100	50	3

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

- a. At fleet vehicle motor fuel-dispensing facilities, a minimum separation distance is not required.
- b. Underground vaults shall be located such that they will not be subject to loading from nearby structures, or they shall be designed to accommodate applied loads from existing or future structures that can be built nearby.
- c. For Class IIIB liquids in protected above-ground tanks, a minimum separation distance is not required.

**Figure 2306.2.3(3)**  
**BIODIESEL FUELER**

For SI: 1 foot = 304.8 mm, 1 gallon = 3.785 L.

**Figure 2306.2.3(5)**  
**GREATER THAN 6,000-GALLON PROTECTED ABOVE-GROUND STORAGE TANKS STORING CLASS I, II OR III LIQUIDS**

For SI: 1 foot = 304.8 mm.

**Figure 2306.2.3(6)**  
**ALL OTHER ABOVE-GROUND STORAGE TANKS STORING CLASS II OR III LIQUIDS ONLY**

**2306.2.4 Above-ground tanks located in above-grade vaults or below-grade vaults.** Above-ground tanks used for storage of Class I, II or IIIA liquid motor fuels are allowed to be installed in vaults located above grade or below grade in accordance with Section 5704.2.8 and shall comply with Sections 2306.2.4.1 and 2306.2.4.2. Tanks in above-grade vaults shall also comply with Table 2306.2.3.

❖ The definition of an “Above-ground tank” is a tank without backfill. An underground tank receives strength from backfill. If the tank is not surrounded by backfill, the tank must be a listed and labeled above-ground tank. Therefore, a tank inside a vault, even if the vault is underground, must be a listed and labeled above-ground tank.

**2306.2.4.1 Tank capacity limits.** Tanks storing Class I and Class II liquids at an individual site shall be limited to a maximum individual capacity of 15,000 gallons (56 775 L) and an aggregate capacity of 48,000 gallons (181 680 L).

❖ This section places limitations on the capacities of tanks inside vaults. At motor fuel-dispensing facilities, the maximum capacity is 15,000 gallons (56 775 L) for a single tank and 48,000 gallons (181 680 L) aggregate capacity. The individual tank capacity allows the facility to receive the largest single product delivery that may be reasonably expected in a single tank. The aggregate capacity affords the facility the marketing flexibility it needs to carry for sale a wide range of motor fuels and specialty fuels, such as kerosene or diesel fuel.

**2306.2.4.2 Fleet vehicle motor fuel-dispensing facilities.** Tanks storing Class II and Class IIIA liquids at a fleet vehicle motor fuel-dispensing facility shall be limited to a maximum individual capacity of 20,000 gallons (75 700 L) and an aggregate capacity of 80,000 gallons (302 800 L).

❖ At fleet vehicle motor fuel-dispensing facilities (where the vehicles are used in connection with the fleet operator’s business) the maximum storage capacity is 20,000 gallons (75 700 L) for a single tank and 80,000 gallons (302 800 L) aggregate. These higher capacities recognize that the relative hazard of fleet facilities is less than at public motor fuel-dispensing facilities because the fleet fuel of choice is typically diesel fuel, a Class II liquid, rather than gasoline, a Class IB liquid. The higher capacities also reduce the hazard of liquid transfer by reducing the number of times the storage tanks must be refilled. Note that the additional capacity in this section applies only to Class II and IIIA liquid fuels. Class I fuels would remain subject to the provisions of Section 2306.2.4.1.

**2306.2.5 Portable tanks.** Where approved by the fire code official, portable tanks are allowed to be temporarily used in conjunction with the dispensing of Class I, II or III liquids into the fuel tanks of motor vehicles or motorized equipment

on premises not normally accessible to the public. The approval shall include a definite time limit.

❖ This section recognizes the need for allowing portable tanks to be used temporarily for fueling vehicles at locations that, because of topography or security, are not accessible to the general public, such as mining sites, logging camps, well-drilling sites, large rail yards, construction projects and the like. The key word here is “temporarily.” If such sites require a permanent fueling facility, then all applicable provisions of the code apply. The fire code official retains control over such temporary uses since approval is required and a definite time limit on such operations is imposed.

**2306.2.6 Special enclosures.** Where installation of tanks in accordance with Section 5704.2.11 is impractical, or because of property or building limitations, tanks for liquid motor fuels are allowed to be installed in buildings in special enclosures in accordance with all of the following:

1. The special enclosure shall be liquid tight and vapor tight.
2. The special enclosure shall not contain backfill.
3. Sides, top and bottom of the special enclosure shall be of reinforced concrete not less than 6 inches (152 mm) thick, with openings for inspection through the top only.
4. Tank connections shall be piped or closed such that neither vapors nor liquid can escape into the enclosed space between the special enclosure and any tanks inside the special enclosure.
5. Means shall be provided whereby portable equipment can be employed to discharge to the outside any vapors that might accumulate inside the special enclosure should leakage occur.
6. Tanks containing Class I, II or IIIA liquids inside a special enclosure shall not exceed 6,000 gallons (22 710 L) in individual capacity or 18,000 gallons (68 130 L) in aggregate capacity.
7. Each tank within special enclosures shall be surrounded by a clear space of not less than 3 feet (910 mm) to allow for maintenance and inspection.

❖ Special enclosures (essentially concrete vaults) can solve installation difficulties on problematic motor fuel-dispensing facility sites by allowing tanks to be installed inside of the facility building. The intent of this provision is to:

- Protect the building from the tank in case there is a fire involving the tank.
- Protect the tank from the building in case there is a fire involving the building.
- Prevent vapors from accumulating in the space between the tank and the enclosure.

- Limit the capacity of the tank inside the enclosure.
- Provide room for a maintenance technician to enter the space between the tank and the enclosure.

**2306.3 Security.** Above-ground tanks for the storage of liquid motor fuels shall be safeguarded from public access or unauthorized entry in an *approved* manner.

❖ This section is intended to protect the above-ground tank from vandalism and at the same time allow enough room for fire fighters to maneuver around the tank.

**2306.4 Physical protection.** Guard posts complying with Section 312 or other *approved* means shall be provided to protect above-ground tanks against impact by a motor vehicle unless the tank is *listed* as a protected above-ground tank with vehicle impact protection.

❖ This provision seeks to prevent leaks and spills caused by vehicle impact. The provision recognizes that vehicle damage can be reduced by placing 4-inch (102 mm) steel posts filled with concrete and spaced on 4-foot (1219 mm) centers around the above-ground tank, or by using a listed protected above-ground tank with vehicle impact protection.

**2306.5 Secondary containment.** Above-ground tanks shall be provided with drainage control or diking in accordance with Chapter 57. Drainage control and diking is not required for *listed* secondary containment tanks. Secondary containment systems shall be monitored either visually or automatically. Enclosed secondary containment systems shall be provided with emergency venting in accordance with Section 2306.6.2.5.

❖ A single-walled, above-ground, UL 142 tank inside a dike, or a double-wall, secondary containment, above-ground tank with emergency relief vents for the inner tank and the interstitial space will provide the level of protection required by this section. Both styles of tanks are listed for above-ground use and both tanks meet the requirements for drainage control and diking.

**2306.6 Piping, valves, fittings and ancillary equipment for use with flammable or combustible liquids.** The design, fabrication, assembly, testing and inspection of piping, valves, fittings and ancillary equipment for use with flammable or *combustible liquids* shall be in accordance with Chapter 57 and Sections 2306.6.1 through 2306.6.3.

❖ The majority of leaks come from piping, valves, fittings and ancillary equipment, not from the tank itself. Therefore, this section is intended to reduce fuel spills by addressing the requirements for this equipment.

**2306.6.1 Protection from damage.** Piping shall be located such that it is protected from physical damage.

❖ Piping is easily damaged by vehicles and other equipment. Piping must be installed and located in a way that will minimize damage either by burying the

pipe or protecting the pipe by some other physical means. More leaks come from piping than any other source.

**2306.6.2 Piping, valves, fittings and ancillary equipment for above-ground tanks for Class I, II and III liquids.** Piping, valves, fittings and ancillary equipment for above-ground tanks storing Class I, II and III liquids shall comply with Sections 2306.6.2.1 through 2306.6.2.6.

❖ Because above-ground tanks have a gravity head and some of the piping is always exposed above ground, special provisions apply to piping for above-ground tanks.

**2306.6.2.1 Tank openings.** Tank openings for above-ground tanks shall be through the top only.

❖ Tank openings must be through the top, above the liquid level, of an above-ground tank to reduce the risk of a liquid spill in the event of a piping failure.

**2306.6.2.2 Fill-pipe connections.** The fill pipe for above-ground tanks shall be provided with a means for making a direct connection to the tank vehicle's fuel-delivery hose so that the delivery of fuel is not exposed to the open air during the filling operation. Where any portion of the fill pipe exterior to the tank extends below the level of the top of the tank, a check valve shall be installed in the fill pipe not more than 12 inches (305 mm) from the fill-hose connection.

❖ The fill-pipe connection must be a liquid-tight connection, such as a cam-lock connection. The connection may be installed on top of the tank, which would require the fuel delivery person to climb on top of the tank, or the connection may be piped down to a lower level to prevent the delivery person from having to climb onto the tank. When the connection is piped down below the fuel level in the tank, a check valve must be installed in the location specified to prevent the discharge of fuel by siphon flow.

**2306.6.2.3 Overfill protection.** Overfill protection shall be provided for above-ground flammable and *combustible liquid* storage tanks in accordance with Sections 5704.2.7.5.8 and 5704.2.9.7.6.

❖ Overfill prevention is a major concern when dealing with above-ground tanks. The first step in preventing a spill is for the delivery truck operator to check the liquid level in the above-ground tank and set the truck up accordingly to fill the tank to the 90-percent level. The second prevention measure is the audible fill alarm that will sound an alarm when the tank reaches 90-percent capacity. The third level of prevention is for a device that will shut off the flow of liquid at 95-percent capacity.

An above-ground tank should be considered full at 90-percent capacity but under no circumstances should the tank be filled beyond 95-percent capacity.

The first thing the delivery driver should do after he or she properly positions the fuel delivery truck is to check and record the ullage (the amount of liquid required to fill the tank to 90-percent capacity).

The second line of defense to prevent an overfill is

an audible alarm set to go off when the tank reaches 90-percent capacity.

The third and final line of defense is the tank fill piping must be equipped with a device that will completely shut off the supply of liquid when the tank reaches 95 percent. This device is usually installed inside the tank fill opening and is part of the tank fill tube that extends down into the tank. The delivery operator should never rely on this device to determine when the tank is full; the delivery should have stopped at 90 percent. In the event that the delivery operator overfills the tank and the complete shutoff device closes, the tank delivery driver must have the means to drain the delivery hose without spilling the liquid on the ground.

As an alternative to the complete shutoff device, the code allows a device that will slow down the delivery rate when the tank reaches 90 percent. Once the tank reaches 90 percent, the rate of flow should slow down to a point where it will take 30 minutes to fill the tank to 95 percent.

**2306.6.2.4 Siphon prevention.** An *approved* antisiphon method shall be provided in the piping system to prevent flow of liquid by siphon action.

❖ Since piping connections to an above-ground tank must enter the tank through the top, this section requires that an approved anti-siphon device be installed in the liquid piping near the top of the tank to prevent liquid flow from the tank by siphon action if the supply pipe from the tank to the dispenser is damaged.

**2306.6.2.5 Emergency relief venting.** Above-ground storage tanks, tank compartments and enclosed secondary containment spaces shall be provided with emergency relief venting in accordance with Chapter 57.

❖ The emergency relief vent is the most important safety device installed on the tank. The emergency relief vent prevents the tank from overpressurizing in the event the tank is exposed to fire. In the case of a secondary containment above-ground tank there must be an emergency relief vent for each tank compartment and an emergency relief vent for the interstitial space.

**2306.6.2.6 Spill containers.** A spill container having a capacity of not less than 5 gallons (19 L) shall be provided for each fill connection. For tanks with a top fill connection, spill containers shall be noncombustible and shall be fixed to the tank and equipped with a manual drain valve that drains into the primary tank. For tanks with a remote fill connection, a portable spill container is allowed.

❖ The fill connection must be equipped with a spill-containment device that will hold at least 5 gallons (19 L). If the tank has a top-fill connection, the container must be noncombustible and attached directly to the tank and equipped with a drain valve that will allow any spilled liquid to be manually drained into the tank.

If the tank is equipped with a remote-fill connection, the container must be located at the connection when a delivery connection is made to the fill pipe.

**2306.6.3 Piping, valves, fittings and ancillary equipment for underground tanks.** Piping, valves, fittings and ancillary equipment for underground tanks shall comply with Chapter 57 and NFPA 30A.

❖ Section 5703.6 and NFPA 30A address the provisions for piping connected to underground tanks:

- Galvanic and corrosion protection.
- Leak detection.
- Special materials.
- Piping supports.
- Backflow protection.
- Flexible connections.
- Testing.

**2306.7 Fuel-dispensing systems for flammable or combustible liquids.** The design, fabrication and installation of fuel-dispensing systems for flammable or *combustible liquid* fuels shall be in accordance with Sections 2306.7.1 through 2306.7.9.2.4. Alcohol-blended fuel-dispensing systems shall also comply with Section 2306.8.

❖ The fuel-dispensing system consists of all the equipment required to get the fuel from the tank into the vehicle being fueled. It consists of the pumps, piping, dispensers, hoses, nozzles, break-away devices and any other equipment required for a particular application. Alternative alcohol-blended fuels, while they are considered in this category of fuels, possess characteristics that require the systems for dispensing them to comply with additional requirements contained in Section 2306.8. The additional provisions are needed because this section requires certain dispensing system components to be listed, and listings for equipment dispensing alcohol-blended fuels, including E85, are not yet available from nationally recognized testing laboratories. These organizations are currently working with stakeholders to address corrosion and material compatibility issues associated with E85 and other alcohol-blended fuels. See the commentary to Section 2306.8 for further information.

**2306.7.1 Listed equipment.** Electrical equipment, dispensers, hose, nozzles and submersible or subsurface pumps used in fuel-dispensing systems shall be *listed*.

❖ The use of listed equipment and devices provides evidence that they have been evaluated by a third-party agency for safe use in the applications for which they are designed. This is especially important where flammable liquids are being transferred or dispensed. See also the commentary for the definition of "Listed" in Chapter 2 for further discussion.

**2306.7.2 Fixed pumps required.** Class I and II liquids shall be transferred from tanks by means of fixed pumps designed

and equipped to allow control of the flow and prevent leakage or accidental discharge.

- ❖ There are two basic types of fixed pumps. One is remote from the dispenser and delivers the fuel under pressure to the dispenser. The most common place to find this type of pump is at the tank. Because the fuel is being delivered to the dispenser under pressure, leak detection devices must be used and a shear valve with a fusible link must be installed in the sump under the dispenser.

The second type of pump is a suction pump mounted in the base of the dispenser. A shear valve and leak detection are not required on this type of pump. Section 2306.7.4 requires an emergency shut-off valve on dispensers equipped with remote pumps.

**2306.7.3 Mounting of dispensers.** Dispensing devices, except those installed on top of a protected above-ground tank that qualifies as vehicle-impact resistant, shall be protected against physical damage by mounting on a concrete island 6 inches (152 mm) or more in height, or shall be protected in accordance with Section 312. Dispensing devices shall be installed and securely fastened to their mounting surface in accordance with the dispenser manufacturer’s instructions. Dispensing devices installed indoors shall be located in an *approved* position where they cannot be struck by an out-of-control vehicle descending a ramp or other slope.

- ❖ This provision addresses two alternatives to mounting dispensers so as to provide impact protection. One is to mount the dispenser on an elevated island and the other is to protect the dispenser in accordance with Section 312, which requires the dispenser to be protected by steel posts filled with concrete (see Commentary Figure 2306.7.3). Note that these provisions do not apply to dispensers mounted on top of a listed impact-resistant above-ground tank. Regardless of which of the above alternatives is chosen, the

stability of an installed dispenser depends on its installation in accordance with the manufacturer’s instructions, particularly with respect to ensuring that all bolts required to firmly mount the dispenser to the mounting surface are provided. It is not unusual to find dispensers with only half or fewer of their mounting bolts in place. Such a haphazard installation can make the dispenser piping and electrical conduits more susceptible to damage from a much less serious impact than might otherwise be tolerated if all bolts were in place or even from rocking action in high-wind conditions. This can lead to a liquid leak, an ignition from a damaged electrical circuit or both. NFPA 30A requires dispensers to be bolted to their mounting surface and UL 87 requires that two bolt holes be part of the dispenser base for dispensers not greater than 6 feet (1829 mm) tall, while four bolt holes are needed for dispensers over 6 feet (1829 mm) tall. These bolting requirements are for dispenser stability and piping protection and should not be considered part of the physical protection required by this section.

**2306.7.4 Dispenser emergency shutoff valve.** An *approved* automatic emergency shutoff valve designed to close in the event of a fire or impact shall be properly installed in the liquid supply line at the base of each dispenser supplied by a remote pump. The valve shall be installed so that the shear groove is flush with or within 1/2 inch (12.7 mm) of the top of the concrete dispenser island and there is clearance provided for maintenance purposes around the valve body and operating parts. The valve shall be installed at the liquid supply line inlet of each overhead-type dispenser. Where installed, a vapor return line located inside the dispenser housing shall have a shear section or *approved* flexible connector for the liquid supply line emergency shutoff valve to function. Emergency shutoff valves shall be installed and maintained in accordance with the manufacturer’s instructions, tested at the

time of initial installation and not less than yearly thereafter in accordance with Section 2305.2.4.

❖ The dispenser emergency valve (shear valve) is designed to close automatically when the dispenser is knocked over or if the dispenser is involved in a fire. This so-called “impact” valve is intended to prevent the free flow of fuel in the event a dispenser is struck by a vehicle. This spring-loaded, fusible-link-operated device may also be tripped by a fire. The relatively low clearance of the shear groove above the top surface of the dispenser island and the manufacturer’s requirement for a rigid mounting of the valve body are intended to enable the valve body to fracture at the shear groove upon impact, thus tripping the hold-open linkage and closing the valve.

These valves are only required on remote pumping systems (pump is on the tank). Suction system (pump is in dispenser) piping, if broken, will cause the system to lose prime, thus stopping liquid flow. Vapor recovery systems are usually interlocked with the liquid-dispensing system. Consequently, the vapor recovery breakaway design must be compatible with the liquid line shutoff so it functions as intended. Installation, maintenance, acceptance and periodic testing must conform to the manufacturer’s instructions. UL 842 describes the tests performed on these valves (see Commentary Figure 2306.7.4). The valve must be tested annually by manually tripping the hold-open linkage in accordance with Section 2305.2.4.

Figure 2306.7.4  
DISPENSER EMERGENCY VALVES

**2306.7.5 Dispenser hose.** Dispenser hoses shall be not more than 18 feet (5486 mm) in length unless otherwise *approved*. Dispenser hoses shall be *listed* and *approved*. When not in use, hoses shall be reeled, racked or otherwise protected from damage.

❖ The 18-foot-maximum (5486 mm) length for dispenser hose has become a standard, although the original reason for the 18-foot (5486 mm) length had nothing to do with fire safety. It was a weights-and-

measures requirement having to do with calibrating the dispenser to accurately give the volume of fuel delivered.

The fire code official should use caution when approving additional lengths of hose because the longer the hose, the harder it is to stow between uses, thus the more susceptible it is to damage by vehicles running over it if not properly stowed. Most dispenser hose-retrieving mechanisms are designed for 18-foot (5486 mm) hoses.

It is also important to remember that, when the hose is fully extended, the nozzle must not reach within 5 feet (1524 mm) of a building opening as regulated in Section 2303.1, Item 4.

**2306.7.5.1 Emergency breakaway devices.** Dispenser hoses for Class I and II liquids shall be equipped with a *listed* emergency breakaway device designed to retain liquid on both sides of a breakaway point. Such devices shall be installed and maintained in accordance with the manufacturer’s instructions. Where hoses are attached to hose-retrieving mechanisms, the emergency breakaway device shall be located between the hose nozzle and the point of attachment of the hose-retrieval mechanism to the hose.

❖ This provision requires a breakaway device on dispenser hoses delivering gasoline, diesel and kerosene (Class I and II liquids). These devices are installed to prevent a pull-down of the motor fuel dispenser in the event a car drives away with the hose nozzle valve still in the car’s fill pipe. The design of these valves is such that when they operate, the separated sections of the hose are sealed to prevent leakage of liquid from the hose. The placement of the breakaway device between the hose-retrieving mechanism clamp and the nozzle is important to the proper operation of the valve by preventing the pulling force of the driveoff from being transmitted via the retrieving cable directly to the dispenser. Commentary Figure 2306.7.5.1 shows a breakaway device installed between the nozzle and the hose-retrieving mechanism.

Figure 2306.7.5.1  
BREAKAWAY DEVICES

**2306.7.6 Fuel delivery nozzles.** A listed automatic-closing-type hose nozzle valve with or without a latch-open device shall be provided on island-type dispensers used for dispensing Class I, II or III liquids.

Overhead-type dispensing units shall be provided with a *listed* automatic-closing-type hose nozzle valve without a latch-open device.

**Exception:** A *listed* automatic-closing-type hose nozzle valve with latch-open device is allowed to be used on overhead-type dispensing units where the design of the system is such that the hose nozzle valve will close automatically in the event the valve is released from a fill opening or upon impact with a driveway.

- ❖ A *listed* automatic-closing-type hose nozzle with or without a latch-open device is designed to automatically close when the fuel spits back through the vent line or if the hose nozzle were to fall out of the car fill pipe and strike the ground. When the nozzle is equipped with certain types of vapor recovery equipment, it is designed to shut off when the nozzle is removed from the vehicle. The nozzle on island-type dispensers may or may not be equipped with a latch-open device. The fire code official may want to consider the fact that when a latch-open device is not installed, the dispenser operator may use some unapproved device to hold the nozzle open.

The distinction between an overhead-type dispenser and an island-type dispenser is included in this section even though the overhead dispenser is rarely used. However, the concern was that since the hose is on a retractable reel built into the canopy, the nozzle would not strike the ground if it were to fall out of the vehicle and a latch-open device would fail to work, allowing dangerous, uncontrolled fuel spills.

The exception is that if the overhead-type dispenser hose mechanism is designed to allow the nozzle to strike the ground and automatically shut off or if the nozzle was equipped with vapor return bellows that would automatically shut off the nozzle if it was removed from the vehicle, the latch-open device would be approved.

**2306.7.6.1 Special requirements for nozzles.** Where dispensing of Class I, II or III liquids is performed, a *listed* automatic-closing-type hose nozzle valve shall be used incorporating all of the following features:

1. The hose nozzle valve shall be equipped with an integral latch-open device.
2. Where the flow of product is normally controlled by devices or equipment other than the hose nozzle valve, the hose nozzle valve shall not be capable of being opened unless the delivery hose is pressurized. If pressure to the hose is lost, the nozzle shall close automatically.

**Exception:** Vapor recovery nozzles incorporating insertion interlock devices designed to achieve shut-off on disconnect from the vehicle fill pipe.

3. The hose nozzle shall be designed such that the nozzle is retained in the fill pipe during the filling operation.
4. The system shall include *listed* equipment with a feature that causes or requires the closing of the hose nozzle valve before the product flow can be resumed or before the hose nozzle valve can be replaced in its normal position in the dispenser.

zle valve before the product flow can be resumed or before the hose nozzle valve can be replaced in its normal position in the dispenser.

#### ❖ Item 1

This provision may seem to be in conflict with Section 2306.7.6, which requires a nozzle with or without a latch-open device. Hose nozzle valves are investigated and labeled by independent testing laboratories and are designed to shut off fuel flow automatically if dropped or jarred, or when fuel flows back into the nozzle spout (tank is full). Many jurisdictions have prohibited the use of latch-open-type hose nozzle valves at retail self-service stations, using the rationale that making customers hold the hose nozzle valve open during fueling would create a safer condition because they will be more alert during the fueling process. Not only does this section prohibit such a ban on a proven safety feature, but the fire record of self-service operations does not support this rationale. In fact, where factory-installed, latch-open devices (part of a tested, labeled hose nozzle valve assembly) are removed, it seems to challenge the creativity of customers in seeing how many different makeshift “hold-open” devices can be used to avoid having to hold manually the valve lever open. Such makeshift devices include gas caps, key rings, wallets, magazines, blocks of wood, rubber balls, etc. In one reported incident, a disposable cigarette lighter was used to prop open the hose nozzle valve lever only to strike a spark when the nozzle fell from the fill pipe. The resultant vapor ignition injured the customer and caused substantial damage to the service station and the customer’s car. UL 842 describes several types of hose nozzle valves and latch-open features and the tests to which they are subjected.

#### Item 2

The statement, “When the flow of product is normally controlled by devices or equipment other than the hose nozzle valve,” is referring to a prepay system; that is, a customer tells the person in the kiosk or convenience store how much fuel he or she wants and the dispenser shuts down and stops the flow, not the nozzle.

The exception addresses the fact that some vapor recovery nozzles are equipped with a bellows. When the nozzle is placed into the vehicle fill pipe, the bellows is compressed and the nozzle will operate. When the nozzle is removed, the bellows expands and the nozzle shuts off. The nozzle does not have to strike something to trigger the automatic shut-off; the nozzle shuts off as soon as the nozzle is removed.

#### Item 3

This device may be nothing more than a coil that looks like a spring around the dispenser nozzle spout. The spring tends to grip the lip of the vehicle’s receiver and helps to prevent the nozzle from falling out of the vehicle receiver.

**Item 4**

This safety feature is intended to prevent a situation in which a customer could finish fueling without releasing the latch-open device and replace the nozzle in the dispenser boot. The next customer could then remove the nozzle from the dispenser boot, authorize the sale and, before getting the nozzle into the vehicle fill pipe, begin discharging fuel in the open, causing an unacceptable spill situation.

**2306.7.7 Remote pumping systems.** Remote pumping systems for liquid fuels shall comply with Sections 2306.7.7.1 and 2306.7.7.2.

❖ Remote pumping systems (sometimes referred to as “pressure systems”) are systems in which liquid motor fuels are transferred from the storage tank to the dispensing devices by submersible pumps located at the storage tank rather than by suction pumps located within the dispensing device. The intent of this section is to require special safety devices on pumping systems that deliver fuel to the dispenser by pressure rather than suction.

**2306.7.7.1 Leak detection.** Where remote pumps are used to supply fuel dispensers, each pump shall have installed on the discharge side a *listed* leak detection device that will detect a leak in the piping and dispensers and provide an indication. A leak detection device is not required if the piping from the pump discharge to under the dispenser is above ground and visible.

❖ In remote pumping systems, the piping between the remote pump and the dispenser, because it is under pressure, is the number-one location of fuel spills caused by leaks. This section addresses both underground and above-ground piping. If the piping is underground, a line leak detector (LLD) must be installed on the discharge side of the remote pump. These devices detect piping leaks by monitoring the pressure in the dispensing system piping. If the LLD detects a pressure loss due to a leak, it will reduce the flow of product in the system to approximately 3 gallons per hour (14.33 L/h) at the hose nozzle as a visual indicator to the attendant that there is a system problem.

The reduced rate of flow fulfills this section’s requirement that detection of a leak be indicated. While an electronic leak detection system could fulfill the requirements of this section, this section does not require electronic leak detection.

If the system piping is above ground where a leak would be immediately noticed and the piping can be visually inspected, the leak detection device is not required.

**2306.7.7.2 Location.** Remote pumps installed above grade, outside of buildings, shall be located not less than 10 feet (3048 mm) from lines of adjoining property that can be built upon and not less than 5 feet (1524 mm) from any building opening. Where an outside pump location is impractical, pumps are permitted to be installed inside buildings as provided for dispensers in Section 2301.4 and Chapter 57.

Pumps shall be substantially anchored and protected against physical damage.

❖ Commentary Figure 2306.7.7.2 shows the minimum distances between an above-grade remote pump, lot lines and openings into a building. Where outside clearances cannot be achieved or are impractical in a given situation, above-grade remote pumps are allowed to be installed inside of buildings on the same basis as motor fuel dispensers.

**2306.7.8 Gravity and pressure dispensing.** Flammable liq-

uids shall not be dispensed by gravity from tanks, drums, barrels or similar containers. Flammable or *combustible liquids* shall not be dispensed by a device operating through pressure within a storage tank, drum or container.

❖ Delivering fuel by gravity is prohibited because the piping or hose between the tank and the nozzle could rupture or leak, causing the contents of the tank to spill. Tank pressurization is prohibited because the tanks will rupture when excessive pressure is applied. The maximum pressure at which an above-ground tank is tested is 5 pounds per square inch (psi) (34 kPa). Also, the application of air to the tank may lean out the very rich fuel vapors to the point where the atmosphere inside the tank is within the flammable range.

**2306.7.9 Vapor-recovery and vapor-processing systems.** Vapor-recovery and vapor-processing systems shall be in accordance with Sections 2306.7.9.1 through 2306.7.9.2.4.

❖ The following provisions address the requirements for vapor-recovery or vapor-processing systems. Because of clean-air environmental concerns, some jurisdictions prohibit fuel vapors displaced during tanker deliveries or routine fuel-dispensing operations from being

discharged into the atmosphere and require vapor-recovery or vapor-processing systems to prevent pollution. This section contains the provisions for returning the vapors to the tank or processing the vapors on site. Note that the code does not require these systems to be installed, but where they are installed, they must comply with these regulations.

**2306.7.9.1 Vapor-balance systems.** Vapor-balance systems shall comply with Sections 2306.7.9.1.1 through 2306.7.9.1.5.

❖ As fuel enters the fuel tank of the vehicle it displaces fuel vapors. The vapor-balance system simply captures these vapors and returns them to the storage tank.

**2306.7.9.1.1 Dispensing devices.** Dispensing devices incorporating provisions for vapor recovery shall be *listed* and *labeled*. Where existing *listed* or *labeled* dispensing devices are modified for vapor recovery, such modifications shall be *listed* by report by a nationally recognized testing laboratory. The listing by report shall contain a description of the component parts used in the modification and recommended method of installation on specific dispensers. Such report shall be made available on request of the *fire code official*.

Means shall be provided to shut down fuel dispensing in the event the vapor return line becomes blocked.

❖ Motor fuel dispensers equipped with vapor-recovery equipment must be listed and labeled by a recognized testing laboratory attesting that they will function properly when installed in accordance with the terms of their listing (see commentary for the definitions of “Listed” and “Labeled” in Chapter 2). When existing dispensing equipment is retrofitted with vapor-recovery equipment, the equipment being added must be listed to work with the existing equipment. In other words, a person cannot modify an existing dispensing device manufactured by one company with vapor-recovery component parts manufactured by the same or a different company unless a report from a recognized testing laboratory is submitted to the fire code official verifying that the retrofit components will work properly with the dispensing device. This is called “listed by report” and is a service provided by major testing laboratories to document equipment compatibility. The report from the testing laboratory must also include the installation instructions.

Means must be provided to shut down fuel dispensing in the event the vapor-return line becomes blocked. This provision is self-explanatory. To prevent vapors from entering the atmosphere, the dispensing operation must be stopped if the vapor return is blocked.

**2306.7.9.1.2 Vapor-return line closeoff.** An acceptable method shall be provided to close off the vapor return line from dispensers when the product is not being dispensed.

❖ To prevent vapors from escaping after dispensing has stopped, some type of device must be installed

that will prevent vapors in the tank from escaping out of the return line. This could be accomplished by a one-way check valve.

**2306.7.9.1.3 Piping.** Piping in vapor-balance systems shall be in accordance with Sections 5703.6, 5704.2.9 and 5704.2.11. Nonmetallic piping shall be installed in accordance with the manufacturer’s instructions.

Existing and new vent piping shall be in accordance with Sections 5703.6 and 5704.2. Vapor return piping shall be installed in a manner that drains back to the tank, without sags or traps in which liquid can become trapped. If necessary, because of grade, condensate tanks are allowed in vapor return piping. Condensate tanks shall be designed and installed so that they can be drained without opening.

❖ Section 5703.6 addresses the general requirements for piping. Section 5704.2.9 addresses piping for above-ground tanks, and Section 5704.2.11 lists the requirements for underground tanks. Special piping materials, as described in Section 5703.6.2.1, must be used underground or, if used above ground, must be protected from fire exposure.

The vent piping must comply with the general requirements of Section 5703.6, and the specific vent requirements of Section 5704.2.

**2306.7.9.1.4 Flexible joints and shear joints.** Flexible joints shall be installed in accordance with Section 5703.6.9.

An *approved* shear joint shall be rigidly mounted and connected by a union in the vapor return piping at the base of each dispensing device. The shear joint shall be mounted flush with the top of the surface on which the dispenser is mounted.

❖ Flexible joints must be listed, approved and installed in the following locations:

1. Where piping connects to underground piping.
2. Where piping ends at pump islands and vent risers.
3. At points where differential movement in the piping can occur.

The shear joint mentioned here serves the same function for the vapor-recovery lines as the dispenser emergency valve does for the pressurized fuel supply piping to the dispenser (see commentary, Section 2306.7.4). This shear valve must be securely mounted so that the shear groove is located flush or within  $\frac{1}{2}$  inch (12.7 mm) of the surface of the dispenser island or top of the sump. This shear valve is designed to close in case of a dispenser fire or a dispenser knock-down.

**2306.7.9.1.5 Testing.** Vapor return lines and vent piping shall be tested in accordance with Section 5703.6.3.

❖ Section 5703.6.3 addresses the testing for flammable and combustible liquid piping.

**2306.7.9.2 Vapor-processing systems.** Vapor-processing systems shall comply with Sections 2306.7.9.2.1 through 2306.7.9.2.4.

- ❖ Where vapor-recovery systems capture the vapors and return them to the tank, vapor-processing systems do not return the vapors to the tank. Instead, they process the vapors either by refrigeration, absorption or burning them off.

**2306.7.9.2.1 Equipment.** Equipment in vapor-processing systems, including hose nozzle valves, vapor pumps, flame arresters, fire checks or systems for prevention of flame propagation, controls and vapor-processing equipment, shall be individually *listed* for the intended use in a specified manner.

Vapor-processing systems that introduce air into the underground piping or storage tanks shall be provided with equipment for prevention of flame propagation that has been tested and *listed* as suitable for the intended use.

- ❖ Unlisted vapor-processing equipment may not be used. Equipment that is used must be done in accordance with its listing.

Vapor-processing systems that introduce air into the underground piping or storage tanks must be provided with equipment for prevention of flame propagation that has been tested and listed as suitable for the intended use.

When blowers are used to introduce air, equipment, such as listed flame arresters, must be used to prevent vapors in the flammable range from being ignited.

**2306.7.9.2.2 Location.** Vapor-processing equipment shall be located at or above grade. Sources of ignition shall be located not less than 50 feet (15 240 mm) from fuel-transfer areas and not less than 18 inches (457 mm) above tank fill openings and tops of dispenser islands. Vapor-processing units shall be located not less than 10 feet (3048 mm) from the nearest building or *lot line* of a property that can be built upon.

**Exception:** Where the required distances to buildings, *lot lines* or fuel-transfer areas cannot be obtained, means shall be provided to protect equipment against fire exposure. Acceptable means shall include but not be limited to either of the following:

1. *Approved* protective enclosures, which extend not less than 18 inches (457 mm) above the equipment, constructed of fire-resistant or noncombustible materials.
  2. Fire protection using an *approved* water-spray system.
- ❖ This section is intended to protect vapor-processing equipment from fire exposure, not to protect other structures or equipment from a fire involving the vapor-recovery equipment. Clearance to lot lines is intended to provide a measure of exposure protection to the vapor-processing equipment from potential off-site fires. The exception provides several acceptable clearance alternatives, recognizing that the required clearances cannot, in all cases, be achieved. This is especially true in the case of vapor-processing equip-

ment being installed at established motor fuel-dispensing facilities where the area available for proper installation is not subject to design but, rather, to the existing site conditions. Note that where Exception 1 is approved, the resulting enclosure should be ventilated in an approved manner, similar to that required for physical protection enclosures by Section 2306.9.2.2.2.

**2306.7.9.2.2.1 Distance from dispensing devices.** Vapor-processing equipment shall be located not less than 20 feet (6096 mm) from dispensing devices.

- ❖ Twenty feet (6096 mm) is the extent of the Class I, Group D, Division 2, electrically classified area for flammable liquid fuel dispensers established by Article 500 of NFPA 70.

**2306.7.9.2.2.2 Physical protection.** Vapor-processing equipment shall be protected against physical damage by guardrails, curbs, protective enclosures or fencing. Where *approved* protective enclosures are used, *approved* means shall be provided to ventilate the volume within the enclosure to prevent pocketing of flammable vapors.

- ❖ Vapor-processing equipment must not only be physically protected from vehicles and other physical damage but, if the protection means includes an enclosure, the enclosed area must be adequately ventilated to prevent the accumulation of flammable vapors within where it could become a hazard to anyone entering the enclosure.

**2306.7.9.2.2.3 Downslopes.** Where a downslope exists toward the location of the vapor-processing unit from a fuel-transfer area, the *fire code official* is authorized to require additional separation by distance and height.

- ❖ If the vapor-processing equipment is situated downhill from the dispensers, vapors will be more likely to accumulate in or around the vapor-processing equipment from the fuel transfer area. Accordingly, the fire code official may require greater protection for the vapor-processing equipment.

**2306.7.9.2.3 Installation.** Vapor-processing units shall be securely mounted on concrete, masonry or structural steel supports on concrete or other noncombustible foundations. Vapor-recovery and vapor-processing equipment is allowed to be installed on roofs where *approved*.

- ❖ This provision is intended to require the vapor-processing equipment to be mounted on a noncombustible, substantial foundation.

**2306.7.9.2.4 Piping.** Piping in a mechanical-assist system shall be in accordance with Section 5703.6.

- ❖ Section 5703.6 addresses the provisions for flammable and combustible liquid piping.

**2306.8 Alcohol-blended fuel-dispensing operations.** The design, fabrication and installation of alcohol-blended fuel-dispensing systems shall be in accordance with Section 2306.7 and Sections 2306.8.1 through 2306.8.5.

- ❖ This section addresses hazards specifically related to the dispensing of alcohol-blended fuels as compared

to gasoline and the more established gasoline-alcohol blends (“gasohol”), which are treated the same as gasoline in the code.

The fuel-dispensing system consists of all equipment required to get the fuel from the tank into the vehicle being fueled. It consists of the pumps, piping, dispensers, hoses, nozzles, break-away devices and any other equipment required for a particular application. Alternative alcohol-blended fuels, although subject to the requirements of Section 2306.7 for flammable and combustible liquid fuel-dispensing equipment, possess characteristics that require the systems for dispensing them to comply with additional requirements contained in Sections 2306.8.1 through 2306.8.5. The additional provisions are needed because Section 2306.7.1 requires certain dispensing system components to be listed; however, listings for equipment dispensing alcohol-blended fuels, including E85, may not yet be available from nationally recognized testing laboratories. These organizations are currently working with stakeholders to address corrosion and material compatibility issues associated with E85 and other alcohol-blended fuels. In an initial step toward developing a listing standard, UL has developed an Outline of Investigation, UL 87A, for dispensing devices for gasoline/ethanol blend fuels. See also the commentary to Section 202 for the definition of “Alcohol-blended fuels” for further information.

**2306.8.1 Listed equipment.** Dispensers shall be *listed* in accordance with UL 87A. Hoses, nozzles, breakaway fittings, swivels, flexible connectors or dispenser emergency shutoff valves, vapor recovery systems, leak detection devices and pumps used in alcohol-blended fuel-dispensing systems shall be *listed* for the specific purpose.

❖ This section requires dispensing equipment to be listed in accordance with UL 87A. It also identifies dispensing system components that must be listed for use with alcohol-blended fuels. The UL 87A *Outline of Investigation for Power-Operated Dispensing Devices for Gasoline and Gasoline/Ethanol Blends with Nominal Ethanol Concentrations up to 85 Percent* was developed to cover dispensers intended for use with high-concentration ethanol blends. Listed dispensers and the related hanging hardware are listed for high-concentration ethanol blends, and are being installed across the United States.

**2306.8.2 Compatibility.** Dispensers shall be used only with the fuels for which they have been *listed* and which are marked on the product. Field-installed components including hose assemblies, breakaway fittings, swivel connectors and hose nozzle valves shall be provided in accordance with the listing and the marking on the unit.

❖ Dispensers and certain field-installed dispensing system components may be made of materials commonly used with gasoline but which may be incompatible with high-level alcohol blends and may degrade over time in their presence. Zinc, brass, lead and aluminum are some of the more sensitive metals.

This section requires that, as added documentation, dispensers and their field-installed components be marked by the equipment manufacturer with the names of the fuels with which they are compatible, confirming their suitability for use with alcohol-blended fuels.

**2306.8.3 Change of system contents.** Fuel-dispensing systems subject to change in contents from gasoline to alcohol-blended fuels shall be subject to *fire code official* review and approval prior to commencing dispensing operations.

❖ This section provides the fire code official the authority to review and reapprove installations that convert from gasoline dispensing to alcohol-blended fuel dispensing. This allows for verification that the installation complies with the new requirements. It also ensures that the fire code official will know that new fuels will be present on a given site, which might impact local fire suppression operations, including the use of alcohol-resistant foam agents.

The same technologies used to store and dispense gasoline and diesel fuels are used for alcohol-based fuels because, like gasoline, they are liquid at ambient pressures and temperatures. However, only E85-compatible materials should be used in the storage and dispensing systems. In many cases, existing gasoline and diesel fuel systems may be converted to store and dispense E85. Most metal underground storage tanks that meet the U.S. Environmental Protection Agency (EPA) regulations can be used to store E85. Many underground fiberglass tanks that meet EPA standards may also be used to store E85.

If another type of fuel was stored in the tank that is to be converted for E85 use, the tank should be cleaned. During storage, particles and moisture can build up over time to form sludge or what is called “water bottoms.” Since ethanol is miscible with water, when introducing E85 or another ethanol blend into a dirty storage tank, ethanol’s “cleaning action” will mix with the water bottoms and remove the sludge, resulting in contaminated fuel. A simple tank cleaning will prevent any problems. There are several methods for cleaning sludge from storage tanks. Each of the cleaning methods should be completed by an approved company that is familiar with cleaning petroleum storage tanks. Note that a permit is required by Section 105.6.17, Item 8 to change stored contents.

**2306.8.4 Facility identification.** Facilities dispensing alcohol-blended fuels shall be identified by an *approved* means.

❖ This section addresses dispensing facility identification for alcohol-blended fuels. Identification of the facility is intended to promote first-responder awareness of the presence of alcohol-blended fuels.

According to the U.S. Department of Energy (DOE) *Handbook for Handling, Storing, and Dispensing E85*, each state, along with the U.S. Department of Trans-

portation (DOT), has developed signage to place at refueling stations. Code users should contact their individual state DOT to obtain the correct signage criteria for their area.

**2306.8.5 Marking.** Dispensers shall be marked in an *approved* manner to identify the types of alcohol-blended fuels to be dispensed.

- ❖ Identification of equipment for specific alcohol-blended fuels communicates the intended use of the installed equipment to both customers and emergency personnel. The Federal Trade Commission (FTC) requires a small sticker to be placed on the face of the fuel dispenser as close as possible to the price per unit of fuel. The sticker should have a black background with orange text (see Commentary Figure 2306.8.5).

**2306.8.6 Maintenance and inspection.** Equipment shall be maintained and inspected in accordance with Section 2305.2.

- ❖ Since a major concern with alcohol-blended fuels is their potentially degrading effect on system components, the equipment maintenance provisions of Section 2305.2 must be carefully followed.

**SECTION 2307**  
**LIQUEFIED PETROLEUM GAS MOTOR**  
**FUEL-DISPENSING FACILITIES**

**2307.1 General.** Motor fuel-dispensing facilities for liquefied petroleum gas (LP-gas) fuel shall be in accordance with this section and Chapter 61.

- ❖ The federal government mandates that automakers move toward alternative fuels to replace conventional gasoline and diesel. One of the more popular alternative fuels is liquefied petroleum gas (LP-gas). As more vehicles use alternative fuels, codes will have to

be modified to address the safe dispensing of these fuels. This section addresses the dispensing of LP-gas at motor fuel-dispensing facilities. Chapter 61 addresses the general provisions for LP-gas.

**2307.2 Approvals.** Storage vessels and equipment used for the storage or dispensing of LP-gas shall be *approved* or *listed* in accordance with Sections 2307.2.1 and 2307.2.2.

- ❖ All equipment used in connection with the storage and dispensing of LP-gas motor fuel must be either approved or listed, as specified in the following sections. The terms “approved” and “listed” are defined in Chapter 2. See the commentary to Chapter 2 for these defined terms for further information.

**2307.2.1 Approved equipment.** Containers, pressure relief devices (including pressure relief valves), pressure regulators and piping for LP-gas shall be *approved*.

- ❖ The equipment identified in this section must be approved by the fire code official.

**2307.2.2 Listed equipment.** Hoses, hose connections, vehicle fuel connections, dispensers, LP-gas pumps and electrical equipment used for LP-gas shall be *listed*.

- ❖ The equipment identified in this section must be listed.

**2307.3 Attendants.** Motor fuel-dispensing operations for LP-gas shall be conducted by qualified attendants or in accordance with Section 2307.6 by persons trained in the proper handling of LP-gas.

- ❖ LP-gas must be dispensed into a vehicle by trained and qualified persons. Unattended and self-service LP-gas stations that are open to the public are not allowed. Section 2307.6 does allow self-service as long as it is closed to the public; that is, the vehicles belong to the operator of the LP-gas-fueling facility and the persons dispensing the fuel are employees of the LP-gas-fueling operation and are properly trained.

**2307.4 Location of dispensing operations and equipment.** The point of transfer for LP-gas dispensing operations shall be separated from buildings and other exposures in accordance with the following:

1. Not less than 25 feet (7620 mm) from buildings where the *exterior wall* is not part of a fire-resistance-rated assembly having a rating of 1 hour or greater.
2. Not less than 25 feet (7620 mm) from combustible overhangs on buildings, measured from a vertical line dropped from the face of the overhang at a point nearest the point of transfer.
3. Not less than 25 feet (7620 mm) from the lot line of property that can be built upon.
4. Not less than 25 feet (7620 mm) from the centerline of the nearest mainline railroad track.
5. Not less than 10 feet (3048 mm) from public streets, highways, thoroughfares, sidewalks and driveways.

6. Not less than 10 feet (3048 mm) from buildings where the *exterior wall* is part of a fire-resistance-rated assembly having a rating of 1 hour or greater.

**Exception:** The point of transfer for LP-gas dispensing operations need not be separated from canopies that are constructed in accordance with the *International Building Code* and that provide weather protection for the dispensing equipment.

LP-gas containers shall be located in accordance with Chapter 61. LP-gas storage and dispensing equipment shall be located outdoors.

- ❖ Whereas Section 2303.1 regulates the location of dispensing devices, this section regulates the location of the point of transfer of the LP gas motor fuel into the vehicle fuel tank. The intent of the term “point of transfer” is to describe the location where LP-gas-fueling connections are made and broken and any location where LP-gas is vented during transfer or fueling operations. Whenever LP-gas is dispensed or transferred, there is always at least a “puff” of LP gas released at the point where the LP-gas dispensing hose connects to and disconnects from the vehicle fuel tank or other LP-gas container, and it is at those locations that a flammable mixture will exist, even if momentarily. This section intends to isolate these “movable locations” by regulating how far away from potential ignition sources or other properties they must remain under in all circumstances. This section is also in agreement with NFPA 58 with respect to separation distances.

The IBC has specific construction requirements for canopies located at motor fuel-dispensing facilities. The exception removes any separation requirements between the dispenser area and the canopy when the canopy is constructed in accordance to the special provision for canopies located at motor fuel-dispensing facilities.

Table 6104.3 lists the separation requirements for the containers in relation to buildings, public ways and property lines that are or might be built upon.

**2307.5 Additional requirements for LP-gas dispensers and equipment.** LP-gas dispensers and related equipment shall comply with the following provisions.

1. Pumps shall be fixed in place and shall be designed to allow control of the flow and to prevent leakage and accidental discharge.
  2. Dispensing devices installed within 10 feet (3048 mm) of where vehicle traffic occurs shall be protected against physical damage by mounting on a concrete island 6 inches (152 mm) or more in height, or shall be protected in accordance with Section 312.
  3. Dispensing devices shall be securely fastened to their mounting surface in accordance with the dispenser manufacturer’s instructions.
- ❖ In order to reduce the likelihood of a leak or the accidental discharge of LP-gas, Item 1 requires that dis-

pensing pumps be fixed in place and equipped with a means of controlling the flow of LP-gas. Similar to the provisions of Section 2306.7.3, Items 2 and 3 of this section address two alternatives for mounting dispensers so as to provide impact protection. One is to mount the dispenser on an elevated island. The other is to protect the dispenser in accordance with Section 312, which requires the dispenser to be protected by steel posts filled with concrete (see also Commentary Figure 2306.7.3). Regardless of which alternative is chosen, the stability and protection of an installed dispenser depends on its installation in accordance with the manufacturer’s instructions.

**2307.6 Installation of LP-gas dispensing devices and equipment.** The installation and operation of LP-gas dispensing systems shall be in accordance with Sections 2307.6.1 through 2307.6.4 and Chapter 61. LP-gas dispensers and dispensing stations shall be installed in accordance with the manufacturer’s specifications and their listing.

- ❖ This provision specifically addresses the requirements for valves, hoses and impact protection for LP-gas-dispensing equipment.

**2307.6.1 Product control valves.** The dispenser system piping shall be protected from uncontrolled discharge in accordance with the following:

1. Where mounted on a concrete base, a means shall be provided and installed within  $\frac{1}{2}$  inch (12.7 mm) of the top of the concrete base that will prevent flow from the supply piping in the event that the dispenser is displaced from its mounting.
2. A manual shutoff valve and an excess flow-control check valve shall be located in the liquid line between the pump and the dispenser inlet where the dispensing device is installed at a remote location and is not part of a complete storage and dispensing unit mounted on a common base.
3. An excess flow-control check valve or an emergency shutoff valve shall be installed in or on the dispenser at the point at which the dispenser hose is connected to the liquid piping.
4. A *listed* automatic-closing type hose nozzle valve with or without a latch-open device shall be provided on island-type dispensers.

- ❖ The provisions of this section are similar to certain provisions in Section 2306.7 that are applicable to flammable and combustible liquid dispensers.

Item 1 is based on Section 2306.7.4, but since the hardware performance requirements in that section for gasoline and diesel dispensers differ from what is currently available for LP-gas dispenser systems, the text more closely resembles the performance requirements currently appearing in Section 6.3.9 of NFPA 30A, with the exception that the location for the protective means must be within  $\frac{1}{2}$  inch of the top surface of the concrete island, as is required in Section 2306.7.4.

Item 2 is based on Section 6.25.3.11 of NFPA 58 and provides protection for the piping system where the storage container is located remotely from the dispenser. When the storage container and dispenser are separate components installed remotely from one another, the likelihood of pipe failure increases.

Item 3 is based on the requirements in Section 3.9.3.4 of NFPA 58. An excess flow-control check valve is one that senses the pressure before and after the LP-gas meter and closes when it senses a loss of the pressure differential such as would occur if the dispensing hose were to become disconnected or broken.

Item 4 is adapted from Section 2306.7.6 and is similar to Section 6.25.3.16 of NFPA 58. A listed (for LP-gas dispensing at motor fuel-dispensing facilities) automatic-closing-type hose nozzle with or without a latch-open device is designed to automatically close when it senses that the fuel tank is full. The hose nozzle on island-type dispensers may or may not be equipped with a latch-open device. The fire code official may want to consider the fact that when a latch-open device is not installed, the dispenser operator may use some unapproved device to hold the nozzle open.

**2307.6.2 Hoses.** Hoses and piping for the dispensing of LP-gas shall be provided with hydrostatic relief valves. The hose length shall not exceed 18 feet (5486 mm). An *approved* method shall be provided to protect the hose against mechanical damage.

❖ To prevent overpressurization of the hoses and piping, a relief valve must be installed in the system. The hose length is limited to 18 feet (5486 mm) to prevent excessive amounts of hose from lying on the ground and being damaged by vehicles. The general public is familiar with the 18-foot (5486 mm) length because of the 18-foot (5486 mm) requirement for liquid fuel-dispensing hoses in Section 2306.7.5 and they know where to position their vehicles for refueling. See the commentary to Section 2306.7.5 for further discussion of hose length.

**2307.6.3 Emergency breakaway devices.** Dispenser hoses shall be equipped with a *listed* emergency breakaway device designed to retain liquid on both sides of the breakaway point. Where hoses are attached to hose-retrieving mechanisms, the emergency breakaway device shall be located such that the breakaway device activates to protect the dispenser from being displaced.

❖ Similar to Section 2306.7.5.1 of the code and Section 6.25.4.2 of NFPA 58, this section requires a breakaway device on dispenser hoses delivering LP-gas motor fuel. These devices are installed to prevent a pull-down of the motor fuel dispenser in the event that a car drives away with the hose nozzle valve still attached to the car's fill pipe. The design of these valves is such that when they operate, the separated sections of the hose are sealed to prevent leakage of fuel from the hose.

This section differs from Section 2306.7.5.1 in that

it does not specify the location of the emergency breakaway device connection to the hose. Where a hose is equipped with a hose retrieval mechanism, placing the breakaway device between the mechanism's clamp and nozzle is important to the proper operation of the valve by preventing the pulling force of the drive-off from being transmitted via the retrieving cable directly to the dispenser.

**2307.6.4 Vehicle impact protection.** Where installed within 10 feet of vehicle traffic, LP-gas storage containers, pumps and dispensers shall be protected in accordance with Section 2307.5, Item 2.

❖ This section is intended to prevent leaks and spills caused by vehicle impact by requiring vehicle impact protection in the form of a 6-inch concrete island or the installation of 4-inch-diameter (102 mm), concrete-filled steel posts on 4-foot (1219 mm) centers, 3 feet (914 mm) high. See Section 312 for more specific construction details, and the commentary to Section 2307.5, Item 2 for further discussion of such protection.

**2307.7 Public fueling of motor vehicles.** Self-service LP-gas dispensing systems, including key, code and card lock dispensing systems, shall be limited to the filling of permanently mounted containers providing fuel to the LP-gas powered vehicle.

The requirements for self-service LP-gas dispensing systems shall be in accordance with the following:

1. The arrangement and operation of the transfer of product into a vehicle shall be in accordance with this section and Chapter 61.
2. The system shall be provided with an emergency shut-off switch located within 100 feet (30 480 mm) of, but not less than 20 feet (6096 mm) from, dispensers.
3. The *owner* of the LP-gas motor fuel-dispensing facility or the owner's designee shall provide for the safe operation of the system and the training of users.
4. The dispenser and hose-end valve shall release not more than 1/8 fluid ounce (4 cc) of liquid to the atmosphere upon breaking the connection with the fill valve on the vehicle.
5. Portable fire extinguishers shall be provided in accordance with Section 2305.5.
6. Warning signs shall be provided in accordance with Section 2305.6.
7. The area around the dispenser shall be maintained in accordance with Section 2305.7.

❖ While the 2012 and earlier editions of the code prohibited self-service LP-gas motor fuel dispensing operated by the public, the 2015 edition allows public refueling from LP-gas dispensers. This revision occurred in response to new technologies available to safeguard refueling operations. If the vehicles being refueled do not belong to the owner of the fuel-dispensing facility and the fuel-dispensing operator is not an employee of the owner, the facility is consid-

ered to be “public.” This section allows vehicle owners to refuel their own vehicles under the supervision of, or after having been trained by, the LP-gas motor fuel-dispensing facility owner or the owner’s designee.

This section contains provisions for the safe operation of the facility and an emergency shutoff switch similar to the emergency shutoff switch required at motor fuel-dispensing facilities in Section 2303.2.

**Figure 2307.7**  
**PUBLIC LP-GAS FUEL DISPENSER**

**2307.8 Overfilling.** LP-gas containers shall not be filled with LP-gas in excess of the volume determined using the fixed maximum liquid level gauge installed on the container, the volume determined by the overfilling prevention device installed on the container or the weight determined by the required percentage of the water capacity marked on the container.

- ❖ To prevent release of gas by pressure relief due to expansion of the gas, the LP-gas container must not be filled beyond the volume determined by one of the methods in this section.

## SECTION 2308 COMPRESSED NATURAL GAS MOTOR FUEL-DISPENSING FACILITIES

**2308.1 General.** Motor fuel-dispensing facilities for compressed natural gas (CNG) fuel shall be in accordance with this section and Chapter 53.

- ❖ The federal government is mandating that automakers move toward alternative fuels to replace conventional gasoline and diesel. One of the more popular alternative fuels is compressed natural gas (CNG). As more vehicles use alternative fuels, codes will have to be modified to address the safe dispensing of these fuels. This section addresses the dispensing of

CNG at motor fuel-dispensing facilities. Chapter 53 contains the general provisions for CNG.

**2308.2 Approvals.** Storage vessels and equipment used for the storage, compression or dispensing of CNG shall be *approved* or *listed* in accordance with Sections 2308.2.1 and 2308.2.2.

- ❖ All equipment used in connection with the storage and dispensing of CNG motor fuel must be either approved or listed, as specified in the following sections. The terms “Approved” and “Listed” are defined in Chapter 2. See the commentary to these defined terms for further information.

**2308.2.1 Approved equipment.** Containers, compressors, pressure relief devices (including pressure relief valves), and pressure regulators and piping used for CNG shall be *approved*.

- ❖ The equipment identified in this section must be approved by the fire code official. Listing of the specified components could be the basis for approval, but listing is not mandated. Any such components must be designed for the application and recommended for the application by the manufacturer.

**2308.2.2 Listed equipment.** Hoses, hose connections, dispensers, gas detection systems and electrical equipment used for CNG shall be *listed*. Vehicle-fueling connections shall be *listed* and *labeled*.

- ❖ The specified components must be listed and labeled by an approved testing agency as complying with the relevant product standards. As with all listed products, the testing/listing agency will apply its seal or mark to the product.

**2308.3 Location of dispensing operations and equipment.** Compression, storage and dispensing equipment shall be located above ground, outside.

### Exceptions:

1. Compression, storage or dispensing equipment shall be allowed in buildings of noncombustible construction, as set forth in the *International Building Code*, that are unenclosed for three-quarters or more of the perimeter.
  2. Compression, storage and dispensing equipment shall be allowed indoors or in vaults in accordance with Chapter 53.
- ❖ Because of the potential for leakage, the compression, storage and dispensing equipment must be located either outdoors or in a noncombustible, substantially open building, except as allowed by Chapter 53. This section allows compression, storage and dispensing equipment to be located:
    1. Outdoors, above ground.
    2. Inside noncombustible buildings where at least 75 percent of the wall area is open to the outside atmosphere.

3. Indoors or in vaults in accordance with Chapter 53, which, in turn, references NFPA 52 and Section 413 of the IFGC.

**2308.3.1 Location on property.** In addition to the requirements of Section 2303.1, compression, storage and dispensing equipment not located in vaults complying with Chapter 53 shall be installed as follows:

1. Not beneath power lines.
2. Ten feet (3048 mm) or more from the nearest building or *lot line* that could be built on, public street, sidewalk or source of ignition.

**Exception:** Dispensing equipment need not be separated from canopies that are constructed in accordance with the *International Building Code* and that provide weather protection for the dispensing equipment.

3. Twenty-five feet (7620 mm) or more from the nearest rail of any railroad track and 50 feet (15 240 mm) or more from the nearest rail of any railroad main track or any railroad or transit line where power for train propulsion is provided by an outside electrical source, such as third rail or overhead catenary.
  4. Fifty feet (15 240 mm) or more from the vertical plane below the nearest overhead wire of a trolley bus line.
- ❖ Natural gas is lighter than air. The requirements for the location of the equipment that compresses and dispenses the gas must take this into consideration. The separation distances from overhead ignition sources should be noted.

**2308.4 Private fueling of motor vehicles.** Self-service CNG-dispensing systems, including key, code and card lock dispensing systems, shall be limited to the filling of permanently mounted fuel containers on CNG-powered vehicles.

In addition to the requirements in Section 2305, the *owner* of a self-service CNG motor fuel-dispensing facility shall ensure the safe operation of the system and the training of users.

- ❖ Unlike LP-gas self-service dispensing stations, CNG self-service dispensing systems can be open to the public. The owner of the system must provide for the training of any users of the system.

**2308.5 Pressure regulators.** Pressure regulators shall be designed and installed or protected so that their operation will not be affected by the elements (freezing rain, sleet, snow or ice), mud or debris. The protection is allowed to be an integral part of the regulator.

- ❖ The pressure regulator must be protected from the elements and is intended to prevent the overpressurization of the vehicle fuel tank and the delivery hose. Pressure regulator failure could result in dangerous overpressure and the opening of relief valves; therefore, they must be dependable. The regulator vent is susceptible to blockage by debris and ice.

**2308.6 Valves.** Gas piping to equipment shall be provided with a remote, readily accessible manual shutoff valve.

- ❖ Shutoff valves allow isolation of components for service, repair, replacement and emergency shutdown (see the definition of “Ready access” in the IFGC). This valve is independent of the emergency shutdown device required by Section 2308.7.

**2308.7 Emergency shutdown control.** An emergency shutdown control shall be located within 75 feet (22 860 mm) of, but not less than 25 feet (7620 mm) from, dispensers and shall also be provided in the compressor area. Upon activation, the emergency shutdown system shall automatically shut off the power supply to the compressor and close valves between the main gas supply and the compressor and between the storage containers and dispensers.

- ❖ CNG systems take natural gas from the utility supply line, compress it to very high pressures and store the compressed gas in vessels from which the dispensers draw the gas for transfer to the vehicle onboard containers. The emergency shutdown device must be located no farther than 75 feet (22 860 mm) from and no closer than 25 feet (7620 mm) to the dispensers. An additional shutdown device must be located near the compressors; the compressors may be remote from the dispensers. The shutdown device must disconnect the power to the compressors, must actuate automatic valves that isolate the gas supply from the compressors and isolate the storage vessels from the dispenser, thus limiting accidental gas discharge.

**2308.8 Discharge of CNG from motor vehicle fuel storage containers.** The discharge of CNG from motor vehicle fuel cylinders for the purposes of maintenance, cylinder certification, calibration of dispensers or other activities shall be in accordance with Sections 2308.8.1 through 2308.8.1.2.6.

- ❖ The equipment referred to in this section is the fixed equipment located at the CNG motor fuel-dispensing facility. Periodically, equipment must be maintained, certified and recalibrated. To do this, the CNG must be discharged from the system. This section regulates how the discharge must be done.

**2308.8.1 Methods of discharge.** The discharge of CNG from motor vehicle fuel cylinders shall be accomplished through a closed transfer system in accordance with Section 2308.8.1.1 or an *approved* method of atmospheric venting in accordance with Section 2308.8.1.2.

- ❖ The intentional discharge of gas from vehicle containers is done for several reasons, including vehicle repairs, certification of container integrity and container replacement. The gas must be discharged in a safe manner as dictated by either Section 2308.8.1.1 or 2308.8.1.2. The vehicle storage container is referred to as a “vessel” and as a “cylinder” in the text to follow.

**2308.8.1.1 Closed transfer system.** A documented procedure that explains the logical sequence for discharging the

cylinder shall be provided to the *fire code official* for review and approval. The procedure shall include what actions the operator will take in the event of a low-pressure or high-pressure natural gas release during the discharging activity. A drawing illustrating the arrangement of piping, regulators and equipment settings shall be provided to the *fire code official* for review and approval. The drawing shall illustrate the piping and regulator arrangement and shall be shown in spatial relation to the location of the compressor, storage vessels and emergency shutdown devices.

- ❖ A closed transfer system uses the same basic components as a dispensing system and withdraws the gas from the vehicle container, storing it in vessels. Drawings and a description of the sequence of operation of the transfer system must be provided to the *fire code official* for approval. This information may then be shared with the fire department for use in case of an emergency where CNG cylinders might need to be discharged.

**2308.8.1.2 Atmospheric venting.** Atmospheric venting of CNG shall comply with Sections 2308.8.1.2.1 through 2308.8.1.2.6.

- ❖ The six subsections that follow provide the conditions and requirements under which gas is allowed to be discharged to the atmosphere. Such discharge should be avoided wherever practical because: 1. There is an inherent hazard in doing so; 2. Methane is an air contaminant and 3. Natural resources should never be wasted. A closed transfer system is the preferable way to remove gas from vehicle containers.

**2308.8.1.2.1 Plans and specifications.** A drawing illustrating the location of the vessel support, piping, the method of grounding and bonding, and other requirements specified herein shall be provided to the *fire code official* for review and approval.

- ❖ Plans of the proposed atmospheric venting apparatus and piping system must be reviewed by the *fire code official* and approved before atmospheric venting can take place.

**2308.8.1.2.2 Cylinder stability.** A method of rigidly supporting the vessel during the venting of CNG shall be provided. The selected method shall provide not less than two points of support and shall prevent the horizontal and lateral movement of the vessel. The system shall be designed to prevent the movement of the vessel based on the highest gas-release velocity through valve orifices at the vessel’s rated pressure and volume. The structure or appurtenance shall be constructed of noncombustible materials.

- ❖ Vehicle CNG containers (vessels) can hold extremely high pressures, which, if released quickly, can produce large thrust forces that would propel the container like a rocket. Natural gas does not liquefy at normal ambient temperatures; therefore, in order to hold the required amount of fuel on board the vehicle, the gaseous fuel must be compressed to extreme pressures of up to 3,600 pounds per square inch absolute (psia) (24 736 kPa).

**2308.8.1.2.3 Separation.** The structure or appurtenance used for stabilizing the cylinder shall be separated from the site equipment, features and exposures and shall be located in accordance with Table 2308.8.1.2.3.

- ❖ This section is intended to separate the combustible vapor produced by venting from buildings, building openings, lot lines, public ways, vehicles, CNG compressor and storage vessels and CNG dispensers. This precaution is reasonable considering the potential hazard of working with highly pressurized containers of a flammable gas.

**TABLE 2308.8.1.2.3  
SEPARATION DISTANCE FOR ATMOSPHERIC VENTING OF CNG**

EQUIPMENT OR FEATURE	MINIMUM SEPARATION (feet)
Buildings	25
Building openings	25
CNG compressor and storage vessels	25
CNG dispensers	25
Lot lines	15
Public ways	15
Vehicles	25

For SI: 1 foot = 304.8 mm.

- ❖ The distances listed in Table 2308.8.1.2.3 are the distances between the equipment or feature and the termination of the vent opening where the gas is entering the atmosphere.

**2308.8.1.2.4 Grounding and bonding.** The structure or appurtenance used for supporting the cylinder shall be grounded in accordance with NFPA 70. The cylinder valve shall be bonded prior to the commencement of venting operations.

- ❖ “Grounding” means to intentionally connect to the earth. This could be accomplished by installing a conductor between the cylinder support and the building grounding electrode system. “Bonding” means to join metallic parts together to form a continuous electrical pathway. Grounding and bonding required by this section are intended to control sparking that could result from current flow produced by voltage differentials across parts of the venting set-up and the building components. Grounding the venting setup and attaching a bonding jumper to the cylinder valve will put all such components and the building components at the same voltage potential, thereby reducing the possibility of sparks that could ignite flammable vapors or harm the cylinder assembly. The provisions of this section will also help prevent the buildup of static electrical charges that could be a source of ignition.

**2308.8.1.2.5 Vent tube.** A vent tube that will divert the gas flow to atmosphere shall be installed on the cylinder prior to commencement of the venting and purging operation. The vent tube shall be constructed of pipe or tubing materials *approved* for use with CNG in accordance with Chapter 53.

The vent tube shall be capable of dispersing the gas not less than 10 feet (3048 mm) above grade level. The vent tube shall not be provided with a rain cap or other feature that would limit or obstruct the gas flow.

At the connection fitting of the vent tube and the CNG cylinder, a *listed* bidirectional *detonation* flame arrester shall be provided.

- ❖ The cylinder must be discharged through a vent tube/pipe constructed of a material compatible with the gas and that has the strength to withstand the pressure to which it will be exposed. The pressure that the vent will be exposed to must be calculated based on the size of the vent tube, the length of the vent, the friction loss through the vent and the maximum pressure and discharge rate of the cylinder. Vent failure could cause injury resulting from projectile debris and could cause a severe fire/explosion hazard. This section is intended to divert the vented vapor upward and away from any potential ignition source.

**2308.8.1.2.6 Signage.** *Approved* “No Smoking” signs complying with Section 310 shall be posted within 10 feet (3048 mm) of the cylinder support structure or appurtenance. *Approved* CYLINDER SHALL BE BONDED signs shall be posted on the cylinder support structure or appurtenance.

- ❖ The purpose of this section is to prevent ignition sources caused by smoking and stray currents. The provision requires two signs: a “No Smoking” sign and a sign reminding the operator that the cylinder must be bonded to divert stray electrical currents.

## SECTION 2309 HYDROGEN MOTOR

### FUEL-DISPENSING AND GENERATION FACILITIES

**2309.1 General.** Hydrogen motor fuel-dispensing and generation facilities shall be in accordance with this section and Chapter 58. Where a fuel-dispensing facility includes a repair garage, the repair operation shall comply with Section 2311.

- ❖ The federal government is mandating that automakers move toward alternative fuels to replace conventional gasoline and diesel. Hydrogen is one alternative fuel likely to grow in popularity.

The United States Department of Energy (DOE), in accordance with the Hydrogen Future Act of 1996, supports a program based on an industry-led cost-sharing approach called the Hydrogen Energy Program. In some markets, government agencies have mandated that automakers move ahead with production of alternative-fuel vehicles to help offset the atmospheric implications of an economy almost entirely driven by petroleum-based fuels, and facilitate a shift to renewable energy supplies. Hydrogen is one of those alternative fuels, and the commercial products industry is responding. As more vehicles use alternative fuels, codes will have to be modified

to address the safe use, dispensing, storage and generation of hydrogen fuels.

Section 2309, along with the provisions of Chapter 58, clearly defines gaseous hydrogen refueling and generating stations within the scope of the code and provides fire code officials with the necessary tools to create a safe consumer environment as the use of hydrogen as a motor fuel increases.

In many cases, the hydrogen fuel is utilized, with air, within a fuel cell to produce electricity and, in some cases, cogenerate heat. Typically, fire code officials will be faced with two classes of equipment—those that generate hydrogen (for use by other devices) and those that utilize hydrogen as their energy input.

Often, hydrogen will be utilized in a manner similar to the current use of natural gas, but two important differences that must be noted. First, while both hydrogen and natural gas are lighter than air, hydrogen is lighter, more diffusive and more buoyant than natural gas. This means that in well-ventilated situations (e.g., outdoors) hydrogen will dissipate more quickly than natural gas, and much more quickly than either propane or gasoline, both of which have fumes that are heavier than air and will linger at an accident scene or release site. However, hydrogen and natural gas can both accumulate in unventilated pockets at the top of indoor structures and could represent a risk in such situations. Similarly, propane and gasoline fumes can accumulate at the floor level in unventilated spaces, posing a different risk. Thus, ignition sources must be regulated at the top of any unventilated spaces for hydrogen and natural gas, while also being regulated near the floor for gasoline or propane vehicles indoors. Second, hydrogen is odorless, colorless and burns with a flame that is not visible to the human eye. This means it is unlikely, without appropriate instrumentation, that people will be able to detect unsafe conditions if they develop (similar to a carbon monoxide buildup in a structure).

It is important to note that a given volume of natural gas has more than three times the energy of the same volume of hydrogen. Therefore, a given volume of pipe containing natural gas will contain the same energy (potential hazard) as a three-times larger volume of hydrogen.

**2309.2 Equipment.** Equipment used for the generation, compression, storage or dispensing of hydrogen shall be designed for the specific application in accordance with Sections 2309.2.1 through 2309.2.3.

- ❖ All equipment used in connection with the storage and dispensing of hydrogen motor fuel must be either approved or listed, as specified in the following sections. The terms “approved” and “listed” are defined in Chapter 2. See the commentary to these defined terms for further information.

**2309.2.1 Approved equipment.** Cylinders, containers and tanks; pressure relief devices, including pressure valves; hydrogen vaporizers; pressure regulators; and piping used for gaseous hydrogen systems shall be designed and constructed in accordance with Chapters 53, 55 and 58.

❖ The equipment identified in this section must be approved by the fire code official. Listing of the specified components could be the basis for approval, but listing is not mandated. Any such components must be designed and recommended for the application by the manufacturer.

Design requirements for various types of storage vessels, pressure relief devices (including pressure valves), hydrogen vaporizers, pressure regulators and piping used for hydrogen, are directly dependent on the type, conditions of use and quantity of material involved. This section is intended to rely on design requirements for this equipment as referenced in Sections 5303 and 5503 and NFPA 55.

**2309.2.2 Listed or approved equipment.** Hoses, hose connections, compressors, hydrogen generators, dispensers, detection systems and electrical equipment used for hydrogen shall be *listed* or *approved* for use with hydrogen. Hydrogen motor-fueling connections shall be *listed* and *labeled* or *approved* for use with hydrogen.

❖ The specified components must be listed and labeled by an approved testing agency as complying with the relevant product standards or they must be approved by the fire code official. As with all listed products, the testing/listing agency will apply its seal or mark to the product. However, although piping, hoses, hose connections, compressors, hydrogen generators, dispensers, detection systems and electrical equipment used for hydrogen service should be built to recognized standards and be compatible with the material handled, this equipment may not always be listed or labeled and labeled given the evolving nature of hydrogen technologies. Accordingly, this section provides an alternative provision that the equipment be approved and provides the fire code official with a means to regulate hydrogen equipment installations. It is also consistent with Section 5003.2.3, which mandates that equipment and machinery associated with the use of hazardous materials be listed or approved.

ASME B31.3 or CGA G-5.4, which references ASME B31.3, may be appropriate for design and construction of the piping involved in hydrogen service and both are examples of common standards employed by industry for piping, tubing and associated distribution equipment involving hazardous materials. Though not specifically referenced here, there are other American Society of Mechanical Engineers (ASME) and industry standards providing further guidance that are considered appropriate for

many aspects of gaseous and liquefied hydrogen systems.

**2309.2.3 Electrical equipment.** Electrical installations shall be in accordance with NFPA 70.

❖ This section addresses electrical equipment at hydrogen motor fuel-dispensing facilities and is correlated with NFPA 70. Electrical equipment must be approved for the particular hazards anticipated at hydrogen motor fuel-dispensing facilities.

**2309.3 Location on property.** In addition to the requirements of Section 2303.1, dispensing equipment shall be located in accordance with Sections 2309.3.1 through Section 2309.3.2.

❖ In order to reduce the likelihood of hydrogen motor fuels coming into contact with ignition sources or posing a hazard to persons, adjoining property or on-site buildings, this section provides equipment location requirements in relation to outdoor equipment, canopies and overhead power lines.

**2309.3.1 Location of operations and equipment.** Generation, compression, storage and dispensing equipment shall be located in accordance with Sections 2309.3.1.1 through 2309.3.1.5.5.

❖ Because of the physical characteristics of hydrogen and the potential for leakage, generation, compression, storage and dispensing equipment must be located above ground outdoors or indoors under rigidly controlled equipment or separation requirements, all in accordance with Sections 2309.3.1.1 through 2309.3.1.5.5.

**2309.3.1.1 Outdoors.** Generation, compression, or storage equipment shall be allowed outdoors in accordance with Chapter 58 and NFPA 2.

❖ This section requires that hydrogen generation, compression and storage equipment installed outdoors be provided with the minimum separations prescribed by Chapter 58 and NFPA 2.

**2309.3.1.2 Indoors.** Generation, compression, storage and dispensing equipment shall be located in indoor rooms or areas constructed in accordance with the requirements of the *International Building Code*, the *International Fuel Gas Code*, the *International Mechanical Code* and NFPA 2.

❖ The overriding theme of the indoor location requirements for the generation, compression, storage or dispensing of hydrogen motor fuel is to never permit the maximum concentration of flammable contaminants in air to exceed 25 percent of the lower flammable limit (LFL) for hydrogen during the period that a credible leak exists. This can be accomplished using natural or mechanical means to maintain adequate ventilation to prevent a hazardous buildup of hydrogen gas in buildings or confined spaces.

**2309.3.1.2.1 Maintenance.** Gaseous hydrogen systems and detection devices shall be maintained in accordance with the manufacturer’s instructions.

- ❖ Key to the safety requirements for the generation, compression, storage or dispensing of hydrogen motor fuel is the ongoing maintenance of the systems and their safety devices. The best approach to proper maintenance is following the instructions and recommendations of the company that made the equipment, as required by this section.

**2309.3.1.2.2 Smoking.** Smoking shall be prohibited in hydrogen cutoff rooms. “No Smoking” signs shall be provided at all entrances to hydrogen fuel gas rooms.

- ❖ Establishing “No Smoking” zones in, around and at the entrance to hydrogen fuel gas rooms is another means of controlling a common ignition source. Section 5003.7.1, Item 4 requires signage within the room or area where flammable materials are stored, dispensed or used. Unless the entire facility is designated as a “No Smoking” facility, entrance doors to flammable gas areas are required to be posted (see Section 5003.7.1, Item 3).

There are a multitude of other instances where flammable gases are used where posting should be provided to warn users of the potential presence of hydrogen prior to entering a room or area in which they are present. Posting at the entrance to the room or area in which hydrogen is compressed or generated provides early warning of the hazard prior to entering the space. Signage on the outside entrances to such areas, as well as inside the area, is warranted. Signs should be in accordance with Section 310.

**2309.3.1.2.3 Ignition source control.** Open flames, flame-producing devices and other sources of ignition shall be controlled in accordance with Chapter 58.

- ❖ See the commentary to Section 5803.1.4.

**2309.3.1.2.4 Housekeeping.** Hydrogen fuel gas rooms shall be kept free from combustible debris and storage.

- ❖ Hydrogen fuel gas rooms are, by definition, “...intended exclusively to house a gaseous hydrogen system.” This section is key to maintaining that limitation by prohibiting unnecessary combustible fuel loads in the rooms.

**2309.3.1.3 Gaseous hydrogen storage.** Storage of gaseous hydrogen shall be in accordance with Chapters 53 and 58.

- ❖ Although Section 2309 includes substantial safeguards for the generation, compression, storage or dispensing of hydrogen motor fuel, gaseous hydrogen is also classified as a flammable gas requiring compliance with Chapter 58 and possesses compressed gas hazards requiring compliance with Chapter 53.

**2309.3.1.4 Liquefied hydrogen storage.** Storage of liquefied hydrogen shall be in accordance with Chapters 55 and 58.

- ❖ Although Section 2309 includes substantial safeguards for the generation, compression, storage or dispensing of hydrogen motor fuel, stored liquefied hydrogen is also classified as a flammable cryogenic fluid requiring compliance with Chapter 55, which in turn requires compliance with NFPA 55. Chapter 58 is referenced because it includes requirements for underground liquid hydrogen storage tanks.

**2309.3.1.5 Canopy tops.** Gaseous hydrogen compression and storage equipment located on top of motor fuel-dispensing facility canopies shall be in accordance with Sections 2309.3.1.5.1 through 2309.3.1.5.5, Chapters 53 and 58 and the *International Fuel Gas Code*.

- ❖ This section allows for the optional placement of hydrogen generation, compression and storage equipment on top of motor fuel-dispensing facility overhead canopies. Overhead placement enhances safety because the equipment remains removed from possible vehicular impact and ground-level ignition sources. This option has gained popularity, especially in more congested urban areas where real estate prices prohibit the purchase of sufficient property to meet the separation requirements of Section 2309.3.2.5.1 for new motor fuel-dispensing facilities. Similarly, existing motor fuel-dispensing facilities that might wish to expand their operations to include hydrogen are usually “land locked” and would benefit from using their existing canopy tops in the manner described in this section.

**2309.3.1.5.1 Construction.** Canopies shall be constructed in accordance with the motor fuel-dispensing facility canopy requirements of Section 406.7 of the *International Building Code*.

- ❖ IBC Section 406.7.2 regulates motor fuel-dispensing facility canopies and includes special requirements for canopies used to support hydrogen motor fuel equipment. See the commentary to that section for additional information.

**2309.3.1.5.2 Fire-extinguishing systems.** Fuel-dispensing areas under canopies shall be equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. The design of the sprinkler system shall be not less than that required for Extra Hazard Group 2 occupancies. Operation of the sprinkler system shall activate the emergency functions of Sections 2309.3.1.5.3 and 2309.3.1.5.4.

- ❖ This section requires the same scope of sprinkler protection for the area under canopies as is required for buildings with walls, i.e., “equipped throughout” as defined in NFPA 13 (referenced in Section 903.3.1.1) with an Extra Hazard Group 2 design. The automatic sprinkler system is to protect the canopy top-mounted hydrogen equipment from any fire scenario that could

develop in the fueling area below. In areas subject to freezing, the automatic sprinkler system must be protected from freezing in an approved manner consistent with NFPA 13. Note that because of the very specific requirement for an automatic sprinkler system in this section, the alternative automatic fire-extinguishing system provisions of Section 904 would not apply.

**2309.3.1.5.3 Emergency discharge.** Operation of the *automatic sprinkler system* shall activate an automatic emergency discharge system, which will discharge the hydrogen gas from the equipment on the canopy top through the vent pipe system.

❖ As part of protecting the hydrogen equipment mounted on top of the canopy from a fire developing below, this section requires that an approved emergency discharge system be provided to “dump” the hydrogen content of the system safely into the atmosphere in the event of water flow in the automatic sprinkler system.

**2309.3.1.5.4 Emergency shutdown control.** Operation of the *automatic sprinkler system* shall activate the emergency shutdown control required by Section 2309.5.3.

❖ Whereas Section 2309.3.2.6.2.1 requires a precautionary hydrogen “dump” from the canopy-mounted hydrogen equipment when the automatic sprinkler system operates, this section provides additional protection to the hydrogen equipment by requiring that the emergency shutoff required by Section 2309.5.3 be automatically activated upon water flow in the automatic sprinkler system. This would complement the automatic emergency discharge required by Section 2309.3.2.6.2.1 by automatically disconnecting the power supply to the hydrogen storage, compression and dispensing equipment, thus preventing the system from contributing any residual hydrogen to a fire or trying to replenish the hydrogen supply.

**2309.3.1.5.5 Signage.** *Approved* signage having 2-inch (51 mm) block letters shall be affixed at *approved* locations on the exterior of the canopy structure stating: CANOPY TOP HYDROGEN STORAGE.

❖ The signs required by this section provide a visual warning to the fire department or other first responders that the canopy includes the presence of hydrogen storage, compression and dispensing equipment. Sign locations must be decided on a case-by-case basis but at a minimum must be posted so as to be readily visible from all possible tactical approaches used by the fire department. Based on site configuration and conditions, multiple signs could be required.

**2309.3.2 Canopies.** Dispensing equipment need not be separated from canopies of Type I or II construction that are constructed in a manner that prevents the accumulation of

hydrogen gas and in accordance with Section 406.7 of the *International Building Code*.

❖ IBC Section 406.7.2 has specific construction requirements for canopies located at motor fuel-dispensing facilities. This section removes any separation requirements between the dispenser area and the canopy when the canopy is constructed in accordance to the special provision for canopies located at motor fuel-dispensing facilities. Note that this section places a condition on the application of IBC canopy construction requirements (i.e., that the canopy be sufficiently open to preclude the accumulation of hydrogen in its construction).

**2309.4 Dispensing into motor vehicles at self-service hydrogen motor fuel-dispensing facilities.** Self-service hydrogen motor fuel-dispensing systems, including key, code and card lock dispensing systems, shall be limited to the filling of permanently mounted fuel containers on hydrogen-powered vehicles.

In addition to the requirements in Section 2311, the *owner* of a self-service hydrogen motor fuel-dispensing facility shall provide for the safe operation of the system through the institution of a fire safety plan submitted in accordance with Section 404, the training of employees and operators who use and maintain the system in accordance with Section 406, and provisions for hazard communication in accordance with Section 407.

❖ This section provides regulations for the dispensing of gaseous hydrogen. The dispensing facility owner must demonstrate minimum competency and control of the dispensing of hydrogen, including training and supervision for the employees and operators who use and maintain the system.

**2309.4.1 Dispensing systems.** Dispensing systems shall be equipped with an overpressure protection device set at not greater than 140 percent of the service pressure of the fueling nozzle it supplies.

❖ This section provides the overpressure protection of the vehicle fuel system by the fuel-dispensing system. The Canadian Standards Association (CSA) publishes a hydrogen dispensing standard, CSA-HGV 4.1. These provisions were written prior to this standard being published. Nearly all of the hydrogen fuel cell vehicles that are currently deployed or will be deployed in the near future rely on the fuel dispenser for overpressure protection. Similar language appears in NFPA 52 and in some state hydrogen storage and dispensing rules.

**2309.5 Safety precautions.** Safety precautions at hydrogen motor fuel-dispensing and generation facilities shall be in accordance with Sections 2309.5.1 through 2309.5.3.1.

❖ This section establishes a minimum level of safety for hydrogen motor fuel generation and dispensing.

**2309.5.1 Protection from vehicles.** Guard posts or other *approved* means shall be provided to protect hydrogen storage systems and use areas subject to vehicular damage in accordance with Section 312.

❖ This provision seeks to prevent hydrogen leaks or catastrophic releases caused by vehicle impact. The provision recognizes that vehicle damage can be reduced by placing 4-inch (102 mm) steel posts filled with concrete and spaced on 4-foot (1219 mm) centers, among other requirements of Section 312, around the hydrogen storage system.

**2309.5.1.1 Vehicle fueling pad.** The vehicle shall be fueled on noncoated concrete or other *approved* paving material having a resistance not exceeding 1 megohm as determined by the methodology specified in EN 1081.

❖ This section provides a requirement that addresses the potential for stray currents that can ignite hydrogen when it is used as a motor vehicle fuel. The same requirement is also found in IBC Section 406.7.1. Motor vehicles can acquire an electrostatic charge while traveling. The resistance offered by the tires through an uncoated concrete surface is low enough that this charge dissipates to ground very quickly (seconds or less). However, under dry conditions, an asphalt surface may offer sufficient resistance that the charge will not dissipate in a timely manner. A small number of incidents have occurred in Europe where a nonabsorbent polymer, having unusually high resistance, was used at motor fuel-dispensing facilities to prevent soil contamination from gasoline spills. Therefore, paved surfaces that result in a resistance greater than 1 megohm should not be used.

Fueling surfaces for hydrogen-powered vehicles should be at least as protective regarding electrostatic discharge (ESD) issues as those fueling surfaces used for petroleum-powered vehicles. This section provides precautions to dissipate static electricity built up on the vehicle from driving before the driver's door is opened upon arrival at the fueling facility to initiate refueling. Plain concrete is allowed for construction of the fueling pad with no resistance measurements needed; however, an alternative material can be used as long as it has a measured resistance less than or equal to 1 megohm. Both the concrete and 1 megohm criteria are cited from the American Petroleum Institute (API) RP 2003. NFPA 77 also points out that a resistance of 1 megohm or less is considered adequate to dissipate any charges. The 1 megohm requirement is also found in Section 5706.5.1.7 as a maximum electrical resistance requirement for loading racks transferring liquid petroleum products into cargo tank vehicles. That requirement has been consistently shown to be a reliable value and design basis for ensuring stray currents are sent to ground.

The referenced standard, EN 1081 is the available standard applicable to measuring the resistance of vehicle fueling pads. It establishes the testing criteria for surface coverings that may be used if the fueling

surface is not concrete or is a coated concrete. Tests are performed in the laboratory and again in the field upon installation of the vehicle fueling pad to demonstrate if the installed material has an electrical resistance of less than 1 megohm. For vehicle fueling pads with an area less than 107 square feet (9.9 m<sup>2</sup>), EN 1081 requires at least three tests. For vehicle fueling pads with a larger area, the standard specifies the number of tests shall be established by the owner and the individual or company contractually obligated to perform the tests.

**2309.5.2 Emergency shutoff valves.** A manual emergency shutoff valve shall be provided to shut down the flow of gas from the hydrogen supply to the piping system.

❖ To prevent spillage and to allow servicing of equipment, a remote accessible manual shutoff valve must be installed. This valve is independent of the emergency shutdown equipment required in Section 2309.5.3.

**2309.5.2.1 Identification.** Manual emergency shutoff valves shall be identified and the location shall be clearly visible, accessible and indicated by means of a sign.

❖ In order to be effective, the manual emergency shutoff valve must be clearly and prominently identified by a sign that will achieve those goals in all types of weather. Section 5003.6 provides some guidance on signage that could be used as a basis for the design of the required sign.

**2309.5.3 Emergency shutdown controls.** In addition to the manual emergency shutoff valve required by Section 2309.5.2, a remotely located, manually activated emergency shutdown control shall be provided. An emergency shutdown control shall be located within 75 feet (22 860 mm) of, but not less than 25 feet (7620 mm) from, dispensers and hydrogen generators.

❖ Two emergency shutdown devices must be installed, one in the compressor area in accordance with Section 2309.5.2 and the other no closer than 25 feet (7620 mm) or farther than 75 feet (22 860 mm) from the dispenser. These distances are such that the emergency shutdown control is, at its furthest, no further from the hydrogen dispensers or generators than a portable fire extinguisher would be but not close enough to put personnel at risk of injury in the event of an emergency.

**2309.5.3.1 System requirements.** Activation of the emergency shutdown control shall automatically shut off the power supply to all hydrogen storage, compression and dispensing equipment; shut off natural gas or other fuel supply to the hydrogen generator; and close valves between the main supply and the compressor and between the storage containers and dispensing equipment.

❖ Emergency shutdown controls must shut down the power supply to the hydrogen storage, compression and dispensing equipment and close the valves leading to and from the compressor and between the storage containers and dispensers in the event of an

emergency. Activation of any one emergency shutdown device would activate total shutdown of all generation and dispensing operations on site.

**2309.6 Defueling of hydrogen from fuel storage containers.** The discharge or defueling of hydrogen from fuel storage tanks for the purpose of maintenance, cylinder certification, calibration of dispensers or other activities shall be in accordance with Sections 2309.6.1 through 2309.6.1.2.4.

❖ Because of the emerging use of alternative fuels and the differences in their properties, repair garages must be designed for the anticipated vehicles and the materials fueling them. Section 2311 includes the provisions for many different fuels, including lighter-than-air fuels. Accordingly, if a repair garage makes hydrogen, which is a lighter-than-air fuel, available for dispensing to motor vehicles, the repair garage must also meet the applicable requirements and hazard-mitigation criteria for servicing hydrogen-fueled vehicles. These requirements were formerly located in Section 2311.8 and were applicable only to motor vehicle fuel storage containers. The benefit of relocating these requirements and modifying the language to apply to “fuel storage,” instead of “motor vehicle fuel storage” is that the ability to defuel hydrogen is needed when repair and servicing of the fixed hydrogen fuel compression, storage and dispensing equipment located at these facilities becomes necessary.

**2309.6.1 Methods of discharge.** The discharge of hydrogen from fuel storage tanks shall be accomplished through a closed transfer system in accordance with Section 2309.6.1.1 or an *approved* method of atmospheric venting in accordance with Section 2309.6.1.2.

❖ The intentional discharge of gas from vehicle containers is done for several reasons, including vehicle repairs, certification of the container integrity and container replacement. The gas must be discharged in a safe manner as dictated by either Section 2311.8.1.1 or 2311.8.1.2. The vehicle storage container is referred to as a “vessel” and as a “cylinder” in the text to follow.

**2309.6.1.1 Closed transfer system.** A documented procedure that explains the logic sequence for discharging the storage tank shall be provided to the *fire code official* for review and approval. The procedure shall include what actions the operator is required to take in the event of a low-pressure or high-pressure hydrogen release during discharging activity. Schematic design documents shall be provided illustrating the arrangement of piping, regulators and equipment settings. The *construction documents* shall illustrate the piping and regulator arrangement and shall be shown in spatial relation to the location of the compressor, storage vessels and emergency shutdown devices.

❖ A closed transfer system uses the same basic components as a dispensing system and withdraws the gas from the vehicle container and stores it in vessels. Drawings and a description of the sequence of operation of the transfer system must be provided to

the fire code official for approval. This information may then be shared with the fire department for use in case of an emergency where hydrogen cylinders might need to be discharged.

**2309.6.1.2 Atmospheric venting of hydrogen from fuel storage containers.** Where atmospheric venting is used for the discharge of hydrogen from fuel storage tanks, such venting shall be in accordance with Sections 2309.6.1.2.1 through 2309.6.1.2.1.4.

❖ The subsections that follow provide the conditions and requirements under which hydrogen is allowed to be discharged to the atmosphere. Such discharge should be avoided wherever practical because there is an inherent hazard in doing so and because resources should never be wasted. A closed transfer system is the preferable way to remove hydrogen from vehicle containers.

**2309.6.1.2.1 Defueling equipment.** Equipment used for defueling shall be listed and labeled or *approved* for the intended use.

❖ The hazards of hydrogen are such that using “jerry-rigged” tools and equipment could have disastrous results. As a further precaution, all defueling equipment must be both listed and labeled for that purpose.

**2309.6.1.2.1.1 Manufacturer’s equipment required.** Equipment supplied by the manufacturer shall be used to connect the storage tanks to be defueled to the vent pipe system.

❖ Since the manufacturer provides the necessary equipment and fittings to mate tanks and containers to the vent system, only that equipment is to be used. The use of incompatible equipment could result in an unexpected gas discharge and possible ignition.

**2309.6.1.2.1.2 Vent pipe maximum diameter.** Defueling vent pipes shall have a maximum inside diameter of 1 inch (25 mm).

❖ When discharging hydrogen to the atmosphere, it is important that the size of the vent pipe be such that it will provide sufficient discharge velocity to disperse the hydrogen in the air.

**2309.6.1.2.1.3 Maximum flow rate.** The maximum rate of hydrogen flow through the vent pipe system shall not exceed 1,000 cfm at NTP (0.47 m<sup>3</sup>/s) and shall be controlled by means of the manufacturer’s equipment, at low pressure and without adjustment.

❖ When gas flows through piping, friction with the pipe wall generates heat. Limiting the flow rate limits the amount of heat generated by the flow of gas.

**2309.6.1.2.1.4 Isolated use.** The vent pipe used for defueling shall not be connected to another venting system used for any other purpose.

❖ To avoid contamination or the reaction of potentially incompatible materials, this section requires that the defueling vent pipe be dedicated to hydrogen-only use.

**2309.6.1.2.2 Construction documents.** *Construction documents* shall be provided illustrating the defueling system to be utilized. Plan details shall be of sufficient detail and clarity to allow for evaluation of the piping and control systems to be utilized and include the method of support for cylinders, containers or tanks to be used as part of a closed transfer system, the method of grounding and bonding and other requirements specified herein.

- ❖ Construction documents, as defined in Section 202, must be drawn to scale with sufficient clarity to be understood by the fire code official, contractors and owners and must address the requirements of the code. State or local laws may require preparation of the construction documents by a registered design professional (see the commentary to IBC Section 106.1 for further information).

**2309.6.1.2.3 Stability of cylinders, containers and tanks.** A method of rigidly supporting cylinders, containers or tanks used during the closed transfer system discharge or defueling of hydrogen shall be provided. The method shall provide not less than two points of support and shall be designed to resist lateral movement of the receiving cylinder, container or tank. The system shall be designed to resist movement of the receiver based on the highest gas-release velocity through valve orifices at the receiver's rated service pressure and volume. Supporting structures or appurtenances used to support receivers shall be constructed of noncombustible materials in accordance with the *International Building Code*.

- ❖ Vehicle hydrogen fuel containers can hold extremely high pressures, which, if released quickly, can produce large thrust forces that would propel the container like a rocket. Hydrogen does not liquefy at normal ambient temperatures; therefore, in order to hold the required amount of fuel on board the vehicle, the gaseous fuel must be compressed to extreme pressures of 3,000 to 5,000 psia (20 613 to 34 355 kPa).

**2309.6.1.2.4 Grounding and bonding.** Cylinders, containers or tanks and piping systems used for defueling shall be bonded and grounded. Structures or appurtenances used for supporting the cylinders, containers or tanks shall be grounded in accordance with NFPA 70. The valve of the vehicle storage tank shall be bonded with the defueling system prior to the commencement of discharge or defueling operations.

- ❖ "Grounding" means to intentionally connect to the earth. This could be accomplished by installing a conductor between the cylinder support and the building grounding electrode system. Bonding means to join metallic parts together to form a continuous electrical pathway. Grounding and bonding required by this section are intended to control sparking that could result from current flow produced by voltage differentials across parts of the venting setup and the building components. Grounding the venting setup and attaching a bonding jumper to the cylinder valve will

put all such components and the building components at the same voltage potential, thereby reducing the possibility of sparks that could ignite flammable vapors or harm the cylinder assembly. The provisions of this section will also help prevent the buildup of static electrical charges that could be a source of ignition.

**2309.6.2 Repair of hydrogen piping.** Piping systems containing hydrogen shall not be opened to the atmosphere for repair without first purging the piping with an inert gas to achieve 1-percent hydrogen or less by volume. Defueling operations and exiting purge flow shall be vented in accordance with Section 2309.6.1.2.

- ❖ To prevent the release of flammable hydrogen gas to the atmosphere and to prevent an explosive hydrogen-air mixture (above 1-percent hydrogen based on the pipe volume) within system piping, this section requires that piping be purged with an inert gas before being disconnected and repaired.

**2309.6.3 Purging.** Each individual manufactured component of a hydrogen generating, compression, storage or dispensing system shall have a label affixed as well as a description in the installation and owner's manuals describing the procedure for purging air from the system during startup, regular maintenance and for purging hydrogen from the system prior to disassembly (to admit air).

For the interconnecting piping between the individual manufactured components, the pressure rating must be not less than 20 times the absolute pressure present in the piping when any hydrogen meets any air.

- ❖ This section places the burden of the purging requirement on the equipment manufacturer. Commensurately, these requirements can be verified by the fire code official before, during and after installation. Requirements for rating the interconnecting piping at 20 times the initial pressure reduces the likelihood that a detonation will rupture the vent piping.

**2309.6.3.1 System purge required.** After installation, repair or maintenance, the hydrogen piping system shall be purged of air in accordance with the manufacturer's procedure for purging air from the system.

- ❖ Reliable purging procedures are essential to the safe use of hydrogen gas systems. This section requires that the system manufacturer's purge method be used. Such methods could include any of several methodologies in common use in the industry, as outlined in ASME B31.3 (see commentary, IFGC Section 705.3). The continuous flow method uses a continuous flow of the inert purge gas to remove the hydrogen gas and prevent air or moisture from entering the system. The dilution method uses a sequence of pressurization and venting. This sequence is repeated several times and is very effective in removing gas from dead-end piping, such as pressure gauge lines.

## SECTION 2310 MARINE MOTOR FUEL-DISPENSING FACILITIES

**2310.1 General.** The construction of marine motor fuel-dispensing facilities shall be in accordance with the *International Building Code* and NFPA 30A. The storage of Class I, II or IIIA liquids at marine motor fuel-dispensing facilities shall be in accordance with this chapter and Chapter 57.

- ❖ This section contains code provisions for marine fuel-dispensing facilities that use automotive-type dispensing equipment. This section does not address bulk fuel transfer facilities that use flange-to-flange connections between the shore and the marine vessel.

**2310.2 Storage and handling.** The storage and handling of Class I, II or IIIA liquids at marine motor fuel-dispensing facilities shall be in accordance with Sections 2310.2.1 through 2310.2.3.

- ❖ This section introduces provisions for the storage and handling of Class I, II and IIIA flammable and combustible liquids at marine motor fuel-dispensing facilities. Class IIIB combustible liquids do not have specific regulations in the sections that follow because of their relatively low hazard due to their higher flash points.

**2310.2.1 Class I, II or IIIA liquid storage.** Class I, II or IIIA liquids stored inside of buildings used for marine motor fuel-dispensing facilities shall be stored in *approved* containers or portable tanks. Storage of Class I liquids shall not exceed 10 gallons (38 L).

**Exception:** Storage in liquid storage rooms in accordance with Section 5704.3.7.

- ❖ This section addresses the storage of flammable and combustible liquids inside marine motor fuel-dispensing facility buildings. The provision limits the storage of Class I liquids (e.g., gasoline) to 10 gallons (38 L), unless the building has a flammable and combustible liquid storage room constructed in accordance with the code.

**2310.2.2 Class II or IIIA liquid storage and dispensing.** Class II or IIIA liquids stored or dispensed inside of buildings used for marine motor fuel-dispensing facilities shall be stored in and dispensed from *approved* containers or portable tanks. Storage of Class II and IIIA liquids shall not exceed 120 gallons (454 L).

- ❖ The storage and dispensing inside of marine motor fuel-dispensing facility buildings of Class II (e.g., diesel or kerosene) or IIIA liquids is limited to 120 gallons (454 L) in aggregate. Lubricating oils and gear lubricants (Class III B) are not limited by this provision.

**2310.2.3 Heating equipment.** Heating equipment installed in Class I, II or IIIA liquid storage or dispensing areas shall comply with Section 2301.6.

- ❖ When flammable and combustible liquids are stored or dispensed inside of marine motor fuel-dispensing facility buildings, heating equipment must comply with

Section 2301.6, which references NFPA 30A, the IFGC and the IMC.

**2310.3 Dispensing.** The dispensing of liquid fuels at marine motor fuel-dispensing facilities shall comply with Sections 2310.3.1 through 2310.3.5.

- ❖ The dispensing of fuel at a marine service station requires special consideration because of the location of the dispensing equipment on piers and floating docks, and the movement of the pier or dock in relationship to the shore. Dispensing of fuel at marinas generally requires longer dispensing hoses and greater quantities of fuel.

**2310.3.1 General.** Wharves, piers or floats at marine motor fuel-dispensing facilities shall be used exclusively for the dispensing or transfer of petroleum products to or from marine craft, except that transfer of essential ship stores is allowed.

- ❖ This section restricts the use of the area adjacent to the fuel-dispensing area to the exclusive use of transferring fuel, with the exception of transferring essential ships' stores. This provision is not intended to restrict the berthing and other uses on the pier or floating structure away from the fuel-transferring docking area. Fuel-dispensing hoses must not be stretched over one vessel to reach another; that is, one vessel cannot be docked parallel and alongside another vessel while taking on fuel.

**2310.3.2 Supervision.** Marine motor fuel-dispensing facilities shall have an attendant or supervisor who is fully aware of the operation, mechanics and hazards inherent to fueling of boats on duty whenever the facility is open for business. The attendant's primary function shall be to supervise, observe and control the dispensing of Class I, II or IIIA liquids or flammable gases.

- ❖ Because of the uniqueness of dispensing fuel at marinas and the inherent dangers, the dispensing must be supervised by a trained attendant or supervisor who knows how to control fuel spills, eliminate possible ignition sources, operate emergency shutoff equipment and notify emergency responders.

**2310.3.3 Hoses and nozzles.** Dispensing of Class I, II or IIIA liquids into the fuel tanks of marine craft shall be by means of an *approved*-type hose equipped with a *listed* automatic-closing nozzle without a latch-open device.

Hoses used for dispensing or transferring Class I, II or IIIA liquids, when not in use, shall be reeled, racked or otherwise protected from mechanical damage.

- ❖ The automatic-closing-type nozzle is designed to operate with automotive-type fuel receivers. Many marine craft are not equipped with automotive-type fuel receivers with the vent line terminating in the receiver tube. It is the fuel returning in the vent line that shuts off the automatic-type nozzle. Therefore, the latch-open device must not be used on marine craft.

Hoses at marinas are not restricted to an 18-foot-maximum (5486 mm) length as are those at automotive motor fuel-dispensing facilities. Therefore, the

longer hoses are more susceptible to damage and must be properly protected by being placed on a rack or rolled on a reel. It is also wise to mark the nozzle to identify it with a certain dispenser. Because of the length of hose, the operator may attempt to use the wrong nozzle when multiple dispensers are on the pier.

**2310.3.4 Portable containers.** Dispensing of Class I, II or IIIA liquids into containers, other than fuel tanks, shall be in accordance with Section 2304.4.1.

❖ See the commentary to Section 2304.4.1.

**2310.3.5 Liquefied petroleum gas.** Liquefied petroleum gas cylinders shall not be filled at marine motor fuel-dispensing facilities unless *approved*. *Approved* storage facilities for LP-gas cylinders shall be provided. See also Section 2307.

❖ Many marine vessels use LP-gas for heating and cooking. LP-gas cylinders may not be refilled at a marina, unless specifically approved by the fire code official. Section 2307 has requirements for dispensing LP-gas at motor fuel-dispensing facilities, and this section can be used by the fire code official in making the decision on whether to approve the dispensing of LP-gas at marinas.

**2310.4 Fueling of marine vehicles at other than approved marine motor fuel-dispensing facilities.** Fueling of floating marine craft at other than a marine motor fuel-dispensing facility shall comply with Sections 2310.4.1 and 2310.4.2.

❖ This section introduces the requirements for dispensing motor fuels into marine vehicles at locations other than approved marine motor fuel-dispensing facilities.

**2310.4.1 Class I liquid fuels.** Fueling of floating marine craft with Class I fuels at other than a marine motor fuel-dispensing facility is prohibited.

❖ The dispensing of fuel into floating marine craft at locations other than approved marine motor fuel-dispensing facilities is limited to Class II and III liquids (e.g., diesel fuel) in accordance with Section 2310.4.2. Because of the inherent dangers of Class I liquid fuels (very low flash point, high vapor pressure, low specific gravity, etc.), gasoline must be dispensed only at approved marine motor fuel-dispensing facilities complying with this chapter.

**2310.4.2 Class II or III liquid fuels.** Fueling of floating marine craft with Class II or III fuels at other than a marine motor fuel-dispensing facility shall be in accordance with all of the following:

1. The premises and operations shall be *approved* by the *fire code official*.
2. Tank vehicles and fueling operations shall comply with Section 5706.6.
3. The dispensing nozzle shall be of the *listed* automatic-closing type without a latch-open device.
4. Nighttime deliveries shall only be made in lighted areas.

5. The tank vehicle flasher lights shall be in operation while dispensing.

6. Fuel expansion space shall be left in each fuel tank to prevent overflow in the event of temperature increase.

❖ Because of their lesser hazard characteristics, Class II and III liquid marine vehicle motor fuels are allowed to be dispensed at other than a marine motor fuel-dispensing facility but must be dispensed in accordance with all of the six special provisions, which provide a level of safety in keeping with that required for a marine motor fuel-dispensing facility.

**2310.5 Fire prevention regulations.** General fire safety regulations for marine motor fuel-dispensing facilities shall comply with Sections 2310.5.1 through 2310.5.7.

❖ This section contains special provisions regarding fire safety at marinas.

**2310.5.1 Housekeeping.** Marine motor fuel-dispensing facilities shall be maintained in a neat and orderly manner. Accumulations of rubbish or waste oils in excessive amounts shall be prohibited.

❖ This provision limits fuel sources that may readily ignite if subjected to an ignition source or may spontaneously combust.

**2310.5.2 Spills.** Spills of Class I, II or IIIA liquids at or on the water shall be reported immediately to the fire department and jurisdictional authorities.

❖ The key point in this requirement is to immediately report spills. Petroleum products have a lower specific gravity than water; thus, they will float on the surface of the water and a small amount of fuel can be spread over a large area of water.

**2310.5.3 Rubbish containers.** Containers with tight-fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material. The rubbish containers shall be constructed entirely of materials that comply with any one of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m<sup>2</sup> when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m<sup>2</sup> in the horizontal orientation.

❖ Rubbish containers can be constructed of metal or other noncombustible materials, including materials that have been shown to be safe by meeting a very severe fire test, like those required by Section 808 for Group I-1, I-2 and I-3 occupancies. Note that the requirement covers all types of rubbish and is not intended to address spills of combustible or flammable liquids (or Class I, II or IIIA liquids) covered by Section 2310.5.2. The best fire extinguisher for a fire in a sturdy trash can is the lid. A tight-fitting lid will extinguish the fire by starving the fire of oxygen. Furthermore, if the lid is in place, the combustibles are not likely to ignite in the first place.

**2310.5.4 Marine vessels and craft.** Vessels or craft shall not be made fast to fuel docks serving other vessels or craft occupying a berth at a marine motor fuel-dispensing facility.

❖ The intent of this provision is to prevent two or more vessels from mooring alongside each other at a fuel dock. If an accident happens at a marine fuel-dispensing facility, the vessels should be able to cast off their docking lines and get underway without having to untie another vessel. Also, the fuel-dispensing hose should never cross one vessel to get to another.

**2310.5.5 Sources of ignition.** Construction, maintenance, repair and reconditioning work involving the use of open flames, arcs or spark-producing devices shall not be performed at marine motor fuel-dispensing facilities or within 50 feet (15 240 mm) of the dispensing facilities, including piers, wharves or floats, except for emergency repair work *approved* in writing by the *fire code official*. Fueling shall not be conducted at the pier, wharf or float during the course of such emergency repairs.

❖ The intent of this requirement is to control possible ignition sources within 50 feet (15 240 mm) of the fuel-dispensing area. In order to control the common ignition hazard of smoking, all hot work within 50 feet (15 240 mm) of a fuel-dispensing area requires a permit from the fire code official in writing and the fuel-dispensing operation must be placed out of service.

**2310.5.5.1 Smoking.** Smoking or open flames shall be prohibited within 50 feet (15 240 mm) of fueling operations. “No Smoking” signs complying with Section 310 shall be posted conspicuously about the premises. Such signs shall have letters not less than 4 inches (102 mm) in height on a background of contrasting color.

❖ “No Smoking” signs must be conspicuously placed around the fuel-dispensing area.

**2310.5.6 Preparation of tanks for fueling.** Boat *owners* and operators shall not offer their craft for fueling unless the tanks being filled are properly vented to dissipate fumes to the outside atmosphere.

❖ Most liquid fuel vapors are heavier than air. Therefore, the vapors, if not properly vented to the atmosphere, will accumulate in the vessel’s bilges, causing a very dangerous explosion hazard.

**2310.5.7 Warning signs.** Warning signs shall be prominently displayed at the face of each wharf, pier or float at such elevation as to be clearly visible from the decks of marine craft being fueled. Such signs shall have letters not less than 3 inches (76 mm) in height on a background of contrasting color bearing the following or *approved* equivalent wording:

WARNING

NO SMOKING—STOP ENGINE WHILE FUELING,  
SHUT OFF ELECTRICITY

DO NOT START ENGINE UNTIL AFTER BELOW  
DECK SPACES ARE VENTILATED.

❖ One of the greatest dangers in dispensing fuel into marine craft is the accumulation of explosive vapors

in the vessel’s bilges and below-deck spaces. The intent here is to warn the vessel operators to control ignition sources until the bilges and below-deck spaces have been cleared of explosive vapors.

**2310.6 Fire protection.** Fire protection features for marine motor fuel-dispensing facilities shall comply with Sections 2310.6.1 through 2310.6.4.

❖ This section addresses the requirements for fire protection at marine fuel-dispensing facilities.

**2310.6.1 Standpipe hose stations.** Fire hose, where provided, shall be enclosed within a cabinet, and hose stations shall be labeled: FIRE HOSE—EMERGENCY USE ONLY.

❖ Section 2310.1 states that the construction requirements for marine motor fuel-dispensing facilities will be found in the IBC and NFPA 30A. NFPA 30A states that marine fuel-dispensing facilities that are located on piers that extend more than a 500-foot (152 400 mm) travel distance from shore are required to have a Class III standpipe installed in accordance with NFPA 14.

**2310.6.2 Obstruction of fire protection equipment.** Materials shall not be placed on a pier in such a manner as to obstruct access to fire-fighting equipment or piping system control valves.

❖ The intent of this section is to make all fire protection equipment, including means for turning off fuel supply lines in an emergency, readily accessible in an emergency.

**2310.6.3 Access.** Where the pier is accessible to vehicular traffic, an unobstructed roadway to the shore end of the wharf shall be maintained for access by fire apparatus.

❖ See Chapter 5 and Appendix D for guidance on fire apparatus access roads.

**2310.6.4 Portable fire extinguishers.** Portable fire extinguishers in accordance with Section 906, each having a minimum rating of 20-B:C, shall be provided as follows:

1. One on each float.
2. One on the pier or wharf within 25 feet (7620 mm) of the head of the gangway to the float, unless the office is within 25 feet (7620 mm) of the gangway or is on the float and an extinguisher is provided thereon.

❖ Section 906 lists the requirements for where and how to mount the portable fire extinguishers. They should be conspicuous and unobstructed.

## SECTION 2311 REPAIR GARAGES

**2311.1 General.** Repair garages shall comply with this section and the *International Building Code*. Repair garages for vehicles that use more than one type of fuel shall comply with the applicable provisions of this section for each type of fuel used.

Where a repair garage includes a motor fuel-dispensing facility, the fuel-dispensing operation shall comply with the

requirements of this chapter for motor fuel-dispensing facilities.

- ❖ Because of the popularity of alternative fuels and the differences in their properties, repair garages must be designed for the anticipated vehicles and the fuels contained in them. This section includes the provisions for many of the different fuels.

If the repair garage dispenses fuel into vehicles, the repair garage must also meet the requirements for a motor fuel-dispensing facility based on the fuels available.

**2311.2 Storage and use of flammable and combustible liquids.** The storage and use of flammable and *combustible liquids* in repair garages shall comply with Chapter 57 and Sections 2311.2.1 through 2311.2.4.

- ❖ For obvious reasons, the storage of flammable and combustible liquids is always a concern, especially inside buildings. Chapter 57 lists the provisions for the storage and quantity limitations on flammable and combustible liquids. This section addresses specific uses associated with repair garages.

**2311.2.1 Cleaning of parts.** Cleaning of parts shall be conducted in *listed* and *approved* parts-cleaning machines in accordance with Chapter 57.

- ❖ Section 5705.3.6 refers to the cleaning operation, the equipment and the quantity limits associated with parts cleaning. Caution must be used when cleaning automotive parts because they may contain Class I liquids that may contaminate the cleaning solvents.

**2311.2.2 Waste oil, motor oil and other Class IIIB liquids.** Waste oil, motor oil and other Class IIIB liquids shall be stored in *approved* tanks or containers, which are allowed to be stored and dispensed from inside repair garages.

- ❖ In addition to waste oil and virgin motor oil, other Class IIIB liquids typically found in repair garages include antifreeze, lubricating oils and greases, power steering fluid, brake fluid, transmission fluid and certain formulations of windshield washer fluid.

Storage tanks for Class IIIB liquids inside buildings must be approved above-ground tanks as required by Section 5704.2, Item 2, and Section 5704.2.7 (e.g., meeting the requirements of UL 142, UL 2080 or UL 2085 as listed in Section 4.2.3.1.1 of NFPA 30). Containers for Class IIIB liquids inside buildings must also be of an approved type as required by Section 5704.3.1 of the code and Section 6.2.1 of NFPA 30.

**2311.2.2.1 Tank location.** Tanks storing Class IIIB liquids in repair garages are allowed to be located at, below or above grade, provided that adequate drainage or containment is provided.

- ❖ The intent of this section is to allow storage of Class IIIB liquids inside when spill protection is provided, as determined by the fire code official. Though the section is not specifically referenced, guidance on this topic may be found in the commentary to Section 5004.2.

**2311.2.2.2 Liquid classification.** Crankcase drainings shall be classified as Class IIIB liquids unless otherwise determined by testing.

- ❖ The declaration of crankcase drainings (waste oil) as being a Class IIIB liquid originated in the 1990 edition of NFPA 30A and resulted from a testing project sponsored by one of the major “quick lube” chains wherein almost 300 waste oil samples from across the nation were actually tested to determine their flash point. The results of the testing indicated that the average flash point determined by the tests was 343°F (173°C), with the lowest flash point result being 296°F (147°C), thus placing all the samples in the Class IIIB liquid category. Based on similar testing results on virgin motor oil conducted in 1976 by the U.S. DOE, it can be concluded that waste motor oil is no more hazardous than fresh motor oil. The waste oil testing project dispelled an old concern that the flash point of used motor oil could be much lower than Class IIIB due to the unknown impact of the variety of impurities that it can contain. See the commentary to Section 5701.5 for a discussion of how the mixing of liquids is regulated.

This section also provides for investigative testing of waste oil if it is suspected that volatile foreign substances, such as raw gasoline, may have been put into a waste oil tank or container in such quantities as to dangerously lower the liquid’s flash point. Some repair garages, in a well-meaning effort to prevent improper disposal of waste gasoline by homeowners, have accepted waste gasoline into their waste oil storage tank or container. In one such incident, the amount of waste gasoline accepted apparently reduced the flash point of the stored liquid to a much more volatile level. An employee of the repair garage apparently went to check the liquid level in the basement tank by opening and looking into one of the fill openings. A spark was apparently accidentally produced near the opening, explosively igniting the vapors and resulting in the employee’s death and substantial damage to the shop. Therefore, care must be taken that repair garage owners and employees do not accept anything from the public for disposal in their waste oil tank unless they are absolutely certain that it is a Class IIIB liquid.

**2311.2.3 Drainage and disposal of liquids and oil-soaked waste.** Garage floor drains, where provided, shall drain to *approved* oil separators or traps discharging to a sewer in accordance with the *International Plumbing Code*. Contents of oil separators, traps and floor drainage systems shall be collected at sufficiently frequent intervals and removed from the premises to prevent oil from being carried into the sewers.

- ❖ This section does not require floor drains but, rather, requires the installation of oil separators or traps when floor drains are provided. Oil separators must be installed in accordance with IPC Sections 1003.4 through 1003.4.2.2. See the commentary to the listed sections of the IPC for further information.

**2311.2.3.1 Disposal of liquids.** Crankcase drainings and liquids shall not be dumped into sewers, streams or on the ground, but shall be stored in *approved* tanks or containers in accordance with Chapter 57 until removed from the premises.

❖ Careless disposal of crankcase drainings by dumping them into sewers, waterways or simply on the ground can lead to dangerous, sometimes deadly and always costly environmental damage. Do-it-yourself weekend oil-changers sometimes take a course of least effort, as noted above, when disposing of their spent motor oil rather than keeping it in an approved container until the next community hazardous materials collection day sponsored by the local environmental protection agency. Another means of proper disposal for home-generated waste oil could be taking it to a local repair garage that will allow it to be added to its approved waste oil storage tank for a modest fee.

**2311.2.3.2 Disposal of oily waste.** Self-closing metal cans shall be used for oily waste.

❖ This provision refers to the storage of oily rags, etc. See the commentary to Section 304.3.1 for further discussion of waste cans.

**2311.2.4 Spray finishing.** Spray finishing with flammable or combustible liquids shall comply with Chapter 24.

❖ Chapter 24 regulates the spraying of flammable and combustible finishes and requires a permit from the fire code official. The spray operation must comply with Section 2404.

**2311.3 Sources of ignition.** Sources of ignition shall not be located within 18 inches (457 mm) of the floor and shall comply with Chapters 3 and 35.

❖ No open flame device or other sources of ignition may be within 18 inches (457 mm) of the floor in a repair garage. Flammable and combustible vapors found in repair garages are heavier than air and will accumulate below the 18-inch (457 mm) level.

**2311.3.1 Equipment.** Appliances and equipment installed in a repair garage shall comply with the provisions of the *International Building Code*, the *International Mechanical Code* and NFPA 70.

❖ Special care must be taken in selecting and installing appliances and equipment in repair garages due to the 18-inch (457 mm) hazard zone identified in Section 2311.3. Electrical equipment must be suitable for classified hazardous locations. Appliances, such as furnaces, must be installed with their fire boxes above the 18-inch (457 mm) hazard zone to reduce the likelihood of them becoming an ignition source for flammable vapors that may have escaped and settled to the floor. See the commentary to the applicable sections of the IBC and the IMC for further information.

**2311.3.2 Smoking.** Smoking shall not be allowed in repair garages except in *approved* locations.

❖ Smoking is a common ignition hazard that does not occur within 18 inches (457 mm) of the floor but can

drop hot ashes into the 18-inch (457 mm) hazard zone near the floor with the potential to ignite any accumulated vapors.

**2311.4 Below-grade areas.** Pits and below-grade work areas in repair garages shall comply with Sections 2311.4.1 through 2311.4.3.

❖ Note that this section describes this area as a pit or a below-grade work area and not a basement.

**2311.4.1 Construction.** Pits and below-grade work areas shall be constructed in accordance with the *International Building Code*.

❖ Construction requirements are found in the IBC.

**2311.4.2 Means of egress.** Pits and below-grade work areas shall be provided with *means of egress* in accordance with Chapter 10.

❖ Section 202 defines a “Motor vehicle repair garage” as a moderate-hazard storage occupancy.

Section 1006 allows one means of egress if the building is a storage occupancy with only one level below grade, the occupancy load is less than 30 occupants and the travel distance does not exceed 100 feet (30 500 mm) for a single-story storage occupancy.

**2311.4.3 Ventilation.** Where Class I liquids or LP-gas are stored or used within a building having a *basement* or pit wherein flammable vapors could accumulate, the *basement* or pit shall be provided with mechanical ventilation in accordance with the *International Mechanical Code*, at a minimum rate of 1½ cubic feet per minute per square foot (cfm/ft<sup>2</sup>) [0.008 m<sup>3</sup>/(s · m<sup>2</sup>)] to prevent the accumulation of flammable vapors.

❖ A ventilation system must be installed in any below-grade area where flammable and combustible vapors might accumulate. The ventilation system must be in operation any time the repair garage is open for business, if a vehicle is left parked over the pit when the garage is closed for business or anytime there is a chance that vapors may accumulate in the below-grade area.

**2311.5 Preparation of vehicles for repair.** For vehicles powered by gaseous fuels, the fuel shutoff valves shall be closed prior to repairing any portion of the vehicle fuel system.

Vehicles powered by gaseous fuels in which the fuel system has been damaged shall be inspected and evaluated for fuel system integrity prior to being brought into the repair garage. The inspection shall include testing of the entire fuel delivery system for leakage.

❖ Gaseous fuels include such fuels as LP-gas and CNG, among other gases. If a leak is detected in the fuel system, it must be stopped or the system purged of fuel before the vehicle can be brought into the garage. The intent is to prevent fuel gases from entering the garage area.

Although vehicles equipped with LP-gas systems for other than propulsion are not specifically

addressed in this section, (e.g., cooking, etc., in a recreational vehicle), they should be prepared for repair in accordance with Section 6111.3 of the code and Section 6.24.9 of NFPA 58.

**2311.6 Fire extinguishers.** Fire extinguishers shall be provided in accordance with Section 906.

❖ A motor vehicle repair garage is classified as a moderate-hazard storage occupancy. See Table 906.3(1) for the size and placement of portable fire extinguishers.

**2311.7 Repair garages for vehicles fueled by lighter-than-air fuels.** Repair garages for the conversion and repair of vehicles that use CNG, liquefied natural gas (LNG), hydrogen or other lighter-than-air motor fuels shall be in accordance with Sections 2311.7 through 2311.7.2.3 in addition to the other requirements of Section 2311.

**Exceptions:**

1. Repair garages where work is not performed on the fuel system and is limited to exchange of parts and maintenance not requiring open flame or welding on the CNG-, LNG-, hydrogen- or other lighter-than-air-fueled motor vehicle.
  2. Repair garages for hydrogen-fueled vehicles where work is not performed on the hydrogen storage tank and is limited to the exchange of parts and maintenance not requiring open flame or welding on the hydrogen-fueled vehicle. During the work, the entire hydrogen fuel system shall contain a quantity that is less than 200 cubic feet (5.6 m<sup>3</sup>) of hydrogen.
- ❖ Repair garages that install and repair CNG, liquefied natural gas (LNG), hydrogen or other lighter-than-air motor fuels must be equipped with ventilation and gas detection systems in accordance with Sections 2311.7.1 through 2311.7.2.3.

An example of Exception 1 would be a garage that works on automobile mufflers, brakes and shock absorbers and does not repair the fuel systems. This type of garage would not have to comply with this section even if the vehicles being repaired are equipped with lighter-than-air fuel systems.

Exception 2 allows work on hydrogen-fueled vehicles (but not on the fuel system of the vehicles) to be conducted provided there is no open flame in use and the vehicle's hydrogen fuel system contains not more than 200 cubic feet of the gas, which is less than 20 percent of the flammable gas MAQ in Table 5003.1.1(1). This would also eliminate the need for an operating permit for these repairs since the permit threshold amount in Section 105.6.9 and Table 105.6.9 is greater than pounds. This exception is intended to be consistent with NFPA 2 requirements on this topic.

In either exception, the fuel shutoff valve must be closed before any maintenance or repair work may begin, as required by Section 2307.5.

**2311.7.1 Ventilation.** Repair garages used for the repair of natural gas- or hydrogen-fueled vehicles shall be provided

with an *approved* mechanical ventilation system. The mechanical ventilation system shall be in accordance with the *International Mechanical Code* and Sections 2311.7.1.1 and 2311.7.1.2.

**Exception:** Repair garages with natural ventilation when *approved*.

❖ This section is intended to prevent the accumulation of lighter-than-air flammable and combustible gases inside the repair garage.

An example of natural ventilation that a fire code official may approve at his or her discretion is a repair garage with at least two opposite sides open all the way to the ceiling. The two opposite sides would allow for cross ventilation. Having the walls open to the ceiling would prevent lighter-than-air gases from accumulating at the ceiling level. The ceiling would have to be sealed to prevent gasses from entering the attic space; otherwise, mechanical ventilation would be required.

**2311.7.1.1 Design.** Indoor locations shall be ventilated utilizing air supply inlets and exhaust outlets arranged to provide uniform air movement to the extent practical. Inlets shall be uniformly arranged on exterior walls near floor level. Outlets shall be located at the high point of the room in exterior walls or the roof.

Ventilation shall be by a continuous mechanical ventilation system or by a mechanical ventilation system activated by a continuously monitoring natural gas detection system or, for hydrogen, a continuously monitoring flammable gas detection system, each activating at a gas concentration of not more than 25 percent of the lower flammable limit (LFL). In all cases, the system shall shut down the fueling system in the event of failure of the ventilation system.

The ventilation rate shall be not less than 1 cubic foot per minute per 12 cubic feet [ $0.00139 \text{ m}^3 \times (\text{s} \cdot \text{m}^3)$ ] of room volume.

❖ This section is intended to provide uniform ventilation throughout the garage area that will exchange at least 1 cubic foot (0.03 m<sup>3</sup>) of air for every 12 cubic feet (0.34 m<sup>3</sup>) of room volume every minute. In garages servicing CNG- or LNG-fueled vehicles, the ventilation must be continuous or be operated by a natural gas detection system. If the repair garage services hydrogen-fueled vehicles, the ventilation must be continuous or be operated by a continuously monitoring flammable gas detection system. In garages servicing vehicles fueled by all manner of lighter-than-air fuels, both types of systems would be required. Both systems must have an activation threshold of not more than 25 percent of the LFL of their respective gas.

**2311.7.1.2 Operation.** The mechanical ventilation system shall operate continuously.

**Exceptions:**

1. Mechanical ventilation systems that are interlocked with a gas detection system designed in accordance with Sections 2311.7.2 through 2311.7.2.3.

2. Mechanical ventilation systems in repair garages that are used only for repair of vehicles fueled by liquid fuels or odorized gases, such as CNG, where the ventilation system is electrically interlocked with the lighting circuit.

❖ The intent of this provision is to prevent the accumulation of lighter-than-air gases inside vehicle repair garages.

**2311.7.2 Gas detection system.** Repair garages used for repair of vehicles fueled by nonodorized gases including, but not limited to, hydrogen and nonodorized LNG, shall be provided with a flammable gas detection system.

❖ Some gases contain additives that produce pungent odors for easy recognition. If the vehicle contains fuel systems that do not use these odorized gases, a gas detection system must be installed.

**2311.7.2.1 System design.** The flammable gas detection system shall be *listed* or *approved* and shall be calibrated to the types of fuels or gases used by vehicles to be repaired. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammable limit (LFL). Gas detection shall be provided in lubrication or chassis service pits of repair garages used for repairing nonodorized LNG-fueled vehicles.

❖ The flammable gas detection system is designed to produce an alarm or signal when exposed to different concentrations of gases or vapor. This section requires quick-lube-type facilities that change oil and lubricate vehicles to install gas detection systems in the pit area if they service vehicles that are equipped with LNG fuel systems using nonodorized LNG.

**2311.7.2.1.1 Gas detection system components.** Gas detection system control units shall be *listed* and *labeled* in accordance with UL 864 or UL 2017. Gas detectors shall be *listed* and *labeled* in accordance with UL 2075 for use with the gases and vapors being detected.

❖ This section requires gas detection equipment to be listed in accordance with UL 2075 for use with the different gases it will detect. Under UL 2075, a set of flammable gases and concentrations, measured in parts per million (ppm), is developed for each detector or sensor, and the manufacturer is required to provide information as to what gases and concentrations the device is designed to detect. Tests under the standard then verify the performance of each detector or sensor for each gas it is designed to detect. The gases that the equipment will detect may be shown in the manufacturer's instructions rather than on the product. This section is also intended to ensure that gas detection system control components are listed in accordance with nationally recognized safety standards. These standards include a comprehensive set of construction and performance requirements that are used to evaluate and list gas detection system control units and gas detectors.

**2311.7.2.2 Operation.** Activation of the gas detection system shall result in all the following:

1. Initiation of distinct audible and visual alarm signals in the repair garage.
2. Deactivation of all heating systems located in the repair garage.
3. Activation of the mechanical ventilation system, where the system is interlocked with gas detection.

❖ The intent of this section is to identify the equipment that the gas detection system must activate in the event the system detects the presence of gas above 25 percent of the LFL.

**2311.7.2.3 Failure of the gas detection system.** Failure of the gas detection system shall result in the deactivation of the heating system, activation of the mechanical ventilation system where the system is interlocked with the gas detection system and cause a trouble signal to sound in an *approved* location.

❖ This section requires all equipment that the gas detector would normally activate when it detects gas to also activate if the detector fails.

**2311.8 Defueling equipment required at vehicle maintenance and repair facilities.** Facilities for repairing hydrogen fuel systems on hydrogen-fueled vehicles shall have equipment to defuel vehicle storage tanks. Where work must be performed on a vehicle's fuel storage tank for the purpose of maintenance, repair or cylinder certification, defueling and purging shall be conducted in accordance with Section 2309.6.

❖ It only makes sense that, if a motor vehicle repair garage offers service for hydrogen-powered vehicles, it must have the proper equipment available for all aspects of that purpose. Section 2309.6 and its subsections (formerly located in Section 2311.8) contain all the requirements for defueling operations. See the commentary to those sections.

## Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

# Chapter 24: Flammable Finishes

## General Comments

Roughly one out of every six fires occurring in industrial occupancies involves the ignition of a flammable or combustible liquid. This extraordinary statistic underscores the importance of proper fire prevention and protection practices where flammable and combustible coatings are applied using spraying, dipping or flow-coating methods.

Chapter 24 requirements govern operations where flammable or combustible finishes are applied by spraying, dipping, powder coating or flow-coating processes. Like all operations involving flammable or combustible liquids and combustible dusts, controlling ignition sources and methods of reducing or controlling flammable vapors or combustible dusts at or near these operations is emphasized. Open flames and smoking are prohibited near spray areas and dip tanks. Electrical installations must comply with the requirements of NFPA 70, especially requirements for electrical equipment and wiring in areas classified as spraying spaces and flammable vapor areas, as defined in this chapter.

Good housekeeping and maintenance practices will significantly reduce fuel supply hazards. Additionally, care must be taken to control the accumulation and dissipation of static electricity. Managing the quantity of flammable and combustible liquids used and stored in and around spraying and dipping operations also discourages ignition. Because ample fuel and adequate oxygen are available in spraying and dipping operations, safeguards must be installed and maintained to manage the impact of a fire, should it occur. For exam-

ple, if a match is dropped into a closed jar full of flammable liquids, the match is typically quenched because the fuel-to-air ratio does not allow flammable vapors to ignite; there is not enough oxygen. If the same liquid is poured onto a large surface, such as the floor, the vapors in the air are mixed in ratios that allow ignition to take place much more easily. The same phenomenon applies to atomization of flammable liquids where the liquid droplets have a greater surface area. Please note that, in addition to this chapter, other chapters such as Chapters 50 (Hazardous Materials—General Provisions), 57 (Flammable and Combustible Liquids) and 62 (Organic Peroxides) are applicable for additional requirements for storage and handling of hazardous materials.

## Purpose

Compliance with the requirements of this chapter is intended to reduce the likelihood of fires involving the application of flammable or combustible liquids/powders through spraying, dipping or flow-coating operations. Additionally, compliance with the requirements of this chapter will reduce the impact of a fire, should one occur. Emphasis is placed on controlling ignition sources, managing the quantity and location of fuels/vapors/dust and maintaining fire protection features.

More information on the development of this chapter, as well as all other revised chapters in the code, can be found in the *Code Changes Resource Collection—2015 International Fire Code*.

## SECTION 2401 GENERAL

**2401.1 Scope.** This chapter shall apply to locations or areas where any of the following activities are conducted:

1. The application of flammable finishes to articles or materials by means of spray apparatus.
2. The application of flammable finishes by dipping or immersing articles or materials into the contents of tanks, vats or containers of flammable or *combustible liquids* for coating, finishing, treatment or similar processes.
3. The application of flammable finishes by applying combustible powders to articles or materials utilizing powder spray guns, electrostatic powder spray guns, fluidized beds or electrostatic fluidized beds.

4. Floor surfacing or finishing operations using Class I or II liquids in areas exceeding 350 square feet (32.5 m<sup>2</sup>).
5. The application of flammable finishes consisting of dual-component coatings or Class I or II liquids when applied by brush or roller in quantities exceeding 1 gallon (4 L).

❖ This section establishes the applicability of this chapter to a variety of locations, areas, operations and activities involving the hazards of atomizing flammable and combustible liquids and spraying of combustible powders. It is important to note that spray-finishing activities do not specifically relate to the maximum allowable quantity (MAQ) per control area as used in Chapters 50 and 57. However, storage related to spray-finishing supplies would be regulated by those chapters, which would require applying the MAQ.

## FLAMMABLE FINISHES

**2401.2 Nonapplicability.** This chapter shall not apply to spray finishing utilizing flammable or *combustible liquids* that do not sustain combustion, including:

1. Liquids that have no fire point when tested in accordance with ASTM D 92.
  2. Liquids with a flashpoint greater than 95°F (35°C) in a water-miscible solution or dispersion with a water and inert (noncombustible) solids content of more than 80 percent by weight.
- ❖ Chapter 24 regulates spray finishing with any material defined as a flammable or combustible liquid by requiring that the spraying operation be confined to either a spray booth or an approved spray room. There are a variety of water-based paint products available on the market today that have a flash point and meet the definition of a “Flammable or Combustible liquid” but cannot sustain combustion due to the sheer quantity of inert solids and water present in their composition. Many consumer latex paints fall into this category.

This section clarifies that liquids having no fire point, and water-miscible liquids with a flash point greater than 95°F (35°C) having an aggregate water and inert solid content by weight of at least 80 percent, are not regulated by Chapter 24. Materials meeting these same criteria have been exempted from the storage and use requirements in Chapter 57 (see Section 5701.2, Exceptions 6 and 7), but it has been unclear to code users whether the same two exemptions should apply when these products are used in spray-finishing operations.

**2401.3 Permits.** Permits shall be required as set forth in Sections 105.6 and 105.7.

- ❖ The process of issuing permits gives the fire code official an opportunity to carefully evaluate and regulate hazardous operations. Permit applicants should be required to demonstrate that their operations comply with the intent of the code before the permit is issued. See the commentary to Section 105.6 for a general discussion of operations requiring an operational permit and Section 105.7 for construction permits. The permit process also notifies the fire department of the need for prefire planning for the hazardous property. Because of the extremely hazardous processes described in this chapter, multiple operational permits are required by Sections 105.6.17, 105.6.18 and 105.6.43. A construction permit is required by Section 105.7.16.

## SECTION 2402 DEFINITIONS

**2402.1 Definitions.** The following terms are defined in Chapter 2:

**DETEARING.**  
**DIP TANK.**

**ELECTROSTATIC FLUIDIZED BED.**

**FLAMMABLE FINISHES.**

**FLAMMABLE VAPOR AREA.**  
**FLUIDIZED BED.**

**LIMITED SPRAYING SPACE.**

**RESIN APPLICATION AREA.**

**ROLL COATING.**

**SPRAY BOOTH.**

**SPRAY ROOM.**

**SPRAYING SPACE.**
